Preface xxiv

About the Authors xxxiii

## 1 Introduction: Matter and Measurement 1

### 1.1 THE STUDY OF CHEMISTRY 2

The Atomic and Molecular Perspective of Chemistry 2 Why Study Chemistry? 3

### 1.2 CLASSIFICATIONS OF MATTER 4

States of Matter 4 Pure Substances 5 Elements 6 Compounds 6 Mixtures 8

### 1.3 PROPERTIES OF MATTER 9

Physical and Chemical Changes 10 Separation of Mixtures 11

### 1.4 UNITS OF MEASUREMENT 13

SI Units 13 Length and Mass 14 Temperature 15 Derived SI Units 16 Volume 16 Density 17

### 1.5 UNCERTAINTY IN MEASUREMENT 20

Precision and Accuracy 20 Significant Figures 21 Significant Figures in Calculations 23

### 1.6 DIMENSIONAL ANALYSIS 24

Using Two or More Conversion Factors 26 Conversions Involving Volume 27

**SUMMARY AND KEY TERMS 29 KEY SKILLS 30**

**KEY EQUATIONS 30 VISUALIZING CONCEPTS 30**

**EXERCISES 31 ADDITIONAL EXERCISES 33**

*Chemistry Put to Work* Chemistry and the Chemical Industry 4

*A Closer Look* The Scientific Method 13

*Chemistry Put to Work* Chemistry in the News 18

*Strategies in Chemistry* Estimating Answers 26

*Strategies in Chemistry* The Importance of Practice 28

## 2 Atoms, Molecules, and Ions 36

### 2.1 THE ATOMIC THEORY OF MATTER 38

### 2.2 THE DISCOVERY OF ATOMIC STRUCTURE 39

Cathode Rays and Electrons 39 Radioactivity 41  
The Nuclear Atom 41

### 2.3 THE MODERN VIEW OF ATOMIC STRUCTURE 43

Atomic Numbers, Mass Numbers, and Isotopes 44

### 2.4 ATOMIC WEIGHTS 46

The Atomic Mass Scale 46 Average Atomic Masses 47

### 2.5 THE PERIODIC TABLE 48

### 2.6 MOLECULES AND MOLECULAR COMPOUNDS 51

Molecules and Chemical Formulas 52 Molecular and Empirical Formulas 52  
Picturing Molecules 53

### 2.7 IONS AND IONIC COMPOUNDS 54

Predicting Ionic Charges 55 Ionic Compounds 56

### 2.8 NAMING INORGANIC COMPOUNDS 59

Names and Formulas of Ionic Compounds 59 Names and Formulas of Acids 64  
Names and Formulas of Binary Molecular Compounds 65

**2.9 SOME SIMPLE ORGANIC COMPOUNDS 66**

Alkanes 66 Some Derivatives of Alkanes 66

**SUMMARY AND KEY TERMS 68 KEY SKILLS 69****VISUALIZING CONCEPTS 69 EXERCISES 70****ADDITIONAL EXERCISES 75***A Closer Look* Basic Forces 45*A Closer Look* The Mass Spectrometer 48*A Closer Look* Glenn Seaborg and Seaborgium 51*Chemistry and Life* Elements Required by Living Organisms 57*Strategies in Chemistry* Pattern Recognition 58**3 Stoichiometry: Calculations with Chemical Formulas and Equations 78****3.1 CHEMICAL EQUATIONS 80**

Balancing Equations 80 Indicating the States of Reactants and Products 83

**3.2 SOME SIMPLE PATTERNS OF CHEMICAL REACTIVITY 84**

Combination and Decomposition Reactions 84 Combustion in Air 86

**3.3 FORMULA WEIGHTS 87**

Formula and Molecular Weights 87 Percentage Composition from Formulas 88

**3.4 AVOGADRO'S NUMBER AND THE MOLE 89**

Molar Mass 91 Interconverting Masses and Moles 93 Interconverting Masses and Numbers of Particles 94

**3.5 EMPIRICAL FORMULAS FROM ANALYSES 95**

Molecular Formula from Empirical Formula 96 Combustion Analysis 97

**3.6 QUANTITATIVE INFORMATION FROM BALANCED EQUATIONS 98****3.7 LIMITING REACTANTS 102**

Theoretical Yields 105

**SUMMARY AND KEY TERMS 107 KEY SKILLS 108****KEY EQUATIONS 108 VISUALIZING CONCEPTS 108****EXERCISES 109 ADDITIONAL EXERCISES 115****INTEGRATIVE EXERCISES 116***Strategies in Chemistry* Problem Solving 89*Chemistry and Life* Glucose Monitoring 102*Strategies in Chemistry* How to Take a Test 106**4 Aqueous Reactions and Solution Stoichiometry 118****4.1 GENERAL PROPERTIES OF AQUEOUS SOLUTIONS 120**

Electrolytic Properties 120 Ionic Compounds in Water 120 Molecular Compounds in Water 122 Strong and Weak Electrolytes 122

**4.2 PRECIPITATION REACTIONS 124**

Solubility Guidelines for Ionic Compounds 124 Exchange (Metathesis) Reactions 126 Ionic Equations 127

**4.3 ACID-BASE REACTIONS 128**

Acids 129 Bases 129 Strong and Weak Acids and Bases 130

Identifying Strong and Weak Electrolytes 131 Neutralization Reactions and Salts 132 Acid-Base Reactions with Gas Formation 134

**4.4 OXIDATION-REDUCTION REACTIONS 135**

Oxidation and Reduction 136 Oxidation Numbers 137

Oxidation of Metals by Acids and Salts 138 The Activity Series 140

- 4.5 CONCENTRATIONS OF SOLUTIONS 142**  
 Molarity 146 Expressing the Concentration of an Electrolyte 145  
 Interconverting Molarity, Moles, and Volume 145 Dilution 146
- 4.6 SOLUTION STOICHIOMETRY AND CHEMICAL ANALYSIS 149**  
 Titrations 150
- SUMMARY AND KEY TERMS 154 KEY SKILLS 155**  
**KEY EQUATIONS 155 VISUALIZING CONCEPTS 156**  
**EXERCISES 156 ADDITIONAL EXERCISES 161**  
**INTEGRATIVE EXERCISES 162**
- Chemistry Put to Work* Antacids 135  
*A Closer Look* The Aura of Gold 143  
*Strategies in Chemistry* Analyzing Chemical Reactions 143  
*Chemistry and Life* Drinking Too Much Water Can Kill You 147

## 5 Thermochemistry 164

- 5.1 THE NATURE OF ENERGY 166**  
 Kinetic Energy and Potential Energy 166 Units of Energy 167 System and Surroundings 168 Transferring Energy: Work and Heat 168
- 5.2 THE FIRST LAW OF THERMODYNAMICS 170**  
 Internal Energy 170 Relating  $\Delta E$  to Heat and Work 171 Endothermic and Exothermic Processes 172 State Functions 172
- 5.3 ENTHALPY 174**
- 5.4 ENTHALPIES OF REACTION 177**
- 5.5 CALORIMETRY 179**  
 Heat Capacity and Specific Heat 179 Constant-Pressure Calorimetry 182  
 Bomb Calorimetry (Constant-Volume Calorimetry) 183
- 5.6 HESS'S LAW 184**
- 5.7 ENTHALPIES OF FORMATION 188**  
 Using Enthalpies of Formation to Calculate Enthalpies of Reaction 190
- 5.8 FOODS AND FUELS 193**  
 Foods 193 Fuels 195 Other Energy Sources 197
- SUMMARY AND KEY TERMS 199 KEY SKILLS 200**  
**KEY EQUATIONS 201 VISUALIZING CONCEPTS 201**  
**EXERCISES 202 ADDITIONAL EXERCISES 207**  
**INTEGRATIVE EXERCISES 209**
- A Closer Look* Energy, Enthalpy, and  $P$ - $V$  Work 176  
*Strategies in Chemistry* Using Enthalpy as a Guide 180  
*Chemistry and Life* The Regulation of Human Body Temperature 185  
*Chemistry Put to Work* The Hybrid Car 196

## 6 Electronic Structure of Atoms 210

- 6.1 THE WAVE NATURE OF LIGHT 212**
- 6.2 QUANTIZED ENERGY AND PHOTONS 215**  
 Hot Objects and the Quantization of Energy 215 The Photoelectric Effect and Photons 216
- 6.3 LINE SPECTRA AND THE BOHR MODEL 218**  
 Line Spectra 218 Bohr's Model 219 The Energy States of the Hydrogen Atom 220 Limitations of the Bohr Model 222
- 6.4 THE WAVE BEHAVIOR OF MATTER 222**  
 The Uncertainty Principle 223
- 6.5 QUANTUM MECHANICS AND ATOMIC ORBITALS 224**  
 Orbitals and Quantum Numbers 226

- 6.6 REPRESENTATIONS OF ORBITALS 228**  
 The *s* Orbitals 228 The *p* Orbitals 231 The *d* and *f* Orbitals 232
- 6.7 MANY-ELECTRON ATOMS 232**  
 Orbitals and Their Energies 232 Electron Spin and the Pauli Exclusion Principle 233
- 6.8 ELECTRON CONFIGURATIONS 234**  
 Hund's Rule 235 Condensed Electron Configurations 237  
 Transition Metals 238 The Lanthanides and Actinides 239
- 6.9 ELECTRON CONFIGURATIONS AND THE PERIODIC TABLE 240**  
 Anomalous Electron Configurations 243  
**SUMMARY AND KEY TERMS 244 KEY SKILLS 245**  
**KEY EQUATIONS 246 VISUALIZING CONCEPTS 246**  
**EXERCISES 247 ADDITIONAL EXERCISES 251**  
**INTEGRATIVE EXERCISES 253**  
*A Closer Look* The Speed of Light 214  
*A Closer Look* Measurement and the Uncertainty Principle 225  
*A Closer Look* Probability Density and Radial Probability Functions 230  
*A Closer Look* Experimental Evidence for Electron Spin 234  
*Chemistry and Life* Nuclear Spin and Magnetic Resonance Imaging 236

## 7 Periodic Properties of the Elements 254

- 7.1 DEVELOPMENT OF THE PERIODIC TABLE 256**
- 7.2 EFFECTIVE NUCLEAR CHARGE 257**
- 7.3 SIZES OF ATOMS AND IONS 259**  
 Periodic Trends in Atomic Radii 262 Periodic Trends in Ionic Radii 263
- 7.4 IONIZATION ENERGY 264**  
 Variations in Successive Ionization Energies 266 Periodic Trends in First Ionization Energies 267 Electron Configurations of Ions 268
- 7.5 ELECTRON AFFINITIES 270**
- 7.6 METALS, NONMETALS, AND METALLOIDS 271**  
 Metals 272 Nonmetals 274 Metalloids 276
- 7.7 GROUP TRENDS FOR THE ACTIVE METALS 276**  
 Group 1A: The Alkali Metals 276 Group 2A: The Alkaline Earth Metals 279
- 7.8 GROUP TRENDS FOR SELECTED NONMETALS 281**  
 Hydrogen 281 Group 6A: The Oxygen Group 282 Group 7A: The Halogens 283 Group 8A: The Noble Gases 284  
**SUMMARY AND KEY TERMS 286 KEY SKILLS 287**  
**KEY EQUATIONS 287 VISUALIZING CONCEPTS 288**  
**EXERCISES 289 ADDITIONAL EXERCISES 292**  
**INTEGRATIVE EXERCISES 294**  
*A Closer Look* Effective Nuclear Charge 260  
*Chemistry and Life* Ionic Size Makes a Big Difference 265  
*Chemistry and Life* The Improbable Development of Lithium Drugs 280

## 8 Basic Concepts of Chemical Bonding 296

- 8.1 CHEMICAL BONDS, LEWIS SYMBOLS, AND THE OCTET RULE 298**  
 Lewis Symbols 298 The Octet Rule 299
- 8.2 IONIC BONDING 299**  
 Energetics of Ionic Bond Formation 301 Electron Configurations of Ions of the *s*- and *p*-Block Elements 302 Transition-Metal Ions 303

- 8.3 COVALENT BONDING 305**  
Lewis Structures 305 Multiple Bonds 307
- 8.4 BOND POLARITY AND ELECTRONEGATIVITY 307**  
Electronegativity 308 Electronegativity and Bond Polarity 308  
Dipole Moments 310 Differentiating Ionic and Covalent Bonding 312
- 8.5 DRAWING LEWIS STRUCTURES 314**  
Formal Charge 316
- 8.6 RESONANCE STRUCTURES 319**  
Resonance in Benzene 321
- 8.7 EXCEPTIONS TO THE OCTET RULE 322**  
Odd Number of Electrons 322 Less than an Octet of Valence Electrons 322  
More than an Octet of Valence Electrons 323
- 8.8 STRENGTHS OF COVALENT BONDS 325**  
Bond Enthalpies and the Enthalpies of Reactions 326  
Bond Enthalpy and Bond Length 329
- SUMMARY AND KEY TERMS 331 KEY SKILLS 332**  
**KEY EQUATIONS 332 VISUALIZING CONCEPTS 332**  
**EXERCISES 333 ADDITIONAL EXERCISES 336**  
**INTEGRATIVE EXERCISES 338**
- A Closer Look* Calculation of Lattice Energies: The Born–Haber Cycle 304  
*A Closer Look* Oxidation Numbers, Formal Charges, and Actual Partial Charges 318  
*Chemistry Put to Work* Explosives and Alfred Nobel 328

## 9 Molecular Geometry and Bonding Theories 340

- 9.1 MOLECULAR SHAPES 342**
- 9.2 THE VSEPR MODEL 344**  
The Effect of Nonbonding Electrons and Multiple Bonds on Bond Angles 348 Molecules with Expanded Valence Shells 349  
Shapes of Larger Molecules 352
- 9.3 MOLECULAR SHAPE AND MOLECULAR POLARITY 353**
- 9.4 COVALENT BONDING AND ORBITAL OVERLAP 355**
- 9.5 HYBRID ORBITALS 357**  
 $sp$  Hybrid Orbitals 357  $sp^2$  and  $sp^3$  Hybrid Orbitals 358  
Hybridization Involving  $d$  Orbitals 360 Hybrid Orbital Summary 360
- 9.6 MULTIPLE BONDS 362**  
Resonance Structures, Delocalization, and  $\pi$  Bonding 365  
General Conclusions 368
- 9.7 MOLECULAR ORBITALS 368**  
The Hydrogen Molecule 368 Bond Order 370
- 9.8 SECOND-ROW DIATOMIC MOLECULES 371**  
Molecular Orbitals for  $Li_2$  and  $Be_2$  371 Molecular Orbitals from  
 $2p$  Atomic Orbitals 372 Electron Configurations for  $B_2$  Through  $Ne_2$  375  
Electron Configurations and Molecular Properties 376  
Heteronuclear Diatomic Molecules 379
- SUMMARY AND KEY TERMS 381 KEY SKILLS 383**  
**KEY EQUATIONS 383 VISUALIZING CONCEPTS 383**  
**EXERCISES 384 ADDITIONAL EXERCISES 388**  
**INTEGRATIVE EXERCISES 390**
- Chemistry and Life* The Chemistry of Vision 367  
*A Closer Look* Phases in Atomic and Molecular Orbitals 373  
*Chemistry Put to Work* Orbitals and Energy 380

## 10 Gases 392

- 10.1 CHARACTERISTICS OF GASES 394**
- 10.2 PRESSURE 395**  
Atmospheric Pressure and the Barometer 395
- 10.3 THE GAS LAWS 398**  
The Pressure-Volume Relationship: Boyle's Law 399 The Temperature-Volume Relationship: Charles's Law 400 The Quantity-Volume Relationship: Avogadro's Law 400
- 10.4 THE IDEAL-GAS EQUATION 402**  
Relating the Ideal-Gas Equation and the Gas Laws 404
- 10.5 FURTHER APPLICATIONS OF THE IDEAL-GAS EQUATION 406**  
Gas Densities and Molar Mass 406 Volumes of Gases in Chemical Reactions 408
- 10.6 GAS MIXTURES AND PARTIAL PRESSURES 410**  
Partial Pressures and Mole Fractions 411 Collecting Gases over Water 412
- 10.7 KINETIC-MOLECULAR THEORY 414**  
Distributions of Molecular Speed 414 Application to the Gas Laws 415
- 10.8 MOLECULAR EFFUSION AND DIFFUSION 417**  
Graham's Law of Effusion 418 Diffusion and Mean Free Path 419
- 10.9 REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR 420**  
The van der Waals Equation 422
- SUMMARY AND KEY TERMS 425 KEY SKILLS 426**  
**KEY EQUATIONS 426 VISUALIZING CONCEPTS 426**  
**EXERCISES 427 ADDITIONAL EXERCISES 432**  
**INTEGRATIVE EXERCISES 434**
- Chemistry and Life* Blood Pressure 398  
*Strategies in Chemistry* Calculations Involving Many Variables 404  
*Chemistry Put to Work* Gas Pipelines 409  
*A Closer Look* The Ideal-Gas Equation 416  
*Chemistry Put to Work* Gas Separations 420

## 11 Intermolecular Forces, Liquids, and Solids 436

- 11.1 A MOLECULAR COMPARISON OF GASES, LIQUIDS, AND SOLIDS 438**
- 11.2 INTERMOLECULAR FORCES 439**  
Ion-Dipole Forces 440 Dipole-Dipole Forces 440 London Dispersion Forces 441 Hydrogen Bonding 443 Comparing Intermolecular Forces 446
- 11.3 SOME PROPERTIES OF LIQUIDS 447**  
Viscosity 447 Surface Tension 448
- 11.4 PHASE CHANGES 449**  
Energy Changes Accompanying Phase Changes 449 Heating Curves 450 Critical Temperature and Pressure 452
- 11.5 VAPOR PRESSURE 453**  
Explaining Vapor Pressure on the Molecular Level 454 Volatility, Vapor Pressure, and Temperature 454 Vapor Pressure and Boiling Point 455
- 11.6 PHASE DIAGRAMS 456**  
The Phase Diagrams of H<sub>2</sub>O and CO<sub>2</sub> 457

- 11.7 STRUCTURES OF SOLIDS 458**  
 Unit Cells 460 The Crystal Structure of Sodium Chloride 461  
 Close Packing of Spheres 463
- 11.8 BONDING IN SOLIDS 464**  
 Molecular Solids 464 Covalent-Network Solids 466 Ionic Solids 467  
 Metallic Solids 467
- SUMMARY AND KEY TERMS 469 KEY SKILLS 470**  
**VISUALIZING CONCEPTS 471 EXERCISES 472**  
**ADDITIONAL EXERCISES 477 INTEGRATIVE EXERCISES 478**
- Chemistry Put to Work* Supercritical Fluid Extraction 453  
*A Closer Look* The Clausius–Clapeyron Equation 456  
*A Closer Look* X-Ray Diffraction by Crystals 465  
*A Closer Look* The Third Form of Carbon 468

## 12 Modern Materials 480

- 12.1 CLASSES OF MATERIALS 482**
- 12.2 ELECTRONIC STRUCTURE OF MATERIALS 482**
- 12.3 SEMICONDUCTORS 484**  
 Semiconductor Doping 488 The Silicon Chip 489 Solar Energy  
 Conversion 489 Semiconductor Light-Emitting Diodes 492
- 12.4 CERAMICS 493**  
 Applications of Ceramics 494 Making Ceramics 494
- 12.5 SUPERCONDUCTORS 495**  
 Ceramic Superconductors 497
- 12.6 POLYMERS AND PLASTICS 499**  
 Making Polymers 499 Structure and Physical Properties of Polymers 502
- 12.7 BIOMATERIALS 505**  
 Characteristics of Biomaterials 507 Polymeric Biomaterials 507  
 Heart Repair 508 Vascular Grafts 509 Artificial Tissue 509
- 12.8 LIQUID CRYSTALS 510**  
 Types of Liquid Crystalline Phases 511
- 12.9 NANOMATERIALS 513**  
 Semiconductors on the Nanoscale 513 Metals on the Nanoscale 515  
 Carbon Nanotubes 515
- SUMMARY AND KEY TERMS 517 KEY SKILLS 519**  
**VISUALIZING CONCEPTS 519 EXERCISES 520**  
**ADDITIONAL EXERCISES 524 INTEGRATIVE EXERCISES 525**
- A Closer Look* The Transistor 490  
*Chemistry Put to Work* Cell Phone Tower Range 498  
*Chemistry Put to Work* Recycling Plastics 501  
*Chemistry Put to Work* Toward the Plastic Car 506  
*Chemistry Put to Work* Liquid Crystal Displays 513

## 13 Properties of Solutions 526

- 13.1 THE SOLUTION PROCESS 528**  
 The Effect of Intermolecular Forces 528 Energy Changes and Solution  
 Formation 529 Solution Formation, Spontaneity, and Entropy 531  
 Solution Formation and Chemical Reactions 533
- 13.2 SATURATED SOLUTIONS AND SOLUBILITY 534**
- 13.3 FACTORS AFFECTING SOLUBILITY 535**  
 Solute–Solvent Interactions 536 Pressure Effects 539  
 Temperature Effects 541

- 13.4 WAYS OF EXPRESSING CONCENTRATION 542**  
 Mass Percentage, ppm, and ppb 542 Mole Fraction, Molarity,  
 and Molality 543 Conversion of Concentration Units 544
- 13.5 COLLIGATIVE PROPERTIES 546**  
 Lowering the Vapor Pressure 546 Boiling-Point Elevation 549  
 Freezing-Point Depression 550 Osmosis 551 Determination of  
 Molar Mass 555
- 13.6 COLLOIDS 556**  
 Hydrophilic and Hydrophobic Colloids 557 Removal of Colloidal  
 Particles 560
- SUMMARY AND KEY TERMS 561 KEY SKILLS 562**  
**KEY EQUATIONS 563 VISUALIZING CONCEPTS 563**  
**EXERCISES 565 ADDITIONAL EXERCISES 569**  
**INTEGRATIVE EXERCISES 570**
- A Closer Look* Hydrates 533  
*Chemistry and Life* Fat- and Water-Soluble Vitamins 538  
*Chemistry and Life* Blood Gases and Deep-Sea Diving 540  
*A Closer Look* Ideal Solutions with Two or More Volatile Components 548  
*A Closer Look* Colligative Properties of Electrolyte Solutions 554  
*Chemistry and Life* Sickle-Cell Anemia 559

## 14 Chemical Kinetics 572

- 14.1 FACTORS THAT AFFECT REACTION RATES 574**
- 14.2 REACTION RATES 575**  
 Change of Rate with Time 577 Instantaneous Rate 577 Reaction Rates  
 and Stoichiometry 578
- 14.3 THE RATE LAW: THE EFFECT OF CONCENTRATION  
 ON RATE 580**  
 Reaction Orders: The Exponents in the Rate Law 581 Units of  
 Rate Constants 583 Using Initial Rates to Determine Rate Laws 584
- 14.4 THE CHANGE OF CONCENTRATION WITH TIME 585**  
 First-Order Reactions 586 Second-Order Reactions 588  
 Half-life 589
- 14.5 TEMPERATURE AND RATE 591**  
 The Collision Model 592 The Orientation Factor 592  
 Activation Energy 592 The Arrhenius Equation 594 Determining the  
 Activation Energy 595
- 14.6 REACTION MECHANISMS 597**  
 Elementary Reactions 597 Multistep Mechanisms 598 Rate Laws for  
 Elementary Reactions 599 The Rate-Determining Step for a Multistep  
 Mechanism 600 Mechanisms with a Slow Initial Step 601 Mechanisms  
 with a Fast Initial Step 602
- 14.7 CATALYSIS 605**  
 Homogeneous Catalysis 605 Heterogeneous Catalysis 606  
 Enzymes 608
- SUMMARY AND KEY TERMS 613 KEY SKILLS 614**  
**KEY EQUATIONS 614 VISUALIZING CONCEPTS 615**  
**EXERCISES 616 ADDITIONAL EXERCISES 622**  
**INTEGRATIVE EXERCISES 624**
- A Closer Look* Using Spectroscopic Methods to Measure Reaction Rates 580  
*Chemistry Put to Work* Methyl Bromide in the Atmosphere 590  
*Chemistry Put to Work* Catalytic Converters 608  
*Chemistry and Life* Nitrogen Fixation and Nitrogenase 610

## 15 Chemical Equilibrium 626

- 15.1 THE CONCEPT OF EQUILIBRIUM 628**
- 15.2 THE EQUILIBRIUM CONSTANT 630**  
Evaluating  $K_c$  632 Equilibrium Constants in Terms of Pressure,  $K_p$  633  
Equilibrium Constants and Units 635
- 15.3 INTERPRETING AND WORKING WITH EQUILIBRIUM  
CONSTANTS 635**  
The Magnitude of Equilibrium Constants 635 The Direction of the  
Chemical Equation and  $K$  636 Relating Chemical Equations and  
Equilibrium Constants 637
- 15.4 HETEROGENEOUS EQUILIBRIA 639**
- 15.5 CALCULATING EQUILIBRIUM CONSTANTS 641**
- 15.6 APPLICATIONS OF EQUILIBRIUM CONSTANTS 644**  
Predicting the Direction of Reaction 644 Calculating Equilibrium  
Concentrations 645
- 15.7 LE CHÂTELIER'S PRINCIPLE 648**  
Change in Reactant or Product Concentrations 649 Effects of Volume and  
Pressure Changes 649 Effect of Temperature Changes 651 The Effect of  
Catalysts 654

## TO THE INSTRUCTOR

---

### Philosophy

This is the eleventh edition of a text that has enjoyed unprecedented success over its many editions. It is fair to ask why there needs to be yet another edition. The answer in part lies in the nature of chemistry itself, a dynamic science in a process of continual discovery. New research leads to new applications of chemistry in other fields of science and in technology. In addition, environmental and economic concerns bring about changes in the place of chemistry in society. We want our textbook to reflect that dynamic, changing character. We also want it to convey the excitement that scientists experience in making new discoveries and contributing to our understanding of the physical world.

In addition, new ideas about how to present chemistry are being offered by teachers of chemistry, and many of these new ideas are reflected in how the textbook is organized and the ways in which individual topics are presented. New technologies and new devices to assist students in learning lead to new ways of presenting learning materials: the Internet, computer-based classroom projection tools, and more effective means of testing, to name just a few. All of these factors impact on how the text and the accompanying supplementary materials are modified from one edition to the next.

Our aim in revising the text has been to ensure that it remains a central, indispensable learning tool for the student. It is the one device that can be carried everywhere and used at any time, and as such, it is a one-stop source of all the information that the student is likely to need for learning, skill development, reference, and test preparation.

We believe that students are more enthusiastic about learning chemistry when they see its importance to their own goals and interests. With this in mind, we have highlighted many important applications of chemistry in everyday life. At the same time, the text provides the background in modern chemistry that students need to serve their professional interests and, as appropriate, to prepare for more advanced chemistry courses.

If the text is to support your role as teacher effectively, it must be addressed to the students. We have done our best to keep our writing clear and interesting and the book attractive and well-illustrated. Furthermore, we have provided numerous in-text study aids for students, including carefully placed descriptions of problem-solving strategies. Together, we have logged many years of teaching experience. We hope this is evident in our pacing and choice of examples.

A textbook is only as useful to students as the instructor permits it to be. This book is loaded with many features that can help students learn and that can guide them as they acquire both conceptual understanding and problem-solving skills. But the text and all the supplementary materials provided to support its use must work in concert with the instructor. There is a great deal for the students to use here, too much for all of it to be absorbed by any one student. You, the instructor, are the guide to a proper use of the book. Only with your active help will the students be able to fully utilize all that the text and its supplements offer. Students care about grades, of course, but with encouragement, they can also care about learning just because the subject matter is interesting. Please consider emphasizing features of the book that can materially enhance student appreciation of chemistry, such as the *Chemistry Put to Work* and *Chemistry and Life* boxes that show how chemistry impacts modern life and its relationship to health and life processes. Learn to use, and urge students to use,

the rich Internet resources available. Emphasize conceptual understanding, and place less emphasis on simple manipulative, algorithmic problem solving. Spending less time on solving a variety of gas law problems, for example, can open up opportunities to talk about chemistry and the environment.

## Organization and Contents

The first five chapters give a largely macroscopic, phenomenological view of chemistry. The basic concepts introduced—such as nomenclature, stoichiometry, and thermochemistry—provide necessary background for many of the laboratory experiments usually performed in general chemistry. We believe that an early introduction to thermochemistry is desirable because so much of our understanding of chemical processes is based on considerations of energy change. Thermochemistry is also important when we come to a discussion of bond enthalpies. We believe we have produced an effective, balanced approach to teaching thermodynamics in general chemistry. It is no easy matter to walk the narrow pathway between—on the one hand—trying to teach too much at too high a level and—on the other—resorting to oversimplifications. As with the book as a whole, the emphasis has been on imparting *conceptual* understanding, as opposed to presenting equations into which students are supposed to plug numbers.

The next four chapters (Chapters 6–9) deal with electronic structure and bonding. We have largely retained our presentation of atomic orbitals. For more advanced students, *Closer Look* boxes deal with radial probability functions and the nature of antibonding orbitals. In Chapter 7 we have improved our discussion of atomic and ionic radii. The focus of the text then changes to the next level of the organization of matter: the states of matter (Chapters 10 and 11) and solutions (Chapter 13). Also included in this section is an applications chapter on the chemistry of modern materials (Chapter 12), which builds on the student's understanding of chemical bonding and intermolecular interactions. This chapter has again received substantial revision, in keeping with the rapid pace of change in technology. It has been reorganized to emphasize a classification of materials based on their electronic bonding characteristics. This chapter provides an opportunity to show how the sometimes abstract concept of chemical bonding impacts real world applications. The modular organization of the chapter allows you to tailor your coverage to focus on those materials (semiconductors, polymers, biomaterials, nanotechnology, etc.) that are most relevant to your students.

The next several chapters examine the factors that determine the speed and extent of chemical reactions: kinetics (Chapter 14), equilibria (Chapters 15–17), thermodynamics (Chapter 19), and electrochemistry (Chapter 20). Also in this section is a chapter on environmental chemistry (Chapter 18), in which the concepts developed in preceding chapters are applied to a discussion of the atmosphere and hydrosphere.

After a discussion of nuclear chemistry (Chapter 21), the final chapters survey the chemistry of nonmetals, metals, organic chemistry, and biochemistry (Chapters 22–25). Chapter 22 has been shortened slightly. Chapter 23 now contains a modern treatment of band structure and bonding in metals. A brief discussion of lipids has been added to Chapter 25. These final chapters are developed in a parallel fashion and can be treated in any order.

Our chapter sequence provides a fairly standard organization, but we recognize that not everyone teaches all the topics in exactly the order we have chosen. We have therefore made sure that instructors can make common changes in teaching sequence with no loss in student comprehension. In particular, many instructors prefer to introduce gases (Chapter 10) after stoichiometry or after thermochemistry rather than with states of matter. The chapter on gases has been written to permit this change with *no* disruption in the flow of material. It is also possible to treat the balancing of redox equations (Sections 20.1 and 20.2)

earlier, after the introduction of redox reactions in Section 4.4. Finally, some instructors like to cover organic chemistry (Chapter 25) right after bonding (Chapter 9). This, too, is a largely seamless move.

We have introduced students to descriptive organic and inorganic chemistry by integrating examples throughout the text. You will find pertinent and relevant examples of “real” chemistry woven into all the chapters as a means to illustrate principles and applications. Some chapters, of course, more directly address the properties of elements and their compounds, especially Chapters 4, 7, 12, 18, and 22–25. We also incorporate descriptive organic and inorganic chemistry in the end-of-chapter exercises.

### Changes in This Edition

Some of the changes in the eleventh edition made in individual chapters have already been mentioned. More broadly, we have introduced a number of new features that are general throughout the text. *Chemistry: The Central Science* has traditionally been valued for its clarity of writing, its scientific accuracy and currency, its strong end-of-chapter exercises, and its consistency in level of coverage. In making changes, we have made sure not to compromise these characteristics. At the same time, we have responded to feedback received from the faculty and students who used previous editions. To make the text easier for students to use, we have continued to employ an open, clean design in the layout of the book. Illustrations that lend themselves to a more schematic, bolder presentation of the underlying principles have been introduced or revised from earlier versions. The art program in general has been strengthened, to better convey the beauty, excitement, and concepts of chemistry to students. The chapter-opening photos have been integrated into the introduction to each chapter, and thus made more relevant to the chapter’s contents.

We have continued to use the What’s Ahead overview at the opening of each chapter, introduced in the ninth edition, but we have changed the format to make the materials more useful to students. *Concept links* (☞) continue to provide easy-to-see cross-references to pertinent material covered earlier in the text. The essays titled *Strategies in Chemistry*, which provide advice to students on problem solving and “thinking like a chemist,” continue to be an important feature. The *Give It Some Thought* exercises that we introduced in the tenth edition have proven to be very popular, and we have increased their number. These are informal, rather sharply focused questions that give students opportunities to test whether they are actually “getting it” as they read along. We have continued to emphasize conceptual exercises in the end-of-chapter exercise materials. The *Visualizing Concepts* category of exercise has been continued in this edition. These exercises are designed to facilitate concept understanding through use of models, graphs, and other visual materials. They precede the regular end-of-chapter exercises and are identified in each case with the relevant chapter section number. We continue to use multi-focus graphics to depict topics in macroscopic, microscopic, symbolic, and conceptual representation so students learn to see chemistry the way scientists do, from a variety of perspectives. The *Integrative Exercises*, which give students the opportunity to solve more challenging problems that integrate concepts from the present chapter with those of previous chapters, have also been increased in number.

New essays in our well-received *Chemistry Put to Work* and *Chemistry and Life* series emphasize world events, scientific discoveries, and medical breakthroughs that have occurred since publication of the tenth edition. We maintain our focus on the positive aspects of chemistry, without neglecting the problems that can arise in an increasingly technological world. Our goal is to help students appreciate the real-world perspective of chemistry and the ways in which chemistry affects their lives.

A minor change that you will see throughout the text is the use of condensed structural formulas for simple carboxylic acids. For example, we now write  $\text{CH}_3\text{COOH}$  for acetic acid instead of  $\text{HC}_2\text{H}_3\text{O}_2$ .

## You'll also find that we've

- Revised or replaced some of the end-of-chapter Exercises, with particular focus on the black-numbered exercises (those not answered in the Appendix).
- Integrated more conceptual questions into the end-of-chapter material. For the convenience of instructors, these are identified by the CQ annotation in the Annotated Instructor's Edition, but not in the student edition of the text.
- Carried the stepwise Analyze, Plan, Solve, Check problem-solving strategy into nearly all of the Sample Exercises of the book to provide additional guidance in problem solving.
- Expanded the use of dual-column problem-solving strategies in many Sample Exercises to more clearly outline the process underlying mathematical calculations, thereby helping students to better perform mathematical calculations.
- Added both Key Skills and Key Equations sections to the end of chapter material to help students focus their study.

## TO THE STUDENT

---

*Chemistry: The Central Science, Eleventh Edition*, has been written to introduce you to modern chemistry. As authors, we have, in effect, been engaged by your instructor to help you learn chemistry. Based on the comments of students and instructors who have used this book in its previous editions, we believe that we have done that job well. Of course, we expect the text to continue to evolve through future editions. We invite you to write to us to tell us what you like about the book so that we will know where we have helped you most. Also, we would like to learn of any shortcomings, so that we might further improve the book in subsequent editions. Our addresses are given at the end of the Preface.

### Advice for Learning and Studying Chemistry

Learning chemistry requires both the assimilation of many new concepts and the development of analytical skills. In this text we have provided you with numerous tools to help you succeed in both. If you are going to succeed in your course in chemistry, you will have to develop good study habits. Science courses, and chemistry in particular, make different demands on your learning skills than other types of courses. We offer the following tips for success in your study of chemistry:

*Don't fall behind!* As your chemistry course moves along, new topics will build on material already presented. If you don't keep up in your reading and problem solving, you will find it much harder to follow the lectures and discussions on current topics. "Cramming" just before an exam has been shown to be an ineffective way to study any subject, chemistry included.

*Focus your study.* The amount of information you will be expected to learn can sometimes seem overwhelming. It is essential to recognize those concepts and skills that are particularly important. Pay attention to what your instructor is emphasizing. As you work through the Sample Exercises and homework assignments, try to see what general principles and skills they deal with. Use the **What's Ahead** feature at the beginning of each chapter to help orient you to what is important in each chapter. A single reading of a chapter will simply not be enough for successful learning of chapter concepts and problem-solving skills. You will need to go over assigned materials more than once. Don't skip the **Give It Some Thought** features, **Sample Exercises**, and **Practice Exercises**.

They are your guides to whether you are actually learning the material. The **Key Skills** and **Key Equations** at the end of each chapter should help you focus your study.

*Keep good lecture notes.* Your lecture notes will provide you with a clear and concise record of what your instructor regards as the most important material to learn. Use your lecture notes in conjunction with this text; that's your best way to determine which material to study.

*Skim topics in the text before they are covered in lecture.* Reviewing a topic before lecture will make it easier for you to take good notes. First read the introduction and Summary, then quickly read through the chapter, skipping Sample Exercises and supplemental sections. Pay attention to the titles of sections and subsections, which give you a feeling for the scope of topics. Try to avoid thinking that you must learn and understand everything right away.

*After lecture, carefully read the topics covered in class.* As you read, pay attention to the concepts presented and to the application of these concepts in the Sample Exercises. Once you think you understand a Sample Exercise, test your understanding by working the accompanying Practice Exercise.

*Learn the language of chemistry.* As you study chemistry, you will encounter many new words. It is important to pay attention to these words and to know their meanings or the entities to which they refer. Knowing how to identify chemical substances from their names is an important skill; it can help you avoid painful mistakes on examinations. For example, "chlorine" and "chloride" refer to very different things.

*Attempt the assigned end-of-chapter exercises.* Working the exercises that have been selected by your instructor provides necessary practice in recalling and using the essential ideas of the chapter. You cannot learn merely by observing; you must be a participant. In particular, try to resist checking the *Student Solutions Manual* (if you have one) until you have made a sincere effort to solve the exercise yourself. If you really get stuck on an exercise, however, get help from your instructor, your teaching assistant, or another student. Spending more than 20 minutes on a single exercise is rarely effective unless you know that it is particularly challenging.

*Make use of the online resources.* Some things are more easily learned by discovery, and others are best shown in three dimensions. If your instructor has included Mastering Chemistry with your book, take advantage of the unique tools it provides to get the most out of your time in chemistry.

The bottom line is to work hard, study effectively, and use the tools that are available to you, including this textbook. We want to help you learn more about the world of chemistry and why chemistry is the central science. If you learn chemistry well, you can be the life of the party, impress your friends and parents, and ... well, also pass the course with a good grade.

## ACKNOWLEDGMENTS

---

The production of a textbook is a team effort requiring the involvement of many people besides the authors. Many people contributed hard work and talent to bring this edition to life. Although their names don't appear on the cover of the book, their creativity, time, and support has been instrumental in all stages of its development and production.

Each of us has benefited greatly from discussions with colleagues and from correspondence with both instructors and students both here and abroad. Colleagues have also helped immensely by reviewing our materials, sharing their insights, and providing suggestions for improvements. On this edition we were particularly blessed with an exceptional group of accuracy checkers who read through our materials looking for both technical inaccuracies and typographical errors.

## Eleventh Edition Reviewers

Patricia Amateis	Virginia Polytechnic Institute and State University	Pamela Marks	Arizona State University
Todd L. Austell	University of North Carolina, Chapel Hill	Shelley Minter	Saint Louis University
Melita Balch	University of Illinois at Chicago	Jessica Orvis	Georgia Southern University

We would also like to express our gratitude to our many team members at Prentice Hall whose hard work, imagination, and commitment have contributed so greatly to the final form of this edition: Nicole Folchetti, our Editor in Chief, who has brought energy and imagination not only to this edition but to earlier ones as well; Andrew Gilfillan, our Chemistry Editor, for his enthusiasm and support; Jonathan Colon, Editorial Assistant, who coordinated all reviews and accuracy checking; Ray Mullaney, our Developmental Editor in Chief, who has been with us since the very first edition of this textbook, helping guide its evolution, infusing it with a sense of style and quality; Karen Nein, our Development Editor, whose diligence and careful attention to detail were invaluable to this revision; Marcia Youngman, our copy editor, for her keen eye; Maureen Eide, our Art Director, who managed the complex task of bringing our sketches into final form; Jennifer Hart, who coordinated all the supplements that accompany the text; Donna Young, our Production Editor, who always seemed to be available for questions any time of the day or night, and who managed the complex responsibilities of bringing the design, photos, artwork, and writing together with efficiency and good cheer. The Prentice Hall team is a first-class operation.

There are many others who also deserve special recognition including the following: Jerry Marshall (Truitt and Marshall), our photo researcher, who was so effective in finding photos to bring chemistry to life for students; Linda Brunauer (Santa Clara University) for her marvelous efforts in preparing the Annotated Instructor's Edition of the text; Roxy Wilson (University of Illinois) for performing the difficult job of working out solutions to the end-of-chapter exercises.

Finally, we wish to thank our families and friends for their love, support, encouragement, and patience as we brought this eleventh edition to completion.

# List of Resources

## For Students

**MasteringChemistry:** MasteringChemistry is the first adaptive-learning online homework system. It provides selected end-of-chapter problems from the text, as well as hundreds of tutorials with automatic grading, immediate answer-specific feedback, and simpler questions on request. Based on extensive research of precise concepts students struggle with, MasteringChemistry uniquely responds to your immediate learning needs, thereby optimizing your study time.

**Solutions to Red Exercises** (0-13-600287-0) Prepared by Roxy Wilson of the University of Illinois–Urbana-Champaign. Full solutions to all of the red-numbered exercises in the text are provided. (Short answers to red exercises are found in the appendix of the text).

**Solutions to Black Exercises** (0-13-600324-9) Prepared by Roxy Wilson of the University of Illinois–Urbana-Champaign. Full solutions to all of the black-numbered exercises in the text are provided.

**Student's Guide** (0-13-600264-1) Prepared by James C. Hill of California State University. This book assists students through the text material with chapter overviews, learning objectives, a review of key terms, as well as self-tests with answers and explanations. This edition also features the addition of MCAT practice questions.

**Laboratory Experiments** (0-13-600285-4) Prepared by John H. Nelson and Kenneth C. Kemp, both of the University of Nevada. This manual contains 43 finely tuned experiments chosen to introduce students to basic lab techniques and to illustrate core chemical principles. This new edition has been revised to correlate more tightly with the text and now features a guide on how to keep a lab report notebook. You can also customize these labs through Catalyst, our custom database program. For more information, visit [www.prenhall.com/catalyst](http://www.prenhall.com/catalyst).

**Virtual ChemLab:** An easy to use simulation of five different general chemistry laboratories that can be used to supplement a wet lab, for pre-laboratory and post-laboratory activities, for homework or quiz assignments, or for classroom demonstrations.

## For Instructors

**Annotated Instructor's Edition** (0-13-601250-7) Prepared by Linda Brunauer of Santa Clara University. Provides marginal notes and information for instructors and TAs, including transparency icons, suggested lecture demonstrations, teaching tips, and background references from the chemical education literature.

**Full Solutions Manual** (0-13-600325-7) Prepared by Roxy Wilson of the University of Illinois–Urbana-Champaign. This manual contains all end-of-chapter exercises in the text. With an instructor's permission, this manual may be made available to students.

**Instructor's Resource Center on CD-DVD** (0-13-600281-1) This resource provides an integrated collection of resources to help you make efficient and effective use of your time. This CD/DVD features most art from the text, including figures and tables in PDF format for high-resolution printing, as well as four pre-built PowerPoint™ presentations. The first presentation contains the images embedded within PowerPoint slides. The second includes a complete lecture outline that is modifiable by the user. The final two presentations contain worked "in chapter" sample exercises and questions to be used with Classroom Response Systems. This CD/DVD also contains movies, animations, and electronic files of the Instructor's Resource Manual.

**Test Item File** (0-13-601251-5) Prepared by Joseph P. Laurino and Donald Cannon, both of the University of Tampa. The Test Item File now provides a selection of more than 4000 test questions.

**Instructor's Resource Manual** (0-13-600237-4) Prepared by Linda Brunauer of Santa Clara University and Elizabeth Cook of the University of Louisiana. Organized by chapter, this manual offers detailed lecture outlines and complete descriptions of all available lecture demonstrations, the interactive media assets, common student misconceptions, and more.

**Transparencies** (0-13-601256-6) Approximately 300 full-color transparencies put principles into visual perspective and save you time when preparing lectures.

**Annotated Instructor's Edition to *Laboratory Experiments*** (0-13-6002862) Prepared by John H. Nelson and Kenneth C. Kemp, both of the University of Nevada. This AIE combines the full student lab manual with appendices covering the proper disposal of chemical waste, safety instructions for the lab, descriptions of standard lab equipment, answers to questions, and more.

**BlackBoard and WebCT:** Practice and assessment materials are available upon request in these course management platforms.

# About the Authors

---

**THEODORE L. BROWN** received his Ph.D. from Michigan State University in 1956. Since then, he has been a member of the faculty of the University of Illinois, Urbana-Champaign, where he is now Professor of Chemistry, Emeritus. He served as Vice Chancellor for Research, and Dean, The Graduate College, from 1980 to 1986, and as Founding Director of the Arnold and Mabel Beckman Institute for Advanced Science and Technology from 1987 to 1993. Professor Brown has been an Alfred P. Sloan Foundation Research Fellow and has been awarded a Guggenheim Fellowship. In 1972 he was awarded the American Chemical Society Award for Research in Inorganic Chemistry, and received the American Chemical Society Award for Distinguished Service in the Advancement of Inorganic Chemistry in 1993. He has been elected a Fellow of both the American Association for the Advancement of Science and the American Academy of Arts and Sciences.

**H. EUGENE LEMAY, JR.**, received his B.S. degree in Chemistry from Pacific Lutheran University (Washington) and his Ph.D. in Chemistry in 1966 from the University of Illinois (Urbana). He then joined the faculty of the University of Nevada, Reno, where he is currently Professor of Chemistry, Emeritus. He has enjoyed Visiting Professorships at the University of North Carolina at Chapel Hill, at the University College of Wales in Great Britain, and at the University of California, Los Angeles. Professor LeMay is a popular and effective teacher, who has taught thousands of students during more than 35 years of university teaching. Known for the clarity of his lectures and his sense of humor, he has received several teaching awards, including the University Distinguished Teacher of the Year Award (1991) and the first Regents' Teaching Award given by the State of Nevada Board of Regents (1997).

**BRUCE E. BURSTEN** received his Ph.D. in Chemistry from the University of Wisconsin in 1978. After two years as a National Science Foundation Postdoctoral Fellow at Texas A&M University, he joined the faculty of The Ohio State University, where he rose to the rank of Distinguished University Professor. In 2005, he moved to his present position at the University of Tennessee, Knoxville as Distinguished Professor of Chemistry and Dean of the College of Arts and Sciences. Professor Bursten has been a Camille and Henry Dreyfus Foundation Teacher-Scholar and an Alfred P. Sloan Foundation Research Fellow, and he has been elected a Fellow of the American Association for the Advancement of Science. At Ohio State he has received the University Distinguished Teaching Award in 1982 and 1996, the Arts and Sciences Student Council Outstanding Teaching Award in 1984, and the University Distinguished Scholar Award in 1990. He received the Spiers Memorial Prize and Medal of the Royal Society of Chemistry in 2003, and the Morley Medal of the Cleveland Section of the American Chemical Society in 2005. He was elected President of the American Chemical Society for 2008. In addition to his teaching and service activities, Professor Bursten's research program focuses on compounds of the transition-metal and actinide elements.

**CATHERINE J. MURPHY** received two B.S. degrees, one in Chemistry and one in Biochemistry, from the University of Illinois, Urbana-Champaign, in 1986. She received her Ph.D. in Chemistry from the University of Wisconsin in 1990. She was a National Science Foundation and National Institutes of Health Postdoctoral Fellow at the California Institute of Technology from 1990 to 1993. In 1993, she joined the faculty of the University of South Carolina, Columbia, where she is currently the Guy F. Lipscomb Professor of Chemistry. Professor Murphy has been honored for both research and teaching as a Camille Dreyfus Teacher-Scholar, an Alfred P. Sloan Foundation Research Fellow, a Cottrell Scholar of the Research Corporation, a National Science Foundation CAREER Award winner, and a subsequent NSF Award for Special Creativity. She has also received a USC Mortar Board Excellence in Teaching Award, the USC Golden Key Faculty Award for Creative Integration of Research and Undergraduate Teaching, the USC Michael J. Mungo Undergraduate Teaching Award, and the USC Outstanding Undergraduate Research Mentor Award. Since 2006, Professor Murphy has served as a Senior Editor to the *Journal of Physical Chemistry*. Professor Murphy's research program focuses on the synthesis and optical properties of inorganic nanomaterials, and on the local structure and dynamics of the DNA double helix.

---

## Contributing Author

**PATRICK M. WOODWARD** received B.S. degrees in both Chemistry and Engineering from Idaho State University in 1991. He received a M.S. degree in Materials Science and a Ph.D. in Chemistry from Oregon State University in 1996. He spent two years as a postdoctoral researcher in the Department of Physics at Brookhaven National Laboratory. In 1998, he joined the faculty of the Chemistry Department at The Ohio State University where he currently holds the rank of Associate Professor. He has enjoyed visiting professorships at the University of Bordeaux, in France, and the University of Sydney, in Australia. Professor Woodward has been an Alfred P. Sloan Foundation Research Fellow and a National Science Foundation CAREER Award winner. He currently serves as an Associate Editor to the *Journal of Solid State Chemistry* and as the director of the Ohio REEL program, an NSF funded center that works to bring authentic research experiments into the laboratories of first and second year chemistry classes in 15 colleges and universities across the state of Ohio. Professor Woodward's research program focuses on understanding the links between bonding, structure, and properties of solid state inorganic functional materials.

CHAPTER  
1

# INTRODUCTION: MATTER AND MEASUREMENT

HUBBLE SPACE TELESCOPE IMAGE of the Crab Nebula, a 6-light-year-wide expanding remnant of a star's supernova explosion. The orange filaments are the tattered remains of the star and consist mostly of hydrogen, the simplest and most plentiful element in the universe. Hydrogen occurs as molecules in cool regions, as atoms in hotter regions, and as ions in the hottest regions. The processes that occur within stars are responsible for creating other chemical elements from hydrogen.

## WHAT'S AHEAD

---

### 1.1 The Study of Chemistry

We begin by providing a brief perspective of what chemistry is about and why it is useful to learn chemistry.

### 1.2 Classifications of Matter

Next, we examine some fundamental ways to classify materials, distinguishing between *pure substances* and *mixtures* and noting that there are two fundamentally different kinds of pure substances: *elements* and *compounds*.

### 1.3 Properties of Matter

We then consider some of the different kinds of characteristics, or *properties*, that we use to characterize, identify, and separate substances.

### 1.4 Units of Measurement

We observe that many properties rely on quantitative measurements, involving both

numbers and units. The units of measurement used throughout science are those of the *metric system*, a decimal system of measurement.

### 1.5 Uncertainty in Measurement

We also observe that the uncertainties inherent in all measured quantities are expressed by the number of *significant figures* used to report the number. Significant figures are also used to express the uncertainties associated with calculations involving measured quantities.

### 1.6 Dimensional Analysis

We recognize that units as well as numbers are carried through calculations and that obtaining correct units for the result of a calculation is an important way to check whether the calculation is correct.

**HAVE YOU EVER WONDERED** why ice melts and water evaporates? Why do leaves turn colors in the fall, and how does a battery generate electricity? Why does keeping foods cold slow their spoilage, and how do our bodies use food to maintain life?

Chemistry answers these questions and countless others like them. **Chemistry** is the study of materials and the changes that materials undergo. One of the joys of learning chemistry is seeing how chemical principles operate in all aspects of our lives, from everyday activities like lighting a match to more far-reaching matters like the development of drugs to cure cancer. Chemical principles also operate in the far reaches of our galaxy (chapter-opening photo) as well as within and around us.

This first chapter lays a foundation for our study of chemistry by providing an overview of what chemistry is about and dealing with some fundamental concepts of matter and scientific measurements. The list above, entitled "What's Ahead," gives a brief overview of the organization of this chapter and some of the ideas that we will consider. As you study, keep in mind that the chemical facts and concepts you are asked to learn are not ends in themselves; they are tools to help you better understand the world around you.

## 1.1 THE STUDY OF CHEMISTRY

Before traveling to an unfamiliar city, you might look at a map to get some sense of where you are heading. Because chemistry may be unfamiliar to you, it's useful to get a general idea of what lies ahead before you embark on your journey. In fact, you might even ask why you are taking the trip.

### The Atomic and Molecular Perspective of Chemistry

Chemistry is the study of the properties and behavior of matter. **Matter** is the physical material of the universe; it is anything that has mass and occupies space. A **property** is any characteristic that allows us to recognize a particular type of matter and to distinguish it from other types. This book, your body, the clothes you are wearing, and the air you are breathing are all samples of matter. Not all forms of matter are so common or so familiar. Countless experiments have shown that the tremendous variety of matter in our world is due to combinations of only about 100 very basic, or elementary, substances called **elements**. As we proceed through this text, we will seek to relate the properties of matter to its composition, that is, to the particular elements it contains.

Chemistry also provides a background to understanding the properties of matter in terms of **atoms**, the almost infinitesimally small building blocks of matter. Each element is composed of a unique kind of atom. We will see that the properties of matter relate to both the kinds of atoms the matter contains (*composition*) and to the arrangements of these atoms (*structure*).

Atoms can combine to form **molecules** in which two or more atoms are joined together in specific shapes. Throughout this text you will see molecules represented using colored spheres to show how their component atoms connect to each other (Figure 1.1 ▼). The color provides a convenient and easy way to distinguish between the atoms of different elements. For examples, compare the molecules of ethanol and ethylene glycol in Figure 1.1. Notice that these molecules have different compositions and structures. Ethanol contains only one oxygen atom, which is depicted by one red sphere. In contrast, ethylene glycol has two atoms of oxygen.

Even apparently minor differences in the composition or structure of molecules can cause profound differences in their properties. Ethanol, also called grain alcohol, is the alcohol in beverages such as beer and wine. Ethylene glycol, on the other hand, is a viscous liquid used as automobile antifreeze. The properties of these two substances differ in many ways, including the temperatures at which they freeze and boil. The biological activities of the two molecules are also quite different. Ethanol is consumed throughout the world, but

you should *never* consume ethylene glycol because it is highly toxic. One of the challenges that chemists undertake is to alter the composition or structure of molecules in a controlled way, creating new substances with different properties.

Every change in the observable world—from boiling water to the changes that occur as our bodies combat invading viruses—has its basis in the world of atoms and molecules. Thus, as we proceed with our study of chemistry, we will find ourselves thinking in two realms: the *macroscopic* realm

▼ **Figure 1.1 Molecular models.** The white, dark gray, and red spheres represent atoms of hydrogen, carbon, and oxygen, respectively.

of ordinary-sized objects (*macro* = large) and the *submicroscopic* realm of atoms and molecules. We make our observations in the macroscopic world—in the laboratory and in our everyday surroundings. To understand that world, however, we must visualize how atoms and molecules behave at the submicroscopic level. Chemistry is the science that seeks to understand the properties and behavior of matter by studying the properties and behavior of atoms and molecules.

### GIVE IT SOME THOUGHT

(a) In round numbers, about how many elements are there? (b) What submicroscopic particles are the building blocks of matter?

## Why Study Chemistry?

Chemistry provides important understanding of our world and how it works. It is an extremely practical science that greatly impacts our daily lives. Indeed, chemistry lies near the heart of many matters of public concern: improvement of health care; conservation of natural resources; protection of the environment; and provision of our everyday needs for food, clothing, and shelter. Using chemistry, we have discovered pharmaceutical chemicals that enhance our health and prolong our lives. We have increased food production through the use of fertilizers and pesticides, and we have developed plastics and other materials that are used in almost every facet of our lives. Unfortunately, some chemicals also have the potential to harm our health or the environment. As educated citizens and consumers, it is in our best interest to understand the profound effects, both positive and negative, that chemicals have on our lives and to strike an informed balance about their uses.

Most of you are studying chemistry, however, not merely to satisfy your curiosity or to become more informed consumers or citizens, but because it is an essential part of your curriculum. Your major might be biology, engineering, pharmacy, agriculture, geology, or some other field. Why do so many diverse subjects share an essential tie to chemistry? The answer is that chemistry, by its very nature, is the *central science*, central to a fundamental understanding of other sciences and technologies. For example, our interactions with the material world raise basic questions about the materials around us. What are their compositions and properties? How do they interact with us and our environment? How, why, and when do they undergo change? These questions are important whether the material is part of high-tech computer chips, a pigment used by a Renaissance painter, or the DNA that transmits genetic information in our bodies (Figure 1.2 ♥).

By studying chemistry, you will learn to use the powerful language and ideas that have evolved to describe and enhance our understanding of matter. The language of chemistry is a universal scientific language that is widely used

▼ **Figure 1.2 Chemistry helps us better understand materials.** (a) A microscopic view of an EPROM (Erasable Programmable Read-Only Memory) silicon microchip. (a)

(b)

(c)

Many people are familiar with common household chemicals such as those shown in Figure 1.3, but few realize the size and importance of the chemical industry. Worldwide sales of chemicals and related products manufactured in the United States total approximately \$550 billion annually. The chemical industry employs more than 10% of all scientists and engineers and is a major contributor to the US economy.

Vast amounts of chemicals are produced each year and serve as raw materials for a variety of uses, including the manufacture of metals, plastics, fertilizers, pharmaceuticals, fuels, paints, adhesives, pesticides, synthetic fibers, microprocessor chips, and numerous other products. Table 1.1 lists the top eight chemicals produced in the United States. We will discuss many of these substances and their uses as the course progresses.

People who have degrees in chemistry hold a variety of positions in industry, government, and academia. Those who work in the chemical industry find positions as laboratory chemists, carrying out experiments to develop new products (research and development), analyzing materials (quality control), or assisting customers in using products (sales and service). Those with more experience or training may work as managers or company directors. A chemistry degree also can prepare you for alternate careers in teaching, medicine, biomedical research, information science, environmental work, technical sales, work with government regulatory agencies, and patent law.

▲ Figure 1.3 Household chemicals. Many common supermarket products have very simple chemical compositions.

TABLE 1.1 ■ The Top Eight Chemicals Produced by the Chemical Industry in 2006<sup>a</sup>

Rank	Chemical	Formula	2006 Production (billions of pounds)	Principal End Uses
1	Sulfuric acid	H <sub>2</sub> SO <sub>4</sub>	79	Fertilizers, chemical manufacturing
2	Ethylene	C <sub>2</sub> H <sub>4</sub>	55	Plastics, antifreeze
3	Lime	CaO	45	Paper, cement, steel
4	Propylene	C <sub>3</sub> H <sub>6</sub>	35	Plastics
5	Phosphoric acid	H <sub>3</sub> PO <sub>4</sub>	24	Fertilizers
6	Ammonia	NH <sub>3</sub>	23	Fertilizers
7	Chlorine	Cl <sub>2</sub>	23	Bleaches, plastics, water purification
8	Sodium hydroxide	NaOH	18	Aluminum production, soap

<sup>a</sup>Most data from *Chemical and Engineering News*, July 2, 2007, pp. 57, 60.

in other disciplines. Furthermore, an understanding of the behavior of atoms and molecules provides powerful insights into other areas of modern science, technology, and engineering.

## 1.2 CLASSIFICATIONS OF MATTER

Let's begin our study of chemistry by examining some fundamental ways in which matter is classified and described. Two principal ways of classifying matter are according to its physical state (as a gas, liquid, or solid) and according to its composition (as an element, compound, or mixture).

### States of Matter

A sample of matter can be a gas, a liquid, or a solid. These three forms of matter are called the **states of matter**. The states of matter differ in some of their simple

observable properties. A **gas** (also known as *vapor*) has no fixed volume or shape; rather, it conforms to the volume and shape of its container. A gas can be compressed to occupy a smaller volume, or it can expand to occupy a larger one. A **liquid** has a distinct volume independent of its container but has no specific shape. A liquid assumes the shape of the portion of the container that it occupies. A **solid** has both a definite shape and a definite volume. Neither liquids nor solids can be compressed to any appreciable extent.

The properties of the states of matter can be understood on the molecular level (Figure 1.4 ▶). In a gas the molecules are far apart and are moving at high speeds, colliding repeatedly with each other and with the walls of the container. Compressing a gas decreases the amount of space between molecules, increases the frequency of collisions between molecules, but does not alter the size or shape of the molecules. In a liquid the molecules are packed closely together but still move rapidly. The rapid movement allows the molecules to slide over each other; thus, a liquid pours easily. In a solid the molecules are held tightly together, usually in definite arrangements in which the molecules can wiggle only slightly in their otherwise fixed positions.

Gas

Liquid

Solid

▲ **Figure 1.4** The three physical states of water—water vapor, liquid water, and ice. In this photo we see both the liquid and solid states of water. We cannot see water vapor. What we see when we look at steam or clouds is tiny droplets of liquid water dispersed in the atmosphere. The molecular views show that the molecules in the gas are much further apart than those in the liquid or solid. The molecules in the liquid do not have the orderly arrangement seen in the solid.

## Pure Substances

Most forms of matter that we encounter—for example, the air we breathe (a gas), gasoline for cars (a liquid), and the sidewalk on which we walk (a solid)—are not chemically pure. We can, however, resolve, or separate, these forms of matter into different pure substances. A **pure substance** (usually referred to simply as a *substance*) is matter that has distinct properties and a composition that does not vary from sample to sample. Water and ordinary table salt (sodium chloride), the primary components of seawater, are examples of pure substances.

All substances are either elements or compounds. **Elements** cannot be decomposed into simpler substances. On the molecular level, each element is composed of only one kind of atom [Figure 1.5(a and b) ▼]. **Compounds** are

(a) Atoms of an element

(b) Molecules of an element

(c) Molecules of a compound

(d) Mixture of elements and a compound

▲ **Figure 1.5** Molecular comparison of element, compounds, and mixtures. Each element contains a unique kind of atom. Elements might consist of individual atoms, as in (a), or molecules, as in (b). Compounds contain two or more different atoms chemically joined together, as in (c). A mixture contains the individual units of its components, shown in (d) as both atoms and molecules.

► **Figure 1.6 Relative abundances of elements.** Elements in percent by mass in (a) Earth's crust (including oceans and atmosphere) and (b) the human body.

substances composed of two or more elements; they contain two or more kinds of atoms [Figure 1.5(c)]. Water, for example, is a compound composed of two elements: hydrogen and oxygen. Figure 1.5(d) shows a mixture of substances. **Mixtures** are combinations of two or more substances in which each substance retains its own chemical identity.

## Elements

Currently, 117 elements are known. These elements vary widely in their abundance, as shown in Figure 1.6 ▲. For example, only five elements—oxygen, silicon, aluminum, iron, and calcium—account for over 90% of Earth's crust (including oceans and atmosphere). Similarly, just three elements—oxygen, carbon, and hydrogen—account for over 90% of the mass of the human body.

Some of the more common elements are listed in Table 1.2 ▼, along with the chemical abbreviations, or chemical *symbols*, used to denote them. The symbol for each element consists of one or two letters, with the first letter capitalized. These symbols are mostly derived from the English name for the element, but sometimes they are derived from a foreign name instead (last column in Table 1.2). You will need to know these symbols and learn others as we encounter them in the text.

All the known elements and their symbols are listed on the front inside cover of this text. The table in which the symbol for each element is enclosed in a box is called the *periodic table*. In the periodic table the elements are arranged in vertical columns so that closely related elements are grouped together. We describe the periodic table in more detail in Section 2.5.

### GIVE IT SOME THOUGHT

Which element is most abundant in both Earth's crust and in the human body? What is the symbol for this element?

## Compounds

Most elements can interact with other elements to form compounds. For example, consider the fact that when hydrogen gas burns in oxygen gas, the

**TABLE 1.2** ■ Some Common Elements and Their Symbols

Carbon	C	Aluminum	Al	Copper	Cu (from <i>cuprum</i> )
Fluorine	F	Bromine	Br	Iron	Fe (from <i>ferrum</i> )
Hydrogen	H	Calcium	Ca	Lead	Pb (from <i>plumbum</i> )
Iodine	I	Chlorine	Cl	Mercury	Hg (from <i>hydrargyrum</i> )
Nitrogen	N	Helium	He	Potassium	K (from <i>kalium</i> )
Oxygen	O	Lithium	Li	Silver	Ag (from <i>argentum</i> )
Phosphorus	P	Magnesium	Mg	Sodium	Na (from <i>natrium</i> )
Sulfur	S	Silicon	Si	Tin	Sn (from <i>stannum</i> )

The observation that the elemental composition of a pure compound is always the same is known as the **law of constant composition** (or the **law of definite proportions**). French chemist Joseph Louis Proust (1754–1826) first put forth the law in about 1800. Although this law has been known for 200 years, the general belief persists among some people that a fundamental difference exists between compounds prepared in the laboratory and the corresponding compounds found in nature. However, a pure compound has the same composition and properties regardless of its source. Both chemists and nature must use the same elements and operate under the same natural laws. When two materials differ in composition and properties, we know that they are composed of different compounds or that they differ in purity.

### GIVE IT SOME THOUGHT

Hydrogen, oxygen, and water are all composed of molecules. What is it about a molecule of water that makes it a compound, whereas hydrogen and oxygen are elements?

## Mixtures

Most of the matter we encounter consists of mixtures of different substances. Each substance in a mixture retains its own chemical identity and its own properties. In contrast to a pure substance that has a fixed composition, the composition of a mixture can vary. A cup of sweetened coffee, for example, can contain either a little sugar or a lot. The substances making up a mixture (such as sugar and water) are called *components* of the mixture.

Some mixtures do not have the same composition, properties, and appearance throughout. Both rocks and wood, for example, vary in texture and appearance throughout any typical sample. Such mixtures are *heterogeneous* [Figure 1.8(a) ▼]. Mixtures that are uniform throughout are *homogeneous*. Air is a homogeneous mixture of the gaseous substances nitrogen, oxygen, and smaller amounts of other substances. The nitrogen in air has all the properties that pure nitrogen does because both the pure substance and the mixture contain the same nitrogen molecules. Salt, sugar, and many other substances dissolve in water to form homogeneous mixtures [Figure 1.8(b)]. Homogeneous mixtures are also called **solutions**. Although the term solution conjures an image of a liquid in a beaker or flask, solutions can be solids, liquids, or gases. Figure 1.9 ► summarizes the classification of matter into elements, compounds, and mixtures.

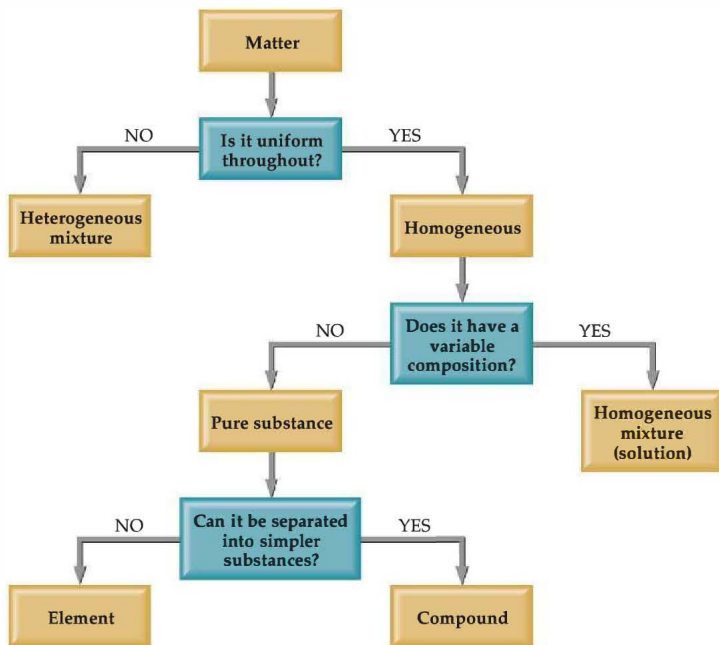

► **Figure 1.8 Mixtures.** (a) Many common materials, including rocks, are heterogeneous. This close-up photo is of malachite, a copper mineral. (b) Homogeneous mixtures are called solutions. Many substances, including the blue solid shown in this photo (copper sulfate), dissolve in water to form solutions.

(a)

(b)

◀ **Figure 1.9 Classification of matter.** At the chemical level all matter is classified ultimately as either elements or compounds.

### ■ SAMPLE EXERCISE 1.1 Distinguishing Among Elements, Compounds, and Mixtures

“White gold,” used in jewelry, contains gold and another “white” metal such as palladium. Two different samples of white gold differ in the relative amounts of gold and palladium that they contain. Both samples are uniform in composition throughout. Without knowing any more about the materials, use Figure 1.9 to classify white gold.

#### ■ SOLUTION

Because the material is uniform throughout, it is homogeneous. Because its composition differs for the two samples, it cannot be a compound. Instead, it must be a homogeneous mixture.

#### ■ PRACTICE EXERCISE

Aspirin is composed of 60.0% carbon, 4.5% hydrogen, and 35.5% oxygen by mass, regardless of its source. Use Figure 1.9 to characterize and classify aspirin.

**Answer:** It is a compound because it has constant composition and can be separated into several elements.

## 1.3 PROPERTIES OF MATTER

Every substance has a unique set of properties. For example, the properties listed in Table 1.3 allow us to distinguish hydrogen, oxygen, and water from one another. The properties of matter can be categorized as physical or chemical. **Physical properties** can be observed without changing the identity and composition of the substance. These properties include color, odor, density, melting point, boiling point, and hardness. **Chemical properties** describe the way a substance may change, or *react*, to form other substances. A common chemical property is flammability, the ability of a substance to burn in the presence of oxygen.

Some properties, such as temperature, melting point, and density, are called **intensive properties**. They do not depend on the amount of the sample being examined and are particularly useful in chemistry because many of these properties can be used to *identify* substances. **Extensive properties** of substances depend on the quantity of the sample, with two examples being mass and volume. Extensive properties relate to the *amount* of substance present.

### Physical and Chemical Changes

As with the properties of a substance, the changes that substances undergo can be classified as either physical or chemical. During a **physical change** a substance changes its physical appearance but not its composition. (That is, it is the same substance before and after the change.) The evaporation of water is a physical change. When water evaporates, it changes from the liquid state to the gas state, but it is still composed of water molecules, as depicted earlier in Figure 1.4. All **changes of state** (for example, from liquid to gas or from liquid to solid) are physical changes.

In a **chemical change** (also called a **chemical reaction**) a substance is transformed into a chemically different substance. When hydrogen burns in air, for example, it undergoes a chemical change because it combines with oxygen to form water. The molecular-level view of this process is depicted in Figure 1.10 ▼.

Chemical changes can be dramatic. In the account that follows, Ira Remsen, author of a popular chemistry text published in 1901, describes his first

▲ Figure 1.10 A chemical reaction.

▲ **Figure 1.11 The chemical reaction between a copper penny and nitric acid.** The dissolved copper produces the blue-green solution; the reddish brown gas produced is nitrogen dioxide.

experiences with chemical reactions. The chemical reaction that he observed is shown in Figure 1.11 ▲.

While reading a textbook of chemistry, I came upon the statement “nitric acid acts upon copper,” and I determined to see what this meant. Having located some nitric acid, I had only to learn what the words “act upon” meant. In the interest of knowledge I was even willing to sacrifice one of the few copper cents then in my possession. I put one of them on the table, opened a bottle labeled “nitric acid,” poured some of the liquid on the copper, and prepared to make an observation. But what was this wonderful thing which I beheld? The cent was already changed, and it was no small change either. A greenish-blue liquid foamed and fumed over the cent and over the table. The air became colored dark red. How could I stop this? I tried by picking the cent up and throwing it out the window. I learned another fact: nitric acid acts upon fingers. The pain led to another unpremeditated experiment. I drew my fingers across my trousers and discovered nitric acid acts upon trousers. That was the most impressive experiment I have ever performed. I tell of it even now with interest. It was a revelation to me. Plainly the only way to learn about such remarkable kinds of action is to see the results, to experiment, to work in the laboratory.

### GIVE IT SOME THOUGHT

Which of the following is a physical change, and which is a chemical change? Explain. (a) Plants use carbon dioxide and water to make sugar. (b) Water vapor in the air on a cold day forms frost.

## Separation of Mixtures

Because each component of a mixture retains its own properties, we can separate a mixture into its components by taking advantage of the differences in their properties. For example, a heterogeneous mixture of iron filings and gold filings could be sorted individually by color into iron and gold. A less tedious approach would be to use a magnet to attract the iron filings, leaving the gold ones behind. We can also take advantage of an important chemical difference between these two metals: Many acids dissolve iron but not gold. Thus, if we put our mixture into an appropriate acid, the acid would dissolve the iron and the gold would be left behind. The two could then be separated by *filtration*, a

procedure illustrated in Figure 1.12 ◀. We would have to use other chemical reactions, which we will learn about later, to transform the dissolved iron back into metal.

An important method of separating the components of a homogeneous mixture is *distillation*, a process that depends on the different abilities of substances to form gases. For example, if we boil a solution of salt and water, the water evaporates, forming a gas, and the salt is left behind. The gaseous water can be converted back to a liquid on the walls of a condenser, as shown in the apparatus depicted in Figure 1.13 ▼.

The differing abilities of substances to adhere to the surfaces of various solids such as paper and starch can also be used to separate mixtures. This ability is the basis of *chromatography* (literally “the writing of colors”), a technique that can give beautiful and dramatic results. An example of the chromatographic separation of ink is shown in Figure 1.14 ▼.

▲ **Figure 1.12 Separation by filtration.** A mixture of a solid and a liquid is poured through a porous medium, in this case filter paper. The liquid passes through the paper while the solid remains on the paper.

► **Figure 1.13 Distillation.** A simple apparatus for the separation of a sodium chloride solution (salt water) into its components. Boiling the solution vaporizes the water, which is condensed, then collected in the receiving flask. After all the water has boiled away, pure sodium chloride remains in the boiling flask.

► **Figure 1.14 Separation of ink into components by paper chromatography.** (a) Water begins to move up the paper. (b) Water moves past the ink spot, dissolving different components of the ink at different rates. (c) The ink has separated into its several different components.

## A Closer Look

## THE SCIENTIFIC METHOD

Although two scientists rarely approach the same problem in exactly the same way, they use guidelines for the practice of science that are known as the **scientific method**. These guidelines are outlined in Figure 1.15. We begin our study by collecting information, or *data*, by observation and experiment. The collection of information, however, is not the ultimate goal. The goal is to find a pattern or sense of order in our observations and to understand the origin of this order.

As we perform our experiments, we may begin to see patterns that lead us to a *tentative explanation*, or **hypothesis**, that guides us in planning further experiments. Eventually, we may be able to tie together a great number of observations in a single statement or equation called a scientific law. A **scientific law** is a *concise verbal statement or a mathematical equation that summarizes a broad variety of observations and experiences*. We tend to think of the laws of nature as the basic rules under which nature operates. However, it is not so much that matter obeys the laws of nature, but rather that the laws of nature describe the behavior of matter.

At many stages of our studies we may propose explanations of why nature behaves in a particular way. If a hypothesis is sufficiently general and is continually effective in predicting facts yet to be observed, it is called a theory. A **theory** is an *explanation of the general causes of certain phenomena, with considerable*

*evidence or facts to support it*. For example, Einstein's theory of relativity was a revolutionary new way of thinking about space and time. It was more than just a simple hypothesis, however, because it could be used to make predictions that could be tested experimentally. When these experiments were conducted, the results were generally in agreement with the predictions and were not explainable by earlier theories. Thus, the theory of relativity was supported, but not proven. Indeed, theories can never be proven to be absolutely correct.

As we proceed through this text, we will rarely have the opportunity to discuss the doubts, conflicts, clashes of personalities, and revolutions of perception that have led to our present ideas. We need to be aware that just because we can spell out the results of science so concisely and neatly in textbooks, it does not mean that scientific progress is smooth, certain, and predictable. Some of the ideas we present in this text took centuries to develop and involved many scientists. We gain our view of the natural world by standing on the shoulders of the scientists who came before us. Take advantage of this view. As you study, exercise your imagination. Don't be afraid to ask daring questions when they occur to you. You may be fascinated by what you discover!

**Related Exercise:** 1.57

▲ **Figure 1.15 The scientific method.** The scientific method is a general approach to solving problems that involves making observations, seeking patterns in the observations, formulating hypotheses to explain the observations, and testing these hypotheses by further experiments. Those hypotheses that withstand such tests and prove themselves useful in explaining and predicting behavior become known as theories.

## 1.4 UNITS OF MEASUREMENT

Many properties of matter are *quantitative*; that is, they are associated with numbers. When a number represents a measured quantity, the units of that quantity must always be specified. To say that the length of a pencil is 17.5 is meaningless. Expressing the number with its units, 17.5 centimeters (cm), properly specifies the length. The units used for scientific measurements are those of the **metric system**.

The metric system, which was first developed in France during the late eighteenth century, is used as the system of measurement in most countries throughout the world. The United States has traditionally used the English system, although use of the metric system has become more common. For example, the contents of most canned goods and soft drinks in grocery stores are now given in metric as well as in English units, as shown in Figure 1.16.

▲ **Figure 1.16 Metric units.** Metric measurements are increasingly common in the United States, as exemplified by the volume printed on this soda can.

### SI Units

In 1960 an international agreement was reached specifying a particular choice of metric units for use in scientific measurements. These preferred units are

TABLE 1.4 ■ SI Base Units

Physical Quantity	Name of Unit	Abbreviation
Mass	Kilogram	kg
Length	Meter	m
Time	Second	s <sup>a</sup>
Temperature	Kelvin	K
Amount of substance	Mole	mol
Electric current	Ampere	A
Luminous intensity	Candela	cd

<sup>a</sup>The abbreviation sec is frequently used.

called **SI units**, after the French *Système International d'Unités*. This system has seven *base units* from which all other units are derived. Table 1.4 ▲ lists these base units and their symbols. In this chapter we will consider the base units for length, mass, and temperature.

In the metric system, prefixes are used to indicate decimal fractions or multiples of various units. For example, the prefix *milli-* represents a  $10^{-3}$  fraction of a unit: A milligram (mg) is  $10^{-3}$  gram (g), a millimeter (mm) is  $10^{-3}$  meter (m), and so forth. Table 1.5 ▼ presents the prefixes commonly encountered in chemistry. In using SI units and in working problems throughout this text, you must be comfortable using exponential notation. If you are unfamiliar with exponential notation or want to review it, refer to Appendix A.1.

Although non-SI units are being phased out, some are still commonly used by scientists. Whenever we first encounter a non-SI unit in the text, the proper SI unit will also be given.

TABLE 1.5 ■ Selected Prefixes Used in the Metric System

Prefix	Abbreviation	Meaning	Example
Giga	G	$10^9$	1 gigameter (Gm) = $1 \times 10^9$ m
Mega	M	$10^6$	1 megameter (Mm) = $1 \times 10^6$ m
Kilo	k	$10^3$	1 kilometer (km) = $1 \times 10^3$ m
Deci	d	$10^{-1}$	1 decimeter (dm) = 0.1 m
Centi	c	$10^{-2}$	1 centimeter (cm) = 0.01 m
Milli	m	$10^{-3}$	1 millimeter (mm) = 0.001 m
Micro	$\mu^a$	$10^{-6}$	1 micrometer ( $\mu\text{m}$ ) = $1 \times 10^{-6}$ m
Nano	n	$10^{-9}$	1 nanometer (nm) = $1 \times 10^{-9}$ m
Pico	p	$10^{-12}$	1 picometer (pm) = $1 \times 10^{-12}$ m
Femto	f	$10^{-15}$	1 femtometer (fm) = $1 \times 10^{-15}$ m

<sup>a</sup>This is the Greek letter mu (pronounced "mew").

### GIVE IT SOME THOUGHT

Which of the following quantities is the smallest: 1 mg,  $1\mu\text{g}$ , or 1 pg?

### Length and Mass

The SI base unit of *length* is the meter (m), a distance only slightly longer than a yard. The relations between the English and metric system units that we will use most frequently in this text appear on the back inside cover. We will discuss how to convert English units into metric units, and vice versa, in Section 1.6.

**Mass\*** is a measure of the amount of material in an object. The SI base unit of mass is the kilogram (kg), which is equal to about 2.2 pounds (lb). This base unit is unusual because it uses a prefix, *kilo-*, instead of the word *gram* alone. We obtain other units for mass by adding prefixes to the word *gram*.

### ■ SAMPLE EXERCISE 1.2 | Using Metric Prefixes

What is the name given to the unit that equals (a)  $10^{-9}$  gram, (b)  $10^{-6}$  second, (c)  $10^{-3}$  meter?

#### SOLUTION

In each case we can refer to Table 1.5, finding the prefix related to each of the decimal fractions: (a) nanogram, ng, (b) microsecond,  $\mu$ s, (c) millimeter, mm.

### ■ PRACTICE EXERCISE

(a) What decimal fraction of a second is a picosecond, ps? (b) Express the measurement  $6.0 \times 10^3$  m using a prefix to replace the power of ten. (c) Use exponential notation to express 3.76 mg in grams.

**Answers:** (a)  $10^{-12}$  second, (b) 6.0 km, (c)  $3.76 \times 10^{-3}$  g

## Temperature

*Temperature* is a measure of the hotness or coldness of an object. Indeed, temperature is a physical property that determines the direction of heat flow. Heat always flows spontaneously from a substance at higher temperature to one at lower temperature. Thus, we feel the influx of heat when we touch a hot object, and we know that the object is at a higher temperature than our hand.

The temperature scales commonly employed in scientific studies are the Celsius and Kelvin scales. The **Celsius scale** is also the everyday scale of temperature in most countries (Figure 1.17 ▶). It was originally based on the assignment of  $0^\circ\text{C}$  to the freezing point of water and  $100^\circ\text{C}$  to its boiling point at sea level (Figure 1.18 ▼).

▲ **Figure 1.17 Australian stamp.** Many countries employ the Celsius temperature scale in everyday use, as illustrated by this stamp.

◀ **Figure 1.18 Comparison of the Kelvin, Celsius, and Fahrenheit temperature scales.** The freezing point and boiling point of water as well as normal human body temperature is indicated on each of the scales.

\*Mass and weight are not interchangeable terms but are often incorrectly thought to be the same. The weight of an object is the force that its mass exerts due to gravity. In space, where gravitational forces are very weak, an astronaut can be weightless, but he or she cannot be massless. In fact, the astronaut's mass in space is the same as it is on Earth.

The **Kelvin scale** is the SI temperature scale, and the SI unit of temperature is the kelvin (K). Historically, the Kelvin scale was based on the properties of gases; its origins will be considered in Chapter 10. Zero on this scale is the lowest attainable temperature,  $-273.15\text{ }^{\circ}\text{C}$ , a temperature referred to as *absolute zero*. Both the Celsius and Kelvin scales have equal-sized units—that is, a kelvin is the same size as a degree Celsius. Thus, the Kelvin and Celsius scales are related as follows:

$$\text{K} = ^{\circ}\text{C} + 273.15 \quad [1.1]$$

The freezing point of water,  $0\text{ }^{\circ}\text{C}$ , is  $273.15\text{ K}$  (Figure 1.18). Notice that we do not use a degree sign ( $^{\circ}$ ) with temperatures on the Kelvin scale.

The common temperature scale in the United States is the *Fahrenheit scale*, which is not generally used in scientific studies. On the Fahrenheit scale, water freezes at  $32\text{ }^{\circ}\text{F}$  and boils at  $212\text{ }^{\circ}\text{F}$ . The Fahrenheit and Celsius scales are related as follows:

$$^{\circ}\text{C} = \frac{5}{9} (^{\circ}\text{F} - 32) \quad \text{or} \quad ^{\circ}\text{F} = \frac{9}{5} (^{\circ}\text{C}) + 32 \quad [1.2]$$

### SAMPLE EXERCISE 1.3 | Converting Units of Temperature

If a weather forecaster predicts that the temperature for the day will reach  $31\text{ }^{\circ}\text{C}$ , what is the predicted temperature (a) in K, (b) in  $^{\circ}\text{F}$ ?

#### SOLUTION

(a) Using Equation 1.1, we have  $\text{K} = 31 + 273 = 304\text{ K}$

(b) Using Equation 1.2, we have  $^{\circ}\text{F} = \frac{9}{5}(31) + 32 = 56 + 32 = 88\text{ }^{\circ}\text{F}$

#### PRACTICE EXERCISE

Ethylene glycol, the major ingredient in antifreeze, freezes at  $-11.5\text{ }^{\circ}\text{C}$ . What is the freezing point in (a) K, (b)  $^{\circ}\text{F}$ ?

Answers: (a)  $261.7\text{ K}$ , (b)  $11.3\text{ }^{\circ}\text{F}$

**▲ Figure 1.19 Volume relationships.** The volume occupied by a cube that is  $1\text{ m}$  on each edge is a cubic meter,  $1\text{ m}^3$  (top). Each cubic meter contains  $1000\text{ dm}^3$  (middle). A liter is the same volume as a cubic decimeter,  $1\text{ L} = 1\text{ dm}^3$ . Each cubic decimeter contains  $1000$  cubic centimeters,  $1\text{ dm}^3 = 1000\text{ cm}^3$ . Each cubic centimeter equals  $1$  milliliter,  $1\text{ cm}^3 = 1\text{ mL}$  (bottom).

## Derived SI Units

The SI base units in Table 1.4 are used to derive the units of other quantities. To do so, we use the defining equation for the quantity, substituting the appropriate base units. For example, speed is defined as the ratio of distance traveled to elapsed time. Thus, the SI unit for speed— $\text{m/s}$ , which we read as “meters per second”—is the SI unit for distance (length),  $\text{m}$ , divided by the SI unit for time,  $\text{s}$ . We will encounter many derived units, such as those for force, pressure, and energy, later in this text. In this chapter we examine the derived units for volume and density.

## Volume

The *volume* of a cube is given by its length cubed,  $(\text{length})^3$ . Thus, the SI unit of volume is the SI unit of length,  $\text{m}$ , raised to the third power. The cubic meter, or  $\text{m}^3$ , is the volume of a cube that is  $1\text{ m}$  on each edge. Smaller units, such as cubic centimeters,  $\text{cm}^3$  (sometimes written as  $\text{cc}$ ), are frequently used in chemistry. Another unit of volume commonly used in chemistry is the *liter* (L), which equals a cubic decimeter,  $\text{dm}^3$ , and is slightly larger than a quart. The liter is the first metric unit we have encountered that is *not* an SI unit. There are  $1000$  milliliters (mL) in a liter (Figure 1.19 ◀), and each milliliter is the same volume as a cubic centimeter:  $1\text{ mL} = 1\text{ cm}^3$ . The terms *milliliter* and *cubic centimeter* are used interchangeably in expressing volume.

The devices used most frequently in chemistry to measure volume are illustrated in Figure 1.20 ▶. Syringes, burets, and pipets deliver liquids with more precision than graduated cylinders. Volumetric flasks are used to contain specific volumes of liquid.

◀ **Figure 1.20 Common volumetric glassware.** The graduated cylinder, syringe, and buret are used in laboratories to deliver variable volumes of liquid. The pipet is used to deliver a specific volume of liquid. The volumetric flask contains a specific volume of liquid when filled to the mark.

### GIVE IT SOME THOUGHT

Which of the following quantities represents a volume measurement:  $15 \text{ m}^2$ ;  $2.5 \times 10^2 \text{ m}^3$ ;  $5.77 \text{ L/s}$ ? How do you know?

### Density

**Density** is a property of matter that is widely used to characterize a substance. Density is defined as the amount of mass in a unit volume of the substance:

$$\text{Density} = \frac{\text{mass}}{\text{volume}} \quad [1.3]$$

The densities of solids and liquids are commonly expressed in units of grams per cubic centimeter ( $\text{g/cm}^3$ ) or grams per milliliter ( $\text{g/mL}$ ). The densities of some common substances are listed in Table 1.6. It is no coincidence that the density of water is  $1.00 \text{ g/mL}$ ; the gram was originally defined as the mass of  $1 \text{ mL}$  of water at a specific temperature. Because most substances change volume when they are heated or cooled, densities are temperature dependent. When reporting densities, the temperature should be specified. If no temperature is reported, we usually assume that the temperature is  $25 \text{ }^\circ\text{C}$ , close to normal room temperature.

The terms *density* and *weight* are sometimes confused. A person who says that iron weighs more than air generally means that iron has a higher density than air— $1 \text{ kg}$  of air has the same mass as  $1 \text{ kg}$  of iron, but the iron occupies a smaller volume, thereby giving it a higher density. If we combine two liquids that do not mix, the less dense liquid will float on the denser liquid.

**TABLE 1.6** ■ Densities of Some Selected Substances at  $25 \text{ }^\circ\text{C}$

Substance	Density ( $\text{g/cm}^3$ )
Air	0.001
Balsa wood	0.16
Ethanol	0.79
Water	1.00
Ethylene glycol	1.09
Table sugar	1.59
Table salt	2.16
Iron	7.9
Gold	19.32

Chemistry is a very lively, active field of science. Because chemistry is so central to our lives, reports on matters of chemical significance appear in the news nearly every day. Some reports tell of recent breakthroughs in the development of new pharmaceuticals, materials, and processes. Others deal with environmental and public safety issues. As you study chemistry, we hope you will develop the skills to better understand the importance of chemistry in your life. By way of examples, here are summaries of a few recent stories in which chemistry plays a role.

### Biofuels Reality Check

With the Energy Policy Act of 2005, the United States Congress has given a big push to fuels derived from biomass as a renewable, homegrown alternative to gasoline. The law requires that 4 billion gallons of the so-called renewable fuel be mixed with gasoline in 2007, increasing to 7.5 billion gallons by 2012. The United States currently consumes about 140 billion gallons of gasoline per year.

Although the Act does not dictate which renewable fuels to use, ethanol derived from corn currently dominates the alternatives with 40% of all gasoline now containing some ethanol. A blend of 10% ethanol and 90% gasoline, called E10, is the most common blend because it can be used in virtually all vehicles. Blends of 85% ethanol and 15% gasoline, called E85, are also available but can be used only with specially modified engines in what are called flexible-fuel vehicles (FFVs) (Figure 1.21 ▼).

▲ Figure 1.21 A gasoline pump that dispenses E85 ethanol.

When it comes to ethanol's pros and cons, there is no shortage of disagreement. In 2006, researchers at the University of Minnesota calculated that "Even dedicating all U.S. corn and soybean production to biofuels would meet only 12% of gasoline and 6% of diesel demand." The conversion of a much wider range of plant material, making use of a much greater fraction of the available plant matter, into fuels will be necessary to improve these numbers substantially. Because most cellulose of which plants are formed does not readily convert to ethanol, a great deal of research will be needed to solve this challenging problem. Meanwhile, it is worth reflecting that a 3% improvement in vehicle efficiency of fuel use would displace more gasoline use than the entire 2006 US ethanol production.

### New Element Created

A new entry has been made to the list of elements. The production of the newest and heaviest element—element 118—was announced in October 2006. The synthesis of element 118 resulted from studies performed from 2002 to 2006 at the Joint Institute for Nuclear Research (JINR) in Dubna, Russia. JINR scientists and their collaborators from Lawrence Livermore National Laboratory in California announced that they had produced three atoms of the new element, one atom in 2002 and two more in 2005.

The new element was formed by striking a target of californium atoms (element 98) with a highly energetic beam consisting of the nuclei of calcium atoms (element 20) in a device called a particle accelerator. Occasionally, the nuclei from the atoms of the two different elements fused to form the new, superheavy element 118. The 2002 experiment took four months and used a beam of  $2.5 \times 10^{19}$  calcium atoms to produce the single atom of element 118.

The three atoms of element 118 created during these experiments came and went in a literal flash. On the average, the atoms survived for just 0.9 milliseconds before decomposing.

These experimental results were met with praise but also caution from other scientists in the field, particularly given the difficult history of element 118. Another California lab, the Lawrence Berkeley National Laboratory, announced that it discovered element 118 in 1999 but retracted the claim two years later after an investigation found that one of the researchers had fabricated data.

This discovery brings the total number of elements created by the Livermore-Dubna collaboration to five: elements 113, 114, 115, 116, and 118. As of this writing, element 118 has not yet been named.

### Important Antibiotic Modified to Combat Bacterial Resistance

Vancomycin is an antibiotic of last resort—used only when other antibacterial agents are ineffective. Some bacteria have developed a resistance to vancomycin, causing researchers to modify the molecular structure of the substance to make it

◀ **Figure 1.22 Comparing CO and CH<sub>2</sub> groups.** Two molecules, one containing the CO group (left) and one containing the CH<sub>2</sub> group (right), are shown. The subtle difference between these two molecules is like that produced when the structure of the much more complex vancomycin molecule was modified.

more effective in killing bacteria. This approach was based on the knowledge that vancomycin works by binding to a particular protein, called a glycoprotein, that is essential to forming the walls of bacterial cells. Researchers have now synthesized an analog of vancomycin in which a CO group in the molecule has been converted to a CH<sub>2</sub> group (Figure 1.22▲). This molecular modification increases the compound's binding affinity with the glycoprotein in the cell walls of vancomycin-resistant bacteria. The analog is 100 times more active than vancomycin against vancomycin-resistant bacteria.

### The Hole Story

Ozone in the upper atmosphere protects life on Earth by blocking harmful ultraviolet rays coming from the sun. The “ozone hole” is a severe depletion of the ozone layer high above Antarctica. Human-produced compounds that release chlorine and bromine into the stratosphere are the primary cause of the ozone hole.

The production of ozone-depleting chemicals has been banned since 1996, although emissions of previously produced and stored amounts of those chemicals that are not destroyed or recycled will continue. Scientists had predicted that the ozone hole would disappear by 2050 because of the ban. The 2006 World Meteorological Organization/United Nations Environment Programme Scientific Assessment of Ozone De-

pletion, however, recently issued its report changing this estimate. Based on a combination of new ozone measurements, computer models, and revised estimates of the existing stores of ozone-depleting chemicals, scientists now estimate the date for full Antarctic ozone recovery to be 2065.

### Replacing the Lightbulb through Chemistry

If you want to save the world from global warming, you can start by replacing incandescent lightbulbs, which waste about 90% of the energy supplied to them by producing heat. A promising place to look for replacement bulbs is in the field of light-emitting diodes (LEDs). Red LEDs and those emitting other colors are found everywhere these days: in flashlights, traffic lights, car taillights, and a host of electronics applications (Figure 1.23▼). But to really make it big in the world, LEDs need to be capable of producing white light at a reasonable cost.

Progress is being made in forming high-efficiency LEDs based on organic films that emit white light. In these devices a light-emitting material is sandwiched between two electrical connectors. When electricity passes through the organic film, oppositely charged particles combine and give off light. White organic LEDs have been steadily improving, and are now about as efficient as fluorescent tubes. More work needs to be done before these devices can replace the lightbulb, but progress has been rapid.

▶ **Figure 1.23 Sign made from LEDs.**

**SAMPLE EXERCISE 1.4 | Determining Density and Using Density to Determine Volume or Mass**

- (a) Calculate the density of mercury if  $1.00 \times 10^2$  g occupies a volume of  $7.36 \text{ cm}^3$ .  
 (b) Calculate the volume of 65.0 g of the liquid methanol (wood alcohol) if its density is 0.791 g/mL.  
 (c) What is the mass in grams of a cube of gold (density =  $19.32 \text{ g/cm}^3$ ) if the length of the cube is 2.00 cm?

**SOLUTION**

(a) We are given mass and volume, so Equation 1.3 yields

$$\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{1.00 \times 10^2 \text{ g}}{7.36 \text{ cm}^3} = 13.6 \text{ g/cm}^3$$

(b) Solving Equation 1.3 for volume and then using the given mass and density gives

$$\text{Volume} = \frac{\text{mass}}{\text{density}} = \frac{65.0 \text{ g}}{0.791 \text{ g/mL}} = 82.2 \text{ mL}$$

(c) We can calculate the mass from the volume of the cube and its density. The volume of a cube is given by its length cubed:

$$\text{Volume} = (2.00 \text{ cm})^3 = (2.00)^3 \text{ cm}^3 = 8.00 \text{ cm}^3$$

Solving Equation 1.3 for mass and substituting the volume and density of the cube, we have

$$\text{Mass} = \text{volume} \times \text{density} = (8.00 \text{ cm}^3)(19.32 \text{ g/cm}^3) = 155 \text{ g}$$

**PRACTICE EXERCISE**

- (a) Calculate the density of a 374.5-g sample of copper if it has a volume of  $41.8 \text{ cm}^3$ . (b) A student needs 15.0 g of ethanol for an experiment. If the density of ethanol is 0.789 g/mL, how many milliliters of ethanol are needed? (c) What is the mass, in grams, of 25.0 mL of mercury (density =  $13.6 \text{ g/mL}$ )?

**Answers:** (a)  $8.96 \text{ g/cm}^3$ , (b) 19.0 mL, (c) 340 g

## 1.5 UNCERTAINTY IN MEASUREMENT

Two kinds of numbers are encountered in scientific work: *exact numbers* (those whose values are known exactly) and *inexact numbers* (those whose values have some uncertainty). Most of the exact numbers that we will encounter in this course have defined values. For example, there are exactly 12 eggs in a dozen, exactly 1000 g in a kilogram, and exactly 2.54 cm in an inch. The number 1 in any conversion factor between units, as in  $1 \text{ m} = 100 \text{ cm}$  or  $1 \text{ kg} = 2.2046 \text{ lb}$ , is also an exact number. Exact numbers can also result from counting numbers of objects. For example, we can count the exact number of marbles in a jar or the exact number of people in a classroom.

Numbers obtained by measurement are always *inexact*. The equipment used to measure quantities always has inherent limitations (equipment errors), and there are differences in how different people make the same measurement (human errors). Suppose that ten students with ten balances are given the same dime and told to determine its mass. The ten measurements will probably vary slightly from one another for various reasons. The balances might be calibrated slightly differently, and there might be differences in how each student reads the mass from the balance. Remember: *Uncertainties always exist in measured quantities*. Counting very large numbers of objects usually has some associated error as well. Consider, for example, how difficult it is to obtain accurate census information for a city or vote counts for an election.

### GIVE IT SOME THOUGHT

Which of the following is an inexact quantity: (a) the number of people in your chemistry class, (b) the mass of a penny, (c) the number of grams in a kilogram?

### Precision and Accuracy

The terms precision and accuracy are often used in discussing the uncertainties of measured values. **Precision** is a measure of how closely individual measurements

agree with one another. **Accuracy** refers to how closely individual measurements agree with the correct, or “true,” value. The analogy of darts stuck in a dartboard pictured in Figure 1.24 ► illustrates the difference between these two concepts.

In the laboratory we often perform several different “trials” of the same experiment and average the results. The precision of the measurements is often expressed in terms of what is called the *standard deviation*, which reflects how much the individual measurements differ from the average, as described in Appendix A. We gain confidence in our measurements if we obtain nearly the same value each time—that is, the standard deviation is small. Figure 1.24 should remind us, however, that precise measurements could be inaccurate. For example, if a very sensitive balance is poorly calibrated, the masses we measure will be consistently either high or low. They will be inaccurate even if they are precise.

### Significant Figures

Suppose you determine the mass of a dime on a balance capable of measuring to the nearest 0.0001 g. You could report the mass as  $2.2405 \pm 0.0001$  g. The  $\pm$  notation (read “plus or minus”) expresses the magnitude of the uncertainty of your measurement. In much scientific work we drop the  $\pm$  notation with the understanding that there is always some uncertainty in the last digit of the measured quantity. That is, *measured quantities are generally reported in such a way that only the last digit is uncertain*.

Figure 1.25 ▼ shows a thermometer with its liquid column between the scale marks. We can read the certain digits from the scale and estimate the uncertain one. From the scale marks on the thermometer, we see that the liquid is between the 25 °C and 30 °C marks. We might estimate the temperature to be 27 °C, being somewhat uncertain of the second digit of our measurement.

All digits of a measured quantity, including the uncertain one, are called **significant figures**. A measured mass reported as 2.2 g has two significant figures, whereas one reported as 2.2405 g has five significant figures. The greater the number of significant figures, the greater is the certainty implied for the measurement. When multiple measurements are made of a quantity, the results can be averaged, and the number of significant figures estimated by using statistical methods.

◀ **Figure 1.25 Significant figures in measurements.** The thermometer has markings every 5 °C. The temperature is between 25 °C and 30 °C and is approximately 27 °C. The two significant figures in the measurement include the second digit, which is estimated by reading between the scale marks.

Good accuracy  
Good precision

Poor accuracy  
Good precision

Poor accuracy  
Poor precision

▲ **Figure 1.24 Precision and accuracy.** The distribution of darts on a target illustrates the difference between accuracy and precision.

### SAMPLE EXERCISE 1.5 Relating Significant Figures to the Uncertainty of a Measurement

What difference exists between the measured values 4.0 g and 4.00 g?

#### SOLUTION

Many people would say there is no difference, but a scientist would note the difference in the number of significant figures in the two measurements. The value 4.0 has two significant figures, while 4.00 has three. This difference implies that the first measurement has more uncertainty. A mass of 4.0 g indicates that the uncertainty is in the first decimal place of the measurement. Thus, the mass might be anything between 3.9 and 4.1 g, which we can represent as  $4.0 \pm 0.1$  g. A measurement of 4.00 g implies that the uncertainty is in the second decimal place. Thus, the mass might be anything between 3.99 and 4.01 g, which we can represent as  $4.00 \pm 0.01$  g. Without further information, we cannot be sure whether the difference in uncertainties of the two measurements reflects the precision or accuracy of the measurement.

#### PRACTICE EXERCISE

A balance has a precision of  $\pm 0.001$  g. A sample that has a mass of about 25 g is placed on this balance. How many significant figures should be reported for this measurement?

**Answer:** five, as in the measurement 24.995 g, the uncertainty being in the third decimal place

To determine the number of significant figures in a reported measurement, read the number from left to right, counting the digits starting with the first digit that is not zero. *In any measurement that is properly reported, all nonzero digits are significant.* Zeros, however, can be used either as part of the measured value or merely to locate the decimal point. Thus, zeros may or may not be significant, depending on how they appear in the number. The following guidelines describe the different situations involving zeros:

1. Zeros *between* nonzero digits are always significant—1005 kg (four significant figures); 1.03 cm (three significant figures).
2. Zeros *at the beginning* of a number are never significant; they merely indicate the position of the decimal point—0.02 g (one significant figure); 0.0026 cm (two significant figures).
3. Zeros *at the end* of a number are significant if the number contains a decimal point—0.0200 g (three significant figures); 3.0 cm (two significant figures).

A problem arises when a number ends with zeros but contains no decimal point. In such cases, it is normally assumed that the zeros are not significant. Exponential notation (Appendix A) can be used to clearly indicate whether zeros at the end of a number are significant. For example, a mass of 10,300 g can be written in exponential notation showing three, four, or five significant figures depending on how the measurement is obtained:

$$1.03 \times 10^4 \text{ g} \quad (\text{three significant figures})$$

$$1.030 \times 10^4 \text{ g} \quad (\text{four significant figures})$$

$$1.0300 \times 10^4 \text{ g} \quad (\text{five significant figures})$$

In these numbers all the zeros to the right of the decimal point are significant (rules 1 and 3). (The exponential term does not add to the number of significant figures.)

### SAMPLE EXERCISE 1.6 Determining the Number of Significant Figures in a Measurement

How many significant figures are in each of the following numbers (assume that each number is a measured quantity): (a) 4.003, (b)  $6.023 \times 10^{23}$ , (c) 5000?

#### SOLUTION

(a) Four; the zeros are significant figures. (b) Four; the exponential term does not add to the number of significant figures. (c) One. We assume that the zeros are not significant when there is no decimal point shown. If the number has more significant figures, a decimal point should be employed or the number written in exponential notation. Thus, 5000. has four significant figures, whereas  $5.00 \times 10^3$  has three.

**PRACTICE EXERCISE**

How many significant figures are in each of the following measurements: (a) 3.549 g, (b)  $2.3 \times 10^4$  cm, (c) 0.00134 m<sup>3</sup>?

**Answers:** (a) four, (b) two, (c) three

**Significant Figures in Calculations**

When carrying measured quantities through calculations, *the least certain measurement limits the certainty of the calculated quantity and thereby determines the number of significant figures in the final answer.* The final answer should be reported with only one uncertain digit. To keep track of significant figures in calculations, we will make frequent use of two rules, one for addition and subtraction, and another for multiplication and division.

1. *For addition and subtraction*, the result has the same number of decimal places as the measurement with the fewest decimal places. When the result contains more than the correct number of significant figures, it must be rounded off. Consider the following example in which the uncertain digits appear in color:

This number limits	20.42	← two decimal places
the number of significant figures in the result →	1.322	← three decimal places
	83.1	← one decimal place
	<u>104.842</u>	← round off to one decimal place (104.8)

We report the result as 104.8 because 83.1 has only one decimal place.

2. *For multiplication and division*, the result contains the same number of significant figures as the measurement with the fewest significant figures. When the result contains more than the correct number of significant figures, it must be rounded off. For example, the area of a rectangle whose measured edge lengths are 6.221 cm and 5.2 cm should be reported as 32 cm<sup>2</sup> even though a calculator shows the product of 6.221 and 5.2 to have more digits:

$$\text{Area} = (6.221 \text{ cm})(5.2 \text{ cm}) = 32.3492 \text{ cm}^2 \Rightarrow \text{round off to } 32 \text{ cm}^2$$

We round off to two significant figures because the least precise number—5.2 cm—has only two significant figures.

*Notice that for addition and subtraction, decimal places are counted; whereas for multiplication and division, significant figures are counted.*

In determining the final answer for a calculated quantity, *exact numbers* can be treated as if they have an infinite number of significant figures. This rule applies to many definitions between units. Thus, when we say, "There are 12 inches in 1 foot," the number 12 is exact, and we need not worry about the number of significant figures in it.

In *rounding off numbers*, look at the leftmost digit to be removed:

- If the leftmost digit removed is less than 5, the preceding number is left unchanged. Thus, rounding 7.248 to two significant figures gives 7.2.
- If the leftmost digit removed is 5 or greater, the preceding number is increased by 1. Rounding 4.735 to three significant figures gives 4.74, and rounding 2.376 to two significant figures gives 2.4.\*

**SAMPLE EXERCISE 1.7** | Determining the Number of Significant Figures in a Calculated Quantity

The width, length, and height of a small box are 15.5 cm, 27.3 cm, and 5.4 cm, respectively. Calculate the volume of the box, using the correct number of significant figures in your answer.

\*Your instructor may want you to use a slight variation on the rule when the leftmost digit to be removed is exactly 5, with no following digits or only zeros. One common practice is to round up to the next higher number if that number will be even, and down to the next lower number otherwise. Thus, 4.7350 would be rounded to 4.74, and 4.7450 would also be rounded to 4.74.

**SOLUTION**

The product of the width, length, and height determines the volume of a box. In reporting the product, we can show only as many significant figures as given in the dimension with the fewest significant figures, that for the height (two significant figures):

$$\begin{aligned}\text{Volume} &= \text{width} \times \text{length} \times \text{height} \\ &= (15.5 \text{ cm})(27.3 \text{ cm})(5.4 \text{ cm}) = 2285.01 \text{ cm}^3 \Rightarrow 23 \times 10^3 \text{ cm}^3\end{aligned}$$

When we use a calculator to do this calculation, the display shows 2285.01, which we must round off to two significant figures. Because the resulting number is 2300, it is best reported in exponential notation,  $2.3 \times 10^3$ , to clearly indicate two significant figures.

**PRACTICE EXERCISE**

It takes 10.5 s for a sprinter to run 100.00 m. Calculate the average speed of the sprinter in meters per second, and express the result to the correct number of significant figures.

*Answer:* 9.52 m/s (three significant figures)

**SAMPLE EXERCISE 1.8 | Determining the Number of Significant Figures in a Calculated Quantity**

A gas at 25 °C fills a container whose volume is  $1.05 \times 10^3 \text{ cm}^3$ . The container plus gas have a mass of 837.6 g. The container, when emptied of all gas, has a mass of 836.2 g. What is the density of the gas at 25 °C?

**SOLUTION**

To calculate the density, we must know both the mass and the volume of the gas. The mass of the gas is just the difference in the masses of the full and empty container:

$$(837.6 - 836.2) \text{ g} = 1.4 \text{ g}$$

In subtracting numbers, we determine the number of significant figures in our result by counting decimal places in each quantity. In this case each quantity has one decimal place. Thus, the mass of the gas, 1.4 g, has one decimal place.

Using the volume given in the question,  $1.05 \times 10^3 \text{ cm}^3$ , and the definition of density, we have

$$\begin{aligned}\text{Density} &= \frac{\text{mass}}{\text{volume}} = \frac{1.4 \text{ g}}{1.05 \times 10^3 \text{ cm}^3} \\ &= 1.3 \times 10^{-3} \text{ g/cm}^3 = 0.0013 \text{ g/cm}^3\end{aligned}$$

In dividing numbers, we determine the number of significant figures in our result by counting the number of significant figures in each quantity. There are two significant figures in our answer, corresponding to the smaller number of significant figures in the two numbers that form the ratio. Notice that in this example, following the rules for determining significant figures gives an answer containing only two significant figures, even though each of the measured quantities contained at least three significant figures.

**PRACTICE EXERCISE**

To how many significant figures should the mass of the container be measured (with and without the gas) in Sample Exercise 1.8 for the density to be calculated to three significant figures?

*Answer:* five (For the difference in the two masses to have three significant figures, there must be two decimal places in the masses of the filled and empty containers. Therefore, each mass must be measured to five significant figures.)

When a calculation involves two or more steps and you write down answers for intermediate steps, retain at least one additional digit—past the number of significant figures—for the intermediate answers. This procedure ensures that small errors from rounding at each step do not combine to affect the final result. When using a calculator, you may enter the numbers one after another, rounding only the final answer. Accumulated rounding-off errors may account for small differences among results you obtain and answers given in the text for numerical problems.

**1.6 DIMENSIONAL ANALYSIS**

Throughout the text we use an approach called **dimensional analysis** as an aid in problem solving. In dimensional analysis we carry units through all calculations. Units are multiplied together, divided into each other, or “canceled.”

Using dimensional analysis helps ensure that the solutions to problems yield the proper units. Moreover, it provides a systematic way of solving many numerical problems and of checking our solutions for possible errors.

The key to using dimensional analysis is the correct use of conversion factors to change one unit into another. A **conversion factor** is a fraction whose numerator and denominator are the same quantity expressed in different units. For example, 2.54 cm and 1 in. are the same length,  $2.54 \text{ cm} = 1 \text{ in.}$  This relationship allows us to write two conversion factors:

$$\frac{2.54 \text{ cm}}{1 \text{ in.}} \quad \text{and} \quad \frac{1 \text{ in.}}{2.54 \text{ cm}}$$

We use the first of these factors to convert inches to centimeters. For example, the length in centimeters of an object that is 8.50 in. long is given by

$$\text{Number of centimeters} = (8.50 \text{ in.}) \frac{2.54 \text{ cm}}{1 \text{ in.}} = 21.6 \text{ cm}$$

Desired unit  
Given unit

The unit inches in the denominator of the conversion factor cancels the unit inches in the given data (8.50 inches). The unit centimeters in the numerator of the conversion factor becomes the unit of the final answer. Because the numerator and denominator of a conversion factor are equal, multiplying any quantity by a conversion factor is equivalent to multiplying by the number 1 and so does not change the intrinsic value of the quantity. The length 8.50 in. is the same as the length 21.6 cm.

In general, we begin any conversion by examining the units of the given data and the units we desire. We then ask ourselves what conversion factors we have available to take us from the units of the given quantity to those of the desired one. When we multiply a quantity by a conversion factor, the units multiply and divide as follows:

$$\text{Given unit} \times \frac{\text{desired unit}}{\text{given unit}} = \text{desired unit}$$

If the desired units are not obtained in a calculation, then an error must have been made somewhere. Careful inspection of units often reveals the source of the error.

### SAMPLE EXERCISE 1.9 | Converting Units

If a woman has a mass of 115 lb, what is her mass in grams? (Use the relationships between units given on the back inside cover of the text.)

#### SOLUTION

Because we want to change from lb to g, we look for a relationship between these units of mass. From the back inside cover we have  $1 \text{ lb} = 453.6 \text{ g}$ . To cancel pounds and leave grams, we write the conversion factor with grams in the numerator and pounds in the denominator:

$$\text{Mass in grams} = (115 \text{ lb}) \left( \frac{453.6 \text{ g}}{1 \text{ lb}} \right) = 5.22 \times 10^4 \text{ g}$$

The answer can be given to only three significant figures, the number of significant figures in 115 lb. The process we have used is diagrammed in the margin.

#### PRACTICE EXERCISE

By using a conversion factor from the back inside cover, determine the length in kilometers of a 500.0-mi automobile race.

*Answer:* 804.7 km

## Strategies in Chemistry

## ESTIMATING ANSWERS

A friend once remarked cynically that calculators let you get the wrong answer more quickly. What he was implying by that remark was that unless you have the correct strategy for solving a problem and have punched in the correct numbers, the answer will be incorrect. If you learn to *estimate* answers, however, you will be able to check whether the answers to your calculations are reasonable.

The idea is to make a rough calculation using numbers that are rounded off in such a way that the arithmetic can be easily performed without a calculator. This approach is often referred to as making a “ballpark” estimate, meaning that while it does not give an exact answer, it gives one that is roughly the right size. By working with units using dimensional analysis and by estimating answers, we can readily check the reasonableness of our answers to calculations.

## GIVE IT SOME THOUGHT

How do we determine how many digits to use in conversion factors, such as the one between pounds and grams in Sample Exercise 1.9?

## Using Two or More Conversion Factors

It is often necessary to use several conversion factors in solving a problem. As an example, let's convert the length of an 8.00-m rod to inches. The table on the back inside cover does not give the relationship between meters and inches. It *does*, however, give the relationship between centimeters and inches. (1 in. = 2.54 cm). From our knowledge of metric prefixes, we know that 1 cm =  $10^{-2}$  m. Thus, we can convert step by step, first from meters to centimeters, and then from centimeters to inches as diagrammed in the margin.

Combining the given quantity (8.00 m) and the two conversion factors, we have

$$\text{Number of inches} = (8.00 \text{ m}) \left( \frac{1 \text{ cm}}{10^{-2} \text{ m}} \right) \left( \frac{1 \text{ in.}}{2.54 \text{ cm}} \right) = 315 \text{ in.}$$

The first conversion factor is applied to cancel meters and convert the length to centimeters. Thus, meters are written in the denominator and centimeters in the numerator. The second conversion factor is written to cancel centimeters, so it has centimeters in the denominator and inches, the desired unit, in the numerator.

**SAMPLE EXERCISE 1.10** Converting Units Using Two or More Conversion Factors

The average speed of a nitrogen molecule in air at 25 °C is 515 m/s. Convert this speed to miles per hour.

**SOLUTION**

To go from the given units, m/s, to the desired units, mi/hr, we must convert meters to miles and seconds to hours. From our knowledge of metric prefixes we know that 1 km =  $10^3$  m. From the relationships given on the back inside cover of the book, we find that 1 mi = 1.6093 km. Thus, we can convert m to km and then convert km to mi. From our knowledge of time we know that 60 s = 1 min and 60 min = 1 hr. Thus, we can convert s to min and then convert min to hr. The overall process is diagrammed in the margin.

Applying first the conversions for distance and then those for time, we can set up one long equation in which unwanted units are canceled:

$$\begin{aligned} \text{Speed in mi/hr} &= \left( 515 \frac{\text{m}}{\text{s}} \right) \left( \frac{1 \text{ km}}{10^3 \text{ m}} \right) \left( \frac{1 \text{ mi}}{1.6093 \text{ km}} \right) \left( \frac{60 \text{ s}}{1 \text{ min}} \right) \left( \frac{60 \text{ min}}{1 \text{ hr}} \right) \\ &= 1.15 \times 10^3 \text{ mi/hr} \end{aligned}$$

Our answer has the desired units. We can check our calculation, using the estimating procedure described in the previous “Strategies” box. The given speed is about

500 m/s. Dividing by 1000 converts m to km, giving 0.5 km/s. Because 1 mi is about 1.6 km, this speed corresponds to  $0.5/1.6 = 0.3$  mi/s. Multiplying by 60 gives about  $0.3 \times 60 = 20$  mi/min. Multiplying again by 60 gives  $20 \times 60 = 1200$  mi/hr. The approximate solution (about 1200 mi/hr) and the detailed solution (1150 mi/hr) are reasonably close. The answer to the detailed solution has three significant figures, corresponding to the number of significant figures in the given speed in m/s.

### ■ PRACTICE EXERCISE

A car travels 28 mi per gallon of gasoline. How many kilometers per liter will it go?

*Answer:* 12 km/L

## Conversions Involving Volume

The conversion factors previously noted convert from one unit of a given measure to another unit of the same measure, such as from length to length. We also have conversion factors that convert from one measure to a different one. The density of a substance, for example, can be treated as a conversion factor between mass and volume. Suppose that we want to know the mass in grams of two cubic inches ( $2.00 \text{ in.}^3$ ) of gold, which has a density of  $19.3 \text{ g/cm}^3$ . The density gives us the following factors:

$$\frac{19.3 \text{ g}}{1 \text{ cm}^3} \quad \text{and} \quad \frac{1 \text{ cm}^3}{19.3 \text{ g}}$$

Because the answer we want is a mass in grams, we can see that we will use the first of these factors, which has mass in grams in the numerator. To use this factor, however, we must first convert cubic inches to cubic centimeters. The relationship between  $\text{in.}^3$  and  $\text{cm}^3$  is not given on the back inside cover, but the relationship between inches and centimeters is given:  $1 \text{ in.} = 2.54 \text{ cm}$  (exactly). Cubing both sides of this equation gives  $(1 \text{ in.})^3 = (2.54 \text{ cm})^3$ , from which we write the desired conversion factor:

$$\frac{(2.54 \text{ cm})^3}{(1 \text{ in.})^3} = \frac{(2.54)^3 \text{ cm}^3}{(1)^3 \text{ in.}^3} = \frac{16.39 \text{ cm}^3}{1 \text{ in.}^3}$$

Notice that both the numbers and the units are cubed. Also, because 2.54 is an exact number, we can retain as many digits of  $(2.54)^3$  as we need. We have used four, one more than the number of digits in the density ( $19.3 \text{ g/cm}^3$ ). Applying our conversion factors, we can now solve the problem:

$$\text{Mass in grams} = (2.00 \text{ in.}^3) \left( \frac{16.39 \text{ cm}^3}{1 \text{ in.}^3} \right) \left( \frac{19.3 \text{ g}}{1 \text{ cm}^3} \right) = 633 \text{ g}$$

The procedure is diagrammed below. The final answer is reported to three significant figures, the same number of significant figures as in  $2.00 \text{ in.}^3$  and  $19.3 \text{ g}$ .

### ■ SAMPLE EXERCISE 1.11 | Converting Volume Units

Earth's oceans contain approximately  $1.36 \times 10^9 \text{ km}^3$  of water. Calculate the volume in liters.

#### SOLUTION

This problem involves conversion of  $\text{km}^3$  to L. From the back inside cover of the text we find  $1 \text{ L} = 10^{-3} \text{ m}^3$ , but there is no relationship listed involving  $\text{km}^3$ . From our

knowledge of metric prefixes, however, we have  $1 \text{ km} = 10^3 \text{ m}$  and we can use this relationship between lengths to write the desired conversion factor between volumes:

$$\left(\frac{10^3 \text{ m}}{1 \text{ km}}\right)^3 = \frac{10^9 \text{ m}^3}{1 \text{ km}^3}$$

Thus, converting from  $\text{km}^3$  to  $\text{m}^3$  to L, we have

$$\text{Volume in liters} = (1.36 \times 10^9 \text{ km}^3) \left(\frac{10^9 \text{ m}^3}{1 \text{ km}^3}\right) \left(\frac{1 \text{ L}}{10^{-3} \text{ m}^3}\right) = 1.36 \times 10^{21} \text{ L}$$

### ■ PRACTICE EXERCISE

If the volume of an object is reported as  $5.0 \text{ ft}^3$ , what is the volume in cubic meters?  
**Answer:**  $0.14 \text{ m}^3$

## Strategies in Chemistry

### THE IMPORTANCE OF PRACTICE

If you have ever played a musical instrument or participated in athletics, you know that the keys to success are practice and discipline. You cannot learn to play a piano merely by listening to music, and you cannot learn how to play basketball merely by watching games on television. Likewise, you cannot learn chemistry by merely watching your instructor do it. Simply reading this book, listening to lectures, or reviewing notes will not usually be sufficient when exam time comes around. Your task is not merely to understand how someone else uses chemistry, but to be able to do it yourself. That takes practice on a regular basis, and anything that you have to do on a regular basis requires self-discipline until it becomes a habit.

Throughout the book, we have provided sample exercises in which the solutions are shown in detail. A practice exercise, for which only the answer is given, accompanies each sample exercise. It is important that you use these exercises as learn-

ing aids. End-of-chapter exercises provide additional questions to help you understand the material in the chapter. Red numbers indicate exercises for which answers are given at the back of the book. A review of basic mathematics is given in Appendix A.

The practice exercises in this text and the homework assignments given by your instructor provide the minimal practice that you will need to succeed in your chemistry course. Only by working all the assigned problems will you face the full range of difficulty and coverage that your instructor expects you to master for exams. There is no substitute for a determined and perhaps lengthy effort to work problems on your own. If you are stuck on a problem, however, ask for help from your instructor, a teaching assistant, a tutor, or a fellow student. Spending an inordinate amount of time on a single exercise is rarely effective unless you know that it is particularly challenging and requires extensive thought and effort.

### ■ SAMPLE EXERCISE 1.12 | Conversions Involving Density

What is the mass in grams of 1.00 gal of water? The density of water is  $1.00 \text{ g/mL}$ .

#### SOLUTION

Before we begin solving this exercise, we note the following:

1. We are given 1.00 gal of water (the known, or given, quantity) and asked to calculate its mass in grams (the unknown).
2. We have the following conversion factors either given, commonly known, or available on the back inside cover of the text:

$$\frac{1.00 \text{ g water}}{1 \text{ mL water}} \quad \frac{1 \text{ L}}{1000 \text{ mL}} \quad \frac{1 \text{ L}}{1.057 \text{ qt}} \quad \frac{1 \text{ gal}}{4 \text{ qt}}$$

The first of these conversion factors must be used as written (with grams in the numerator) to give the desired result, whereas the last conversion factor must be inverted in order to cancel gallons:

$$\begin{aligned} \text{Mass in grams} &= (1.00 \text{ gal}) \left(\frac{4 \text{ qt}}{1 \text{ gal}}\right) \left(\frac{1 \text{ L}}{1.057 \text{ qt}}\right) \left(\frac{1000 \text{ mL}}{1 \text{ L}}\right) \left(\frac{1.00 \text{ g}}{1 \text{ mL}}\right) \\ &= 3.78 \times 10^3 \text{ g water} \end{aligned}$$

The units of our final answer are appropriate, and we've also taken care of our significant figures. We can further check our calculation by the estimation procedure. We can round 1.057 off to 1. Focusing on the numbers that do not equal 1 then gives merely  $4 \times 1000 = 4000 \text{ g}$ , in agreement with the detailed calculation.

In cases such as this you may also be able to use common sense to assess the reasonableness of your answer. In this case we know that most people can lift a

gallon of milk with one hand, although it would be tiring to carry it around all day. Milk is mostly water and will have a density that is not too different than water. Therefore, we might estimate that in familiar units a gallon of water would have mass that was more than 5 lbs but less than 50 lbs. The mass we have calculated is  $3.78 \text{ kg} \times 2.2 \text{ lb/kg} = 8.3 \text{ lbs}$ —an answer that is reasonable at least as an order of magnitude estimate.

#### **PRACTICE EXERCISE**

The density of benzene is 0.879 g/mL. Calculate the mass in grams of 1.00 qt of benzene.

*Answer:* 832 g

## CHAPTER REVIEW

Following each chapter you will find a summary that highlights important content of the chapter. The summary contains all the key terms from the chapter in their contexts. A list of key skills and key equations follows the summary. These review materials are important tools to help you prepare for exams.

### SUMMARY AND KEY TERMS

**Introduction and Section 1.1** Chemistry is the study of the composition, structure, properties, and changes of **matter**. The composition of matter relates to the kinds of **elements** it contains. The structure of matter relates to the ways the **atoms** of these elements are arranged. A **property** is any characteristic that gives a sample of matter its unique identity. A **molecule** is an entity composed of two or more atoms with the atoms attached to one another in a specific way.

**Section 1.2** Matter exists in three physical states, **gas**, **liquid**, and **solid**, which are known as the **states of matter**. There are two kinds of **pure substances**: **elements** and **compounds**. Each element has a single kind of atom and is represented by a chemical symbol consisting of one or two letters, with the first letter capitalized. Compounds are composed of two or more elements joined chemically. The **law of constant composition**, also called the **law of definite proportions**, states that the elemental composition of a pure compound is always the same. Most matter consists of a mixture of substances. **Mixtures** have variable compositions and can be either homogeneous or heterogeneous; homogeneous mixtures are called **solutions**.

**Section 1.3** Each substance has a unique set of **physical properties** and **chemical properties** that can be used to identify it. During a **physical change**, matter does not change its composition. **Changes of state** are physical changes. In a **chemical change (chemical reaction)** a substance is transformed into a chemically different substance. **Intensive properties** are independent of the amount of matter examined and are used to identify substances. **Extensive properties** relate to the amount of substance present. Differences in physical and chemical properties are used to separate substances.

The **scientific method** is a dynamic process used to answer questions about our physical world. Observations

and experiments lead to **scientific laws**, general rules that summarize how nature behaves. Observations also lead to tentative explanations or **hypotheses**. As a hypothesis is tested and refined, a **theory** may be developed.

**Section 1.4** Measurements in chemistry are made using the **metric system**. Special emphasis is placed on a particular set of metric units called **SI units**, which are based on the meter, the kilogram, and the second as the basic units of length, **mass**, and time, respectively. The metric system employs a set of prefixes to indicate decimal fractions or multiples of the base units. The SI temperature scale is the **Kelvin scale**, although the **Celsius scale** is frequently used as well. **Density** is an important property that equals mass divided by volume.

**Section 1.5** All measured quantities are inexact to some extent. The **precision** of a measurement indicates how closely different measurements of a quantity agree with one another. The **accuracy** of a measurement indicates how well a measurement agrees with the accepted or “true” value. The **significant figures** in a measured quantity include one estimated digit, the last digit of the measurement. The significant figures indicate the extent of the uncertainty of the measurement. Certain rules must be followed so that a calculation involving measured quantities is reported with the appropriate number of significant figures.

**Section 1.6** In the **dimensional analysis** approach to problem solving, we keep track of units as we carry measurements through calculations. The units are multiplied together, divided into each other, or canceled like algebraic quantities. Obtaining the proper units for the final result is an important means of checking the method of calculation. When converting units and when carrying out several other types of problems, **conversion factors** can be used. These factors are ratios constructed from valid relations between equivalent quantities.

## KEY SKILLS

- Distinguish among elements, compounds, and mixtures.
- Memorize symbols of common elements and common metric prefixes.
- Use significant figures, scientific notation, metric units, and dimensional analysis in calculations.

## KEY EQUATIONS

$$\bullet K = ^\circ\text{C} + 273.15 \quad [1.1]$$

$$\bullet ^\circ\text{C} = \frac{5}{9} (^{\circ}\text{F} - 32) \quad \text{or} \quad ^{\circ}\text{F} = \frac{9}{5} (^{\circ}\text{C}) + 32 \quad [1.2]$$

$$\bullet \text{Density} = \frac{\text{mass}}{\text{volume}} \quad [1.3]$$

Interconverting between Celsius ( $^{\circ}\text{C}$ ) and Kelvin (K) temperatures scales

Interconverting between Celsius ( $^{\circ}\text{C}$ ) and Fahrenheit ( $^{\circ}\text{F}$ ) temperature scales

Definition of density

## VISUALIZING CONCEPTS

The exercises in this section are intended to probe your understanding of key concepts rather than your ability to utilize formulas and perform calculations. Those exercises with red exercise numbers have answers in the back of the book.

- 1.1 Which of the following figures represents (a) a pure element, (b) a mixture of two elements, (c) a pure compound, (d) a mixture of an element and a compound? (More than one picture might fit each description.) [Section 1.2]

- 1.2 Does the following diagram represent a chemical or physical change? How do you know? [Section 1.3]

- 1.3 Identify each of the following as measurements of length, area, volume, mass, density, time, or temperature: (a) 5 ns, (b)  $5.5 \text{ kg/m}^3$ , (c) 0.88 pm, (d)  $540 \text{ km}^2$ , (e) 173 K, (f)  $2 \text{ mm}^3$ , (g)  $23 ^\circ\text{C}$ . [Section 1.4]

- 1.4 Three spheres of equal size are composed of aluminum (density =  $2.70 \text{ g/cm}^3$ ), silver (density =  $10.49 \text{ g/cm}^3$ ), and nickel (density =  $8.90 \text{ g/cm}^3$ ). List the spheres from lightest to heaviest.
- 1.5 The following dartboards illustrate the types of errors often seen when one measurement is repeated several

times. The bull's-eye represents the "true value," and the darts represent the experimental measurements. Which board best represents each of the following scenarios: (a) measurements both accurate and precise, (b) measurements precise but inaccurate, (c) measurements imprecise but yield an accurate average? [Section 1.5]

- 1.6 (a) What is the length of the pencil in the following figure if the scale reads in centimeters? How many significant figures are there in this measurement? (b) An oven thermometer with a circular scale reading degrees Fahrenheit is shown. What temperature does the scale indicate? How many significant figures are in the measurement? [Section 1.5]

- 1.7 What is wrong with the following statement? Twenty years ago an ancient artifact was determined to be 1900 years old. It must now be 1920 years old. [Section 1.5]
- 1.8 (a) How many significant figures should be reported for the volume of the metal bar shown below? (b) If the mass of the bar is 104.7 g, how many significant figures should be reported when its density is calculated using the calculated volume? [Section 1.5]

## EXERCISES

### Classification and Properties of Matter

The following exercises are divided into sections that deal with specific topics in the chapter. These exercises are grouped in pairs, with the answer given in the back of the book to the odd-numbered exercise, as indicated by the red exercise number. Those exercises whose number appears in brackets are more challenging than the nonbracketed exercises.

- 1.11 Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: (a) rice pudding, (b) seawater, (c) magnesium, (d) gasoline.
- 1.12 Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: (a) air, (b) tomato juice, (c) iodine crystals, (d) sand.
- 1.13 Give the chemical symbol or name for the following elements, as appropriate: (a) sulfur, (b) magnesium, (c) potassium, (d) chlorine, (e) copper, (f) F, (g) Ni, (h) Na, (i) Al, (j) Si.
- 1.14 Give the chemical symbol or name for each of the following elements, as appropriate: (a) carbon, (b) nitrogen, (c) bromine, (d) zinc, (e) iron, (f) P, (g) Ca, (h) He, (i) Pb, (j) Ag.
- 1.15 A solid white substance A is heated strongly in the absence of air. It decomposes to form a new white substance B and a gas C. The gas has exactly the same properties as the product obtained when carbon is burned in an excess of oxygen. Based on these observations, can we determine whether solids A and B and the gas C are elements or compounds? Explain your conclusions for each substance.
- 1.16 In 1807 the English chemist Humphry Davy passed an electric current through molten potassium hydroxide and isolated a bright, shiny reactive substance. He claimed the discovery of a new element, which he named potassium. In those days, before the advent of modern instruments, what was the basis on which one could claim that a substance was an element?

- 1.9 When you convert units, how do you decide which part of the conversion factor is in the numerator and which is in the denominator? [Section 1.6]
- 1.10 Draw a logic map indicating the steps you would take to convert miles per hour to kilometers per second. Write down the conversion factor for each step, as done in the diagram on page 26. [Section 1.6]

- 1.17 In the process of attempting to characterize a substance, a chemist makes the following observations: The substance is a silvery white, lustrous metal. It melts at 649 °C and boils at 1105 °C. Its density at 20 °C is 1.738 g/cm<sup>3</sup>. The substance burns in air, producing an intense white light. It reacts with chlorine to give a brittle white solid. The substance can be pounded into thin sheets or drawn into wires. It is a good conductor of electricity. Which of these characteristics are physical properties, and which are chemical properties?
- 1.18 Read the following description of the element zinc, and indicate which are physical properties and which are chemical properties. Zinc is a silver-gray-colored metal that melts at 420 °C. When zinc granules are added to dilute sulfuric acid, hydrogen is given off and the metal dissolves. Zinc has a hardness on the Mohs scale of 2.5 and a density of 7.13 g/cm<sup>3</sup> at 25 °C. It reacts slowly with oxygen gas at elevated temperatures to form zinc oxide, ZnO.
- 1.19 Label each of the following as either a physical process or a chemical process: (a) corrosion of aluminum metal, (b) melting of ice, (c) pulverizing an aspirin, (d) digesting a candy bar, (e) explosion of nitroglycerin.
- 1.20 A match is lit and held under a cold piece of metal. The following observations are made: (a) The match burns. (b) The metal gets warmer. (c) Water condenses on the metal. (d) Soot (carbon) is deposited on the metal. Which of these occurrences are due to physical changes, and which are due to chemical changes?
- 1.21 Suggest a method of separating each of the following mixtures into two components: (a) sugar and sand, (b) iron and sulfur.
- 1.22 A beaker contains a clear, colorless liquid. If it is water, how could you determine whether it contained dissolved table salt? Do *not* taste it!

## Units and Measurement

- 1.23** What exponential notation do the following abbreviations represent: (a) d, (b) c, (c) f, (d)  $\mu$ , (e) M, (f) k, (g) n, (h) m, (i) p?
- 1.24** Use appropriate metric prefixes to write the following measurements without use of exponents:  
 (a)  $6.35 \times 10^{-2}$  L, (b)  $6.5 \times 10^{-6}$  s, (c)  $9.5 \times 10^{-4}$  m,  
 (d)  $4.23 \times 10^{-9}$  m<sup>3</sup>, (e)  $12.5 \times 10^{-8}$  kg, (f)  $3.5 \times 10^{-10}$  g,  
 (g)  $6.54 \times 10^9$  fs.
- 1.25** Make the following conversions: (a) 62 °F to °C, (b) 216.7 °C to °F, (c) 233 °C to K, (d) 315 K to °F, (e) 2500 °F to K.
- 1.26** (a) The temperature on a warm summer day is 87 °F. What is the temperature in °C? (b) Many scientific data are reported at 25 °C. What is this temperature in kelvins and in degrees Fahrenheit? (c) Suppose that a recipe calls for an oven temperature of 175 °F. Convert this temperature to degrees Celsius and to kelvins. (d) The melting point of sodium bromide (a salt) is 755 °C. Calculate this temperature in °F and in kelvins. (e) Neon, a gaseous element at room temperature, is used to make electronic signs. Neon has a melting point of -248.6 °C and a boiling point of -246.1 °C. Convert these temperatures to kelvins.
- 1.27** (a) A sample of carbon tetrachloride, a liquid once used in dry cleaning, has a mass of 39.73 g and a volume of 25.0 mL at 25 °C. What is its density at this temperature? Will carbon tetrachloride float on water? (Materials that are less dense than water will float.) (b) The density of platinum is 21.45 g/cm<sup>3</sup> at 20 °C. Calculate the mass of 75.00 cm<sup>3</sup> of platinum at this temperature. (c) The density of magnesium is 1.738 g/cm<sup>3</sup> at 20 °C. What is the volume of 87.50 g of this metal at this temperature?
- 1.28** (a) A cube of osmium metal 1.500 cm on a side has a mass of 76.31 g at 25 °C. What is its density in g/cm<sup>3</sup> at this temperature? (b) The density of titanium metal is 4.51 g/cm<sup>3</sup> at 25 °C. What mass of titanium displaces 125.0 mL of water at 25 °C? (c) The density of benzene at 15 °C is 0.8787 g/mL. Calculate the mass of 0.1500 L of benzene at this temperature.
- 1.29** (a) To identify a liquid substance, a student determined its density. Using a graduated cylinder, she measured out a 45-mL sample of the substance. She then measured the mass of the sample, finding that it weighed 38.5 g. She knew that the substance had to be either isopropyl alcohol (density 0.785 g/mL) or toluene (density 0.866 /mL). What are the calculated density and the probable identity of the substance? (b) An experiment requires 45.0 g of ethylene glycol, a liquid whose density is 1.114 g/mL. Rather than weigh the sample on a balance, a chemist chooses to dispense the liquid using a graduated cylinder. What volume of the liquid should he use? (c) A cubic piece of metal measures 5.00 cm on each edge. If the metal is nickel, whose density is 8.90 g/cm<sup>3</sup>, what is the mass of the cube?
- 1.30** (a) After the label fell off a bottle containing a clear liquid believed to be benzene, a chemist measured the density of the liquid to verify its identity. A 25.0-mL portion of the liquid had a mass of 21.95 g. A chemistry handbook lists the density of benzene at 15 °C as 0.8787 g/mL. Is the calculated density in agreement with the tabulated value? (b) An experiment requires 15.0 g of cyclohexane, whose density at 25 °C is 0.7781 g/mL. What volume of cyclohexane should be used? (c) A spherical ball of lead has a diameter of 5.0 cm. What is the mass of the sphere if lead has a density of 11.34 g/cm<sup>3</sup>? (The volume of a sphere is  $\frac{4}{3}\pi r^3$  where  $r$  is the radius.)
- 1.31** Gold can be hammered into extremely thin sheets called gold leaf. If a 200-mg piece of gold (density = 19.32 g/cm<sup>3</sup>) is hammered into a sheet measuring 24 × 1.0 ft, what is the average thickness of the sheet in meters? How might the thickness be expressed without exponential notation, using an appropriate metric prefix?
- 1.32** A cylindrical rod formed from silicon is 16.8 cm long and has a mass of 2.17 kg. The density of silicon is 2.33 g/cm<sup>3</sup>. What is the diameter of the cylinder? (The volume of a cylinder is given by  $\pi r^2 h$ , where  $r$  is the radius, and  $h$  is its length.)

## Uncertainty in Measurement

- 1.33** Indicate which of the following are exact numbers:  
 (a) the mass of a paper clip, (b) the surface area of a dime, (c) the number of inches in a mile, (d) the number of ounces in a pound, (e) the number of microseconds in a week, (f) the number of pages in this book.
- 1.34** Indicate which of the following are exact numbers:  
 (a) the mass of a 32-oz can of coffee, (b) the number of students in your chemistry class, (c) the temperature of the surface of the sun, (d) the mass of a postage stamp, (e) the number of milliliters in a cubic meter of water, (f) the average height of students in your school.
- 1.35** What is the number of significant figures in each of the following measured quantities? (a) 358 kg, (b) 0.054 s, (c) 6.3050 cm, (d) 0.0105 L, (e)  $7.0500 \times 10^{-3}$  m<sup>3</sup>.
- 1.36** Indicate the number of significant figures in each of the following measured quantities: (a) 3.774 km, (b) 205 m<sup>2</sup>, (c) 1.700 cm, (d) 350.00 K, (e) 307.080 g.
- 1.37** Round each of the following numbers to four significant figures, and express the result in standard exponential notation: (a) 102.53070, (b) 656,980, (c) 0.008543210, (d) 0.000257870, (e) -0.0357202.
- 1.38** (a) The diameter of Earth at the equator is 7926.381 mi. Round this number to three significant figures, and express it in standard exponential notation. (b) The circumference of Earth through the poles is 40,008 km. Round this number to four significant figures, and express it in standard exponential notation.

- 1.39 Carry out the following operations, and express the answers with the appropriate number of significant figures.
- (a)  $12.0550 + 9.05$   
 (b)  $257.2 - 19.789$   
 (c)  $(6.21 \times 10^3)(0.1050)$   
 (d)  $0.0577/0.753$
- 1.40 Carry out the following operations, and express the answer with the appropriate number of significant figures.
- (a)  $320.5 - (6104.5/2.3)$   
 (b)  $[(285.3 \times 10^5) - (1.200 \times 10^3)] \times 2.8954$   
 (c)  $(0.0045 \times 20,000.0) + (2813 \times 12)$   
 (d)  $863 \times [1255 - (3.45 \times 108)]$

## Dimensional Analysis

- 1.41 Using your knowledge of metric units, English units, and the information on the back inside cover, write down the conversion factors needed to convert (a) mm to nm, (b) mg to kg, (c) km to ft, (d)  $\text{in.}^3$  to  $\text{cm}^3$ .
- 1.42 Using your knowledge of metric units, English units, and the information on the back inside cover, write down the conversion factors needed to convert (a)  $\mu\text{m}$  to mm, (b) ms tons, (c) mi to km, (d)  $\text{ft}^3$  to L.
- 1.43 Perform the following conversions: (a) 0.076 L to mL, (b)  $5.0 \times 10^{-8}$  m to nm, (c)  $6.88 \times 10^5$  ns to s, (d) 0.50 lb to g, (e)  $1.55 \text{ kg/m}^3$  to g/L, (f) 5.850 gal/hr to L/s.
- 1.44 (a) The speed of light in a vacuum is  $2.998 \times 10^8$  m/s. Calculate its speed in km/hr. (b) The Sears Tower in Chicago is 1454 ft tall. Calculate its height in meters. (c) The Vehicle Assembly Building at the Kennedy Space Center in Florida has a volume of 3,666,500  $\text{m}^3$ . Convert this volume to liters, and express the result in standard exponential notation. (d) An individual suffering from a high cholesterol level in her blood has 232 mg of cholesterol per 100 mL of blood. If the total blood volume of the individual is 5.2 L, how many grams of total blood cholesterol does the individual's body contain?
- 1.45 Perform the following conversions: (a) 5.00 days to s, (b) 0.0550 mi to m, (c) \$1.89/gal to dollars per liter, (d) 0.510 in./ms to km/hr, (e) 22.50 gal/min to L/s, (f)  $0.02500 \text{ ft}^3$  to  $\text{cm}^3$ .
- 1.46 Carry out the following conversions: (a) 0.105 in. to mm, (b) 0.650 qt to mL, (c)  $8.75 \mu\text{m/s}$  to km/hr, (d)  $1.955 \text{ m}^3$  to  $\text{yd}^3$ , (e) \$3.99/lb to dollars per kg, (f)  $8.75 \text{ lb/ft}^3$  to g/mL.
- 1.47 (a) How many liters of wine can be held in a wine barrel whose capacity is 31 gal? (b) The recommended adult dose of Elixophyllin<sup>®</sup>, a drug used to treat asthma, is 6 mg/kg of body mass. Calculate the dose in milligrams for a 150-lb person. (c) If an automobile is able to travel 254 mi on 11.2 gal of gasoline, what is the gas mileage in km/L? (d) A pound of coffee beans yields 50 cups of coffee (4 cups = 1 qt). How many milliliters of coffee can be obtained from 1 g of coffee beans?
- 1.48 (a) If an electric car is capable of going 225 km on a single charge, how many charges will it need to travel from Boston, Massachusetts, to Miami, Florida, a distance of 1486 mi, assuming that the trip begins with a full charge? (b) If a migrating loon flies at an average speed of 14 m/s, what is its average speed in mi/hr? (c) What is the engine piston displacement in liters of an engine whose displacement is listed as 450  $\text{in.}^3$ ? (d) In March 1989 the *Exxon Valdez* ran aground and spilled 240,000 barrels of crude petroleum off the coast of Alaska. One barrel of petroleum is equal to 42 gal. How many liters of petroleum were spilled?
- 1.49 The density of air at ordinary atmospheric pressure and 25 °C is 1.19 g/L. What is the mass, in kilograms, of the air in a room that measures  $12.5 \times 15.5 \times 80$  ft?
- 1.50 The concentration of carbon monoxide in an urban apartment is  $48 \mu\text{g/m}^3$ . What mass of carbon monoxide in grams is present in a room measuring  $9.0 \times 14.5 \times 18.8$  ft?
- 1.51 By using estimation techniques, arrange these items in order from shortest to longest: a 57-cm length of string, a 14-in. long shoe, and a 1.1-m length of pipe.
- 1.52 By using estimation techniques, determine which of the following is the heaviest and which is the lightest: a 5-lb bag of potatoes, a 5-kg bag of sugar, or 1 gal of water (density = 1.0 g/mL).
- 1.53 The Morgan silver dollar has a mass of 26.73 g. By law, it was required to contain 90% silver, with the remainder being copper. (a) When the coin was minted in the late 1800s, silver was worth \$1.18 per troy ounce (31.1 g). At this price, what is the value of the silver in the silver dollar? (b) Today, silver sells for about \$13.25 per troy ounce. How many Morgan silver dollars are required to obtain \$25.00 worth of pure silver?
- 1.54 A copper refinery produces a copper ingot weighing 150 lb. If the copper is drawn into wire whose diameter is 8.25 mm, how many feet of copper can be obtained from the ingot? The density of copper is  $8.94 \text{ g/cm}^3$  (Assume that the wire is a cylinder whose volume is  $V = \pi r^2 h$ , where  $r$  is its radius and  $h$  is its height or length.)

## ADDITIONAL EXERCISES

The exercises in this section are not divided by category, although they are roughly in the order of the topics in the chapter. They are not paired.

- 1.55 What is meant by the terms composition and structure when referring to matter?
- 1.56 (a) Classify each of the following as a pure substance, a solution, or a heterogeneous mixture: a gold coin, a cup of coffee, a wood plank. (b) What ambiguities are there in answering part (a) from the descriptions given?
- 1.57 (a) What is the difference between a hypothesis and a theory? (b) Explain the difference between a theory and a scientific law. Which addresses how matter behaves, and which addresses why it behaves that way?
- 1.58 A sample of ascorbic acid (vitamin C) is synthesized in the laboratory. It contains 1.50 g of carbon and 2.00 g of

oxygen. Another sample of ascorbic acid isolated from citrus fruits contains 6.35 g of carbon. How many grams of oxygen does it contain? Which law are you assuming in answering this question?

- 1.59 Two students determine the percentage of lead in a sample as a laboratory exercise. The true percentage is 22.52%. The students' results for three determinations are as follows:
- 22.52, 22.48, 22.54
  - 22.64, 22.58, 22.62
- (a) Calculate the average percentage for each set of data, and tell which set is the more accurate based on the average. (b) Precision can be judged by examining the average of the deviations from the average value for that data set. (Calculate the average value for each data set, then calculate the average value of the absolute deviations of each measurement from the average.) Which set is more precise?
- 1.60 Is the use of significant figures in each of the following statements appropriate? Why or why not? (a) The 2005 circulation of *National Geographic* was 7,812,564. (b) On July 1, 2005, the population of Cook County, Illinois, was 5,303,683. (c) In the United States, 0.621% of the population has the surname Brown.
- 1.61 What type of quantity (for example, length, volume, density) do the following units indicate: (a) mL, (b) cm<sup>2</sup>, (c) mm<sup>3</sup>, (d) mg/L, (e) ps, (f) nm, (g) K?
- 1.62 Give the derived SI units for each of the following quantities in base SI units: (a) acceleration = distance/time<sup>2</sup>; (b) force = mass × acceleration; (c) work = force × distance; (d) pressure = force/area; (e) power = work/time.
- 1.63 The distance from Earth to the Moon is approximately 240,000 mi. (a) What is this distance in meters? (b) The peregrine falcon has been measured as traveling up to 350 km/hr in a dive. If this falcon could fly to the Moon at this speed, how many seconds would it take?
- 1.64 The US quarter has a mass of 5.67 g and is approximately 1.55 mm thick. (a) How many quarters would have to be stacked to reach 575 ft, the height of the Washington Monument? (b) How much would this stack weigh? (c) How much money would this stack contain? (d) At the beginning of 2007, the national debt was \$8.7 trillion. How many stacks like the one described would be necessary to pay off this debt?
- 1.65 In the United States, water used for irrigation is measured in acre-feet. An acre-foot of water covers an acre to a depth of exactly 1 ft. An acre is 4840 yd<sup>2</sup>. An acre-foot is enough water to supply two typical households for 1.00 yr. (a) If desalinated water costs \$1950 per acre-foot, how much does desalinated water cost per liter? (b) How much would it cost one household per day if it were the only source of water?
- 1.66 Suppose you decide to define your own temperature scale using the freezing point (−11.5 °C) and boiling point (197.6 °C) of ethylene glycol. If you set the freezing point as 0 °C and the boiling point as 100 °C, what is the freezing point of water on this new scale?
- 1.67 The liquid substances mercury (density = 13.5 g/mL), water (1.00 g/mL), and cyclohexane (0.778 g/mL) do not form a solution when mixed, but separate in distinct layers. Sketch how the liquids would position themselves in a test tube.
- 1.68 Small spheres of equal mass are made of lead (density = 11.3 g/cm<sup>3</sup>), silver (10.5 g/cm<sup>3</sup>), and aluminum (2.70 g/cm<sup>3</sup>). Without doing a calculation, list the spheres in order from the smallest to the largest.
- 1.69 Water has a density of 0.997 g/cm<sup>3</sup> at 25 °C; ice has a density of 0.917 g/cm<sup>3</sup> at −10 °C. (a) If a soft-drink bottle whose volume is 1.50 L is completely filled with water and then frozen to −10 °C, what volume does the ice occupy? (b) Can the ice be contained within the bottle?
- 1.70 A 32.65-g sample of a solid is placed in a flask. Toluene, in which the solid is insoluble, is added to the flask so that the total volume of solid and liquid together is 50.00 mL. The solid and toluene together weigh 58.58 g. The density of toluene at the temperature of the experiment is 0.864 g/mL. What is the density of the solid?
- 1.71 (a) You are given a bottle that contains 4.59 cm<sup>3</sup> of a metallic solid. The total mass of the bottle and solid is 35.66 g. The empty bottle weighs 14.23 g. What is the density of the solid? (b) Mercury is traded by the "flask," a unit that has a mass of 34.5 kg. What is the volume of a flask of mercury if the density of mercury is 13.5 g/mL? (c) A thief plans to steal a gold sphere with a radius of 28.9 cm from a museum. If the gold has a density of 19.3 g/cm<sup>3</sup> what is the mass of the sphere? [The volume of a sphere is  $V = (4/3)\pi r^3$ .] Is he likely to be able to walk off with it unassisted?
- 1.72 Automobile batteries contain sulfuric acid, which is commonly referred to as "battery acid." Calculate the number of grams of sulfuric acid in 0.500 L of battery acid if the solution has a density of 1.28 g/mL and is 38.1% sulfuric acid by mass.
- 1.73 A 40-lb container of peat moss measures 14 × 20 × 30 in. A 40-lb container of topsoil has a volume of 1.9 gal. (a) Calculate the average densities of peat moss and topsoil in units of g/cm<sup>3</sup>. Would it be correct to say that peat moss is "lighter" than topsoil? Explain. (b) How many bags of the peat moss are needed to cover an area measuring 10. ft by 20. ft to a depth of 2.0 in.?
- 1.74 A coin dealer offers to sell you an ancient gold coin that is 2.2 cm in diameter and 3.0 mm in thickness. (a) The density of gold is 19.3 g/cm<sup>3</sup>. How much should the coin weigh if it is pure gold? (b) If gold sells for \$640 per troy ounce, how much is the gold content worth? (1 troy ounce = 31.1 g).
- 1.75 A package of aluminum foil contains 50 ft<sup>2</sup> of foil, which weighs approximately 8.0 oz. Aluminum has a density of 2.70 g/cm<sup>3</sup>. What is the approximate thickness of the foil in millimeters?
- 1.76 A 15.0-cm long cylindrical glass tube, sealed at one end, is filled with ethanol. The mass of ethanol needed to fill the tube is found to be 11.86 g. The density of ethanol is 0.789 g/mL. Calculate the inner diameter of the tube in centimeters.
- 1.77 Gold is alloyed (mixed) with other metals to increase its hardness in making jewelry. (a) Consider a piece of gold jewelry that weighs 9.85 g and has a volume of

0.675 cm<sup>3</sup>. The jewelry contains only gold and silver, which have densities of 19.3 g/cm<sup>3</sup> and 10.5 g/cm<sup>3</sup>, respectively. If the total volume of the jewelry is the sum of the volumes of the gold and silver that it contains, calculate the percentage of gold (by mass) in the jewelry. (b) The relative amount of gold in an alloy is commonly expressed in units of karats. Pure gold is 24-karat, and the percentage of gold in an alloy is given as a percentage of this value. For example, an alloy that is 50% gold is 12-karat. State the purity of the gold jewelry in karats.

- 1.78 Suppose you are given a sample of a homogeneous liquid. What would you do to determine whether it is a solution or a pure substance?
- 1.79 Chromatography (Figure 1.14) is a simple, but reliable, method for separating a mixture into its constituent substances. Suppose you are using chromatography to separate a mixture of two substances. How would you know whether the separation is successful? Can you propose a means of quantifying how good or how poor the separation is?
- 1.80 You are assigned the task of separating a desired granular material, with a density of 3.62 g/cm<sup>3</sup>, from an undesired granular material that has a density of 2.04 g/cm<sup>3</sup>. You want to do this by shaking the mixture in a liquid in which the heavier material will fall to the bottom and the lighter material will float. A solid will float on any liquid that is more dense. Using the internet or a handbook of chemistry, find the densities of the following substances: carbon tetrachloride, hexane, benzene, and methylene iodide. Which of these liquids will serve your purpose, assuming no chemical interaction between the liquid and the solids?
- 1.81 In 2006, Professor Galen Suppes, from the University of Missouri-Columbia, was awarded a Presidential Green Challenge Award for his system of converting glycerin, C<sub>3</sub>H<sub>5</sub>(OH)<sub>3</sub>, a by-product of biodiesel production, to propylene glycol, C<sub>3</sub>H<sub>6</sub>(OH)<sub>2</sub>. Propylene glycol pro-

duced in this way will be cheap enough to replace the more toxic ethylene glycol that is the primary ingredient in automobile antifreeze. (a) If 50.0 mL of propylene glycol has a mass of 51.80 g, what is its density? (b) To obtain the same antifreeze protection requires 76 g of propylene glycol to replace each 62 g of ethylene glycol. Calculate the mass of propylene glycol required to replace 1.00 gal of ethylene glycol. The density of ethylene glycol is 1.12 g/mL. (c) Calculate the volume of propylene glycol, in gallons, needed to produce the same antifreeze protection as 1.00 gallon of ethylene glycol.

- 1.82 The concepts of accuracy and precision are not always easy to grasp. Here are two sets of studies: (a) The mass of a secondary weight standard is determined by weighing it on a very precise balance under carefully controlled laboratory conditions. The average of 18 different weight measurements is taken as the weight of the standard. (b) A group of 10,000 males between the ages of 50 and 55 is surveyed to ascertain a relationship between calorie intake and blood cholesterol level. The survey questionnaire is quite detailed, asking the respondents about what they eat, smoking and drinking habits, and so on. The results are reported as showing that for men of comparable lifestyles, there is a 40% chance of the blood cholesterol level being above 230 for those who consume more than 40 calories per gram of body weight per day, as compared with those who consume fewer than 30 calories per gram of body weight per day.

Discuss and compare these two studies in terms of the precision and accuracy of the result in each case. How do the two studies differ in nature in ways that affect the accuracy and precision of the results? What makes for high precision and accuracy in any given study? In each of these studies, what factors might not be controlled that could affect the accuracy and precision? What steps can be taken generally to attain higher precision and accuracy?

CHAPTER  
2

# ATOMS, MOLECULES, AND IONS

**A CIRCLE OF INDIVIDUAL IRON ATOMS** on a copper surface, as viewed by a technique known as scanning tunneling microscopy (STM). The image is artificially colored to enhance it. The shapes of the iron atoms in the STM image are distorted, and the atoms of the copper surface are not revealed.

## WHAT'S AHEAD

---

- 2.1 The Atomic Theory of Matter**  
We begin by giving a brief history of the notion of *atoms*—the smallest pieces of matter.
- 2.2 The Discovery of Atomic Structure**  
We then look at some of the key experiments that led to the discovery of *electrons* and to the *nuclear model* of the atom.
- 2.3 The Modern View of Atomic Structure**  
We explore the modern theory of atomic structure, including the ideas of *atomic numbers*, *mass numbers*, and *isotopes*.
- 2.4 Atomic Weights**  
We introduce the concept of *atomic weights* and how they relate to the masses of individual atoms.
- 2.5 The Periodic Table**  
We examine the organization of the elements into the *periodic table*, in which elements are put in order of increasing atomic number and grouped by chemical similarity.
- 2.6 Molecules and Molecular Compounds**  
We discuss the assemblies of atoms called *molecules* and how their compositions are represented by *empirical* and *molecular formulas*.
- 2.7 Ions and Ionic Compounds**  
We learn that atoms can gain or lose electrons to form *ions*. We also look at how to use the periodic table to predict the charges on ions and the empirical formulas of *ionic compounds*.
- 2.8 Naming Inorganic Compounds**  
We consider the systematic way in which substances are named, called *nomenclature*, and how this nomenclature is applied to inorganic compounds.
- 2.9 Some Simple Organic Compounds**  
We introduce some basic ideas of *organic chemistry*, which is the chemistry of the element carbon.

**LOOK AROUND YOU.** Notice the great variety of colors, textures, and other properties in the materials that surround you—the colors in a garden scene, the texture of the fabric in your clothes, the solubility of sugar in a cup of coffee, the

transparency of a window. The materials in our world exhibit a striking and seemingly infinite variety.

We can classify properties in different ways, but how do we understand and explain them? What makes diamonds transparent and hard, while table salt is brittle and dissolves in water? Why does paper burn, and why does water quench fires? The structure and behavior of atoms are key to understanding both the physical and chemical properties of matter.

Remarkably, the diversity of these properties we see around us results from only about 100 different elements and therefore about 100 chemically different kinds of atoms. In a sense, the atoms are like the 26 letters of the English alphabet that join in different combinations to form the immense number of words in our language. But how do atoms combine with one another? What rules govern the ways in which atoms can combine? How do the properties of a substance relate to the kinds of atoms it contains? Indeed, what is an atom like, and what makes the atoms of one element different from those of another?

The chapter-opening photograph is an image of a circle of 48 iron atoms arranged on a copper metal surface. The diameter of the circle is about 1/20,000 the diameter of a human hair. Atoms are indeed very tiny entities.

This very striking image reveals the power of modern experimental methods to identify individual atoms, but it does not reveal the structures of the atoms themselves. Fortunately, we can use a variety of experimental techniques to probe the atom to gain a clearer understanding of what it is like. In this chapter we begin to explore the fascinating world of atoms that we discover by such experiments. We will examine the basic structure of the atom and briefly discuss the formation of molecules and ions, thereby providing a foundation for exploring chemistry more deeply in later chapters.

## 2.1 THE ATOMIC THEORY OF MATTER

Philosophers from the earliest times have speculated about the nature of the fundamental “stuff” from which the world is made. Democritus (460–370 BC) and other early Greek philosophers thought that the material world must be made up of tiny indivisible particles that they called *atomos*, meaning “indivisible or uncuttable.” Later, Plato and Aristotle formulated the notion that there can be no ultimately indivisible particles. The “atomic” view of matter faded for many centuries during which Aristotelean philosophy dominated Western culture.

The notion of atoms reemerged in Europe during the seventeenth century, when scientists tried to explain the properties of gases. Air is composed of something invisible and in constant motion; we can feel the motion of the wind against us, for example. It is natural to think of tiny invisible particles as giving rise to these familiar effects. Isaac Newton (1642–1727), the most famous scientist of his time, favored the idea of atoms. But thinking of atoms as invisible particles in air is very different from thinking of atoms as the fundamental building blocks of elements.

As chemists learned to measure the amounts of elements that reacted with one another to form new substances, the ground was laid for an atomic theory that linked the idea of elements with the idea of atoms. That theory came from the work of an English schoolteacher, John Dalton (Figure 2.1 ◀), during the period from 1803–1807. Dalton’s atomic theory involved the following postulates:

1. Each element is composed of extremely small particles called atoms.
2. All atoms of a given element are identical to one another in mass and other properties, but the atoms of one element are different from the atoms of all other elements.
3. The atoms of one element cannot be changed into atoms of a different element by chemical reactions; atoms are neither created nor destroyed in chemical reactions.
4. Compounds are formed when atoms of more than one element combine; a given compound always has the same relative number and kind of atoms.

According to Dalton’s atomic theory, **atoms** are the smallest particles of an element that retain the chemical identity of the element. ∞ (Section 1.1) As noted in the postulates of Dalton’s theory, an element is composed of only one kind of atom. A compound, in contrast, contains atoms of two or more elements.

Dalton’s theory explains several simple laws of chemical combination that were known during his time. One of these laws was the *law of constant composition*: In a given compound, the relative numbers and kinds of atoms are constant. ∞ (Section 1.2) This law is the basis of Dalton’s Postulate 4. Another fundamental chemical law was the *law of conservation of mass* (also known as the *law of conservation of matter*): The total mass of materials present after a chemical reaction is the same as the total mass present before the reaction. This law is the basis for Postulate 3. Dalton proposed that atoms always retain their identities and that atoms taking part in a chemical reaction rearrange to give new chemical combinations.

▲ **Figure 2.1 John Dalton (1766–1844).** Dalton was the son of a poor English weaver. He began teaching at the age of 12. He spent most of his years in Manchester, where he taught both grammar school and college. His lifelong interest in meteorology led him to study gases, then chemistry, and eventually atomic theory.

A good theory should explain the known facts and predict new ones. Dalton used his theory to deduce the *law of multiple proportions*: If two elements A and B combine to form more than one compound, the masses of B that can combine with a given mass of A are in the ratio of small whole numbers. We can illustrate this law by considering the substances water and hydrogen peroxide, both of which consist of the elements hydrogen and oxygen. In forming water, 8.0 g of oxygen combine with 1.0 g of hydrogen. In forming hydrogen peroxide, 16.0 g of oxygen combine with 1.0 g of hydrogen. In other words, the ratio of the mass of oxygen per gram of hydrogen in the two compounds is 2 : 1. Using the atomic theory, we can conclude that hydrogen peroxide contains twice as many atoms of oxygen per hydrogen atom as does water.

### GIVE IT SOME THOUGHT

One compound of carbon and oxygen contains 1.333 g of oxygen per gram of carbon, whereas a second compound contains 2.666 g of oxygen per gram of carbon. (a) What chemical law do these data illustrate? (b) If the first compound has an equal number of oxygen and carbon atoms, what can we conclude about the composition of the second compound?

## 2.2 THE DISCOVERY OF ATOMIC STRUCTURE

Dalton reached his conclusion about atoms based on chemical observations in the macroscopic world of the laboratory. Neither he nor those who followed him during the century after his work was published had direct evidence for the existence of atoms. Today, however, we can use powerful instruments to measure the properties of individual atoms and even provide images of them (Figure 2.2▶).

As scientists began to develop methods for more detailed probing of the nature of matter, the atom, which was supposed to be indivisible, began to show signs of a more complex structure: We now know that the atom is composed of still smaller **subatomic particles**. Before we summarize the current model of atomic structure, we will briefly consider a few of the landmark discoveries that led to that model. We will see that the atom is composed in part of electrically charged particles, some with a positive (+) charge and some with a negative (−) charge. As we discuss the development of our current model of the atom, keep in mind a simple statement of the behavior of charged particles: *Particles with the same charge repel one another, whereas particles with unlike charges attract one another.*

### Cathode Rays and Electrons

During the mid-1800s, scientists began to study electrical discharge through partially evacuated tubes (tubes that had been pumped almost empty of air), such as those shown in Figure 2.3▼. When a high voltage was applied to the

▲ **Figure 2.2** An image of the surface of the semiconductor GaAs (gallium arsenide). This image was obtained by a technique called scanning tunneling microscopy. The color was added to the image by computer to distinguish the gallium atoms (blue spheres) from the arsenic atoms (red spheres).

▼ **Figure 2.3** Cathode-ray tube. (a) In a cathode-ray tube, electrons move from the negative electrode (cathode) to the positive electrode (anode). (b) A photo of a cathode-ray tube containing a fluorescent screen to show the path of the cathode rays. (c) The path of the cathode rays is deflected by the presence of a magnet.

► **Figure 2.4 Cathode-ray tube with perpendicular magnetic and electric fields.** The cathode rays (electrons) originate from the negative plate on the left and are accelerated toward the positive plate on the right, which has a hole in its center. A narrow beam of electrons passes through the hole and is then deflected by the magnetic and electric fields. The three paths result from different strengths of the magnetic and electric fields. The charge-to-mass ratio of the electron can be determined by measuring the effects that the magnetic and electric fields have on the direction of the beam.

electrodes in the tube, radiation was produced. This radiation, called **cathode rays**, originated from the negative electrode, or cathode. Although the rays themselves could not be seen, their movement was detected because the rays cause certain materials, including glass, to *fluoresce*, or to give off light.

Scientists held conflicting views about the nature of the cathode rays. It was not initially clear whether the rays were an invisible stream of particles or a new form of radiation. Experiments showed that cathode rays are deflected by electric or magnetic fields in a way consistent with their being a stream of negative electrical charge [Figure 2.3(c)]. The British scientist J. J. Thomson observed many properties of the cathode rays, including the fact that they are the same regardless of the identity of the cathode material. In a paper published in 1897, Thomson summarized his observations and concluded that cathode rays are streams of negatively charged particles. Thomson's paper is generally accepted as the "discovery" of what later became known as the *electron*.

Thomson constructed a cathode-ray tube having a fluorescent screen at one end, such as that shown in Figure 2.4 ▲, so that he could quantitatively measure the effects of electric and magnetic fields on the thin stream of electrons passing through a hole in the positively charged electrode. These measurements made it possible to calculate a value of  $1.76 \times 10^8$  coulombs per gram for the ratio of the electron's electrical charge to its mass.\*

Once the charge-to-mass ratio of the electron was known, measuring either the charge or the mass of an electron would yield the value of the other quantity. In 1909, Robert Millikan (1868–1953) of the University of Chicago succeeded in measuring the charge of an electron by performing a series of experiments described in Figure 2.5 ▼. He then calculated the mass of the electron by using

► **Figure 2.5 Millikan's oil-drop experiment.** A representation of the apparatus Millikan used to measure the charge of the electron. Small drops of oil, which had picked up extra electrons, were allowed to fall between two electrically charged plates. Millikan monitored the drops, measuring how the voltage on the plates affected their rate of fall. From these data he calculated the charges on the drops. His experiment showed that the charges were always integral multiples of  $1.602 \times 10^{-19}$  C, which he deduced was the charge of a single electron.

\*The coulomb (C) is the SI unit for electrical charge.

his experimental value for the charge,  $1.602 \times 10^{-19}$  C, and Thomson's charge-to-mass ratio,  $1.76 \times 10^8$  C/g:

$$\text{Electron mass} = \frac{1.602 \times 10^{-19} \text{ C}}{1.76 \times 10^8 \text{ C/g}} = 9.10 \times 10^{-28} \text{ g}$$

This result agrees well with the presently accepted value for the mass of the electron,  $9.10938 \times 10^{-28}$  g. This mass is about 2000 times smaller than that of hydrogen, the lightest atom.

## Radioactivity

In 1896 the French scientist Henri Becquerel (1852–1908) was studying a uranium compound when he discovered that it spontaneously emits high-energy radiation. This spontaneous emission of radiation is called **radioactivity**. At Becquerel's suggestion Marie Curie (Figure 2.6▶) and her husband, Pierre, began experiments to isolate the radioactive components of the compound.

Further study of the nature of radioactivity, principally by the British scientist Ernest Rutherford (Figure 2.7▶), revealed three types of radiation: alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ) radiation. Each type differs in its response to an electric field, as shown in Figure 2.8▼. The paths of both  $\alpha$  and  $\beta$  radiation are bent by the electric field, although in opposite directions;  $\gamma$  radiation is unaffected.

Rutherford showed that both  $\alpha$  and  $\beta$  rays consist of fast-moving particles, which were called  $\alpha$  and  $\beta$  particles. In fact,  $\beta$  particles are high-speed electrons and can be considered the radioactive equivalent of cathode rays. They are attracted to a positively charged plate. The  $\alpha$  particles have a positive charge and are attracted toward a negative plate. In units of the charge of the electron,  $\beta$  particles have a charge of  $1-$  and  $\alpha$  particles a charge of  $2+$ . Each  $\alpha$  particle has a mass about 7400 times that of an electron. Gamma radiation is high-energy radiation similar to X-rays; it does not consist of particles and carries no charge. We will discuss radioactivity in greater detail in Chapter 21.

## The Nuclear Atom

With the growing evidence that the atom is composed of smaller particles, attention was given to how the particles fit together. During the early 1900s Thomson reasoned that because electrons contribute only a very small fraction of the mass of an atom, they probably were responsible for an equally small fraction of the atom's size. He proposed that the atom consisted of a uniform positive sphere of matter in which the electrons were embedded, as shown in

▲ **Figure 2.8 Behavior of alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ) rays in an electric field.** The  $\alpha$  rays consist of positively charged particles and are therefore attracted to the negatively charged plate. The  $\beta$  rays consist of negatively charged particles and are attracted to the positively charged plate. The  $\gamma$  rays, which carry no charge, are unaffected by the electric field.

▲ **Figure 2.6 Marie Skłodowska Curie (1867–1934).** When M. Curie presented her doctoral thesis, it was described as the greatest single contribution of any doctoral thesis in the history of science. Among other things, Curie discovered two new elements, polonium and radium. In 1903 Henri Becquerel, M. Curie, and her husband, Pierre, were jointly awarded the Nobel Prize in physics. In 1911 M. Curie won a second Nobel Prize, this time in chemistry.

▲ **Figure 2.7 Ernest Rutherford (1871–1937).** Rutherford, whom Einstein called “the second Newton,” was born and educated in New Zealand. In 1895 he was the first overseas student ever to be awarded a position at the Cavendish Laboratory at Cambridge University in England, where he worked with J. J. Thomson. In 1898 he joined the faculty of McGill University in Montreal. While at McGill, Rutherford did his research on radioactivity that led to his being awarded the 1908 Nobel Prize in chemistry. In 1907 Rutherford moved back to England to be a faculty member at Manchester University, where in 1910 he performed his famous  $\alpha$ -particle scattering experiments that led to the nuclear model of the atom. In 1992 his native New Zealand honored Rutherford by putting his likeness, along with his Nobel Prize medal, on their \$100 currency note.

▲ **Figure 2.9** J. J. Thomson's "plum-pudding" model of the atom. Thomson pictured the small electrons to be embedded in the atom much like raisins in a pudding or seeds in a watermelon. Ernest Rutherford proved this model wrong.

Figure 2.9 ◀. This so-called "plum-pudding" model, named after a traditional English dessert, was very short lived.

In 1910, Rutherford and his coworkers performed an experiment that disproved Thomson's model. Rutherford was studying the angles at which  $\alpha$  particles were deflected, or *scattered*, as they passed through a thin gold foil only a few thousand atoms thick (Figure 2.10 ▼). Rutherford and his coworkers discovered that almost all the  $\alpha$  particles passed directly through the foil without deflection. A few particles were found to be deflected by approximately 1 degree, consistent with Thomson's plum-pudding model. Just for the sake of completeness, Rutherford suggested that Ernest Marsden, an undergraduate student working in the laboratory, look for evidence of scattering at large angles. To everyone's surprise, a small amount of scattering was observed at large angles. Some particles were even scattered back in the direction from which they had come. The explanation for these results was not immediately obvious, but they were clearly inconsistent with Thomson's plum-pudding model.

By 1911, Rutherford was able to explain these observations. He postulated that most of the mass of each gold atom in his foil and all of its positive charge reside in a very small, extremely dense region, which he called the **nucleus**. He postulated further that most of the total volume of an atom is empty space in which electrons move around the nucleus. In the  $\alpha$ -scattering experiment, most  $\alpha$  particles passed directly through the foil because they did not encounter the minute nucleus of any gold atom; they merely passed through the empty space making up the greatest part of all the atoms in the foil. Occasionally, however, an  $\alpha$  particle came close to a gold nucleus. The repulsion between the highly charged gold nucleus and the  $\alpha$  particle was strong enough to deflect the less massive  $\alpha$  particle, as shown in Figure 2.11 ▶.

Subsequent experimental studies led to the discovery of both positive particles (*protons*) and neutral particles (*neutrons*) in the nucleus. Protons were discovered in 1919 by Rutherford. In 1932 British scientist James Chadwick (1891–1972) discovered neutrons. We examine these particles more closely in Section 2.3.

▶ **Figure 2.10** Rutherford's experiment on the scattering of  $\alpha$  particles. The red lines represent the paths of the  $\alpha$  particles. When the incoming beam strikes the gold foil, most particles pass straight through the foil, but some are scattered.

## GIVE IT SOME THOUGHT

What happens to most of the  $\alpha$  particles that strike the gold foil in Rutherford's experiment? Why do they behave that way?

## 2.3 THE MODERN VIEW OF ATOMIC STRUCTURE

Since the time of Rutherford, physicists have learned much about the detailed composition of atomic nuclei. In the course of these discoveries, the list of particles that make up nuclei has grown long and continues to increase. As chemists, however, we can take a very simple view of the atom because only three subatomic particles—the **proton**, **neutron**, and **electron**—have a bearing on chemical behavior.

The charge of an electron is  $-1.602 \times 10^{-19}$  C, and that of a proton is  $+1.602 \times 10^{-19}$  C. The quantity  $1.602 \times 10^{-19}$  C is called the **electronic charge**. For convenience, the charges of atomic and subatomic particles are usually expressed as multiples of this charge rather than in coulombs. Thus, the charge of the electron is  $1-$ , and that of the proton is  $1+$ . Neutrons are uncharged and are therefore electrically neutral (which is how they received their name). *Every atom has an equal number of electrons and protons, so atoms have no net electrical charge.*

Protons and neutrons reside together in the nucleus of the atom, which, as Rutherford proposed, is extremely small. The vast majority of an atom's volume is the space in which the electrons reside. The electrons are attracted to the protons in the nucleus by the electrostatic force that exists between particles of opposite electrical charge. In later chapters we will see that the strength of the attractive forces between electrons and nuclei can be used to explain many of the differences between different elements.

## GIVE IT SOME THOUGHT

(a) If an atom has 15 protons, how many electrons does it have? (b) Where do the protons reside in an atom?

Atoms have extremely small masses. The mass of the heaviest known atom, for example, is approximately  $4 \times 10^{-22}$  g. Because it would be cumbersome to express such small masses in grams, we use instead the **atomic mass unit**, or amu.\* One amu equals  $1.66054 \times 10^{-24}$  g. The masses of the proton and neutron are very nearly equal, and both are much greater than that of the electron: A proton has a mass of 1.0073 amu, a neutron 1.0087 amu, and an electron  $5.486 \times 10^{-4}$  amu. Because it would take 1836 electrons to equal the mass of 1 proton, the nucleus contains most of the mass of an atom. Table 2.1 summarizes the charges and masses of the subatomic particles. We will have more to say about atomic masses in Section 2.4.

Atoms are also extremely small. Most atoms have diameters between  $1 \times 10^{-10}$  m and  $5 \times 10^{-10}$  m, or 100–500 pm. A convenient, although non-SI, unit of length used to express atomic dimensions is the **angstrom** (Å). One

▲ **Figure 2.11 Rutherford's model explaining the scattering of  $\alpha$  particles.** The gold foil is several thousand atoms thick. Because most of the volume of each atom is empty space, most  $\alpha$  particles pass through the foil without deflection. When an  $\alpha$  particle passes very close to a gold nucleus, however, it is repelled, causing its path to be altered.

**TABLE 2.1** ■ Comparison of the Proton, Neutron, and Electron

Particle	Charge	Mass (amu)
Proton	Positive (1+)	1.0073
Neutron	None (neutral)	1.0087
Electron	Negative (1-)	$5.486 \times 10^{-4}$

\*The SI abbreviation for the atomic mass unit is u. We will use the more common abbreviation amu.

angstrom equals  $10^{-10}$  m. Thus, atoms have diameters of approximately  $1\text{--}5 \text{ \AA}$ . The diameter of a chlorine atom, for example, is 200 pm, or  $2.0 \text{ \AA}$ . Both picometers and angstroms are commonly used to express the dimensions of atoms and molecules.

### ■ SAMPLE EXERCISE 2.1 | Illustrating the Size of an Atom

The diameter of a US penny is 19 mm. The diameter of a silver atom, by comparison, is only  $2.88 \text{ \AA}$ . How many silver atoms could be arranged side by side in a straight line across the diameter of a penny?

#### SOLUTION

The unknown is the number of silver (Ag) atoms. We use the relationship  $1 \text{ Ag atom} = 2.88 \text{ \AA}$  as a conversion factor relating the number of atoms and distance. Thus, we can start with the diameter of the penny, first converting this distance into angstroms and then using the diameter of the Ag atom to convert distance to the number of Ag atoms:

$$\text{Ag atoms} = (19 \text{ mm}) \left( \frac{10^{-3} \text{ m}}{1 \text{ mm}} \right) \left( \frac{1 \text{ \AA}}{10^{-10} \text{ m}} \right) \left( \frac{1 \text{ Ag atom}}{2.88 \text{ \AA}} \right) = 6.6 \times 10^7 \text{ Ag atoms}$$

That is, 66 million silver atoms could sit side by side across a penny!

### ■ PRACTICE EXERCISE

The diameter of a carbon atom is  $1.54 \text{ \AA}$ . (a) Express this diameter in picometers. (b) How many carbon atoms could be aligned side by side in a straight line across the width of a pencil line that is  $0.20 \text{ mm}$  wide?

*Answers:* (a)  $154 \text{ pm}$ , (b)  $1.3 \times 10^6 \text{ C atoms}$

The diameters of atomic nuclei are approximately  $10^{-4} \text{ \AA}$ , only a small fraction of the diameter of the atom as a whole. You can appreciate the relative sizes of the atom and its nucleus by imagining that if the hydrogen atom were as large as a football stadium, the nucleus would be the size of a small marble. Because the tiny nucleus carries most of the mass of the atom in such a small volume, it has an incredible density—on the order of  $10^{13}\text{--}10^{14} \text{ g/cm}^3$ . A matchbox full of material of such density would weigh over 25 billion tons! Astrophysicists have suggested that the interior of a collapsed star may approach this density.

An illustration of the atom that incorporates the features we have just discussed is shown in Figure 2.12 ▼. The electrons, which take up most of the volume of the atom, play the major role in chemical reactions. The significance of representing the region containing the electrons as an indistinct cloud will become clear in later chapters when we consider the energies and spatial arrangements of the electrons.

▼ **Figure 2.12 The structure of the atom.** Neon gas is composed of atoms. The nucleus, which contains protons and neutrons, is the location of virtually all the mass of the atom. The rest of the atom is the space in which the light, negatively charged electrons reside.

## Atomic Numbers, Mass Numbers, and Isotopes

What makes an atom of one element different from an atom of another element? For example, how does an atom of carbon differ from an atom of oxygen? The significant difference is in their subatomic compositions. The atoms of each element have a characteristic number of protons. Indeed, the number

## A Closer Look

## BASIC FORCES

There are four basic forces known in nature: (1) gravitational, (2) electromagnetic, (3) strong nuclear, and (4) weak nuclear. *Gravitational forces* are attractive forces that act between all objects in proportion to their masses. Gravitational forces between atoms or between subatomic particles are so small that they are of no chemical significance.

*Electromagnetic forces* are attractive or repulsive forces that act between either electrically charged or magnetic objects. Electric and magnetic forces are intimately related. Electric forces are of fundamental importance in understanding the chemical behavior of atoms. The magnitude of the electric force between two charged particles is given by *Coulomb's law*:  $F = kQ_1Q_2/d^2$ , where  $Q_1$  and  $Q_2$  are the magnitudes of the charges on the two particles,  $d$  is the distance between their

centers, and  $k$  is a constant determined by the units for  $Q$  and  $d$ . A negative value for the force indicates attraction, whereas a positive value indicates repulsion.

All nuclei except those of hydrogen atoms contain two or more protons. Because like charges repel, electrical repulsion would cause the protons to fly apart if a stronger attractive force, called the *strong nuclear force*, did not keep them together. This force acts between subatomic particles, as in the nucleus. At this distance, the strong nuclear force is stronger than the electric force and holds the nucleus together.

The *weak nuclear force* is weaker than the electric force but stronger than the gravitational force. We are aware of its existence only because it shows itself in certain types of radioactivity.

**Related Exercises:** 2.83(b) and 2.89

of protons in the nucleus of an atom of any particular element is called that element's **atomic number**. Because an atom has no net electrical charge, the number of electrons it contains must equal the number of protons. All atoms of carbon, for example, have six protons and six electrons, whereas all atoms of oxygen have eight protons and eight electrons. Thus, carbon has atomic number 6, whereas oxygen has atomic number 8. The atomic number of each element is listed with the name and symbol of the element on the inside front cover of the text.

Atoms of a given element can differ in the number of neutrons they contain and consequently in mass. For example, most atoms of carbon have six neutrons, although some have more and some have less. The symbol  $^{12}_6\text{C}$  (read "carbon twelve," carbon-12) represents the carbon atom containing six protons and six neutrons. The atomic number is shown by the subscript, and the superscript, called the **mass number**, is the total number of protons plus neutrons in the atom:

Because all atoms of a given element have the same atomic number, the subscript is redundant and is often omitted. Thus, the symbol for carbon-12 can be represented simply as  $^{12}\text{C}$ . As one more example of this notation, atoms that contain six protons and eight neutrons have a mass number of 14 and are represented as  $^{14}_6\text{C}$  or  $^{14}\text{C}$  and referred to as carbon-14.

Atoms with identical atomic numbers but different mass numbers (that is, same number of protons but different numbers of neutrons) are called **isotopes** of one another. Several isotopes of carbon are listed in Table 2.2 ▼. We will

TABLE 2.2 ■ Some Isotopes of Carbon\*

Symbol	Number of Protons	Number of Electrons	Number of Neutrons
$^{11}\text{C}$	6	6	5
$^{12}\text{C}$	6	6	6
$^{13}\text{C}$	6	6	7
$^{14}\text{C}$	6	6	8

\*Almost 99% of the carbon found in nature is  $^{12}\text{C}$ .

generally use the notation with superscripts only when referring to a particular isotope of an element.

### SAMPLE EXERCISE 2.2 | Determining the Number of Subatomic Particles in Atoms

How many protons, neutrons, and electrons are in (a) an atom of  $^{197}\text{Au}$ ; (b) an atom of strontium-90?

#### SOLUTION

(a) The superscript 197 is the mass number, the sum of the number of protons plus the number of neutrons. According to the list of elements given inside the front cover, gold has an atomic number of 79. Consequently, an atom of  $^{197}\text{Au}$  has 79 protons, 79 electrons, and  $197 - 79 = 118$  neutrons. (b) The atomic number of strontium (listed inside the front cover) is 38. Thus, all atoms of this element have 38 protons and 38 electrons. The strontium-90 isotope has  $90 - 38 = 52$  neutrons.

### PRACTICE EXERCISE

How many protons, neutrons, and electrons are in (a) a  $^{138}\text{Ba}$  atom, (b) an atom of phosphorus-31?

**Answer:** (a) 56 protons, 56 electrons, and 82 neutrons; (b) 15 protons, 15 electrons, and 16 neutrons.

### SAMPLE EXERCISE 2.3 | Writing Symbols for Atoms

Magnesium has three isotopes, with mass numbers 24, 25, and 26. (a) Write the complete chemical symbol (superscript and subscript) for each of them. (b) How many neutrons are in an atom of each isotope?

#### SOLUTION

(a) Magnesium has atomic number 12, so all atoms of magnesium contain 12 protons and 12 electrons. The three isotopes are therefore represented by  $^{24}_{12}\text{Mg}$ ,  $^{25}_{12}\text{Mg}$ , and  $^{26}_{12}\text{Mg}$ . (b) The number of neutrons in each isotope is the mass number minus the number of protons. The numbers of neutrons in an atom of each isotope are therefore 12, 13, and 14, respectively.

### PRACTICE EXERCISE

Give the complete chemical symbol for the atom that contains 82 protons, 82 electrons, and 126 neutrons.

**Answer:**  $^{208}_{82}\text{Pb}$

## 2.4 ATOMIC WEIGHTS

Atoms are small pieces of matter, so they have mass. In this section we will discuss the mass scale used for atoms and introduce the concept of *atomic weights*. In Section 3.3 we will extend these concepts to show how atomic masses are used to determine the masses of compounds and *molecular weights*.

### The Atomic Mass Scale

Although scientists of the nineteenth century knew nothing about subatomic particles, they were aware that atoms of different elements have different masses. They found, for example, that each 100.0 g of water contains 11.1 g of hydrogen and 88.9 g of oxygen. Thus, water contains  $88.9/11.1 = 8$  times as much oxygen, by mass, as hydrogen. Once scientists understood that water contains two hydrogen atoms for each oxygen atom, they concluded that an oxygen atom must have  $2 \times 8 = 16$  times as much mass as a hydrogen atom. Hydrogen, the lightest atom, was arbitrarily assigned a relative mass of 1 (no units). Atomic masses of other elements were at first determined relative to this value. Thus, oxygen was assigned an atomic mass of 16.

Today we can determine the masses of individual atoms with a high degree of accuracy. For example, we know that the  $^1\text{H}$  atom has a mass of  $1.6735 \times 10^{-24}$  g and the  $^{16}\text{O}$  atom has a mass of  $2.6560 \times 10^{-23}$  g. As we noted in Section 2.3, it is convenient to use the *atomic mass unit* (amu) when dealing with these extremely small masses:

$$1 \text{ amu} = 1.66054 \times 10^{-24} \text{ g and } 1 \text{ g} = 6.02214 \times 10^{23} \text{ amu}$$

The atomic mass unit is presently defined by assigning a mass of exactly 12 amu to an atom of the  $^{12}\text{C}$  isotope of carbon. In these units, an  $^1\text{H}$  atom has a mass of 1.0078 amu and an  $^{16}\text{O}$  atom has a mass of 15.9949 amu.

## Average Atomic Masses

Most elements occur in nature as mixtures of isotopes. We can determine the *average atomic mass* of an element by using the masses of its various isotopes and their relative abundances. Naturally occurring carbon, for example, is composed of 98.93%  $^{12}\text{C}$  and 1.07%  $^{13}\text{C}$ . The masses of these isotopes are 12 amu (exactly) and 13.00335 amu, respectively. We calculate the average atomic mass of carbon from the fractional abundance of each isotope and the mass of that isotope:

$$(0.9893)(12 \text{ amu}) + (0.0107)(13.00335 \text{ amu}) = 12.01 \text{ amu}$$

The average atomic mass of each element (expressed in atomic mass units) is also known as its **atomic weight**. Although the term *average atomic mass* is more proper, the term *atomic weight* is more common. The atomic weights of the elements are listed in both the periodic table and the table of elements inside the front cover of this text.

### GIVE IT SOME THOUGHT

A particular atom of chromium has a mass of 52.94 amu, whereas the atomic weight of chromium is 51.99 amu. Explain the difference in the two masses.

#### SAMPLE EXERCISE 2.4 Calculating the Atomic Weight of an Element from Isotopic Abundances

Naturally occurring chlorine is 75.78%  $^{35}\text{Cl}$ , which has an atomic mass of 34.969 amu, and 24.22%  $^{37}\text{Cl}$ , which has an atomic mass of 36.966 amu. Calculate the average atomic mass (that is, the atomic weight) of chlorine.

#### SOLUTION

We can calculate the average atomic mass by multiplying the abundance of each isotope by its atomic mass and summing these products. Because 75.78% = 0.7578 and 24.22% = 0.2422, we have

$$\begin{aligned} \text{Average atomic mass} &= (0.7578)(34.969 \text{ amu}) + (0.2422)(36.966 \text{ amu}) \\ &= 26.50 \text{ amu} + 8.953 \text{ amu} \\ &= 35.45 \text{ amu} \end{aligned}$$

This answer makes sense: The average atomic mass of Cl is between the masses of the two isotopes and is closer to the value of  $^{35}\text{Cl}$ , which is the more abundant isotope.

#### PRACTICE EXERCISE

Three isotopes of silicon occur in nature:  $^{28}\text{Si}$  (92.23%), which has an atomic mass of 27.97693 amu;  $^{29}\text{Si}$  (4.68%), which has an atomic mass of 28.97649 amu; and  $^{30}\text{Si}$  (3.09%), which has an atomic mass of 29.97377 amu. Calculate the atomic weight of silicon.

**Answer:** 28.09 amu

## A Closer Look

## THE MASS SPECTROMETER

The most direct and accurate means for determining atomic and molecular weights is provided by the **mass spectrometer** (Figure 2.13). A gaseous sample is introduced at *A* and bombarded by a stream of high-energy electrons at *B*. Collisions between the electrons and the atoms or molecules of the gas produce positively charged particles, mostly with a 1+ charge. These charged particles are accelerated toward a negatively charged wire grid (*C*). After the particles pass through the grid, they encounter two slits that allow only a narrow beam of particles to pass. This beam then passes between the poles of a magnet, which deflects the particles into a curved path, much as electrons are deflected by a magnetic field (Figure 2.4). For charged particles with the same charge, the extent of deflection depends on mass—the more massive the particle, the less the deflection. The particles are thereby separated according to their masses. By changing the strength of the magnetic field or the accelerating voltage on the negatively charged grid, charged particles of various masses can be selected to enter the detector at the end of the instrument.

A graph of the intensity of the detector signal versus particle atomic mass is called a *mass spectrum*. The mass spectrum of chlorine atoms, shown in Figure 2.14, reveals the presence of two isotopes. Analysis of a mass spectrum gives both the masses of the charged particles reaching the detector and their relative abundances. The abundances are obtained from the signal intensities. Knowing the atomic mass and the abundance of each isotope allows us to calculate the atomic weight of an element, as shown in Sample Exercise 2.4.

Mass spectrometers are used extensively today to identify chemical compounds and analyze mixtures of substances. Any molecule that loses electrons can fall apart, forming an array of positively charged fragments. The mass spectrometer measures the masses of these fragments, producing a chemical “fingerprint” of the molecule and providing clues about how the atoms were connected in the original molecule. Thus, a chemist might use this technique to determine the molecular structure of a newly synthesized compound or to identify a pollutant in the environment.

*Related Exercises:* 2.33, 2.34, 2.35(b), 2.36, 2.93, and 2.94

▲ **Figure 2.13** A mass spectrometer. Cl atoms are introduced on the left side of the spectrometer and are ionized to form  $\text{Cl}^+$  ions, which are then directed through a magnetic field. The paths of the ions of the two isotopes of Cl diverge as they pass through the magnetic field. As drawn, the spectrometer is tuned to detect  $^{35}\text{Cl}^+$  ions. The heavier  $^{37}\text{Cl}^+$  ions are not deflected enough for them to reach the detector.

▲ **Figure 2.14** Mass spectrum of atomic chlorine. The fractional abundances of the  $^{35}\text{Cl}$  and  $^{37}\text{Cl}$  isotopes of chlorine are indicated by the relative signal intensities of the beams reaching the detector of the mass spectrometer.

## 2.5 THE PERIODIC TABLE

Dalton's atomic theory set the stage for a vigorous growth in chemical experimentation during the early 1800s. As the body of chemical observations grew and the list of known elements expanded, attempts were made to find regular patterns in chemical behavior. These efforts culminated in the development of the periodic table in 1869. We will have much to say about the periodic table in later chapters, but it is so important and useful that you should become acquainted with it now. You will quickly learn that *the periodic table is the most significant tool that chemists use for organizing and remembering chemical facts.*

Many elements show very strong similarities to one another. The elements lithium (Li), sodium (Na), and potassium (K) are all soft, very reactive metals,

The horizontal rows of the periodic table are called **periods**. The first period consists of only two elements, hydrogen (H) and helium (He). The second and third periods, which begin with lithium (Li) and sodium (Na), respectively, consist of eight elements each. The fourth and fifth periods contain 18 elements. The sixth period has 32 elements, but for it to fit on a page, 14 of these elements (those with atomic numbers 57–70) appear at the bottom of the table. The seventh and last period is incomplete, but it also has 14 of its members placed in a row at the bottom of the table.

The vertical columns of the periodic table are called **groups**. The way in which the groups are labeled is somewhat arbitrary. Three labeling schemes are in common use, two of which are shown in Figure 2.16. The top set of labels, which have A and B designations, is widely used in North America. Roman numerals, rather than Arabic ones, are often employed in this scheme. Group 7A, for example, is often labeled VIIA. Europeans use a similar convention that numbers the columns from 1A through 8A and then from 1B through 8B, thereby giving the label 7B (or VIIB) instead of 7A to the group headed by fluorine (F). In an effort to eliminate this confusion, the International Union of Pure and Applied Chemistry (IUPAC) has proposed a convention that numbers the groups from 1 through 18 with no A or B designations, as shown in the lower set of labels at the top of the table in Figure 2.16. We will use the traditional North American convention with Arabic numerals.

Elements that belong to the same group often exhibit similarities in physical and chemical properties. For example, the “coinage metals”—copper (Cu), silver (Ag), and gold (Au)—belong to group 1B. As their name suggests, the coinage metals are used throughout the world to make coins. Many other groups in the periodic table also have names, as listed in Table 2.3 ▼.

We will learn in Chapters 6 and 7 that the elements in a group of the periodic table have similar properties because they have the same arrangement of electrons at the periphery of their atoms. However, we need not wait until then to make good use of the periodic table; after all, chemists who knew nothing about electrons developed the table! We can use the table, as they intended, to correlate the behaviors of elements and to aid in remembering many facts. You will find it helpful to refer to the periodic table frequently when studying the remainder of this chapter.

Except for hydrogen, all the elements on the left side and in the middle of the periodic table are **metallic elements**, or **metals**. The majority of elements are metallic; they all share characteristic properties, such as luster and high electrical and heat conductivity. All metals, with the exception of mercury (Hg), are solids at room temperature. The metals are separated from the **nonmetallic elements**, or **nonmetals**, by a diagonal steplike line that runs from boron (B) to astatine (At), as shown in Figure 2.16. Hydrogen, although on the left side of the periodic table, is a nonmetal. At room temperature some of the nonmetals are gaseous, some are solid, and one is liquid. Nonmetals generally differ from the metals in appearance (Figure 2.17 ◀) and in other physical properties. Many of the elements that lie along the line that separates metals from nonmetals, such as antimony (Sb), have properties that fall between those of metals and those of nonmetals. These elements are often referred to as **metalloids**.

▲ **Figure 2.17** Some familiar examples of metals and nonmetals. The nonmetals (from bottom left) are sulfur (yellow powder), iodine (dark, shiny crystals), bromine (reddish brown liquid and vapor in glass vial), and three samples of carbon (black charcoal powder, diamond, and graphite in the pencil lead). The metals are in the form of an aluminum wrench, copper pipe, lead shot, silver coins, and gold nuggets.

**TABLE 2.3** ■ Names of Some Groups in the Periodic Table

Group	Name	Elements
1A	Alkali metals	Li, Na, K, Rb, Cs, Fr
2A	Alkaline earth metals	Be, Mg, Ca, Sr, Ba, Ra
6A	Chalcogens	O, S, Se, Te, Po
7A	Halogens	F, Cl, Br, I, At
8A	Noble gases (or rare gases)	He, Ne, Ar, Kr, Xe, Rn

## A Closer Look

## GLENN SEABORG AND SEABORGIUM

Prior to 1940 the periodic table ended at uranium, element number 92. Since that time, no scientist has had a greater effect on the periodic table than Glenn Seaborg. Seaborg (Figure 2.18) became a faculty member in the chemistry department at the University of California, Berkeley in 1937. In 1940 he and his colleagues Edwin McMillan, Arthur Wahl, and Joseph Kennedy succeeded in isolating plutonium (Pu) as a product of the reaction between uranium and neutrons. We will talk about reactions of this type, called *nuclear reactions*, in Chapter 21.

During the period 1944 through 1958, Seaborg and his coworkers also identified various products of nuclear reactions as being the elements having atomic numbers 95 through 102. All these elements are radioactive and are not found in nature; they can be synthesized only via nuclear reactions. For their efforts in identifying the elements beyond uranium (the *transuranium* elements), McMillan and Seaborg shared the 1951 Nobel Prize in chemistry.

From 1961 to 1971, Seaborg served as the chairman of the U.S. Atomic Energy Commission (now the Department of Energy). In this position he had an important role in establishing international treaties to limit the testing of nuclear weapons. Upon his return to Berkeley, he was part of the team that in 1974 first identified element number 106. Another team at Berkeley corroborated that discovery in 1993. In 1994, to honor Seaborg's many contributions to the discovery of new elements, the American Chemical Society proposed that element

◀ **Figure 2.18 Glenn Seaborg (1912–1999).** The photograph shows Seaborg at Berkeley in 1941 using a Geiger counter to try to detect radiation produced by plutonium. Geiger counters will be discussed in Section 21.5.

number 106 be named “seaborgium,” with a proposed symbol of Sg. After several years of controversy about whether an element should be named after a living person, the IUPAC officially adopted the name seaborgium in 1997. Seaborg became the first person to have an element named after him while he was still alive.

**Related Exercise:** 2.96

## GIVE IT SOME THOUGHT

Chlorine is a halogen. Locate this element in the periodic table. (a) What is its symbol? (b) In what period and in what group is the element located? (c) What is its atomic number? (d) Is chlorine a metal or nonmetal?

### SAMPLE EXERCISE 2.5 | Using the Periodic Table

Which two of the following elements would you expect to show the greatest similarity in chemical and physical properties: B, Ca, F, He, Mg, P?

#### SOLUTION

Elements that are in the same group of the periodic table are most likely to exhibit similar chemical and physical properties. We therefore expect that Ca and Mg should be most alike because they are in the same group (2A, the alkaline earth metals).

#### PRACTICE EXERCISE

Locate Na (sodium) and Br (bromine) on the periodic table. Give the atomic number of each, and label each a metal, metalloid, or nonmetal.

**Answer:** Na, atomic number 11, is a metal; Br, atomic number 35, is a nonmetal.

## 2.6 MOLECULES AND MOLECULAR COMPOUNDS

Even though the atom is the smallest representative sample of an element, only the noble-gas elements are normally found in nature as isolated atoms. Most matter is composed of molecules or ions, both of which are formed from atoms. We examine molecules here and ions in Section 2.7.

► **Figure 2.19 Diatomic molecules.** Seven common elements exist as diatomic molecules at room temperature.

A **molecule** is an assembly of two or more atoms tightly bound together. The resultant “package” of atoms behaves in many ways as a single, distinct object, just as a cell phone composed of many parts can be recognized as a single object. We will discuss the forces that hold the atoms together (the chemical bonds) in Chapters 8 and 9.

### Molecules and Chemical Formulas

Many elements are found in nature in molecular form; that is, two or more of the same type of atom are bound together. For example, the oxygen normally found in air consists of molecules that contain two oxygen atoms. We represent this molecular form of oxygen by the **chemical formula**  $O_2$  (read “oh two”). The subscript in the formula tells us that two oxygen atoms are present in each molecule. A molecule that is made up of two atoms is called a **diatomic molecule**. Oxygen also exists in another molecular form known as *ozone*. Molecules of ozone consist of three oxygen atoms, making the chemical formula for this substance  $O_3$ . Even though “normal” oxygen ( $O_2$ ) and ozone ( $O_3$ ) are both composed only of oxygen atoms, they exhibit very different chemical and physical properties. For example,  $O_2$  is essential for life, but  $O_3$  is toxic;  $O_2$  is odorless, whereas  $O_3$  has a sharp, pungent smell.

The elements that normally occur as diatomic molecules are hydrogen, oxygen, nitrogen, and the halogens. Their locations in the periodic table are shown in Figure 2.19▲. When we speak of the substance hydrogen, we mean  $H_2$  unless we explicitly indicate otherwise. Likewise, when we speak of oxygen, nitrogen, or any of the halogens, we are referring to  $O_2$ ,  $N_2$ ,  $F_2$ ,  $Cl_2$ ,  $Br_2$ , or  $I_2$ . Thus, the properties of oxygen and hydrogen listed in Table 1.3 are those of  $O_2$  and  $H_2$ . Other, less common forms of these elements behave much differently.

Compounds that are composed of molecules contain more than one type of atom and are called **molecular compounds**. A molecule of water, for example, consists of two hydrogen atoms and one oxygen atom and is therefore represented by the chemical formula  $H_2O$ . Lack of a subscript on the O indicates one atom of O per water molecule. Another compound composed of these same elements (in different relative proportions) is hydrogen peroxide,  $H_2O_2$ . The properties of hydrogen peroxide are very different from the properties of water.

Several common molecules are shown in Figure 2.20◀. Notice how the composition of each compound is given by its chemical formula. Notice also that these substances are composed only of nonmetallic elements. *Most molecular substances that we will encounter contain only nonmetals.*

### Molecular and Empirical Formulas

Chemical formulas that indicate the actual numbers and types of atoms in a molecule are called **molecular formulas**. (The formulas in Figure 2.20 are molecular formulas.) Chemical formulas that give only the relative number of atoms of each type in a molecule are called **empirical formulas**. The subscripts in an empirical formula are always the smallest possible whole-number ratios. The molecular formula for hydrogen peroxide is  $H_2O_2$ , for example, whereas its empirical formula is HO. The molecular formula for ethylene is  $C_2H_4$ , and its

▲ **Figure 2.20 Molecular models of some simple molecules.** Notice how the chemical formulas of these substances correspond to their compositions.

empirical formula is  $\text{CH}_2$ . For many substances, the molecular formula and the empirical formula are identical, as in the case of water,  $\text{H}_2\text{O}$ .

Molecular formulas provide more information about molecules than do empirical formulas. Whenever we know the molecular formula of a compound, we can determine its empirical formula. The converse is not true, however. If we know the empirical formula of a substance, we cannot determine its molecular formula unless we have more information. So why do chemists bother with empirical formulas? As we will see in Chapter 3, certain common methods of analyzing substances lead to the empirical formula only. Once the empirical formula is known, additional experiments can give the information needed to convert the empirical formula to the molecular one. In addition, there are substances, such as the most common forms of elemental carbon, that do not exist as isolated molecules. For these substances, we must rely on empirical formulas. Thus, all the common forms of elemental carbon are represented by the element's chemical symbol, C, which is the empirical formula for all the forms.

### SAMPLE EXERCISE 2.6 | Relating Empirical and Molecular Formulas

Write the empirical formulas for the following molecules: (a) glucose, a substance also known as either blood sugar or dextrose, whose molecular formula is  $\text{C}_6\text{H}_{12}\text{O}_6$ ; (b) nitrous oxide, a substance used as an anesthetic and commonly called laughing gas, whose molecular formula is  $\text{N}_2\text{O}$ .

#### SOLUTION

(a) The subscripts of an empirical formula are the smallest whole-number ratios. The smallest ratios are obtained by dividing each subscript by the largest common factor, in this case 6. The resultant empirical formula for glucose is  $\text{CH}_2\text{O}$ .

(b) Because the subscripts in  $\text{N}_2\text{O}$  are already the lowest integral numbers, the empirical formula for nitrous oxide is the same as its molecular formula,  $\text{N}_2\text{O}$ .

#### PRACTICE EXERCISE

Give the empirical formula for the substance called *diborane*, whose molecular formula is  $\text{B}_2\text{H}_6$ .

*Answer:*  $\text{BH}_3$

## Picturing Molecules

The molecular formula of a substance summarizes the composition of the substance but does not show how the atoms come together to form the molecule. The **structural formula** of a substance shows which atoms are attached to which within the molecule. For example, the structural formulas for water, hydrogen peroxide, and methane ( $\text{CH}_4$ ) can be written as follows:

The atoms are represented by their chemical symbols, and lines are used to represent the bonds that hold the atoms together.

A structural formula usually does not depict the actual geometry of the molecule, that is, the actual angles at which atoms are joined together. A structural formula can be written as a *perspective drawing*, however, to give some sense of three-dimensional shape, as shown in Figure 2.21 ▶.

Scientists also rely on various models to help visualize molecules. *Ball-and-stick models* show atoms as spheres and bonds as sticks. This type of model has the advantage of accurately representing the angles at which the atoms are attached to one another within the molecule (Figure 2.21). In a ball-and-stick

▲ **Figure 2.21** Different representations of the methane ( $\text{CH}_4$ ) molecule. Structural formulas, perspective drawings, ball-and-stick models, and space-filling models each help us visualize the ways atoms are attached to each other in molecules. In the perspective drawing, solid lines represent bonds in the plane of the paper, the solid wedge represents a bond that extends out from the plane of the paper, and dashed lines represent bonds behind the paper.

model, balls of the same size may represent all atoms, or the relative sizes of the balls may reflect the relative sizes of the atoms. Sometimes the chemical symbols of the elements are superimposed on the balls, but often the atoms are identified simply by color.

A *space-filling model* depicts what the molecule would look like if the atoms were scaled up in size (Figure 2.21). These models show the relative sizes of the atoms, but the angles between atoms, which help define their molecular geometry, are often more difficult to see than in ball-and-stick models. As in ball-and-stick models, the identities of the atoms are indicated by their colors, but they may also be labeled with the element's symbol.

### GIVE IT SOME THOUGHT

The structural formula for the substance ethane is shown here:

(a) What is the molecular formula for ethane? (b) What is its empirical formula? (c) Which kind of molecular model would most clearly show the angles between atoms?

## 2.7 IONS AND IONIC COMPOUNDS

The nucleus of an atom is unchanged by chemical processes, but some atoms can readily gain or lose electrons. If electrons are removed from or added to a neutral atom, a charged particle called an **ion** is formed. An ion with a positive charge is called a **cation** (pronounced CAT-ion); a negatively charged ion is called an **anion** (AN-ion).

To see how ions form, consider the sodium atom, which has 11 protons and 11 electrons. This atom easily loses one electron. The resulting cation has 11 protons and 10 electrons, which means it has a net charge of  $1+$ .

The net charge on an ion is represented by a superscript. The superscripts  $+$ ,  $2+$ , and  $3+$ , for instance, mean a net charge resulting from the *loss* of one, two, and three electrons, respectively. The superscripts  $-$ ,  $2-$ , and  $3-$  represent net charges resulting from the *gain* of one, two, and three electrons, respectively. Chlorine, with 17 protons and 17 electrons, for example, can gain an electron in chemical reactions, producing the  $\text{Cl}^-$  ion:

*In general, metal atoms tend to lose electrons to form cations, whereas nonmetal atoms tend to gain electrons to form anions.*

**SAMPLE EXERCISE 2.7** | Writing Chemical Symbols for Ions

Give the chemical symbol, including mass number, for each of the following ions: (a) The ion with 22 protons, 26 neutrons, and 19 electrons; (b) the ion of sulfur that has 16 neutrons and 18 electrons.

**SOLUTION**

(a) The number of protons (22) is the atomic number of the element. By referring to a periodic table or list of elements, we see that the element with atomic number 22 is titanium (Ti). The mass number of this isotope of titanium is  $22 + 26 = 48$  (the sum of the protons and neutrons). Because the ion has three more protons than electrons, it has a net charge of  $3+$ . Thus, the symbol for the ion is  ${}^{48}\text{Ti}^{3+}$ .

(b) By referring to a periodic table or a table of elements, we see that sulfur (S) has an atomic number of 16. Thus, each atom or ion of sulfur must contain 16 protons. We are told that the ion also has 16 neutrons, meaning the mass number of the ion is  $16 + 16 = 32$ . Because the ion has 16 protons and 18 electrons, its net charge is  $2-$ . Thus, the symbol for the ion is  ${}^{32}\text{S}^{2-}$ .

In general, we will focus on the net charges of ions and ignore their mass numbers unless the circumstances dictate that we specify a certain isotope.

**PRACTICE EXERCISE**

How many protons, neutrons, and electrons does the  ${}^{79}\text{Se}^{2-}$  ion possess?

*Answer:* 34 protons, 45 neutrons, and 36 electrons

In addition to simple ions, such as  $\text{Na}^+$  and  $\text{Cl}^-$ , there are **polyatomic ions**, such as  $\text{NH}_4^+$  (ammonium ion) and  $\text{SO}_4^{2-}$  (sulfate ion). These latter ions consist of atoms joined as in a molecule, but they have a net positive or negative charge. We will consider further examples of polyatomic ions in Section 2.8.

It is important to realize that the chemical properties of ions are very different from the chemical properties of the atoms from which the ions are derived. The difference is like the change from Dr. Jekyll to Mr. Hyde: Although a given atom and its ion may be essentially the same (plus or minus a few electrons), the behavior of the ion is very different from that of the atom.

**Predicting Ionic Charges**

Many atoms gain or lose electrons to end up with the same number of electrons as the noble gas closest to them in the periodic table. The members of the noble-gas family are chemically very nonreactive and form very few compounds. We might deduce that this is because their electron arrangements are very stable. Nearby elements can obtain these same stable arrangements by losing or gaining electrons. For example, the loss of one electron from an atom of sodium leaves it with the same number of electrons as the neutral neon atom (atomic number 10). Similarly, when chlorine gains an electron, it ends up with 18, the same number of electrons as in argon (atomic number 18). We will use this simple observation to explain the formation of ions until Chapter 8, where we discuss chemical bonding.

**SAMPLE EXERCISE 2.8** | Predicting the Charges of Ions

Predict the charge expected for the most stable ion of barium and for the most stable ion of oxygen.

**SOLUTION**

We will assume that these elements form ions that have the same number of electrons as the nearest noble-gas atom. From the periodic table, we see that barium has atomic number 56. The nearest noble gas is xenon, atomic number 54. Barium can attain a stable arrangement of 54 electrons by losing two of its electrons, forming the  $\text{Ba}^{2+}$  cation.

Oxygen has atomic number 8. The nearest noble gas is neon, atomic number 10. Oxygen can attain this stable electron arrangement by gaining two electrons, thereby forming the  $\text{O}^{2-}$  anion.

**PRACTICE EXERCISE**

Predict the charge expected for the most stable ion of (a) aluminum and (b) fluorine.

*Answer:* (a)  $3+$ ; (b)  $1-$

1A	2A	Transition metals										3A	4A	5A	6A	7A	8A	
H <sup>+</sup>															N <sup>3-</sup>	O <sup>2-</sup>	F <sup>-</sup>	NOBLE GASES

K <sup>+</sup>	Ca <sup>2+</sup>															Te <sup>2-</sup>	I <sup>-</sup>	
Rb <sup>+</sup>	Sr <sup>2+</sup>																	
Cs <sup>+</sup>	Ba <sup>2+</sup>																	

▲ **Figure 2.22 Charges of some common ions.** Notice that the steplike line that divides metals from nonmetals also separates cations from anions. Hydrogen forms both 1+ and 1- ions.

The periodic table is very useful for remembering the charges of ions, especially those of the elements on the left and right sides of the table. As Figure 2.22 ▲ shows, the charges of these ions relate in a simple way to their positions in the table. On the left side of the table, for example, the group 1A elements (the alkali metals) form 1+ ions, and the group 2A elements (the alkaline earths) form 2+ ions. On the other side of the table the group 7A elements (the halogens) form 1- ions, and the group 6A elements form 2- ions. As we will see later in the text, many of the other groups do not lend themselves to such simple rules.

### Ionic Compounds

A great deal of chemical activity involves the transfer of electrons from one substance to another. As we just saw, ions form when one or more electrons transfer from one neutral atom to another. Figure 2.23 ▼ shows that when elemental sodium is allowed to react with elemental chlorine, an electron transfers from a neutral sodium atom to a neutral chlorine atom. We are left with a Na<sup>+</sup> ion and a Cl<sup>-</sup> ion. Because objects of opposite charge attract, the Na<sup>+</sup> and the Cl<sup>-</sup> ions bind together to form the compound sodium chloride (NaCl). Sodium chloride, which we know better as common table salt, is an example of an **ionic compound**, a compound that contains both positively and negatively charged ions.

We can often tell whether a compound is ionic (consisting of ions) or molecular (consisting of molecules) from its composition. In general, cations are metal ions, whereas anions are nonmetal ions. Consequently, *ionic compounds*

▼ **Figure 2.23 The formation of an ionic compound.** (a) The transfer of an electron from a neutral Na atom to a neutral Cl atom leads to the formation of a Na<sup>+</sup> ion and a Cl<sup>-</sup> ion. (b) Arrangement of these ions in solid sodium chloride (NaCl). (c) A sample of sodium chloride crystals.

Someone once said that drinking at the fountain of knowledge in a chemistry course is like drinking from a fire hydrant. Indeed, the pace can sometimes seem brisk. More to the point, however, we can drown in the facts if we do not see the general patterns. The value of recognizing patterns and learning rules and generalizations is that the patterns, rules, and generalizations free us from learning (or trying to memorize) many individual facts. The patterns, rules, and generalizations tie ideas together so that we do not get lost in the details.

Many students struggle with chemistry because they do not see how the topics relate to one another, how ideas connect together. They therefore treat every idea and problem as being unique instead of as an example or application of a general rule, procedure, or relationship. You can avoid this pitfall by remembering the following: Begin to notice the structure of the

topic you are studying. Pay attention to the trends and rules given to summarize a large body of information. Notice, for example, how atomic structure helps us understand the existence of isotopes (as seen in Table 2.2) and how the periodic table aids us in remembering the charges of ions (as seen in Figure 2.22). You may surprise yourself by observing patterns that are not even explicitly spelled out yet. Perhaps you have even noticed certain trends in chemical formulas. Moving across the periodic table from element 11 (Na), we find that the elements form compounds with F having the following compositions: NaF, MgF<sub>2</sub>, and AlF<sub>3</sub>. Does this trend continue? Do SiF<sub>4</sub>, PF<sub>5</sub>, and SF<sub>6</sub> exist? Indeed they do. If you have noticed trends like this from the scraps of information you have seen so far, then you are ahead of the game and you have already prepared yourself for some topics we will address in later chapters.

We can readily write the empirical formula for an ionic compound if we know the charges of the ions of which the compound is composed. Chemical compounds are always electrically neutral. Consequently, the ions in an ionic compound always occur in such a ratio that the total positive charge equals the total negative charge. Thus, there is one Na<sup>+</sup> to one Cl<sup>-</sup> (giving NaCl), one Ba<sup>2+</sup> to two Cl<sup>-</sup> (giving BaCl<sub>2</sub>), and so forth.

As you consider these and other examples, you will see that if the charges on the cation and anion are equal, the subscript on each ion will be 1. If the charges are not equal, the charge on one ion (without its sign) will become the subscript on the other ion. For example, the ionic compound formed from Mg (which forms Mg<sup>2+</sup> ions) and N (which forms N<sup>3-</sup> ions) is Mg<sub>3</sub>N<sub>2</sub>:

### GIVE IT SOME THOUGHT

Why don't we write the formula for the compound formed by Ca<sup>2+</sup> and O<sup>2-</sup> as Ca<sub>2</sub>O<sub>2</sub>?

#### SAMPLE EXERCISE 2.10 Using Ionic Charge to Write Empirical Formulas for Ionic Compounds

What are the empirical formulas of the compounds formed by (a) Al<sup>3+</sup> and Cl<sup>-</sup> ions, (b) Al<sup>3+</sup> and O<sup>2-</sup> ions, (c) Mg<sup>2+</sup> and NO<sub>3</sub><sup>-</sup> ions?

#### SOLUTION

(a) Three Cl<sup>-</sup> ions are required to balance the charge of one Al<sup>3+</sup> ion. Thus, the formula is AlCl<sub>3</sub>.

(b) Two Al<sup>3+</sup> ions are required to balance the charge of three O<sup>2-</sup> ions (that is, the total positive charge is 6+, and the total negative charge is 6-). Thus, the formula is Al<sub>2</sub>O<sub>3</sub>.

(c) Two NO<sub>3</sub><sup>-</sup> ions are needed to balance the charge of one Mg<sup>2+</sup>. Thus, the formula is Mg(NO<sub>3</sub>)<sub>2</sub>. In this case the formula for the entire polyatomic ion NO<sub>3</sub><sup>-</sup> must be enclosed in parentheses so that it is clear that the subscript 2 applies to all the atoms of that ion.

#### PRACTICE EXERCISE

Write the empirical formulas for the compounds formed by the following ions:

(a) Na<sup>+</sup> and PO<sub>4</sub><sup>3-</sup>, (b) Zn<sup>2+</sup> and SO<sub>4</sub><sup>2-</sup>, (c) Fe<sup>3+</sup> and CO<sub>3</sub><sup>2-</sup>.

Answers: (a) Na<sub>3</sub>PO<sub>4</sub>, (b) ZnSO<sub>4</sub>, (c) Fe<sub>2</sub>(CO<sub>3</sub>)<sub>3</sub>

## 2.8 NAMING INORGANIC COMPOUNDS

To obtain information about a particular substance, you must know its chemical formula and name. The names and formulas of compounds are essential vocabulary in chemistry. The system used in naming substances is called **chemical nomenclature** from the Latin words *nomen* (name) and *calare* (to call).

There are now more than 19 million known chemical substances. Naming them all would be a hopelessly complicated task if each had a special name independent of all others. Many important substances that have been known for a long time, such as water ( $\text{H}_2\text{O}$ ) and ammonia ( $\text{NH}_3$ ), do have individual, traditional names (so-called “common” names). For most substances, however, we rely on a systematic set of rules that leads to an informative and unique name for each substance, a name based on the composition of the substance.

The rules for chemical nomenclature are based on the division of substances into categories. The major division is between organic and inorganic compounds. *Organic compounds* contain carbon, usually in combination with hydrogen, oxygen, nitrogen, or sulfur. All others are *inorganic compounds*. Early chemists associated organic compounds with plants and animals, and they associated inorganic compounds with the nonliving portion of our world. Although this distinction between living and nonliving matter is no longer pertinent, the classification between organic and inorganic compounds continues to be useful. In this section we consider the basic rules for naming inorganic compounds, and in Section 2.9 we will introduce the names of some simple organic compounds. Among inorganic compounds, we will consider three categories: ionic compounds, molecular compounds, and acids.

### Names and Formulas of Ionic Compounds

Recall from Section 2.7 that ionic compounds usually consist of metal ions combined with nonmetal ions. The metals form the positive ions, and the nonmetals form the negative ions. Let's examine the naming of positive ions, then the naming of negative ones. After that, we will consider how to put the names of the ions together to identify the complete ionic compound.

#### 1. Positive Ions (Cations)

(a) *Cations formed from metal atoms have the same name as the metal:*

$\text{Na}^+$  sodium ion       $\text{Zn}^{2+}$  zinc ion       $\text{Al}^{3+}$  aluminum ion

Ions formed from a single atom are called *monatomic ions*.

(b) *If a metal can form different cations, the positive charge is indicated by a Roman numeral in parentheses following the name of the metal:*

$\text{Fe}^{2+}$  iron(II) ion       $\text{Cu}^+$  copper(I) ion  
 $\text{Fe}^{3+}$  iron(III) ion       $\text{Cu}^{2+}$  copper(II) ion

Ions of the same element that have different charges exhibit different properties, such as different colors (Figure 2.25 ▶).

Most of the metals that can form more than one cation are *transition metals*, elements that occur in the middle block of elements, from group 3B to group 2B in the periodic table. The charges of these ions are indicated by Roman numerals. The metals that form only one cation are those of group 1A ( $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Rb}^+$ ) and group 2A ( $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ , and  $\text{Ba}^{2+}$ ), as well as  $\text{Al}^{3+}$  (group 3A) and two transition-metal ions:  $\text{Ag}^+$  (group 1B) and  $\text{Zn}^{2+}$  (group 2B). Charges are not expressed explicitly when naming these ions. However, if there is any doubt in your mind whether a metal forms more than one cation, use a Roman numeral to indicate the charge. It is never wrong to do so, even though it may be unnecessary.

An older method still widely used for distinguishing between two differently charged ions of a metal is to apply the ending *-ous* or *-ic*.

▲ **Figure 2.25** Ions of the same element with different charges exhibit different properties.

Compounds containing ions of the same element but with different charge can be very different in appearance and properties. Both substances shown are complex compounds of iron that also contain  $\text{K}^+$  and  $\text{CN}^-$  ions. The substance on the left is potassium ferrocyanide, which contains Fe(II) bound to  $\text{CN}^-$  ions. The substance on the right is potassium ferricyanide, which contains Fe(III) bound to  $\text{CN}^-$  ions. Both substances are used extensively in blueprinting and other dyeing processes.

These endings represent the lower and higher charged ions, respectively. They are added to the root of the element's Latin name:

Although we will only rarely use these older names in this text, you might encounter them elsewhere.

- (c) *Cations formed from nonmetal atoms have names that end in -ium:*

These two ions are the only ions of this kind that we will encounter frequently in the text. They are both polyatomic. The vast majority of cations are monatomic metal ions.

The names and formulas of some common cations are shown in Table 2.4 ▼; they are also included in a table of common ions in the back inside cover of the text. The ions listed on the left side in Table 2.4 are the monatomic ions that do not have variable charges. Those listed on the right side are either polyatomic cations or cations with variable charges. The  $\text{Hg}_2^{2+}$  ion is unusual because this metal ion is not monatomic. It is called the mercury(I) ion because it can be thought of as two  $\text{Hg}^+$  ions bound together. The cations that you will encounter most frequently are shown in boldface. You should learn these cations first.

### GIVE IT SOME THOUGHT

Why is CrO named using a Roman numeral, chromium(II) oxide, whereas CaO is named without a Roman numeral in the name, calcium oxide?

## 2. Negative Ions (Anions)

- (a) *The names of monatomic anions are formed by replacing the ending of the name of the element with -ide:*

TABLE 2.4 ■ Common Cations\*

Charge	Formula	Name	Formula	Name
1+	<b>H<sup>+</sup></b>	<b>Hydrogen ion</b>	<b>NH<sub>4</sub><sup>+</sup></b>	<b>Ammonium ion</b>
	Li <sup>+</sup>	Lithium ion	Cu <sup>+</sup>	Copper(I) or cuprous ion
	Na <sup>+</sup>	Sodium ion		
	K <sup>+</sup>	Potassium ion		
	Cs <sup>+</sup>	Cesium ion		
	Ag <sup>+</sup>	Silver ion		
2+	<b>Mg<sup>2+</sup></b>	<b>Magnesium ion</b>	Co <sup>2+</sup>	Cobalt(II) or cobaltous ion
	<b>Ca<sup>2+</sup></b>	<b>Calcium ion</b>	<b>Cu<sup>2+</sup></b>	<b>Copper(II)</b> or cupric ion
	Sr <sup>2+</sup>	Strontium ion	<b>Fe<sup>2+</sup></b>	<b>Iron(II)</b> or ferrous ion
	Ba <sup>2+</sup>	Barium ion	Mn <sup>2+</sup>	Manganese(II) or manganous ion
	<b>Zn<sup>2+</sup></b>	<b>Zinc ion</b>	<b>Hg<sub>2</sub><sup>2+</sup></b>	<b>Mercury(I)</b> or mercurous ion
	Cd <sup>2+</sup>	Cadmium ion	<b>Hg<sup>2+</sup></b>	<b>Mercury(II)</b> or mercuric ion
			Ni <sup>2+</sup>	Nickel(II) or nickelous ion
			<b>Pb<sup>2+</sup></b>	<b>Lead(II)</b> or plumbous ion
			Sn <sup>2+</sup>	Tin(II) or stannous ion
	3+	<b>Al<sup>3+</sup></b>	<b>Aluminum ion</b>	Cr <sup>3+</sup>
			<b>Fe<sup>3+</sup></b>	<b>Iron(III)</b> or ferric ion

\*The most common ions are in boldface.

▲ **Figure 2.26** Summary of the procedure for naming anions. The root of the name (such as “chlor” for chlorine) goes in the blank.

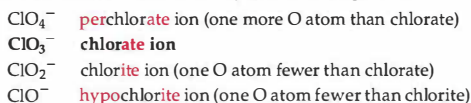

A few simple polyatomic anions also have names ending in *-ide*:

- (b) Polyatomic anions containing oxygen have names ending in *-ate* or *-ite*. These anions are called **oxyanions**. The ending *-ate* is used for the most common oxyanion of an element. The ending *-ite* is used for an oxyanion that has the same charge but one O atom fewer:

Prefixes are used when the series of oxyanions of an element extends to four members, as with the halogens. The prefix *per-* indicates one more O atom than the oxyanion ending in *-ate*; the prefix *hypo-* indicates one O atom fewer than the oxyanion ending in *-ite*:

These rules are summarized in Figure 2.26▲.

### GIVE IT SOME THOUGHT

What information is conveyed by the endings *-ide*, *-ate*, and *-ite* in the name of an anion?

Students often have a hard time remembering the number of oxygen atoms in the various oxyanions and the charges of these ions. Figure 2.27▼ lists the oxyanions of C, N, P, S, and Cl that contain the maximum number of O atoms. The periodic pattern seen in these formulas can help you remember them. Notice that C and N, which are in the second period of the periodic table, have only three O atoms each, whereas P, S, and Cl, which are in the third period, have four O atoms each. If we begin at the lower right side of the figure, with Cl, we see that the charges increase from right to left, from 1<sup>-</sup> for Cl ( $\text{ClO}_4^-$ ) to 3<sup>-</sup> for P ( $\text{PO}_4^{3-}$ ). In the second period the charges also increase from right to left, from 1<sup>-</sup> for N ( $\text{NO}_3^-$ ) to 2<sup>-</sup> for C ( $\text{CO}_3^{2-}$ ). Each anion

	4A	5A	6A	7A
2	$\text{CO}_3^{2-}$ Carbonate ion	$\text{NO}_3^-$ Nitrate ion		
3		$\text{PO}_4^{3-}$ Phosphate ion	$\text{SO}_4^{2-}$ Sulfate ion	$\text{ClO}_4^-$ Perchlorate ion

◀ **Figure 2.27** Common oxyanions. The composition and charges of common oxyanions are related to their location in the periodic table.

shown in Figure 2.27 has a name ending in *-ate*. The  $\text{ClO}_4^-$  ion also has a *per-* prefix. If you know the rules summarized in Figure 2.26 and the names and formulas of the five oxyanions in Figure 2.27, you can deduce the names for the other oxyanions of these elements.

### GIVE IT SOME THOUGHT

Predict the formulas for the borate ion and silicate ion, assuming that they contain a single B and Si atom, respectively, and follow the trends shown in Figure 2.27 ▲.

#### SAMPLE EXERCISE 2.11 | Determining the Formula of an Oxyanion from Its Name

Based on the formula for the sulfate ion, predict the formula for (a) the selenate ion and (b) the selenite ion. (Sulfur and selenium are both members of group 6A and form analogous oxyanions.)

#### SOLUTION

(a) The sulfate ion is  $\text{SO}_4^{2-}$ . The analogous selenate ion is therefore  $\text{SeO}_4^{2-}$ .  
 (b) The ending *-ite* indicates an oxyanion with the same charge but one O atom fewer than the corresponding oxyanion that ends in *-ate*. Thus, the formula for the selenite ion is  $\text{SeO}_3^{2-}$ .

#### PRACTICE EXERCISE

The formula for the bromate ion is analogous to that for the chlorate ion. Write the formula for the hypobromite and perbromate ions.

**Answer:**  $\text{BrO}^-$  and  $\text{BrO}_4^-$

(c) *Anions derived by adding  $\text{H}^+$  to an oxyanion are named by adding as a prefix the word hydrogen or dihydrogen, as appropriate:*

$\text{CO}_3^{2-}$  carbonate ion       $\text{PO}_4^{3-}$  phosphate ion  
 $\text{HCO}_3^-$  **hydrogen** carbonate ion       $\text{H}_2\text{PO}_4^-$  **dihydrogen** phosphate ion

Notice that each  $\text{H}^+$  reduces the negative charge of the parent anion by one. An older method for naming some of these ions is to use the prefix *bi-*. Thus, the  $\text{HCO}_3^-$  ion is commonly called the bicarbonate ion, and  $\text{HSO}_4^-$  is sometimes called the bisulfate ion.

The names and formulas of the common anions are listed in Table 2.5 ▼ and on the back inside cover of the text. Those anions whose names end in *-ide* are listed on the left portion of Table 2.5, and those

TABLE 2.5 ■ Common Anions\*

Charge	Formula	Name	Formula	Name
1-	$\text{H}^-$	Hydride ion	$\text{CH}_3\text{COO}^-$ (or $\text{C}_2\text{H}_3\text{O}_2^-$ ) $\text{ClO}_3^-$ $\text{ClO}_4^-$ $\text{NO}_3^-$ $\text{MnO}_4^-$	<b>Acetate ion</b>
	$\text{F}^-$	<b>Fluoride ion</b>		Chlorate ion
	$\text{Cl}^-$	<b>Chloride ion</b>		<b>Perchlorate ion</b>
	$\text{Br}^-$	<b>Bromide ion</b>		<b>Nitrate ion</b>
	$\text{I}^-$	<b>Iodide ion</b>		Permanganate ion
	$\text{CN}^-$	Cyanide ion		
	$\text{OH}^-$	<b>Hydroxide ion</b>		
2-	$\text{O}^{2-}$	<b>Oxide ion</b>	$\text{CO}_3^{2-}$ $\text{CrO}_4^{2-}$ $\text{Cr}_2\text{O}_7^{2-}$ $\text{SO}_4^{2-}$	<b>Carbonate ion</b>
	$\text{O}_2^{2-}$	Peroxide ion		Chromate ion
	$\text{S}^{2-}$	<b>Sulfide ion</b>		Dichromate ion
3-	$\text{N}^{3-}$	Nitride ion	$\text{PO}_4^{3-}$	<b>Phosphate ion</b>

\*The most common ions are in boldface.

whose names end in *-ate* are listed on the right. The most common of these ions are shown in boldface. You should learn names and formulas of these anions first. The formulas of the ions whose names end with *-ite* can be derived from those ending in *-ate* by removing an O atom. Notice the location of the monatomic ions in the periodic table. Those of group 7A always have a 1- charge ( $\text{F}^-$ ,  $\text{Cl}^-$ ,  $\text{Br}^-$ , and  $\text{I}^-$ ), and those of group 6A have a 2- charge ( $\text{O}^{2-}$  and  $\text{S}^{2-}$ ).

### 3. Ionic Compounds

*Names of ionic compounds consist of the cation name followed by the anion name:*

$\text{CaCl}_2$	calcium chloride
$\text{Al}(\text{NO}_3)_3$	aluminum nitrate
$\text{Cu}(\text{ClO}_4)_2$	copper(II) perchlorate (or cupric perchlorate)

In the chemical formulas for aluminum nitrate and copper(II) perchlorate, parentheses followed by the appropriate subscript are used because the compounds contain two or more polyatomic ions.

#### **SAMPLE EXERCISE 2.12** Determining the Names of Ionic Compounds from Their Formulas

Name the following compounds: (a)  $\text{K}_2\text{SO}_4$ , (b)  $\text{Ba}(\text{OH})_2$ , (c)  $\text{FeCl}_3$ .

#### **SOLUTION**

Each compound is ionic and is named using the guidelines we have already discussed. In naming ionic compounds, it is important to recognize polyatomic ions and to determine the charge of cations with variable charge.

(a) The cation in this compound is  $\text{K}^+$ , and the anion is  $\text{SO}_4^{2-}$ . (If you thought the compound contained  $\text{S}^{2-}$  and  $\text{O}^{2-}$  ions, you failed to recognize the polyatomic sulfate ion.) Putting together the names of the ions, we have the name of the compound, potassium sulfate.

(b) In this case the compound is composed of  $\text{Ba}^{2+}$  and  $\text{OH}^-$  ions.  $\text{Ba}^{2+}$  is the barium ion and  $\text{OH}^-$  is the hydroxide ion. Thus, the compound is called barium hydroxide.

(c) You must determine the charge of Fe in this compound because an iron atom can form more than one cation. Because the compound contains three  $\text{Cl}^-$  ions, the cation must be  $\text{Fe}^{3+}$  which is the iron(III), or ferric, ion. The  $\text{Cl}^-$  ion is the chloride ion. Thus, the compound is iron(III) chloride or ferric chloride.

#### **PRACTICE EXERCISE**

Name the following compounds: (a)  $\text{NH}_4\text{Br}$ , (b)  $\text{Cr}_2\text{O}_3$ , (c)  $\text{Co}(\text{NO}_3)_2$ .

*Answers:* (a) ammoniumbromide, (b) chromium(III) oxide, (c) cobalt(II) nitrate

#### **SAMPLE EXERCISE 2.13** Determining the Formulas of Ionic Compounds from Their Names

Write the chemical formulas for the following compounds: (a) potassium sulfide, (b) calcium hydrogen carbonate, (c) nickel(II) perchlorate.

#### **SOLUTION**

In going from the name of an ionic compound to its chemical formula, you must know the charges of the ions to determine the subscripts.

(a) The potassium ion is  $\text{K}^+$ , and the sulfide ion is  $\text{S}^{2-}$ . Because ionic compounds are electrically neutral, two  $\text{K}^+$  ions are required to balance the charge of one  $\text{S}^{2-}$  ion, giving the empirical formula of the compound,  $\text{K}_2\text{S}$ .

(b) The calcium ion is  $\text{Ca}^{2+}$ . The carbonate ion is  $\text{CO}_3^{2-}$ , so the hydrogen carbonate ion is  $\text{HCO}_3^-$ . Two  $\text{HCO}_3^-$  ions are needed to balance the positive charge of  $\text{Ca}^{2+}$ , giving  $\text{Ca}(\text{HCO}_3)_2$ .

(c) The nickel(II) ion is  $\text{Ni}^{2+}$ . The perchlorate ion is  $\text{ClO}_4^-$ . Two  $\text{ClO}_4^-$  ions are required to balance the charge on one  $\text{Ni}^{2+}$  ion, giving  $\text{Ni}(\text{ClO}_4)_2$ .

#### **PRACTICE EXERCISE**

Give the chemical formula for (a) magnesium sulfate, (b) silver sulfide, (c) lead(II) nitrate.

*Answers:* (a)  $\text{MgSO}_4$ , (b)  $\text{Ag}_2\text{S}$ , (c)  $\text{Pb}(\text{NO}_3)_2$

► **Figure 2.28 Relating names of anions and acids.** Summary of the way in which anion names and acid names are related. The prefixes *per-* and *hypo-* are retained in going from the anion to the acid.

## Names and Formulas of Acids

Acids are an important class of hydrogen-containing compounds, and they are named in a special way. For our present purposes, an *acid* is a substance whose molecules yield hydrogen ions ( $\text{H}^+$ ) when dissolved in water. When we encounter the chemical formula for an acid at this stage of the course, it will be written with H as the first element, as in  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$ .

An acid is composed of an anion connected to enough  $\text{H}^+$  ions to neutralize, or balance, the anion's charge. Thus, the  $\text{SO}_4^{2-}$  ion requires two  $\text{H}^+$  ions, forming  $\text{H}_2\text{SO}_4$ . The name of an acid is related to the name of its anion, as summarized in Figure 2.28 ▲.

1. Acids containing anions whose names end in *-ide* are named by changing the *-ide* ending to *-ic*, adding the prefix *hydro-* to this anion name, and then following with the word *acid*, as in the following examples:

Anion	Corresponding Acid
$\text{Cl}^-$ (chloride)	$\text{HCl}$ (hydrochloric acid)
$\text{S}^{2-}$ (sulfide)	$\text{H}_2\text{S}$ (hydrosulfuric acid)

2. Acids containing anions whose names end in *-ate* or *-ite* are named by changing *-ate* to *-ic* and *-ite* to *-ous*, and then adding the word *acid*. Prefixes in the anion name are retained in the name of the acid. These rules are illustrated by the oxyacids of chlorine:

Anion	Corresponding Acid
$\text{ClO}_4^-$ (perchloric)	$\text{HClO}_4$ (perchloric acid)
$\text{ClO}_3^-$ (chlorate)	$\text{HClO}_3$ (chloric acid)
$\text{ClO}_2^-$ (chlorite)	$\text{HClO}_2$ (chlorous acid)
$\text{ClO}^-$ (hypochlorite)	$\text{HClO}$ (hypochlorous acid)

### ■ SAMPLE EXERCISE 2.14 Relating the Names and Formulas of Acids

Name the following acids: (a)  $\text{HCN}$ , (b)  $\text{HNO}_3$ , (c)  $\text{H}_2\text{SO}_4$ , (d)  $\text{H}_2\text{SO}_3$ .

#### SOLUTION

(a) The anion from which this acid is derived is  $\text{CN}^-$ , the cyanide ion. Because this ion has an *-ide* ending, the acid is given a *hydro-* prefix and an *-ic* ending: hydrocyanic acid. Only water solutions of  $\text{HCN}$  are referred to as hydrocyanic acid: The pure compound, which is a gas under normal conditions, is called hydrogen cyanide. Both hydrocyanic acid and hydrogen cyanide are *extremely* toxic.

- (b) Because  $\text{NO}_3^-$  is the nitrate ion,  $\text{HNO}_3$  is called nitric acid (the *-ate* ending of the anion is replaced with an *-ic* ending in naming the acid).
- (c) Because  $\text{SO}_4^{2-}$  is the sulfate ion,  $\text{H}_2\text{SO}_4$  is called sulfuric acid.
- (d) Because  $\text{SO}_3^{2-}$  is the sulfite ion,  $\text{H}_2\text{SO}_3$  is sulfurous acid (the *-ite* ending of the anion is replaced with an *-ous* ending).

### PRACTICE EXERCISE

Give the chemical formulas for (a) hydrobromic acid, (b) carbonic acid.

Answers: (a) HBr, (b)  $\text{H}_2\text{CO}_3$

## Names and Formulas of Binary Molecular Compounds

The procedures used for naming *binary* (two-element) molecular compounds are similar to those used for naming ionic compounds:

1. The name of the element farther to the left in the periodic table is usually written first. An exception to this rule occurs in the case of compounds that contain oxygen. Oxygen is always written last except when combined with fluorine.
2. If both elements are in the same group in the periodic table, the one having the higher atomic number is named first.
3. The name of the second element is given an *-ide* ending.
4. Greek prefixes (Table 2.6) are used to indicate the number of atoms of each element. The prefix *mono-* is never used with the first element. When the prefix ends in *a* or *o* and the name of the second element begins with a vowel (such as *oxide*), the *a* or *o* of the prefix is often dropped.

The following examples illustrate these rules:

It is important to realize that you cannot predict the formulas of most molecular substances in the same way that you predict the formulas of ionic compounds. For this reason, we name molecular compounds using prefixes that explicitly indicate their composition. Molecular compounds that contain hydrogen and one other element are an important exception, however. These compounds can be treated as if they were neutral substances containing  $\text{H}^+$  ions and anions. Thus, you can predict that the substance named hydrogen chloride has the formula HCl, containing one  $\text{H}^+$  to balance the charge of one  $\text{Cl}^-$ . (The name hydrogen chloride is used only for the pure compound; water solutions of HCl are called hydrochloric acid.) Similarly, the formula for hydrogen sulfide is  $\text{H}_2\text{S}$  because two  $\text{H}^+$  are needed to balance the charge on  $\text{S}^{2-}$ .

### SAMPLE EXERCISE 2.15 Relating the Names and Formulas of Binary Molecular Compounds

Name the following compounds: (a)  $\text{SO}_2$ , (b)  $\text{PCl}_5$ , (c)  $\text{N}_2\text{O}_3$ .

#### SOLUTION

The compounds consist entirely of nonmetals, so they are molecular rather than ionic. Using the prefixes in Table 2.6, we have (a) sulfur dioxide, (b) phosphorus pentachloride, and (c) dinitrogen trioxide.

### PRACTICE EXERCISE

Give the chemical formula for (a) silicon tetrabromide, (b) disulfur dichloride.

Answers: (a)  $\text{SiBr}_4$ , (b)  $\text{S}_2\text{Cl}_2$

TABLE 2.6 Prefixes Used in Naming Binary Compounds Formed between Nonmetals

Prefix	Meaning
Mono-	1
Di-	2
Tri-	3
Tetra-	4
Penta-	5
Hexa-	6
Hepta-	7
Octa-	8
Nona-	9
Deca-	10

## 2.9 SOME SIMPLE ORGANIC COMPOUNDS

The study of compounds of carbon is called **organic chemistry**, and as noted earlier in the chapter, compounds that contain carbon and hydrogen, often in combination with oxygen, nitrogen, or other elements, are called *organic compounds*. We will examine organic compounds and organic chemistry in some detail in Chapter 25. You will see a number of organic compounds throughout this text; many of them have practical applications or are relevant to the chemistry of biological systems. Here we present a very brief introduction to some of the simplest organic compounds to provide you with a sense of what these molecules look like and how they are named.

### Alkanes

Compounds that contain only carbon and hydrogen are called **hydrocarbons**. In the most basic class of hydrocarbons, each carbon atom is bonded to four other atoms. These compounds are called **alkanes**. The three simplest alkanes, which contain one, two, and three carbon atoms, respectively, are methane ( $\text{CH}_4$ ), ethane ( $\text{C}_2\text{H}_6$ ), and propane ( $\text{C}_3\text{H}_8$ ). The structural formulas of these three alkanes are as follows:

We can make longer alkanes by adding additional carbon atoms to the “skeleton” of the molecule.

Although the hydrocarbons are binary molecular compounds, they are not named like the binary inorganic compounds discussed in Section 2.8. Instead, each alkane has a name that ends in *-ane*. The alkane with four carbon atoms is called butane. For alkanes with five or more carbon atoms, the names are derived from prefixes such as those in Table 2.6. An alkane with eight carbon atoms, for example, is called *octane* ( $\text{C}_8\text{H}_{18}$ ), where the *octa-* prefix for eight is combined with the *-ane* ending for an alkane. Gasoline consists primarily of octanes, as will be discussed in Chapter 25.

### Some Derivatives of Alkanes

Other classes of organic compounds are obtained when hydrogen atoms of alkanes are replaced with *functional groups*, which are specific groups of atoms. An **alcohol**, for example, is obtained by replacing an H atom of an alkane with an  $\text{—OH}$  group. The name of the alcohol is derived from that of the alkane by adding an *-ol* ending:

Alcohols have properties that are very different from the properties of the alkanes from which the alcohols are obtained. For example, methane, ethane, and propane are all colorless gases under normal conditions, whereas methanol, ethanol, and propanol are colorless liquids. We will discuss the reasons for these differences in properties in Chapter 11.

The prefix “1” in the name 1-propanol indicates that the replacement of H with OH has occurred at one of the “outer” carbon atoms rather than the “middle” carbon atom. A different compound called 2-propanol (also known as isopropyl alcohol) is obtained if the OH functional group is attached to the middle carbon atom:

Ball-and-stick models of these two molecules are presented in Figure 2.29 ▶.

Much of the richness of organic chemistry is possible because organic compounds can form long chains of carbon–carbon bonds. The series of alkanes that begins with methane, ethane, and propane and the series of alcohols that begins with methanol, ethanol, and propanol can both be extended for as long as we desire, in principle. The properties of alkanes and alcohols change as the chains get longer. Octanes, which are alkanes with eight carbon atoms, are liquids under normal conditions. If the alkane series is extended to tens of thousands of carbon atoms, we obtain *polyethylene*, a solid substance that is used to make thousands of plastic products, such as plastic bags, food containers, and laboratory equipment.

▲ **Figure 2.29** The two forms of propanol ( $\text{C}_3\text{H}_7\text{OH}$ ). (a) 1-Propanol, in which the OH group is attached to one of the end carbon atoms, and (b) 2-propanol, in which the OH group is attached to the middle carbon atom.

### SAMPLE EXERCISE 2.16 Writing Structural and Molecular Formulas for Hydrocarbons

Consider the alkane called *pentane*. (a) Assuming that the carbon atoms are in a straight line, write a structural formula for pentane. (b) What is the molecular formula for pentane?

#### SOLUTION

(a) Alkanes contain only carbon and hydrogen, and each carbon atom is attached to four other atoms. Because the name pentane contains the prefix *penta-* for five (Table 2.6), we can assume that pentane contains five carbon atoms bonded in a chain. If we then add enough hydrogen atoms to make four bonds to each carbon atom, we obtain the following structural formula:

This form of pentane is often called *n*-pentane, where the *n*- stands for “normal” because all five carbon atoms are in one line in the structural formula.

(b) Once the structural formula is written, we can determine the molecular formula by counting the atoms present. Thus, *n*-pentane has the formula  $\text{C}_5\text{H}_{12}$ .

### PRACTICE EXERCISE

Butane is the alkane with four carbon atoms. (a) What is the molecular formula of butane? (b) What are the name and molecular formula of an alcohol derived from butane?

**Answers:** (a)  $\text{C}_4\text{H}_{10}$ , (b) butanol,  $\text{C}_4\text{H}_{10}\text{O}$  or  $\text{C}_4\text{H}_9\text{OH}$

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Sections 2.1 and 2.2** Atoms are the basic building blocks of matter. They are the smallest units of an element that can combine with other elements. Atoms are composed of even smaller particles, called **subatomic particles**. Some of these subatomic particles are charged and follow the usual behavior of charged particles: Particles with the same charge repel one another, whereas particles with unlike charges are attracted to one another. We considered some of the important experiments that led to the discovery and characterization of subatomic particles. Thomson's experiments on the behavior of **cathode rays** in magnetic and electric fields led to the discovery of the electron and allowed its charge-to-mass ratio to be measured. Millikan's oil-drop experiment determined the charge of the electron. Becquerel's discovery of **radioactivity**, the spontaneous emission of radiation by atoms, gave further evidence that the atom has a substructure. Rutherford's studies of how thin metal foils scatter  $\alpha$  particles showed that the atom has a dense, positively charged **nucleus**.

**Section 2.3** Atoms have a nucleus that contains **protons** and **neutrons**; **electrons** move in the space around the nucleus. The magnitude of the charge of the electron,  $1.602 \times 10^{-19}$  C, is called the **electronic charge**. The charges of particles are usually represented as multiples of this charge—an electron has a 1− charge, and a proton has a 1+ charge. The masses of atoms are usually expressed in terms of **atomic mass units** (1 amu =  $1.66054 \times 10^{-24}$  g). The dimensions of atoms are often expressed in units of **angstroms** ( $1 \text{ \AA} = 10^{-10}$  m).

Elements can be classified by **atomic number**, the number of protons in the nucleus of an atom. All atoms of a given element have the same atomic number. The **mass number** of an atom is the sum of the numbers of protons and neutrons. Atoms of the same element that differ in mass number are known as **isotopes**.

**Section 2.4** The atomic mass scale is defined by assigning a mass of exactly 12 amu to a  $^{12}\text{C}$  atom. The **atomic weight** (average atomic mass) of an element can be calculated from the relative abundances and masses of that element's isotopes. The **mass spectrometer** provides the most direct and accurate means of experimentally measuring atomic (and molecular) weights.

**Section 2.5** The **periodic table** is an arrangement of the elements in order of increasing atomic number. Elements with similar properties are placed in vertical columns. The elements in a column are known as a **periodic group**. The elements in a horizontal row are known as a **period**. The **metallic elements (metals)**, which comprise the majority of the elements, dominate the left side and the middle of the table; the **nonmetallic elements (nonmetals)**

are located on the upper right side. Many of the elements that lie along the line that separates metals from nonmetals are **metalloids**.

**Section 2.6** Atoms can combine to form **molecules**. Compounds composed of molecules (**molecular compounds**) usually contain only nonmetallic elements. A molecule that contains two atoms is called a **diatomic molecule**. The composition of a substance is given by its **chemical formula**. A molecular substance can be represented by its **empirical formula**, which gives the relative numbers of atoms of each kind. It is usually represented by its **molecular formula**, however, which gives the actual numbers of each type of atom in a molecule. **Structural formulas** show the order in which the atoms in a molecule are connected. Ball-and-stick models and space-filling models are often used to represent molecules.

**Section 2.7** Atoms can either gain or lose electrons, forming charged particles called **ions**. Metals tend to lose electrons, becoming positively charged ions (**cations**). Nonmetals tend to gain electrons, forming negatively charged ions (**anions**). Because **ionic compounds** are electrically neutral, containing both cations and anions, they usually contain both metallic and nonmetallic elements. Atoms that are joined together, as in a molecule, but carry a net charge are called **polyatomic ions**. The chemical formulas used for ionic compounds are empirical formulas, which can be written readily if the charges of the ions are known. The total positive charge of the cations in an ionic compound equals the total negative charge of the anions.

**Section 2.8** The set of rules for naming chemical compounds is called **chemical nomenclature**. We studied the systematic rules used for naming three classes of inorganic substances: ionic compounds, acids, and binary molecular compounds. In naming an ionic compound, the cation is named first and then the anion. Cations formed from metal atoms have the same name as the metal. If the metal can form cations of differing charges, the charge is given using Roman numerals. Monatomic anions have names ending in *-ide*. Polyatomic anions containing oxygen and another element (**oxyanions**) have names ending in *-ate* or *-ite*.

**Section 2.9** **Organic chemistry** is the study of compounds that contain carbon. The simplest class of organic molecules is the **hydrocarbons**, which contain only carbon and hydrogen. Hydrocarbons in which each carbon atom is attached to four other atoms are called **alkanes**. Alkanes have names that end in *-ane*, such as methane and ethane. Other organic compounds are formed when an H atom of a hydrocarbon is replaced with a functional

- 2.4 Does the following drawing represent a neutral atom or an ion? Write its complete chemical symbol including mass number, atomic number, and net charge (if any). [Sections 2.3 and 2.7]

- 2.5 Which of the following diagrams most likely represents an ionic compound, and which represents a molecular one? Explain your choice. [Sections 2.6 and 2.7]

- 2.6 Write the chemical formula for the following compound. Is the compound ionic or molecular? Name the compound. [Sections 2.6 and 2.8]

- 2.7 Five of the boxes in the following periodic table are colored. Predict the charge on the ion associated with each of these elements. [Section 2.7]

- 2.8 The following diagram represents an ionic compound in which the red spheres represent cations and blue spheres represent anions. Which of the following formulas is consistent with the drawing:  $\text{KBr}$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{Ca}(\text{NO}_3)_2$ ,  $\text{Fe}_2(\text{SO}_4)_3$ ? Name the compound. [Sections 2.7 and 2.8]

## EXERCISES

### Atomic Theory and the Discovery of Atomic Structure

- 2.9 How does Dalton's atomic theory account for the fact that when 1.000 g of water is decomposed into its elements, 0.111 g of hydrogen and 0.889 g of oxygen are obtained regardless of the source of the water?
- 2.10 Hydrogen sulfide is composed of two elements: hydrogen and sulfur. In an experiment, 6.500 g of hydrogen sulfide is fully decomposed into its elements. (a) If 0.384 g of hydrogen is obtained in this experiment, how many grams of sulfur must be obtained? (b) What fundamental law does this experiment demonstrate? (c) How is this law explained by Dalton's atomic theory?
- 2.11 A chemist finds that 30.82 g of nitrogen will react with 17.60 g, 35.20 g, 70.40 g, or 88.00 g of oxygen to form four different compounds. (a) Calculate the mass of oxygen per gram of nitrogen in each compound. (b) How do the numbers in part (a) support Dalton's atomic theory?
- 2.12 In a series of experiments, a chemist prepared three different compounds that contain only iodine and fluorine

and determined the mass of each element in each compound:

Compound	Mass of Iodine (g)	Mass of Fluorine (g)
1	4.75	3.56
2	7.64	3.43
3	9.41	9.86

- (a) Calculate the mass of fluorine per gram of iodine in each compound. (b) How do the numbers in part (a) support the atomic theory?
- 2.13 Summarize the evidence used by J. J. Thomson to argue that cathode rays consist of negatively charged particles.
- 2.14 An unknown particle is caused to move between two electrically charged plates, as illustrated in Figure 2.8. Its path is deflected by a smaller magnitude in the

opposite direction from that of a beta particle. What can you conclude about the charge and mass of this unknown particle?

- 2.15** (a) Figure 2.5 shows the apparatus used in the Millikan oil-drop experiment with the positively charged plate above the negatively charged plate. What do you think would be the effect on the rate of oil drops descending if the charges on the plates were reversed (negative above positive)? (b) In his original series of experiments, Millikan measured the charge on 58 separate oil drops. Why do you suppose he chose so many drops before reaching his final conclusions?
- 2.16** Millikan determined the charge on the electron by studying the static charges on oil drops falling in an electric field. A student carried out this experiment using several oil drops for her measurements and calcu-

lated the charges on the drops. She obtained the following data:

Droplet	Calculated Charge (C)
A	$1.60 \times 10^{-19}$
B	$3.15 \times 10^{-19}$
C	$4.81 \times 10^{-19}$
D	$6.31 \times 10^{-19}$

- (a) What is the significance of the fact that the droplets carried different charges? (b) What conclusion can the student draw from these data regarding the charge of the electron? (c) What value (and to how many significant figures) should she report for the electronic charge?

## Modern View of Atomic Structure; Atomic Weights

- 2.17** The radius of an atom of krypton (Kr) is about  $1.9 \text{ \AA}$ . (a) Express this distance in nanometers (nm) and in picometers (pm). (b) How many krypton atoms would have to be lined up to span  $1.0 \text{ mm}$ ? (c) If the atom is assumed to be a sphere, what is the volume in  $\text{cm}^3$  of a single Kr atom?
- 2.18** An atom of tin (Sn) has a diameter of about  $2.8 \times 10^{-8} \text{ cm}$ . (a) What is the radius of a tin atom in angstroms ( $\text{\AA}$ ) and in meters (m)? (b) How many Sn atoms would have to be placed side by side to span a distance of  $6.0 \text{ }\mu\text{m}$ ? (c) If you assume that the tin atom is a sphere, what is the volume in  $\text{m}^3$  of a single atom?

- 2.19** Answer the following questions without referring to Table 2.1: (a) What are the main subatomic particles that make up the atom? (b) What is the relative charge (in multiples of the electronic charge) of each of the particles? (c) Which of the particles is the most massive? (d) Which is the least massive?

- 2.20** Determine whether each of the following statements is true or false. If false, correct the statement to make it true: (a) The nucleus has most of the mass and comprises most of the volume of an atom; (b) every atom of a given element has the same number of protons; (c) the number of electrons in an atom equals the number of neutrons in the atom; (d) the protons in the nucleus of the helium atom are held together by a force called the strong nuclear force.

- 2.21** (a) Define atomic number and mass number. (b) Which of these can vary without changing the identity of the element?
- 2.22** (a) Which two of the following are isotopes of the same element:  ${}^3_1\text{X}$ ,  ${}^4_1\text{X}$ ,  ${}^3_2\text{X}$ ? (b) What is the identity of the element whose isotopes you have selected?

- 2.23** How many protons, neutrons, and electrons are in the following atoms: (a)  ${}^{40}\text{Ar}$ , (b)  ${}^{63}\text{Zn}$ , (c)  ${}^{70}\text{Ga}$ , (d)  ${}^{80}\text{Br}$ , (e)  ${}^{184}\text{W}$ , (f)  ${}^{243}\text{Am}$ ?

- 2.24** Each of the following isotopes is used in medicine. Indicate the number of protons and neutrons in each isotope: (a) phosphorus-32, (b) chromium-51, (c) cobalt-60, (d) technetium-99, (e) iodine-131; (f) thallium-201.

- 2.25** Fill in the gaps in the following table, assuming each column represents a neutral atom:

Symbol	${}^{52}\text{Cr}$			
Protons		25		82
Neutrons		30	64	
Electrons			48	86
Mass no.				207

- 2.26** Fill in the gaps in the following table, assuming each column represents a neutral atom:

Symbol	${}^{65}\text{Zn}$			
Protons		44		92
Neutrons		57	49	
Electrons			38	47
Mass no.				108
				235

- 2.27** Write the correct symbol, with both superscript and subscript, for each of the following. Use the list of elements inside the front cover as needed: (a) the isotope of platinum that contains 118 neutrons, (b) the isotope of krypton with mass number 84, (c) the isotope of arsenic with

- mass number 75, (d) the isotope of magnesium that has an equal number of protons and neutrons.
- 2.28 One way in which Earth's evolution as a planet can be understood is by measuring the amounts of certain isotopes in rocks. One quantity recently measured is the ratio of  $^{129}\text{Xe}$  to  $^{130}\text{Xe}$  in some minerals. In what way do these two isotopes differ from one another? In what respects are they the same?
- 2.29 (a) What isotope is used as the standard in establishing the atomic mass scale? (b) The atomic weight of boron is reported as 10.81, yet no atom of boron has the mass of 10.81 amu. Explain.
- 2.30 (a) What is the mass in amu of a carbon-12 atom? (b) Why is the atomic weight of carbon reported as 12.011 in the table of elements and the periodic table in the front inside cover of this text?
- 2.31 Only two isotopes of copper occur naturally,  $^{63}\text{Cu}$  (atomic mass = 62.9296 amu; abundance 69.17%) and  $^{65}\text{Cu}$  (atomic mass = 64.9278 amu; abundance 30.83%). Calculate the atomic weight (average atomic mass) of copper.
- 2.32 Rubidium has two naturally occurring isotopes, rubidium-85 (atomic mass = 84.9118 amu; abundance = 72.15%) and rubidium-87 (atomic mass = 86.9092 amu; abundance = 27.85%). Calculate the atomic weight of rubidium.
- 2.33 (a) In what fundamental way is mass spectrometry related to Thomson's cathode-ray experiments (Figure 2.4)? (b) What are the labels on the axes of a mass spectrum? (c) To measure the mass spectrum of an atom, the atom must first lose one or more electrons. Why is this so?
- 2.34 (a) The mass spectrometer in Figure 2.13 has a magnet as one of its components. What is the purpose of the magnet? (b) The atomic weight of Cl is 35.5 amu. However, the mass spectrum of Cl (Figure 2.14) does not show a peak at this mass. Explain. (c) A mass spectrum of phosphorus (P) atoms shows only a single peak at a mass of 31. What can you conclude from this observation?
- 2.35 Naturally occurring magnesium has the following isotopic abundances:

Isotope	Abundance	Atomic mass (amu)
$^{24}\text{Mg}$	78.99%	23.98504
$^{25}\text{Mg}$	10.00%	24.98584
$^{26}\text{Mg}$	11.01%	25.98259

- (a) What is the average atomic mass of Mg? (b) Sketch the mass spectrum of Mg.
- 2.36 Mass spectrometry is more often applied to molecules than to atoms. We will see in Chapter 3 that the *molecular weight* of a molecule is the sum of the atomic weights of the atoms in the molecule. The mass spectrum of  $\text{H}_2$  is taken under conditions that prevent decomposition into H atoms. The two naturally occurring isotopes of hydrogen are  $^1\text{H}$  (atomic mass = 1.00783 amu; abundance 99.9885%) and  $^2\text{H}$  (atomic mass = 2.01410 amu; abundance 0.0115%). (a) How many peaks will the mass spectrum have? (b) Give the relative atomic masses of each of these peaks. (c) Which peak will be the largest, and which the smallest?

## The Periodic Table; Molecules and Ions

- 2.37 For each of the following elements, write its chemical symbol, locate it in the periodic table, and indicate whether it is a metal, metalloid, or nonmetal: (a) chromium, (b) helium, (c) phosphorus, (d) zinc, (e) magnesium, (f) bromine, (g) arsenic.
- 2.38 Locate each of the following elements in the periodic table; indicate whether it is a metal, metalloid, or nonmetal; and give the name of the element: (a) Ca, (b) Ti, (c) Ga, (d) Th, (e) Pt, (f) Se, (g) Kr.
- 2.39 For each of the following elements, write its chemical symbol, determine the name of the group to which it belongs (Table 2.3), and indicate whether it is a metal, metalloid, or nonmetal: (a) potassium, (b) iodine, (c) magnesium, (d) argon, (e) sulfur.
- 2.40 The elements of group 4A show an interesting change in properties moving down the group. Give the name and chemical symbol of each element in the group, and label it as a nonmetal, metalloid, or metal.
- 2.41 What can we tell about a compound when we know the empirical formula? What additional information is conveyed by the molecular formula? By the structural formula? Explain in each case.
- 2.42 Two compounds have the same empirical formula. One substance is a gas, the other is a viscous liquid. How is it possible for two substances with the same empirical formula to have markedly different properties?
- 2.43 Write the empirical formula corresponding to each of the following molecular formulas: (a)  $\text{Al}_2\text{Br}_6$ , (b)  $\text{C}_8\text{H}_{10}$ , (c)  $\text{C}_4\text{H}_8\text{O}_2$ , (d)  $\text{P}_4\text{O}_{10}$ , (e)  $\text{C}_6\text{H}_4\text{Cl}_2$ , (f)  $\text{B}_3\text{N}_3\text{H}_6$ .
- 2.44 Determine the molecular and empirical formulas of the following: (a) The organic solvent *benzene*, which has six carbon atoms and six hydrogen atoms; (b) the compound *silicon tetrachloride*, which has a silicon atom and four chlorine atoms and is used in the manufacture of computer chips; (c) the reactive substance *diborane*, which has two boron atoms and six hydrogen atoms; (d) the sugar called *glucose*, which has six carbon atoms, twelve hydrogen atoms, and six oxygen atoms.
- 2.45 How many hydrogen atoms are in each of the following: (a)  $\text{C}_2\text{H}_5\text{OH}$ , (b)  $\text{Ca}(\text{CH}_3\text{COO})_2$ , (c)  $(\text{NH}_4)_3\text{PO}_4$ ?
- 2.46 How many of the indicated atoms are represented by each chemical formula: (a) carbon atoms in  $\text{C}_2\text{H}_5\text{COOCH}_3$ , (b) oxygen atoms in  $\text{Ca}(\text{ClO}_4)_2$ , (c) hydrogen atoms in  $(\text{NH}_4)_2\text{HPO}_4$ ?

2.47 Write the molecular and structural formulas for the compounds represented by the following molecular models:

(a)

(b)

(c)

(d)

2.48 Write the molecular and structural formulas for the compounds represented by the following models:

(a)

(b)

(c)

(d)

2.49 Fill in the gaps in the following table:

Symbol	$^{59}\text{Co}^{3+}$			
Protons		34	76	80
Neutrons		46	116	120
Electrons		36		78
Net charge			2+	

2.50 Fill in the gaps in the following table:

Symbol	$^{31}\text{P}^{3-}$			
Protons		35	49	
Neutrons		45	66	118
Electrons			46	76
Net charge		1-		3+

2.51 Each of the following elements is capable of forming an ion in chemical reactions. By referring to the periodic table, predict the charge of the most stable ion of each: (a) Mg, (b) Al, (c) K, (d) S, (e) F.

2.52 Using the periodic table, predict the charges of the ions of the following elements: (a) Ga, (b) Sr, (c) As, (d) Br, (e) Se.

2.53 Using the periodic table to guide you, predict the chemical formula and name of the compound formed by the following elements: (a) Ga and F, (b) Li and H, (c) Al and I, (d) K and S.

2.54 The most common charge associated with silver in its compounds is 1+. Indicate the chemical formulas you would expect for compounds formed between Ag and (a) iodine, (b) sulfur, (c) fluorine.

2.55 Predict the chemical formula for the ionic compound formed by (a)  $\text{Ca}^{2+}$  and  $\text{Br}^-$ , (b)  $\text{K}^+$  and  $\text{CO}_3^{2-}$ , (c)  $\text{Al}^{3+}$  and  $\text{CH}_3\text{COO}^-$ , (d)  $\text{NH}_4^+$  and  $\text{SO}_4^{2-}$ , (e)  $\text{Mg}^{2+}$  and  $\text{PO}_4^{3-}$ .

2.56 Predict the chemical formulas of the compounds formed by the following pairs of ions: (a)  $\text{Cu}^{2+}$  and  $\text{Br}^-$ , (b)  $\text{Fe}^{3+}$  and  $\text{O}^{2-}$ , (c)  $\text{Hg}_2^{2+}$  and  $\text{CO}_3^{2-}$ , (d)  $\text{Ca}^{2+}$  and  $\text{AsO}_4^{3-}$ , (e)  $\text{NH}_4^+$  and  $\text{CO}_3^{2-}$ .

2.57 Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

Ion	$\text{K}^+$	$\text{NH}_4^+$	$\text{Mg}^{2+}$	$\text{Fe}^{3+}$
$\text{Cl}^-$	KCl			
$\text{OH}^-$				
$\text{CO}_3^{2-}$				
$\text{PO}_4^{3-}$				

2.58 Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

Ion	$\text{Na}^+$	$\text{Ca}^{2+}$	$\text{Fe}^{2+}$	$\text{Al}^{3+}$
$\text{O}^{2-}$	$\text{Na}_2\text{O}$			
$\text{NO}_3^-$				
$\text{SO}_4^{2-}$				
$\text{AsO}_4^{3-}$				

2.59 Predict whether each of the following compounds is molecular or ionic: (a)  $\text{B}_2\text{H}_6$ , (b)  $\text{CH}_3\text{OH}$ , (c)  $\text{LiNO}_3$ , (d)  $\text{Sc}_2\text{O}_3$ , (e)  $\text{CsBr}$ , (f)  $\text{NOCl}$ , (g)  $\text{NF}_3$ , (h)  $\text{Ag}_2\text{SO}_4$ .

2.60 Which of the following are ionic, and which are molecular? (a)  $\text{PF}_5$ , (b)  $\text{NaI}$ , (c)  $\text{SnCl}_2$ , (d)  $\text{Ca}(\text{NO}_3)_2$ , (e)  $\text{FeCl}_3$ , (f)  $\text{LaP}$ , (g)  $\text{CoCO}_3$ , (h)  $\text{N}_2\text{O}_4$ .

## Naming Inorganic Compounds; Organic Molecules

- 2.61** Give the chemical formula for (a) chlorite ion, (b) chloride ion, (c) chlorate ion, (d) perchlorate ion, (e) hypochlorite ion.
- 2.62** Selenium, an element required nutritionally in trace quantities, forms compounds analogous to sulfur. Name the following ions: (a)  $\text{SeO}_4^{2-}$ , (b)  $\text{Se}^{2-}$ , (c)  $\text{HSe}^-$ , (d)  $\text{HSeO}_3^-$ .
- 2.63** Give the names and charges of the cation and anion in each of the following compounds: (a)  $\text{CaO}$ , (b)  $\text{Na}_2\text{SO}_4$ , (c)  $\text{KClO}_4$ , (d)  $\text{Fe}(\text{NO}_3)_2$ , (e)  $\text{Cr}(\text{OH})_3$ .
- 2.64** Give the names and charges of the cation and anion in each of the following compounds: (a)  $\text{CuS}$ , (b)  $\text{Ag}_2\text{SO}_4$ , (c)  $\text{Al}(\text{ClO}_3)_3$ , (d)  $\text{Co}(\text{OH})_2$ , (e)  $\text{PbCO}_3$ .
- 2.65** Name the following ionic compounds: (a)  $\text{MgO}$ , (b)  $\text{AlCl}_3$ , (c)  $\text{Li}_3\text{PO}_4$ , (d)  $\text{Ba}(\text{ClO}_4)_2$ , (e)  $\text{Cu}(\text{NO}_3)_2$ , (f)  $\text{Fe}(\text{OH})_2$ , (g)  $\text{Ca}(\text{C}_2\text{H}_3\text{O}_2)_2$ , (h)  $\text{Cr}_2(\text{CO}_3)_3$ , (i)  $\text{K}_2\text{CrO}_4$ , (j)  $(\text{NH}_4)_2\text{SO}_4$ .
- 2.66** Name the following ionic compounds: (a)  $\text{K}_2\text{O}$ , (b)  $\text{NaClO}_2$ , (c)  $\text{Sr}(\text{CN})_2$ , (d)  $\text{Co}(\text{OH})_2$ , (e)  $\text{Fe}_2(\text{CO}_3)_3$ , (f)  $\text{Cr}(\text{NO}_3)_3$ , (g)  $(\text{NH}_4)_2\text{SO}_3$ , (h)  $\text{NaH}_2\text{PO}_4$ , (i)  $\text{KMnO}_4$ , (j)  $\text{Ag}_2\text{Cr}_2\text{O}_7$ .
- 2.67** Write the chemical formulas for the following compounds: (a) aluminum hydroxide, (b) potassium sulfate, (c) copper(I) oxide, (d) zinc nitrate, (e) mercury(II) bromide, (f) iron(III) carbonate, (g) sodium hypobromite.
- 2.68** Give the chemical formula for each of the following ionic compounds: (a) sodium phosphate, (b) zinc nitrate, (c) barium bromate, (d) iron(II) perchlorate, (e) cobalt(II) hydrogen carbonate, (f) chromium(III) acetate, (g) potassium dichromate.
- 2.69** Give the name or chemical formula, as appropriate, for each of the following acids: (a)  $\text{HBrO}_3$ , (b)  $\text{HBr}$ , (c)  $\text{H}_3\text{PO}_4$ , (d) hypochlorous acid, (e) iodic acid, (f) sulfurous acid.
- 2.70** Provide the name or chemical formula, as appropriate, for each of the following acids: (a) hydrobromic acid, (b) hydrosulfuric acid, (c) nitrous acid, (d)  $\text{H}_2\text{CO}_3$ , (e)  $\text{HClO}_3$ , (f)  $\text{HC}_2\text{H}_3\text{O}_2$ .
- 2.71** Give the name or chemical formula, as appropriate, for each of the following binary molecular substances: (a)  $\text{SF}_6$ , (b)  $\text{IF}_5$ , (c)  $\text{XeO}_3$ , (d) dinitrogen tetroxide, (e) hydrogen cyanide, (f) tetraphosphorus hexasulfide.
- 2.72** The oxides of nitrogen are very important components in urban air pollution. Name each of the following compounds: (a)  $\text{N}_2\text{O}$ , (b)  $\text{NO}$ , (c)  $\text{NO}_2$ , (d)  $\text{N}_2\text{O}_5$ , (e)  $\text{N}_2\text{O}_4$ .
- 2.73** Write the chemical formula for each substance mentioned in the following word descriptions (use the front inside cover to find the symbols for the elements you don't know). (a) Zinc carbonate can be heated to form zinc oxide and carbon dioxide. (b) On treatment with hydrofluoric acid, silicon dioxide forms silicon tetrafluoride and water. (c) Sulfur dioxide reacts with water to form sulfurous acid. (d) The substance phosphorus trihydride, commonly called phosphine, is a toxic gas. (e) Perchloric acid reacts with cadmium to form cadmium(II) perchlorate. (f) Vanadium(III) bromide is a colored solid.
- 2.74** Assume that you encounter the following sentences in your reading. What is the chemical formula for each substance mentioned? (a) Sodium hydrogen carbonate is used as a deodorant. (b) Calcium hypochlorite is used in some bleaching solutions. (c) Hydrogen cyanide is a very poisonous gas. (d) Magnesium hydroxide is used as a cathartic. (e) Tin(II) fluoride has been used as a fluoride additive in toothpastes. (f) When cadmium sulfide is treated with sulfuric acid, fumes of hydrogen sulfide are given off.
- 2.75** (a) What is a hydrocarbon? (b) Butane is the alkane with a chain of four carbon atoms. Write a structural formula for this compound, and determine its molecular and empirical formulas.
- 2.76** (a) What ending is used for the names of alkanes? (b) Hexane is an alkane whose structural formula has all its carbon atoms in a straight chain. Draw the structural formula for this compound, and determine its molecular and empirical formulas. (*Hint:* You might need to refer to Table 2.6.)
- 2.77** (a) What is a functional group? (b) What functional group characterizes an alcohol? (c) With reference to Exercise 2.75, write a structural formula for 1-butanol, the alcohol derived from butane, by making a substitution on one of the end carbon atoms.
- 2.78** (a) What do ethane and ethanol have in common? (b) How does 1-propanol differ from propane?

## ADDITIONAL EXERCISES

- 2.79 Describe a major contribution to science made by each of the following scientists: (a) Dalton, (b) Thomson, (c) Millikan, (d) Rutherford.
- 2.80 How did Rutherford interpret the following observations made during his  $\alpha$ -particle scattering experiments? (a) Most  $\alpha$  particles were not appreciably deflected as they passed through the gold foil. (b) A few  $\alpha$  particles were deflected at very large angles. (c) What differences would you expect if beryllium foil were used instead of gold foil in the  $\alpha$ -particle scattering experiment?
- 2.81 Suppose a scientist repeats the Millikan oil-drop experiment, but reports the charges on the drops using an unusual (and imaginary) unit called the *warmomb* (*wa*). He obtains the following data for four of the drops:

Droplet	Calculated Charge ( <i>wa</i> )
A	$3.84 \times 10^{-8}$
B	$4.80 \times 10^{-8}$
C	$2.88 \times 10^{-8}$
D	$8.64 \times 10^{-8}$

- (a) If all the droplets were the same size, which would fall most slowly through the apparatus? (b) From these data, what is the best choice for the charge of the electron in warmombs? (c) Based on your answer to part (b), how many electrons are there on each of the droplets? (d) What is the conversion factor between warmombs and coulombs?
- 2.82 The natural abundance of  $^3\text{He}$  is 0.000137%. (a) How many protons, neutrons, and electrons are in an atom of  $^3\text{He}$ ? (b) Based on the sum of the masses of their subatomic particles, which is expected to be more massive, an atom of  $^3\text{He}$  or an atom of  $^3\text{H}$  (which is also called *tritium*)? (c) Based on your answer for part (b), what would need to be the precision of a mass spectrometer that is able to differentiate between peaks that are due to  $^3\text{He}^+$  and  $^3\text{H}^+$ ?
- 2.83 An  $\alpha$  particle is the nucleus of an  $^4\text{He}$  atom. (a) How many protons and neutrons are in an  $\alpha$  particle? (b) What force holds the protons and neutrons together in the  $\alpha$  particle? (c) What is the charge on an  $\alpha$  particle in units of electronic charge? (d) The charge-to-mass ratio of an  $\alpha$  particle is  $4.8224 \times 10^4 \text{ C/g}$ . Based on the charge on the particle, calculate its mass in grams and in amu. (e) By using the data in Table 2.1, compare your answer for part (d) with the sum of the masses of the individual subatomic particles. Can you explain the difference in mass? (If not, we will discuss such mass differences further in Chapter 21.)
- 2.84 A cube of gold that is 1.00 cm on a side has a mass of 19.3 g. A single gold atom has a mass of 197.0 amu. (a) How many gold atoms are in the cube? (b) From the information given, estimate the diameter in  $\text{\AA}$  of a single gold atom. (c) What assumptions did you make in arriving at your answer for part (b)?
- 2.85 The diameter of a rubidium atom is 4.95  $\text{\AA}$ . We will consider two different ways of placing the atoms on a surface. In arrangement A, all the atoms are lined up with one another. Arrangement B is called a *close-packed* arrangement because the atoms sit in the “depressions” formed by the previous row of atoms:

- (a) Using arrangement A, how many Rb atoms could be placed on a square surface that is 1.0 cm on a side? (b) How many Rb atoms could be placed on a square surface that is 1.0 cm on a side, using arrangement B? (c) By what factor has the number of atoms on the surface increased in going to arrangement B from arrangement A? If extended to three dimensions, which arrangement would lead to a greater density for Rb metal?
- 2.86 (a) Assuming the dimensions of the nucleus and atom shown in Figure 2.12, what fraction of the *volume* of the atom is taken up by the nucleus? (b) Using the mass of the proton from Table 2.1 and assuming its diameter is  $1.0 \times 10^{-15} \text{ m}$ , calculate the density of a proton in  $\text{g/cm}^3$ .
- 2.87 Identify the element represented by each of the following symbols and give the number of protons and neutrons in each: (a)  $^{24}_{13}\text{X}$ , (b)  $^{127}_{53}\text{X}$ , (c)  $^{153}_{63}\text{X}$ , (d)  $^{209}_{83}\text{X}$ .
- 2.88 The element oxygen has three naturally occurring isotopes, with 8, 9, and 10 neutrons in the nucleus, respectively. (a) Write the full chemical symbols for these three isotopes. (b) Describe the similarities and differences between the three kinds of atoms of oxygen.
- 2.89 Use Coulomb's law,  $F = kQ_1Q_2/d^2$ , to calculate the electric force on an electron ( $Q = -1.6 \times 10^{-19} \text{ C}$ ) exerted by a single proton if the particles are  $0.53 \times 10^{-10} \text{ m}$  apart. The constant  $k$  in Coulomb's law is  $9.0 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2$ . (The unit abbreviated N is the Newton, the SI unit of force.)
- 2.90 The element lead (Pb) consists of four naturally occurring isotopes with atomic masses 203.97302, 205.97444, 206.97587, and 207.97663 amu. The relative abundances of these four isotopes are 1.4, 24.1, 22.1, and 52.4%, respectively. From these data, calculate the atomic weight of lead.

- 2.91 Gallium (Ga) consists of two naturally occurring isotopes with masses of 68.926 and 70.925 amu. (a) How many protons and neutrons are in the nucleus of each isotope? Write the complete atomic symbol for each, showing the atomic number and mass number. (b) The average atomic mass of Ga is 69.72 amu. Calculate the abundance of each isotope.
- 2.92 Using a suitable reference such as the *CRC Handbook of Chemistry and Physics* or <http://www.webelements.com>, look up the following information for nickel: (a) the number of known isotopes, (b) the atomic masses (in amu) and the natural abundance of the five most abundant isotopes.
- 2.93 There are two different isotopes of bromine atoms. Under normal conditions, elemental bromine consists of  $\text{Br}_2$  molecules (Figure 2.19), and the mass of a  $\text{Br}_2$  molecule is the sum of the masses of the two atoms in the molecule. The mass spectrum of  $\text{Br}_2$  consists of three peaks:

Mass (amu)	Relative Size
157.836	0.2569
159.834	0.4999
161.832	0.2431

- (a) What is the origin of each peak (of what isotopes does each consist)? (b) What is the mass of each isotope? (c) Determine the average molecular mass of a  $\text{Br}_2$  molecule. (d) Determine the average atomic mass of a bromine atom. (e) Calculate the abundances of the two isotopes.
- 2.94 It is common in mass spectrometry to assume that the mass of a cation is the same as that of its parent atom. (a) Using data in Table 2.1, determine the number of significant figures that must be reported before the difference in mass of  $^1\text{H}$  and  $^1\text{H}^+$  is significant. (b) What percentage of the mass of an  $^1\text{H}$  atom does the electron represent?
- 2.95 From the following list of elements—Ar, H, Ga, Al, Ca, Br, Ge, K, O—pick the one that best fits each description. Use each element only once: (a) an alkali metal, (b) an alkaline earth metal, (c) a noble gas, (d) a halogen, (e) a metalloid, (f) a nonmetal listed in group 1A, (g) a metal that forms a  $3+$  ion, (h) a nonmetal that forms a  $2-$  ion, (i) an element that resembles aluminum.
- 2.96 The first atoms of seaborgium (Sg) were identified in 1974. The longest-lived isotope of Sg has a mass number of 266. (a) How many protons, electrons, and neutrons are in an  $^{266}\text{Sg}$  atom? (b) Atoms of Sg are very unstable, and it is therefore difficult to study this element's properties. Based on the position of Sg in the periodic table, what element should it most closely resemble in its chemical properties?
- 2.97 From the molecular structures shown here, identify the one that corresponds to each of the following species: (a) chlorine gas; (b) propane, (c) nitrate ion; (d) sulfur trioxide; (e) methyl chloride,  $\text{CH}_3\text{Cl}$ .

- 2.98 Name each of the following oxides. Assuming that the compounds are ionic, what charge is associated with the metallic element in each case? (a)  $\text{NiO}$ , (b)  $\text{MnO}_2$ , (c)  $\text{Cr}_2\text{O}_3$ , (d)  $\text{MoO}_3$ .
- 2.99 Iodic acid has the molecular formula  $\text{HIO}_3$ . Write the formulas for the following: (a) the iodate anion, (b) the periodate anion, (c) the hypoiodite anion, (d) hypoiodous acid, (e) periodic acid.
- 2.100 Elements in the same group of the periodic table often form oxyanions with the same general formula. The anions are also named in a similar fashion. Based on these observations, suggest a chemical formula or name, as appropriate, for each of the following ions: (a)  $\text{BrO}_4^-$ , (b)  $\text{SeO}_3^{2-}$ , (c) arsenate ion, (d) hydrogen tellurate ion.
- 2.101 Carbonic acid occurs in carbonated beverages. When allowed to react with lithium hydroxide it produces lithium carbonate. Lithium carbonate is used to treat depression and bipolar disorder. Write chemical formulas for carbonic acid, lithium hydroxide, and lithium carbonate.
- 2.102 Give the chemical names of each of the following familiar compounds: (a)  $\text{NaCl}$  (table salt), (b)  $\text{NaHCO}_3$  (baking soda), (c)  $\text{NaOCl}$  (in many bleaches), (d)  $\text{NaOH}$  (caustic soda), (e)  $(\text{NH}_4)_2\text{CO}_3$  (smelling salts), (f)  $\text{CaSO}_4$  (plaster of Paris).
- 2.103 Many familiar substances have common, unsystematic names. For each of the following, give the correct

systematic name: (a) saltpeter,  $\text{KNO}_3$ ; (b) soda ash,  $\text{Na}_2\text{CO}_3$ ; (c) lime,  $\text{CaO}$ ; (d) muriatic acid,  $\text{HCl}$ ; (e) Epsom salts,  $\text{MgSO}_4$ ; (f) milk of magnesia,  $\text{Mg}(\text{OH})_2$ .

- 2.104 Many ions and compounds have very similar names, and there is great potential for confusing them. Write the correct chemical formulas to distinguish between (a) calcium sulfide and calcium hydrogen sulfide, (b) hydrobromic acid and bromic acid, (c) aluminum nitride and aluminum nitrite, (d) iron(II) oxide and iron(III) oxide, (e) ammonia and ammonium ion, (f) potassium sulfite and potassium bisulfite, (g) mercurous chloride and mercuric chloride, (h) chloric acid and perchloric acid.
- 2.105 The compound *cyclohexane* is an alkane in which six carbon atoms form a ring. The partial structural formula of the compound is as follows:

- (a) Complete the structural formula for cyclohexane. (b) Is the molecular formula for cyclohexane the same as that for *n*-hexane, in which the carbon atoms are in a straight line? If possible, comment on the source of any differences. (c) Propose a structural formula for *cyclohexanol*, the alcohol derived from cyclohexane.
- 2.106 The periodic table helps organize the chemical behaviors of the elements. As a class discussion or as a short essay, describe how the table is organized, and mention as many ways as you can think of in which the position of an element in the table relates to the chemical and physical properties of the element.

# STOICHIOMETRY: CALCULATIONS WITH CHEMICAL FORMULAS AND EQUATIONS

**SUGAR CARAMELIZING.** Major changes in the appearance of compounds are indications of chemical reactions. Here, prolonged heating of sucrose, common table sugar, produces caramel.

## WHAT'S AHEAD

---

### 3.1 Chemical Equations

We begin by considering how we can use chemical formulas to write equations that represent chemical reactions.

### 3.2 Some Simple Patterns of Chemical Reactivity

We then examine some simple chemical reactions: *combination reactions*, *decomposition reactions*, and *combustion reactions*.

### 3.3 Formula Weights

We can obtain quantitative information from chemical formulas by using their *formula weights*.

### 3.4 Avogadro's Number and the Mole

We use chemical formulas to relate the masses of substances to the numbers of atoms, molecules, or ions contained in the substances, a relationship that leads to the crucially important concept of a *mole*. A *mole* is  $6.022 \times 10^{23}$  objects (atoms, molecules, ions, etc.).

### 3.5 Empirical Formulas from Analyses

We apply the mole concept to determine chemical formulas from the masses of each element in a given quantity of a compound.

### 3.6 Quantitative Information from Balanced Equations

We use the quantitative information inherent in chemical formulas and equations together with the mole concept to predict the amounts of substances consumed or produced in chemical reactions.

### 3.7 Limiting Reactants

We recognize that one of the reactants may be used up before the others in a chemical reaction. This is the *limiting reactant*. The reaction therefore stops, leaving some of the excess starting material unreacted.

**YOU POUR VINEGAR INTO A** glass of water containing baking soda, and bubbles form. You strike a match and use the flame to light a candle. You heat sugar in a pan, and it turns brown (caramelizes). The bubbles, the flame, and the color change are visual evidence that something is happening.

To an experienced eye, these visual changes indicate a chemical change, or chemical reaction. The study of chemical changes is at the heart of chemistry. Some chemical changes are simple; others are complex. Some are dramatic; some are very subtle. Even as you sit reading this chapter, chemical changes are occurring within your body. Chemical changes that occur in your eyes and brain, for example, allow you to see these words and think about them. Although such chemical changes are not as obvious as some, they are nevertheless remarkable for how they allow us to function.

In this chapter we begin to explore some important aspects of chemical change. Our focus will be both on the use of chemical formulas to represent reactions and on the quantitative information we can obtain about the amounts of substances involved in reactions. **Stoichiometry** (pronounced stoy-key-OM-uh-tree) is the area of study that examines the quantities of substances consumed and produced in chemical reactions. The name is derived from the Greek *stoicheion* ("element") and *metron* ("measure"). This study of stoichiometry provides an essential set of tools that is widely used in chemistry. Aspects of stoichiometry include such diverse problems as measuring the concentration of ozone in the atmosphere, determining the potential yield of gold from an ore, and assessing different processes for converting coal into gaseous fuels.

Stoichiometry is built on an understanding of atomic masses [∞∞](#) (Section 2.4), chemical formulas, and the law of conservation of mass. [∞∞](#) (Section 2.1)

▲ **Figure 3.1 Antoine Lavoisier (1734–1794).** Lavoisier conducted many important studies on combustion reactions. Unfortunately, the French Revolution cut his career short. He was a member of the French nobility and a tax collector. He was guillotined in 1794 during the final months of the Reign of Terror. He is now generally considered to be the father of modern chemistry because he conducted carefully controlled experiments and used quantitative measurements.

The French nobleman and scientist Antoine Lavoisier (Figure 3.1 ◀) discovered this important chemical law during the late 1700s. In a chemistry text published in 1789, Lavoisier stated the law in this eloquent way: “We may lay it down as an incontestable axiom that, in all the operations of art and nature, nothing is created; an equal quantity of matter exists both before and after the experiment. Upon this principle, the whole art of performing chemical experiments depends.” With the advent of Dalton’s atomic theory, chemists understood the basis for this law: *Atoms are neither created nor destroyed during any chemical reaction.* The changes that occur during any reaction merely rearrange the atoms. The same collection of atoms is present both before and after the reaction.

### 3.1 CHEMICAL EQUATIONS

Chemical reactions are represented in a concise way by **chemical equations**. When the gas hydrogen ( $\text{H}_2$ ) burns, for example, it reacts with oxygen ( $\text{O}_2$ ) in the air to form water ( $\text{H}_2\text{O}$ ). We write the chemical equation for this reaction as follows:

We read the + sign as “reacts with” and the arrow as “produces.” The chemical formulas to the left of the arrow represent the starting substances, called **reactants**. The chemical formulas to the right of the arrow represent substances produced in the reaction, called **products**. The numbers in front of the formulas are **coefficients**. (As in algebraic equations, the numeral 1 is usually not written.) The coefficients indicate the relative numbers of molecules of each kind involved in the reaction.

Because atoms are neither created nor destroyed in any reaction, a chemical equation must have an equal number of atoms of each element on each side of the arrow. When this condition is met, the equation is said to be *balanced*. On the right side of Equation 3.1, for example, there are two molecules of  $\text{H}_2\text{O}$ , each composed of two atoms of hydrogen and one atom of oxygen. Thus,  $2 \text{H}_2\text{O}$  (read “two molecules of water”) contains  $2 \times 2 = 4$  H atoms and  $2 \times 1 = 2$  O atoms. Notice that the number of atoms is obtained by multiplying the coefficient and the subscripts in the chemical formula. Because there are four H atoms and two O atoms on each side of the equation, the equation is balanced. We can represent the balanced equation by the following molecular models, which illustrate that the number of atoms of each kind is the same on both sides of the arrow:

#### GIVE IT SOME THOUGHT

How many atoms of Mg, O, and H are represented by  $3 \text{Mg}(\text{OH})_2$ ?

#### Balancing Equations

Once we know the formulas of the reactants and products in a reaction, we can write an unbalanced equation. We then balance the equation by determining the coefficients that provide equal numbers of each type of atom on each side of the equation. For most purposes, a balanced equation should contain the smallest possible whole-number coefficients.

In balancing an equation, you need to understand the difference between a coefficient in front of a formula and a subscript within a formula. Refer to Figure 3.2 ▶. Notice that changing a subscript in a formula—from  $\text{H}_2\text{O}$  to  $\text{H}_2\text{O}_2$ ,

Chemical symbol	Meaning		Composition
H <sub>2</sub> O	One molecule of water:		Two H atoms and one O atom
2 H <sub>2</sub> O	Two molecules of water:		Four H atoms and two O atoms
H <sub>2</sub> O <sub>2</sub>	One molecule of hydrogen peroxide:		Two H atoms and two O atoms

for example—changes the identity of the chemical. The substance H<sub>2</sub>O<sub>2</sub>, hydrogen peroxide, is quite different from the substance H<sub>2</sub>O, water. *You should never change subscripts when balancing an equation.* In contrast, placing a coefficient in front of a formula changes only the *amount* of the substance and not its *identity*. Thus, 2 H<sub>2</sub>O means two molecules of water, 3 H<sub>2</sub>O means three molecules of water, and so forth.

To illustrate the process of balancing an equation, consider the reaction that occurs when methane (CH<sub>4</sub>), the principal component of natural gas, burns in air to produce carbon dioxide gas (CO<sub>2</sub>) and water vapor (H<sub>2</sub>O) (Figure 3.3 ♥). Both of these products contain oxygen atoms that come from O<sub>2</sub> in the air. Thus, O<sub>2</sub> is a reactant, and the unbalanced equation is

It is usually best to balance first those elements that occur in the fewest chemical formulas on each side of the equation. In our example both C and H appear in only one reactant and, separately, in one product each. So we begin by focusing on CH<sub>4</sub>. Let's consider first carbon and then hydrogen.

One molecule of the reactant CH<sub>4</sub> contains the same number of C atoms (one) as one molecule of the product CO<sub>2</sub>. The coefficients for these substances *must* be the same, therefore, we start the balancing process by choosing the coefficient one for each. However, one molecule of CH<sub>4</sub> contains more H atoms (four) than one molecule of the product H<sub>2</sub>O (two). If we place a coefficient 2 in front of H<sub>2</sub>O, there will be four H atoms on each side of the equation:

◀ **Figure 3.2** The difference between a subscript and a coefficient. Notice how adding the coefficient 2 in front of the formula (line 2) has a different effect on the implied composition than adding the subscript 2 to the formula (in line 3). The number of atoms of each type (listed under composition) is obtained by multiplying the coefficient and the subscript associated with each element in the formula.

◀ **Figure 3.3** Methane reacts with oxygen to produce the flame in a Bunsen burner. The methane (CH<sub>4</sub>) in natural gas and oxygen (O<sub>2</sub>) from the air are the reactants in the reaction, while carbon dioxide (CO<sub>2</sub>) and water vapor (H<sub>2</sub>O) are the products.

At this stage the products have more O atoms (four—two from  $\text{CO}_2$  and two from 2  $\text{H}_2\text{O}$ ) than the reactants (two). If we place the coefficient 2 in front of the reactant  $\text{O}_2$ , we balance the equation by making the number of O atoms equal on both sides of the equation:

▲ **Figure 3.4** Balanced chemical equation for the combustion of  $\text{CH}_4$ . The drawings of the molecules involved call attention to the conservation of atoms through the reaction.

The molecular view of the balanced equation is shown in Figure 3.4 ◀. We see one C, four H, and four O atoms on each side of the arrow, indicating that the equation is balanced.

The approach we have taken in arriving at balanced Equation 3.4 is largely trial and error. We balance each kind of atom in succession, adjusting coefficients as necessary. This approach works for most chemical equations.

### ■ SAMPLE EXERCISE 3.1 | Interpreting and Balancing Chemical Equations

The following diagram represents a chemical reaction in which the red spheres are oxygen atoms and the blue spheres are nitrogen atoms. (a) Write the chemical formulas for the reactants and products. (b) Write a balanced equation for the reaction. (c) Is the diagram consistent with the law of conservation of mass?

#### SOLUTION

- (a) The left box, which represents the reactants, contains two kinds of molecules, those composed of two oxygen atoms ( $\text{O}_2$ ) and those composed of one nitrogen atom and one oxygen atom ( $\text{NO}$ ). The right box, which represents the products, contains only molecules composed of one nitrogen atom and two oxygen atoms ( $\text{NO}_2$ ).
- (b) The unbalanced chemical equation is

This equation has three O atoms on the left side of the arrow and two O atoms on the right side. We can increase the number of O atoms by placing a coefficient 2 on the product side:

Now there are two N atoms and four O atoms on the right. Placing the coefficient 2 in front of  $\text{NO}$  balances both the number of N atoms and O atoms:

- (c) The left box (reactants) contains four  $\text{O}_2$  molecules and eight  $\text{NO}$  molecules. Thus, the molecular ratio is one  $\text{O}_2$  for each two  $\text{NO}$  as required by the balanced equation. The right box (products) contains eight  $\text{NO}_2$  molecules. The number of  $\text{NO}_2$  molecules on the right equals the number of  $\text{NO}$  molecules on the left as the balanced equation requires. Counting the atoms, we find eight N atoms in the eight  $\text{NO}$  molecules in the box on the left. There are also  $4 \times 2 = 8$  O atoms in the  $\text{O}_2$  molecules and eight O atoms in the  $\text{NO}$  molecules, giving a total of 16 O atoms. In the box on the right, we find eight N atoms and  $8 \times 2 = 16$  O atoms in the eight  $\text{NO}_2$  molecules. Because there are equal numbers of both N and O atoms in the two boxes, the drawing is consistent with the law of conservation of mass.

**PRACTICE EXERCISE**

In the following diagram, the white spheres represent hydrogen atoms, and the blue spheres represent nitrogen atoms. To be consistent with the law of conservation of mass, how many  $\text{NH}_3$  molecules should be shown in the right box?

**Answer:** Six  $\text{NH}_3$  molecules

**Indicating the States of Reactants and Products**

Additional information is often added to the formulas in balanced equations to indicate the physical state of each reactant and product. We use the symbols  $(g)$ ,  $(l)$ ,  $(s)$ , and  $(aq)$  for gas, liquid, solid, and aqueous (water) solution, respectively. Thus, Equation 3.4 can be written

Sometimes the conditions (such as temperature or pressure) under which the reaction proceeds appear above or below the reaction arrow. The symbol  $\Delta$  (the Greek uppercase letter delta) is often placed above the arrow to indicate the addition of heat.

**SAMPLE EXERCISE 3.2 | Balancing Chemical Equations**

Balance this equation:

**SOLUTION**

Begin by counting each kind of atom on both sides of the arrow. The Na and O atoms are balanced—one Na and one O on each side—but there are two H atoms on the left and three H atoms on the right. Thus, we need to increase the number of H atoms on the left. To begin balancing H, let's try placing the coefficient 2 in front of  $\text{H}_2\text{O}$ :

Beginning this way does not balance H but does increase the number of H atoms among the reactants, which we need to do. Adding the coefficient 2 causes O to be unbalanced; we will take care of that after we balance H. Now that we have 2  $\text{H}_2\text{O}$  on the left, we can balance H by putting the coefficient 2 in front of NaOH on the right:

Balancing H in this way fortuitously brings O into balance. But notice that Na is now unbalanced, with one Na on the left and two on the right. To rebalance Na, we put the coefficient 2 in front of the reactant:

Finally, we check the number of atoms of each element and find that we have two Na atoms, four H atoms, and two O atoms on each side of the equation. The equation is balanced.

**Comment** Notice that in balancing this equation, we moved back and forth placing a coefficient in front of  $\text{H}_2\text{O}$ , then NaOH, and finally Na. In balancing equations, we often find ourselves following this pattern of moving back and forth from one side of the arrow to the other, placing coefficients first in front of a formula on one side and then in front of a formula on the other side until the equation is balanced. You can always tell if you have balanced your equation correctly, no matter how you did it, by checking that the number of atoms of each element is the same on both sides of the arrow.

**PRACTICE EXERCISE**

Balance the following equations by providing the missing coefficients:

- (a)  $\text{Fe}(s) + \text{O}_2(g) \longrightarrow \text{Fe}_2\text{O}_3(s)$   
 (b)  $\text{C}_2\text{H}_4(g) + \text{O}_2(g) \longrightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$   
 (c)  $\text{Al}(s) + \text{HCl}(aq) \longrightarrow \text{AlCl}_3(aq) + \text{H}_2(g)$

**Answers:** (a) 4, 3, 2; (b) 1, 3, 2, 2; (c) 2, 6, 2, 3

## 3.2 SOME SIMPLE PATTERNS OF CHEMICAL REACTIVITY

In this section we examine three simple kinds of reactions that we will see frequently throughout this chapter. Our first reason for examining these reactions is merely to become better acquainted with chemical reactions and their balanced equations. Our second reason is to consider how we might predict the products of some of these reactions knowing only their reactants. The key to predicting the products formed by a given combination of reactants is recognizing general patterns of chemical reactivity. Recognizing a pattern of reactivity for a class of substances gives you a broader understanding than merely memorizing a large number of unrelated reactions.

### Combination and Decomposition Reactions

Table 3.1 ▼ summarizes two simple types of reactions: combination and decomposition reactions. In **combination reactions** two or more substances react to form one product. There are many examples of combination reactions, especially those in which elements combine to form compounds. For example, magnesium metal burns in air with a dazzling brilliance to produce magnesium oxide, as shown in Figure 3.5 ►:

This reaction is used to produce the bright flame generated by flares and some fireworks.

When a combination reaction occurs between a metal and a nonmetal, as in Equation 3.6, the product is an ionic solid. Recall that the formula of an ionic compound can be determined from the charges of the ions involved. ∞ (Section 2.7) When magnesium reacts with oxygen, for example, the magnesium loses electrons and forms the magnesium ion,  $\text{Mg}^{2+}$ . The oxygen gains electrons and forms the oxide ion,  $\text{O}^{2-}$ . Thus, the reaction product is  $\text{MgO}$ . You should be able to recognize when a reaction is a combination reaction and to predict the products of a combination reaction in which the reactants are a metal and a nonmetal.

### GIVE IT SOME THOUGHT

When Na and S undergo a combination reaction, what is the chemical formula of the product?

In a **decomposition reaction** one substance undergoes a reaction to produce two or more other substances. Many compounds undergo decomposition reactions when heated. For example, many metal carbonates decompose to form metal oxides and carbon dioxide when heated:

TABLE 3.1 ■ Combination and Decomposition Reactions

#### Combination Reactions

Two reactants combine to form a single product. Many elements react with one another in this fashion to form compounds.

#### Decomposition Reactions

A single reactant breaks apart to form two or more substances. Many compounds react this way when heated.

▲ **Figure 3.5** Combustion of magnesium metal in air.

The decomposition of  $\text{CaCO}_3$  is an important commercial process. Limestone or seashells, which are both primarily  $\text{CaCO}_3$ , are heated to prepare  $\text{CaO}$ , which is known as lime or quicklime. About  $2 \times 10^{10}$  kg (20 million tons) of  $\text{CaO}$  is used in the United States each year, principally in making glass, in obtaining iron from its ores, and in making mortar to bind bricks.

The decomposition of sodium azide ( $\text{NaN}_3$ ) rapidly releases  $\text{N}_2(g)$ , so this reaction is used to inflate safety air bags in automobiles (Figure 3.6 ▶):

The system is designed so that an impact ignites a detonator cap, which in turn causes  $\text{NaN}_3$  to decompose explosively. A small quantity of  $\text{NaN}_3$  (about 100 g) forms a large quantity of gas (about 50 L). We will consider the volumes of gases produced in chemical reactions in Section 10.5.

▲ **Figure 3.6** An automobile air bag. The decomposition of sodium azide,  $\text{NaN}_3(s)$ , is used to inflate automobile air bags. When properly ignited, the  $\text{NaN}_3$  decomposes rapidly, forming nitrogen gas,  $\text{N}_2(g)$ , which expands the air bag.

### SAMPLE EXERCISE 3.3 Writing Balanced Equations for Combination and Decomposition Reactions

Write balanced equations for the following reactions: (a) The combination reaction that occurs when lithium metal and fluorine gas react. (b) The decomposition reaction that occurs when solid barium carbonate is heated. (Two products form: a solid and a gas.)

#### SOLUTION

(a) The symbol for lithium is Li. With the exception of mercury, all metals are solids at room temperature. Fluorine occurs as a diatomic molecule (see Figure 2.19). Thus, the reactants are  $\text{Li}(s)$  and  $\text{F}_2(g)$ . The product will be composed of a metal and a nonmetal, so we expect it to be an ionic solid. Lithium ions have a 1+ charge,  $\text{Li}^+$ ,

whereas fluoride ions have a 1− charge, F<sup>−</sup>. Thus, the chemical formula for the product is LiF. The balanced chemical equation is

(b) The chemical formula for barium carbonate is BaCO<sub>3</sub>. As noted in the text, many metal carbonates decompose to form metal oxides and carbon dioxide when heated. In Equation 3.7, for example, CaCO<sub>3</sub> decomposes to form CaO and CO<sub>2</sub>. Thus, we would expect that BaCO<sub>3</sub> decomposes to form BaO and CO<sub>2</sub>. Barium and calcium are both in group 2A in the periodic table, which further suggests they would react in the same way:

### ■ PRACTICE EXERCISE

Write balanced chemical equations for the following reactions: (a) Solid mercury(II) sulfide decomposes into its component elements when heated. (b) The surface of aluminum metal undergoes a combination reaction with oxygen in the air.

**Answers:** (a)  $\text{HgS}(s) \longrightarrow \text{Hg}(l) + \text{S}(s)$ ; (b)  $4 \text{Al}(s) + 3 \text{O}_2(g) \longrightarrow 2 \text{Al}_2\text{O}_3(s)$

## Combustion in Air

**Combustion reactions** are rapid reactions that produce a flame. Most of the combustion reactions we observe involve O<sub>2</sub> from air as a reactant. Equation 3.5 illustrates a general class of reactions that involve the burning, or combustion, of hydrocarbon compounds (compounds that contain only carbon and hydrogen, such as CH<sub>4</sub> and C<sub>2</sub>H<sub>4</sub>). ⇔ (Section 2.9)

When hydrocarbons are combusted in air, they react with O<sub>2</sub> to form CO<sub>2</sub> and H<sub>2</sub>O.\* The number of molecules of O<sub>2</sub> required in the reaction and the number of molecules of CO<sub>2</sub> and H<sub>2</sub>O formed depend on the composition of the hydrocarbon, which acts as the fuel in the reaction. For example, the combustion of propane (C<sub>3</sub>H<sub>8</sub>), a gas used for cooking and home heating, is described by the following equation:

The state of the water, H<sub>2</sub>O(g) or H<sub>2</sub>O(l), depends on the conditions of the reaction. Water vapor, H<sub>2</sub>O(g), is formed at high temperature in an open container. The blue flame produced when propane burns is shown in Figure 3.7 ◀

Combustion of oxygen-containing derivatives of hydrocarbons, such as CH<sub>3</sub>OH, also produces CO<sub>2</sub> and H<sub>2</sub>O. The simple rule that hydrocarbons and related oxygen-containing derivatives of hydrocarbons form CO<sub>2</sub> and H<sub>2</sub>O when they burn in air summarizes the behavior of about 3 million compounds. Many substances that our bodies use as energy sources, such as the sugar glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>), similarly react in our bodies with O<sub>2</sub> to form CO<sub>2</sub> and H<sub>2</sub>O. In our bodies, however, the reactions take place in a series of intermediate steps that occur at body temperature. These reactions that involve intermediate steps are described as *oxidation reactions* instead of combustion reactions.

▲ **Figure 3.7 Propane burning in air.** The liquid propane, C<sub>3</sub>H<sub>8</sub>, vaporizes and mixes with air as it escapes through the nozzle. The combustion reaction of C<sub>3</sub>H<sub>8</sub> and O<sub>2</sub> produces a blue flame.

### ■ SAMPLE EXERCISE 3.4 Writing Balanced Equations for Combustion Reactions

Write the balanced equation for the reaction that occurs when methanol, CH<sub>3</sub>OH(l), is burned in air.

#### SOLUTION

When any compound containing C, H, and O is combusted, it reacts with the O<sub>2</sub>(g) in air to produce CO<sub>2</sub>(g) and H<sub>2</sub>O(g). Thus, the unbalanced equation is

\*When there is an insufficient quantity of O<sub>2</sub> present, carbon monoxide (CO) will be produced along with the CO<sub>2</sub>; this is called *incomplete combustion*. If the amount of O<sub>2</sub> is severely restricted, *fine particles of carbon* that we call *soot* will be produced. Complete combustion produces only CO<sub>2</sub> and H<sub>2</sub>O. Unless specifically stated to the contrary, we will always take combustion to mean complete combustion.

In this equation the C atoms are balanced with one carbon on each side of the arrow. Because  $\text{CH}_3\text{OH}$  has four H atoms, we place the coefficient 2 in front of  $\text{H}_2\text{O}$  to balance the H atoms:

Adding the coefficient balances H but gives four O atoms in the products. Because there are only three O atoms in the reactants (one in  $\text{CH}_3\text{OH}$  and two in  $\text{O}_2$ ), we are not finished yet. We can place the fractional coefficient  $\frac{3}{2}$  in front of  $\text{O}_2$  to give a total of four O atoms in the reactants (there are  $\frac{3}{2} \times 2 = 3$  O atoms in  $\frac{3}{2} \text{O}_2$ ):

Although the equation is now balanced, it is not in its most conventional form because it contains a fractional coefficient. If we multiply each side of the equation by 2, we will remove the fraction and achieve the following balanced equation:

### PRACTICE EXERCISE

Write the balanced equation for the reaction that occurs when ethanol,  $\text{C}_2\text{H}_5\text{OH}(l)$ , is burned in air.

*Answer:*  $\text{C}_2\text{H}_5\text{OH}(l) + 3 \text{O}_2(g) \longrightarrow 2 \text{CO}_2(g) + 3 \text{H}_2\text{O}(g)$

## 3.3 FORMULA WEIGHTS

Chemical formulas and chemical equations both have a *quantitative* significance; the subscripts in formulas and the coefficients in equations represent precise quantities. The formula  $\text{H}_2\text{O}$  indicates that a molecule of this substance (water) contains exactly two atoms of hydrogen and one atom of oxygen. Similarly, the coefficients in a balanced chemical equation indicate the relative quantities of reactants and products. But how do we relate the numbers of atoms or molecules to the amounts we measure in the laboratory? Although we cannot directly count atoms or molecules, we can indirectly determine their numbers if we know their masses. Therefore, before we can pursue the quantitative aspects of chemical formulas or equations, we must examine the masses of atoms and molecules, which we do in this section and the next.

### Formula and Molecular Weights

The **formula weight** of a substance is the sum of the atomic weights of each atom in its chemical formula. Using atomic masses from a periodic table, we find, for example, that the formula weight of sulfuric acid ( $\text{H}_2\text{SO}_4$ ) is 98.1 amu.\*

$$\begin{aligned} \text{FW of H}_2\text{SO}_4 &= 2(\text{AW of H}) + (\text{AW of S}) + 4(\text{AW of O}) \\ &= 2(1.0 \text{ amu}) + 32.1 \text{ amu} + 4(16.0 \text{ amu}) \\ &= 98.1 \text{ amu} \end{aligned}$$

For convenience, we have rounded off all the atomic weights to one place beyond the decimal point. We will round off the atomic weights in this way for most problems.

If the chemical formula is merely the chemical symbol of an element, such as Na, then the formula weight equals the atomic weight of the element, in this case 23.0 amu. If the chemical formula is that of a molecule, then the formula weight is also called the **molecular weight**. The molecular weight of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), for example, is

$$\text{MW of C}_6\text{H}_{12}\text{O}_6 = 6(12.0 \text{ amu}) + 12(1.0 \text{ amu}) + 6(16.0 \text{ amu}) = 180.0 \text{ amu}$$

Because ionic substances, such as NaCl, exist as three-dimensional arrays of ions (Figure 2.23), it is inappropriate to speak of molecules of NaCl. Instead,

\*The abbreviation AW is used for atomic weight, FW for formula weight, and MW for molecular weight.

we speak of *formula units*, represented by the chemical formula of the substance. The formula unit of NaCl consists of one  $\text{Na}^+$  ion and one  $\text{Cl}^-$  ion. Thus, the formula weight of NaCl is the mass of one formula unit:

$$\text{FW of NaCl} = 23.0 \text{ amu} + 35.5 \text{ amu} = 58.5 \text{ amu}$$

### SAMPLE EXERCISE 3.5 | Calculating Formula Weights

Calculate the formula weight of (a) sucrose,  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  (table sugar), and (b) calcium nitrate,  $\text{Ca}(\text{NO}_3)_2$ .

#### SOLUTION

(a) By adding the atomic weights of the atoms in sucrose, we find the formula weight to be 342.0 amu:

$$\begin{aligned} 12 \text{ C atoms} &= 12(12.0 \text{ amu}) = 144.0 \text{ amu} \\ 22 \text{ H atoms} &= 22(1.0 \text{ amu}) = 22.0 \text{ amu} \\ 11 \text{ O atoms} &= 11(16.0 \text{ amu}) = 176.0 \text{ amu} \\ &= 342.0 \text{ amu} \end{aligned}$$

(b) If a chemical formula has parentheses, the subscript outside the parentheses is a multiplier for all atoms inside. Thus, for  $\text{Ca}(\text{NO}_3)_2$ , we have

$$\begin{aligned} 1 \text{ Ca atom} &= 1(40.1 \text{ amu}) = 40.1 \text{ amu} \\ 2 \text{ N atoms} &= 2(14.0 \text{ amu}) = 28.0 \text{ amu} \\ 6 \text{ O atoms} &= 6(16.0 \text{ amu}) = 96.0 \text{ amu} \\ &= 164.1 \text{ amu} \end{aligned}$$

### PRACTICE EXERCISE

Calculate the formula weight of (a)  $\text{Al}(\text{OH})_3$  and (b)  $\text{CH}_3\text{OH}$ .

Answers: (a) 78.0 amu, (b) 32.0 amu

## Percentage Composition from Formulas

Occasionally we must calculate the *percentage composition* of a compound—that is, the percentage by mass contributed by each element in the substance. For example, to verify the purity of a compound, we can compare the calculated percentage composition of the substance with that found experimentally. Forensic chemists, for example, will measure the percentage composition of an unknown white powder and compare it to the percentage compositions for sugar, salt, or cocaine to identify the powder. Calculating percentage composition is a straightforward matter if the chemical formula is known. The calculation depends on the formula weight of the substance, the atomic weight of the element of interest, and the number of atoms of that element in the chemical formula:

$$\% \text{ element} = \frac{\left( \begin{array}{c} \text{number of atoms} \\ \text{of that element} \end{array} \right) \left( \begin{array}{c} \text{atomic weight} \\ \text{of element} \end{array} \right)}{\text{formula weight of compound}} \times 100\% \quad [3.10]$$

### SAMPLE EXERCISE 3.6 | Calculating Percentage Composition

Calculate the percentage of carbon, hydrogen, and oxygen (by mass) in  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ .

#### SOLUTION

Let's examine this question using the problem-solving steps in the "Strategies in Chemistry: Problem Solving" essay that appears on the next page.

**Analyze** We are given a chemical formula,  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ , and asked to calculate the percentage by mass of its component elements (C, H, and O).

**Plan** We can use Equation 3.10, relying on a periodic table to obtain the atomic weight of each component element. The atomic weights are first used to determine the formula weight of the compound. (The formula weight of  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ , 342.0 amu, was calculated in Sample Exercise 3.5.) We must then do three calculations, one for each element.

**Solve** Using Equation 3.10, we have

$$\begin{aligned} \% \text{C} &= \frac{(12)(12.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 42.1\% \\ \% \text{H} &= \frac{(22)(1.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 6.4\% \end{aligned}$$

$$\%O = \frac{(11)(16.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 51.5\%$$

**Check** The percentages of the individual elements must add up to 100%, which they do in this case. We could have used more significant figures for our atomic weights, giving more significant figures for our percentage composition, but we have adhered to our suggested guideline of rounding atomic weights to one digit beyond the decimal point.

### ■ PRACTICE EXERCISE

Calculate the percentage of nitrogen, by mass, in  $\text{Ca}(\text{NO}_3)_2$ .

*Answer:* 17.1%

## 3.4 AVOGADRO'S NUMBER AND THE MOLE

Even the smallest samples that we deal with in the laboratory contain enormous numbers of atoms, ions, or molecules. For example, a teaspoon of water (about 5 mL) contains  $2 \times 10^{23}$  water molecules, a number so large that it almost defies comprehension. Chemists, therefore, have devised a special counting unit for describing such large numbers of atoms or molecules.

In everyday life we use counting units such as a dozen (12 objects) and a gross (144 objects) to deal with modestly large quantities. In chemistry the unit for dealing with the number of atoms, ions, or molecules in a common-sized sample is the **mole**, abbreviated mol.\* A mole is the amount of matter that contains as many objects (atoms, molecules, or whatever objects we are considering) as the number of atoms in exactly 12 g of isotopically pure  $^{12}\text{C}$ . From experiments, scientists have determined this number to be  $6.0221421 \times 10^{23}$ . Scientists call this number **Avogadro's number**, in honor of the Italian scientist Amedeo Avogadro (1776–1856). Avogadro's number has the symbol  $N_A$ , which we will usually round to  $6.02 \times 10^{23} \text{ mol}^{-1}$ . The unit  $\text{mol}^{-1}$  (“inverse mole” or “per mole”) reminds us that there are  $6.02 \times 10^{23}$  objects per one mole. A mole of atoms, a mole of molecules, or a mole of anything else all contain Avogadro's number of these objects:

$$1 \text{ mol } ^{12}\text{C} \text{ atoms} = 6.02 \times 10^{23} \text{ } ^{12}\text{C} \text{ atoms}$$

$$1 \text{ mol H}_2\text{O} \text{ molecules} = 6.02 \times 10^{23} \text{ H}_2\text{O} \text{ molecules}$$

$$1 \text{ mol NO}_3^- \text{ ions} = 6.02 \times 10^{23} \text{ NO}_3^- \text{ ions}$$

### Strategies in Chemistry

#### PROBLEM SOLVING

**P**ractice is the key to success in problem solving. As you practice, you can improve your skills by following these steps:

*Step 1: Analyze the problem.* Read the problem carefully for understanding. What does it say? Draw any picture or diagram that will help you to visualize the problem. Write down both the data you are given and the quantity that you need to obtain (the unknown).

*Step 2: Develop a plan for solving the problem.* Consider the possible paths between the given information and the unknown. What principles or equations relate the known data to the unknown? Recognize that some data may not be given explicitly in the problem; you may be expected to know certain quantities (such as Avogadro's number) or look them up in tables (such as

atomic weights). Recognize also that your plan may involve either a single step or a series of steps with intermediate answers.

*Step 3: Solve the problem.* Use the known information and suitable equations or relationships to solve for the unknown. Dimensional analysis (Section 1.6) is a very useful tool for solving a great number of problems. Be careful with significant figures, signs, and units.

*Step 4: Check the solution.* Read the problem again to make sure you have found all the solutions asked for in the problem. Does your answer make sense? That is, is the answer outrageously large or small, or is it in the ballpark? Finally, are the units and significant figures correct?

\*The term mole comes from the Latin word moles, meaning “a mass.” The term molecule is the diminutive form of this word and means “a small mass.”

Avogadro's number is so large that it is difficult to imagine. Spreading  $6.02 \times 10^{23}$  marbles over the entire surface of Earth would produce a continuous layer about 3 miles thick. If Avogadro's number of pennies were placed side by side in a straight line, they would encircle Earth 300 trillion ( $3 \times 10^{14}$ ) times.

### SAMPLE EXERCISE 3.7 | Estimating Numbers of Atoms

Without using a calculator, arrange the following samples in order of increasing numbers of carbon atoms: 12 g  $^{12}\text{C}$ , 1 mol  $\text{C}_2\text{H}_2$ ,  $9 \times 10^{23}$  molecules of  $\text{CO}_2$ .

#### SOLUTION

**Analyze** We are given amounts of different substances expressed in grams, moles, and number of molecules and asked to arrange the samples in order of increasing numbers of C atoms.

**Plan** To determine the number of C atoms in each sample, we must convert g  $^{12}\text{C}$ , 1 mol  $\text{C}_2\text{H}_2$ , and  $9 \times 10^{23}$  molecules  $\text{CO}_2$  all to numbers of C atoms. To make these conversions, we use the definition of mole and Avogadro's number.

**Solve** A mole is defined as the amount of matter that contains as many units of the matter as there are C atoms in exactly 12 g of  $^{12}\text{C}$ . Thus, 12 g of  $^{12}\text{C}$  contains 1 mol of C atoms (that is,  $6.02 \times 10^{23}$  C atoms). One mol of  $\text{C}_2\text{H}_2$  contains  $6 \times 10^{23}$   $\text{C}_2\text{H}_2$  molecules. Because there are two C atoms in each  $\text{C}_2\text{H}_2$  molecule, this sample contains  $12 \times 10^{23}$  C atoms. Because each  $\text{CO}_2$  molecule contains one C atom, the sample of  $\text{CO}_2$  contains  $9 \times 10^{23}$  C atoms. Hence, the order is 12 g  $^{12}\text{C}$  ( $6 \times 10^{23}$  C atoms)  $<$   $9 \times 10^{23}$   $\text{CO}_2$  molecules ( $9 \times 10^{23}$  C atoms)  $<$  1 mol  $\text{C}_2\text{H}_2$  ( $12 \times 10^{23}$  C atoms).

**Check** We can check our results by comparing the number of moles of C atoms in each sample because the number of moles is proportional to the number of atoms. Thus, 12 g of  $^{12}\text{C}$  is 1 mol C; 1 mol of  $\text{C}_2\text{H}_2$  contains 2 mol C, and  $9 \times 10^{23}$  molecules of  $\text{CO}_2$  contain 1.5 mol C, giving the same order as above: 12 g  $^{12}\text{C}$  (1 mol C)  $<$   $9 \times 10^{23}$   $\text{CO}_2$  molecules (1.5 mol C)  $<$  1 mol  $\text{C}_2\text{H}_2$  (2 mol C).

### PRACTICE EXERCISE

Without using a calculator, arrange the following samples in order of increasing number of O atoms: 1 mol  $\text{H}_2\text{O}$ , 1 mol  $\text{CO}_2$ ,  $3 \times 10^{23}$  molecules  $\text{O}_3$ .

**Answer:** 1 mol  $\text{H}_2\text{O}$  ( $6 \times 10^{23}$  O atoms)  $<$   $3 \times 10^{23}$  molecules  $\text{O}_3$  ( $9 \times 10^{23}$  O atoms)  $<$  1 mol  $\text{CO}_2$  ( $12 \times 10^{23}$  O atoms)

### SAMPLE EXERCISE 3.8 | Converting Moles to Number of Atoms

Calculate the number of H atoms in 0.350 mol of  $\text{C}_6\text{H}_{12}\text{O}_6$ .

#### SOLUTION

**Analyze** We are given both the amount of a substance (0.350 mol) and its chemical formula ( $\text{C}_6\text{H}_{12}\text{O}_6$ ). The unknown is the number of H atoms in the sample.

**Plan** Avogadro's number provides the conversion factor between the number of moles of  $\text{C}_6\text{H}_{12}\text{O}_6$  and the number of molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$ . Once we know the number of molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$ , we can use the chemical formula, which tells us that each molecule of  $\text{C}_6\text{H}_{12}\text{O}_6$  contains 12 H atoms. Thus, we convert moles of  $\text{C}_6\text{H}_{12}\text{O}_6$  to molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$  and then determine the number of atoms of H from the number of molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$ :

#### Solve

$$\begin{aligned} \text{H atoms} &= (0.350 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6) \left( \frac{6.02 \times 10^{23} \text{ molecules } \text{C}_6\text{H}_{12}\text{O}_6}{1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6} \right) \left( \frac{12 \text{ H atoms}}{1 \text{ molecule } \text{C}_6\text{H}_{12}\text{O}_6} \right) \\ &= 2.53 \times 10^{24} \text{ H atoms} \end{aligned}$$

**Check** The magnitude of our answer is reasonable. It is a large number about the magnitude of Avogadro's number. We can also make the following ballpark calculation: Multiplying  $0.35 \times 6 \times 10^{23}$  gives about  $2 \times 10^{23}$  molecules. Multiplying this result by 12 gives  $24 \times 10^{23} = 2.4 \times 10^{24}$  H atoms, which agrees with the previous, more detailed calculation. Because we were asked for the number of H atoms, the units of our answer are correct. The given data had three significant figures, so our answer has three significant figures.

**PRACTICE EXERCISE**

How many oxygen atoms are in (a) 0.25 mol  $\text{Ca}(\text{NO}_3)_2$  and (b) 1.50 mol of sodium carbonate?

Answers: (a)  $9.0 \times 10^{23}$ , (b)  $2.71 \times 10^{24}$

**Molar Mass**

A dozen (12) is the same number whether we have a dozen eggs or a dozen elephants. Clearly, however, a dozen eggs does not have the same mass as a dozen elephants. Similarly, a mole is always the *same number* ( $6.02 \times 10^{23}$ ), but 1-mole samples of different substances will have *different masses*. Compare, for example, 1 mol of  $^{12}\text{C}$  and 1 mol of  $^{24}\text{Mg}$ . A single  $^{12}\text{C}$  atom has a mass of 12 amu, whereas a single  $^{24}\text{Mg}$  atom is twice as massive, 24 amu (to two significant figures). Because a mole always has the same number of particles, a mole of  $^{24}\text{Mg}$  must be twice as massive as a mole of  $^{12}\text{C}$ . Because a mole of  $^{12}\text{C}$  has a mass of 12 g (by definition), then a mole of  $^{24}\text{Mg}$  must have a mass of 24 g. This example illustrates a general rule relating the mass of an atom to the mass of Avogadro's number (1 mol) of these atoms: *The mass of a single atom of an element (in amu) is numerically equal to the mass (in grams) of 1 mol of that element.* This statement is true regardless of the element:

1 atom of  $^{12}\text{C}$  has a mass of 12 amu  $\Rightarrow$  1 mol  $^{12}\text{C}$  has a mass of 12 g

1 atom of Cl has an atomic weight of 35.5 amu  $\Rightarrow$  1 mol Cl has a mass of 35.5 g

1 atom of Au has an atomic weight of 197 amu  $\Rightarrow$  1 mol Au has a mass of 197 g

Notice that when we are dealing with a particular isotope of an element, we use the mass of that isotope; otherwise we use the atomic weight (the average atomic mass) of the element.  $\Leftrightarrow$  (Section 2.4)

For other kinds of substances, the same numerical relationship exists between the formula weight (in amu) and the mass (in grams) of one mole of that substance:

1  $\text{H}_2\text{O}$  molecule has a mass of 18.0 amu  $\Rightarrow$  1 mol  $\text{H}_2\text{O}$  has a mass of 18.0 g

1  $\text{NO}_3^-$  ion has a mass of 62.0 amu  $\Rightarrow$  1 mol  $\text{NO}_3^-$  has a mass of 62.0 g

1 NaCl unit has a mass of 58.5 amu  $\Rightarrow$  1 mol NaCl has a mass of 58.5 g

Figure 3.8  $\blacktriangledown$  illustrates the relationship between the mass of a single molecule of  $\text{H}_2\text{O}$  and that of a mole of  $\text{H}_2\text{O}$ .

**GIVE IT SOME THOUGHT**

- (a) Which has more mass, a mole of water ( $\text{H}_2\text{O}$ ) or a mole of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ )?  
 (b) Which contains more molecules, a mole of water or a mole of glucose?

The mass in grams of one mole of a substance (that is, the mass in grams per mol) is called the **molar mass** of the substance. *The molar mass (in g/mol) of any substance is always numerically equal to its formula weight (in amu).* The substance NaCl, for example, has a formula weight of 58.5 amu and a molar mass

**► Figure 3.8 Comparing the mass of 1 molecule  $\text{H}_2\text{O}$  and 1 mol  $\text{H}_2\text{O}$ .**

Notice that both masses have the same number but have different units (18.0 amu compared to 18.0 g) representing the huge difference in mass.

TABLE 3.2 ■ Mole Relationships

Name of Substance	Formula	Formula Weight (amu)	Molar Mass (g/mol)	Number and Kind of Particles in One Mole
Atomic nitrogen	N	14.0	14.0	$6.02 \times 10^{23}$ N atoms
Molecular nitrogen	N <sub>2</sub>	28.0	28.0	$6.02 \times 10^{23}$ N <sub>2</sub> molecules $2(6.02 \times 10^{23})$ N atoms
Silver	Ag	107.9	107.9	$6.02 \times 10^{23}$ Ag atoms
Silver ions	Ag <sup>+</sup>	107.9 <sup>a</sup>	107.9	$6.02 \times 10^{23}$ Ag <sup>+</sup> ions
Barium chloride	BaCl <sub>2</sub>	208.2	208.2	$6.02 \times 10^{23}$ BaCl <sub>2</sub> units $6.02 \times 10^{23}$ Ba <sup>2+</sup> ions $2(6.02 \times 10^{23})$ Cl <sup>-</sup> ions

<sup>a</sup>Recall that the electron has negligible mass; thus, ions and atoms have essentially the same mass.

▲ **Figure 3.9** One mole each of a solid, a liquid, and a gas. One mole of NaCl, the solid, has a mass of 58.45 g. One mole of H<sub>2</sub>O, the liquid, has a mass of 18.0 g and occupies a volume of 18.0 mL. One mole of O<sub>2</sub>, the gas, has a mass of 32.0 g and occupies a balloon whose diameter is 35 cm.

of 58.5 g/mol. Further examples of mole relationships are shown in Table 3.2 ▲. Figure 3.9 ◀ shows 1-mole quantities of several common substances.

The entries in Table 3.2 for N and N<sub>2</sub> point out the importance of stating the exact chemical form of a substance when we use the mole concept. Suppose you read that 1 mol of nitrogen is produced in a particular reaction. You might interpret this statement to mean 1 mol of nitrogen atoms (14.0 g). Unless otherwise stated, however, what is probably meant is 1 mol of nitrogen molecules, N<sub>2</sub> (28.0 g), because N<sub>2</sub> is the most common chemical form of the element. To avoid ambiguity, it is important to state explicitly the chemical form being discussed. Using the chemical formula N<sub>2</sub> avoids ambiguity.

### ■ SAMPLE EXERCISE 3.9 | Calculating Molar Mass

What is the mass in grams of 1.000 mol of glucose, C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>?

#### SOLUTION

**Analyze** We are given a chemical formula and asked to determine its molar mass.

**Plan** The molar mass of a substance is found by adding the atomic weights of its component atoms.

**Solve**

$$\begin{aligned}
 6 \text{ C atoms} &= 6(12.0 \text{ amu}) = 72.0 \text{ amu} \\
 12 \text{ H atoms} &= 12(1.0 \text{ amu}) = 12.0 \text{ amu} \\
 6 \text{ O atoms} &= 6(16.0 \text{ amu}) = 96.0 \text{ amu} \\
 &\hline
 &180.0 \text{ amu}
 \end{aligned}$$

Because glucose has a formula weight of 180.0 amu, one mole of this substance has a mass of 180.0 g. In other words, C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> has a molar mass of 180.0 g/mol.

**Check** The magnitude of our answer seems reasonable, and g/mol is the appropriate unit for the molar mass.

**Comment** Glucose is sometimes called dextrose. Also known as blood sugar, glucose is found widely in nature, occurring in honey and fruits. Other types of sugars used as food are converted into glucose in the stomach or liver before the body uses them as energy sources. Because glucose requires no conversion, it is often given intravenously to patients who need immediate nourishment. People who have diabetes must carefully monitor the amount of glucose in their blood (See “Chemistry and Life” box in Section 3.6).

### ■ PRACTICE EXERCISE

Calculate the molar mass of Ca(NO<sub>3</sub>)<sub>2</sub>.

*Answer:* 164.1 g/mol

## Interconverting Masses and Moles

Conversions of mass to moles and of moles to mass are frequently encountered in calculations using the mole concept. These calculations are simplified using dimensional analysis, as shown in Sample Exercises 3.10 and 3.11.

### SAMPLE EXERCISE 3.10 | Converting Grams to Moles

Calculate the number of moles of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in 5.380 g of  $\text{C}_6\text{H}_{12}\text{O}_6$ .

#### SOLUTION

**Analyze** We are given the number of grams of a substance and its chemical formula and asked to calculate the number of moles.

**Plan** The molar mass of a substance provides the factor for converting grams to moles. The molar mass of  $\text{C}_6\text{H}_{12}\text{O}_6$  is 180.0 g/mol (Sample Exercise 3.9).

**Solve** Using 1 mol  $\text{C}_6\text{H}_{12}\text{O}_6 = 180.0 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6$  to write the appropriate conversion factor, we have

$$\text{Moles } \text{C}_6\text{H}_{12}\text{O}_6 = (5.380 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6} \right) = 0.02989 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6$$

**Check** Because 5.380 g is less than the molar mass, a reasonable answer is less than one mole. The units of our answer (mol) are appropriate. The original data had four significant figures, so our answer has four significant figures.

#### PRACTICE EXERCISE

How many moles of sodium bicarbonate ( $\text{NaHCO}_3$ ) are in 508 g of  $\text{NaHCO}_3$ ?

**Answer:** 6.05 mol  $\text{NaHCO}_3$

### SAMPLE EXERCISE 3.11 | Converting Moles to Grams

Calculate the mass, in grams, of 0.433 mol of calcium nitrate.

#### SOLUTION

**Analyze** We are given the number of moles and the name of a substance and asked to calculate the number of grams in the sample.

**Plan** To convert moles to grams, we need the molar mass, which we can calculate using the chemical formula and atomic weights.

**Solve** Because the calcium ion is  $\text{Ca}^{2+}$  and the nitrate ion is  $\text{NO}_3^-$ , calcium nitrate is  $\text{Ca}(\text{NO}_3)_2$ . Adding the atomic weights of the elements in the compound gives a formula weight of 164.1 amu. Using 1 mol  $\text{Ca}(\text{NO}_3)_2 = 164.1 \text{ g } \text{Ca}(\text{NO}_3)_2$  to write the appropriate conversion factor, we have

$$\text{Grams } \text{Ca}(\text{NO}_3)_2 = (0.433 \text{ mol } \text{Ca}(\text{NO}_3)_2) \left( \frac{164.1 \text{ g } \text{Ca}(\text{NO}_3)_2}{1 \text{ mol } \text{Ca}(\text{NO}_3)_2} \right) = 71.1 \text{ g } \text{Ca}(\text{NO}_3)_2$$

**Check** The number of moles is less than 1, so the number of grams must be less than the molar mass, 164.1 g. Using rounded numbers to estimate, we have  $0.5 \times 150 = 75 \text{ g}$ . The magnitude of our answer is reasonable. Both the units (g) and the number of significant figures (3) are correct.

#### PRACTICE EXERCISE

What is the mass, in grams, of (a) 6.33 mol of  $\text{NaHCO}_3$  and (b)  $3.0 \times 10^{-5}$  mol of sulfuric acid?

**Answers:** (a) 532 g, (b)  $2.9 \times 10^{-3} \text{ g}$

► **Figure 3.10 Procedure for interconverting the mass and the number of formula units of a substance.**

The number of moles of the substance is central to the calculation; thus, the mole concept can be thought of as the bridge between the mass of a substance in grams and the number of formula units.

### Interconverting Masses and Numbers of Particles

The mole concept provides the bridge between mass and the number of particles. To illustrate how we can interconvert mass and numbers of particles, let's calculate the number of copper atoms in an old copper penny. Such a penny weighs about 3 g, and we will assume that it is 100% copper:

$$\begin{aligned} \text{Cu atoms} &= (3 \text{ g Cu}) \left( \frac{1 \text{ mol Cu}}{63.5 \text{ g Cu}} \right) \left( \frac{6.02 \times 10^{23} \text{ Cu atoms}}{1 \text{ mol Cu}} \right) \\ &= 3 \times 10^{22} \text{ Cu atoms} \end{aligned}$$

We have rounded our answer to one significant figure, since we used only one significant figure for the mass of the penny. Notice how dimensional analysis  $\rightleftharpoons$  (Section 1.6) provides a straightforward route from grams to numbers of atoms. The molar mass and Avogadro's number are used as conversion factors to convert  $\text{grams} \rightarrow \text{moles} \rightarrow \text{atoms}$ . Notice also that our answer is a very large number. Any time you calculate the number of atoms, molecules, or ions in an ordinary sample of matter, you can expect the answer to be very large. In contrast, the number of moles in a sample will usually be much smaller, often less than 1. The general procedure for interconverting mass and number of formula units (atoms, molecules, ions, or whatever is represented by the chemical formula) of a substance is summarized in Figure 3.10 ▲.

#### ■ SAMPLE EXERCISE 3.12 | Calculating the Number of Molecules and Number of Atoms from Mass

(a) How many glucose molecules are in 5.23 g of  $\text{C}_6\text{H}_{12}\text{O}_6$ ? (b) How many oxygen atoms are in this sample?

#### SOLUTION

**Analyze** We are given the number of grams and the chemical formula and asked to calculate (a) the number of molecules and (b) the number of O atoms in the sample.

**(a) Plan** The strategy for determining the number of molecules in a given quantity of a substance is summarized in Figure 3.10. We must convert 5.23 g  $\text{C}_6\text{H}_{12}\text{O}_6$  to moles  $\text{C}_6\text{H}_{12}\text{O}_6$ , which can then be converted to molecules  $\text{C}_6\text{H}_{12}\text{O}_6$ . The first conversion uses the molar mass of  $\text{C}_6\text{H}_{12}\text{O}_6$ : 1 mol  $\text{C}_6\text{H}_{12}\text{O}_6 = 180.0 \text{ g C}_6\text{H}_{12}\text{O}_6$ . The second conversion uses Avogadro's number.

#### Solve

Molecules  $\text{C}_6\text{H}_{12}\text{O}_6$

$$\begin{aligned} &= (5.23 \text{ g C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g C}_6\text{H}_{12}\text{O}_6} \right) \left( \frac{6.02 \times 10^{23} \text{ molecules C}_6\text{H}_{12}\text{O}_6}{1 \text{ mol C}_6\text{H}_{12}\text{O}_6} \right) \\ &= 1.75 \times 10^{22} \text{ molecules C}_6\text{H}_{12}\text{O}_6 \end{aligned}$$

**Check** The magnitude of the answer is reasonable. Because the mass we began with is less than a mole, there should be fewer than  $6.02 \times 10^{23}$  molecules. We can make a ballpark estimate of the answer:  $5/200 = 2.5 \times 10^{-2} \text{ mol}$ ;  $2.5 \times 10^{-2} \times 6 \times 10^{23} = 15 \times 10^{21} = 1.5 \times 10^{22}$  molecules. The units (molecules) and significant figures (three) are appropriate.

**(b) Plan** To determine the number of O atoms, we use the fact that there are six O atoms in each molecule of  $\text{C}_6\text{H}_{12}\text{O}_6$ . Thus, multiplying the number of molecules  $\text{C}_6\text{H}_{12}\text{O}_6$  by the factor (6 atoms O/1 molecule  $\text{C}_6\text{H}_{12}\text{O}_6$ ) gives the number of O atoms.

#### Solve

$$\begin{aligned} \text{Atoms O} &= (1.75 \times 10^{22} \text{ molecules C}_6\text{H}_{12}\text{O}_6) \left( \frac{6 \text{ atoms O}}{1 \text{ molecule C}_6\text{H}_{12}\text{O}_6} \right) \\ &= 1.05 \times 10^{23} \text{ atoms O} \end{aligned}$$

**Check** The answer is simply 6 times as large as the answer to part (a). The number of significant figures (three) and the units (atoms O) are correct.

**PRACTICE EXERCISE**

(a) How many nitric acid molecules are in 4.20 g of  $\text{HNO}_3$ ? (b) How many O atoms are in this sample?

Answers: (a)  $4.01 \times 10^{22}$  molecules  $\text{HNO}_3$ , (b)  $1.20 \times 10^{23}$  atoms O

**3.5 EMPIRICAL FORMULAS FROM ANALYSES**

As we learned in Section 2.6, the empirical formula for a substance tells us the relative number of atoms of each element it contains. The empirical formula  $\text{H}_2\text{O}$  shows that water contains two H atoms for each O atom. This ratio also applies on the molar level: 1 mol of  $\text{H}_2\text{O}$  contains 2 mol of H atoms and 1 mol of O atoms. Conversely, *the ratio of the number of moles of each element in a compound gives the subscripts in a compound's empirical formula.* In this way, the mole concept provides a way of calculating the empirical formulas of chemical substances, as shown in the following examples.

Mercury and chlorine combine to form a compound that is 73.9% mercury and 26.1% chlorine by mass. This means that if we had a 100.0-g sample of the solid, it would contain 73.9 g of mercury (Hg) and 26.1 g of chlorine (Cl). (Any size sample can be used in problems of this type, but we will generally use 100.0 g to simplify the calculation of mass from percentage.) Using the atomic weights of the elements to give us molar masses, we can calculate the number of moles of each element in the sample:

$$(73.9 \text{ g Hg}) \left( \frac{1 \text{ mol Hg}}{200.6 \text{ g Hg}} \right) = 0.368 \text{ mol Hg}$$

$$(26.1 \text{ g Cl}) \left( \frac{1 \text{ mol Cl}}{35.5 \text{ g Cl}} \right) = 0.735 \text{ mol Cl}$$

We then divide the larger number of moles (0.735) by the smaller (0.368) to obtain a Cl:Hg mole ratio of 1.99:1:

$$\frac{\text{moles of Cl}}{\text{moles of Hg}} = \frac{0.735 \text{ mol Cl}}{0.368 \text{ mol Hg}} = \frac{1.99 \text{ mol Cl}}{1 \text{ mol Hg}}$$

Because of experimental errors, the results may not lead to exact integers for the ratios of moles. The number 1.99 is very close to 2, so we can confidently conclude that the empirical formula for the compound is  $\text{HgCl}_2$ . The empirical formula is correct because its subscripts are the smallest integers that express the *ratios* of atoms present in the compound.  $\Leftrightarrow$  (Section 2.6) The general procedure for determining empirical formulas is outlined in Figure 3.11  $\blacktriangledown$ .

Given:

**▲ Figure 3.11 Procedure for calculating an empirical formula from percentage composition.** The central part of the calculation is determining the number of moles of each element in the compound. The procedure is also summarized as “percent to mass, mass to mole, divide by small, multiply ‘til whole.”

**SAMPLE EXERCISE 3.13 | Calculating an Empirical Formula**

Ascorbic acid (vitamin C) contains 40.92% C, 4.58% H, and 54.50% O by mass. What is the empirical formula of ascorbic acid?

**SOLUTION**

**Analyze** We are to determine an empirical formula of a compound from the mass percentages of its elements.

**Plan** The strategy for determining the empirical formula involves the three steps given in Figure 3.11.

**Solve** We *first* assume, for simplicity, that we have exactly 100 g of material (although any mass can be used). In 100 g of ascorbic acid, therefore, we have

40.92 g C, 4.58 g H, and 54.50 g O.

*Second*, we calculate the number of moles of each element:

$$\text{Moles C} = (40.92 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.01 \text{ g C}} \right) = 3.407 \text{ mol C}$$

$$\text{Moles H} = (4.58 \text{ g H}) \left( \frac{1 \text{ mol H}}{1.008 \text{ g H}} \right) = 4.54 \text{ mol H}$$

$$\text{Moles O} = (54.50 \text{ g O}) \left( \frac{1 \text{ mol O}}{16.00 \text{ g O}} \right) = 3.406 \text{ mol O}$$

*Third*, we determine the simplest whole-number ratio of moles by dividing each number of moles by the smallest number of moles, 3.406:

$$\text{C:} \frac{3.407}{3.406} = 1.000 \quad \text{H:} \frac{4.54}{3.406} = 1.33 \quad \text{O:} \frac{3.406}{3.406} = 1.000$$

The ratio for H is too far from 1 to attribute the difference to experimental error; in fact, it is quite close to  $1\frac{1}{3}$ . This suggests that if we multiply the ratio by 3, we will obtain whole numbers:

$$\text{C:H:O} = 3(1:1.33:1) = 3:4:3$$

The whole-number mole ratio gives us the subscripts for the empirical formula:

**Check** It is reassuring that the subscripts are moderately sized whole numbers. Otherwise, we have little by which to judge the reasonableness of our answer.

### ■ PRACTICE EXERCISE

A 5.325-g sample of methyl benzoate, a compound used in the manufacture of perfumes, contains 3.758 g of carbon, 0.316 g of hydrogen, and 1.251 g of oxygen. What is the empirical formula of this substance?

*Answer:*  $\text{C}_4\text{H}_4\text{O}$

## Molecular Formula from Empirical Formula

For any compound, the formula obtained from percentage compositions is always the empirical formula. We can obtain the molecular formula from the empirical formula if we are given the molecular weight or molar mass of the compound. *The subscripts in the molecular formula of a substance are always a whole-number multiple of the corresponding subscripts in its empirical formula.*  $\infty$  (Section 2.6) This multiple can be found by comparing the empirical formula weight with the molecular weight:

$$\text{Whole-number multiple} = \frac{\text{molecular weight}}{\text{empirical formula weight}} \quad [3.11]$$

In Sample Exercise 3.13, for example, the empirical formula of ascorbic acid was determined to be  $\text{C}_3\text{H}_4\text{O}_3$ , giving an empirical formula weight of  $3(12.0 \text{ amu}) + 4(1.0 \text{ amu}) + 3(16.0 \text{ amu}) = 88.0 \text{ amu}$ . The experimentally determined molecular weight is 176 amu. Thus, the molecular weight is 2 times the empirical formula weight ( $176/88.0 = 2.00$ ), and the molecular formula must therefore have twice as many of each kind of atom as the empirical formula. Consequently, we multiply the subscripts in the empirical formula by 2 to obtain the molecular formula:  $\text{C}_6\text{H}_8\text{O}_6$ .

### ■ SAMPLE EXERCISE 3.14 | Determining a Molecular Formula

Mesitylene, a hydrocarbon that occurs in small amounts in crude oil, has an empirical formula of  $\text{C}_3\text{H}_4$ . The experimentally determined molecular weight of this substance is 121 amu. What is the molecular formula of mesitylene?

#### SOLUTION

**Analyze** We are given an empirical formula and a molecular weight and asked to determine a molecular formula.

**Plan** The subscripts in the molecular formula of a compound are whole-number multiples of the subscripts in its empirical formula. To find the appropriate multiple, we must compare the molecular weight with the formula weight of the empirical formula.

**Solve** First, we calculate the formula weight of the empirical formula,  $C_3H_4$ :

$$3(12.0 \text{ amu}) + 4(1.0 \text{ amu}) = 40.0 \text{ amu}$$

Next, we divide the molecular weight by the empirical formula weight to obtain the multiple used to multiply the subscripts in  $C_3H_4$ :

$$\frac{\text{Molecular weight}}{\text{Empirical formula weight}} = \frac{121}{40.0} = 3.02$$

Only whole-number ratios make physical sense because we must be dealing with whole atoms. The 3.02 in this case could result from a small experimental error in the molecular weight. We therefore multiply each subscript in the empirical formula by 3 to give the molecular formula:  $C_9H_{12}$ .

**Check** We can have confidence in the result because dividing the molecular weight by the formula weight yields nearly a whole number.

### ■ PRACTICE EXERCISE

Ethylene glycol, the substance used in automobile antifreeze, is composed of 38.7% C, 9.7% H, and 51.6% O by mass. Its molar mass is 62.1 g/mol. (a) What is the empirical formula of ethylene glycol? (b) What is its molecular formula?

**Answers:** (a)  $CH_3O$ , (b)  $C_2H_6O_2$

## Combustion Analysis

The empirical formula of a compound is based on experiments that give the number of moles of each element in a sample of the compound. The word “empirical” means “based on observation and experiment.” Chemists have devised a number of experimental techniques to determine empirical formulas. One technique is combustion analysis, which is commonly used for compounds containing principally carbon and hydrogen as their component elements.

When a compound containing carbon and hydrogen is completely combusted in an apparatus such as that shown in Figure 3.12, the carbon in the compound is converted to  $CO_2$ , and the hydrogen is converted to  $H_2O$ . (Section 3.2) The amounts of  $CO_2$  and  $H_2O$  produced are determined by measuring the mass increase in the  $CO_2$  and  $H_2O$  absorbers. From the masses of  $CO_2$  and  $H_2O$  we can calculate the number of moles of C and H in the original compound and thereby the empirical formula. If a third element is present in the compound, its mass can be determined by subtracting the masses of C and H from the compound’s original mass. Sample Exercise 3.15 shows how to determine the empirical formula of a compound containing C, H, and O.

**▲ Figure 3.12 Apparatus to determine percentages of carbon and hydrogen in a compound.** The compound is combusted to form  $CO_2$  and  $H_2O$ . Copper oxide helps to oxidize traces of carbon and carbon monoxide to carbon dioxide and to oxidize hydrogen to water.

### ■ SAMPLE EXERCISE 3.15 | Determining Empirical Formula by Combustion Analysis

Isopropyl alcohol, a substance sold as rubbing alcohol, is composed of C, H, and O. Combustion of 0.255 g of isopropyl alcohol produces 0.561 g of  $CO_2$  and 0.306 g of  $H_2O$ . Determine the empirical formula of isopropyl alcohol.

#### SOLUTION

**Analyze** We are told that isopropyl alcohol contains C, H, and O atoms and given the quantities of  $CO_2$  and  $H_2O$  produced when a given quantity of the alcohol is combusted. We must use this information to determine the empirical formula for isopropyl alcohol, a task that requires us to calculate the number of moles of C, H, and O in the sample.

**Plan** We can use the mole concept to calculate the number of grams of C present in the  $CO_2$  and the number of grams of H present in the  $H_2O$ . These amounts are the quantities of C and H present in the isopropyl alcohol before combustion. The number of grams of O in the compound equals the mass of the isopropyl alcohol minus the sum of the C and H masses. Once we have the number of grams of C, H, and O in the sample, we can then proceed as in Sample Exercise 3.13. We can calculate the number of moles of each element, and determine the mole ratio, which gives the subscripts in the empirical formula.

**Solve** To calculate the number of grams of C, we first use the molar mass of  $\text{CO}_2$ , 1 mol  $\text{CO}_2 = 44.0 \text{ g CO}_2$ , to convert grams of  $\text{CO}_2$  to moles of  $\text{CO}_2$ . Because each  $\text{CO}_2$  molecule has only 1 C atom, there is 1 mol of C atoms per mole of  $\text{CO}_2$  molecules. This fact allows us to convert the moles of  $\text{CO}_2$  to moles of C. Finally, we use the molar mass of C, 1 mol C = 12.0 g C, to convert moles of C to grams of C. Combining the three conversion factors, we have

$$\text{Grams C} = (0.561 \text{ g } \cancel{\text{CO}_2}) \left( \frac{1 \text{ mol } \cancel{\text{CO}_2}}{44.0 \text{ g } \cancel{\text{CO}_2}} \right) \left( \frac{1 \text{ mol C}}{1 \text{ mol } \cancel{\text{CO}_2}} \right) \left( \frac{12.0 \text{ g C}}{1 \text{ mol C}} \right) = 0.153 \text{ g C}$$

The calculation of the number of grams of H from the grams of  $\text{H}_2\text{O}$  is similar, although we must remember that there are 2 mol of H atoms per 1 mol of  $\text{H}_2\text{O}$  molecules:

$$\text{Grams H} = (0.306 \text{ g } \cancel{\text{H}_2\text{O}}) \left( \frac{1 \text{ mol } \cancel{\text{H}_2\text{O}}}{18.0 \text{ g } \cancel{\text{H}_2\text{O}}} \right) \left( \frac{2 \text{ mol H}}{1 \text{ mol } \cancel{\text{H}_2\text{O}}} \right) \left( \frac{1.01 \text{ g H}}{1 \text{ mol H}} \right) = 0.0343 \text{ g H}$$

The total mass of the sample, 0.255 g, is the sum of the masses of the C, H, and O. Thus, we can calculate the mass of O as follows:

$$\begin{aligned} \text{Mass of O} &= \text{mass of sample} - (\text{mass of C} + \text{mass of H}) \\ &= 0.255 \text{ g} - (0.153 \text{ g} + 0.0343 \text{ g}) = 0.068 \text{ g O} \end{aligned}$$

We then calculate the number of moles of C, H, and O in the sample:

$$\text{Moles C} = (0.153 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.0 \text{ g C}} \right) = 0.0128 \text{ mol C}$$

$$\text{Moles H} = (0.0343 \text{ g H}) \left( \frac{1 \text{ mol H}}{1.01 \text{ g H}} \right) = 0.0340 \text{ mol H}$$

$$\text{Moles O} = (0.068 \text{ g O}) \left( \frac{1 \text{ mol O}}{16.0 \text{ g O}} \right) = 0.0043 \text{ mol O}$$

To find the empirical formula, we must compare the relative number of moles of each element in the sample. The relative number of moles of each element is found by dividing each number by the smallest number, 0.0043. The mole ratio of C:H:O so obtained is 2.98:7.91:1.00. The first two numbers are very close to the whole numbers 3 and 8, giving the empirical formula  $\text{C}_3\text{H}_8\text{O}$ .

**Check** The subscripts work out to be moderately sized whole numbers, as expected.

### PRACTICE EXERCISE

(a) Caproic acid, which is responsible for the foul odor of dirty socks, is composed of C, H, and O atoms. Combustion of a 0.225-g sample of this compound produces 0.512 g  $\text{CO}_2$  and 0.209 g  $\text{H}_2\text{O}$ . What is the empirical formula of caproic acid? (b) Caproic acid has a molar mass of 116 g/mol. What is its molecular formula?

**Answers:** (a)  $\text{C}_3\text{H}_6\text{O}$ , (b)  $\text{C}_6\text{H}_{12}\text{O}_2$

### GIVE IT SOME THOUGHT

In Sample Exercise 3.15, how do you explain the fact that the ratios C:H:O are 2.98:7.91:1.00, rather than exact integers 3:8:1?

## 3.6 QUANTITATIVE INFORMATION FROM BALANCED EQUATIONS

The coefficients in a chemical equation represent the relative numbers of molecules in a reaction. The mole concept allows us to convert this information to the masses of the substances. Consider the following balanced equation:

The coefficients indicate that two molecules of  $\text{H}_2$  react with each molecule of  $\text{O}_2$  to form two molecules of  $\text{H}_2\text{O}$ . It follows that the relative numbers of moles are identical to the relative numbers of molecules:

We can generalize this observation for all balanced chemical equations: *The coefficients in a balanced chemical equation indicate both the relative numbers of molecules (or formula units) in the reaction and the relative numbers of moles.* Table 3.3 further summarizes this result and shows how it corresponds to the law of conservation of mass. Notice that the total mass of the reactants (4.0 g + 32.0 g) equals the total mass of the products (36.0 g).

TABLE 3.3 ■ Information from a Balanced Equation

<b>Equation:</b>	$2 \text{H}_2(\text{g})$	+	$\text{O}_2(\text{g})$	$\longrightarrow$	$2 \text{H}_2\text{O}(\text{l})$
Molecules:	2 molecules $\text{H}_2$	+	1 molecule $\text{O}_2$	$\longrightarrow$	2 molecules $\text{H}_2\text{O}$
					
Mass (amu):	4.0 amu $\text{H}_2$	+	32.0 amu $\text{O}_2$	$\longrightarrow$	36.0 amu $\text{H}_2\text{O}$
Amount (mol):	2 mol $\text{H}_2$	+	1 mol $\text{O}_2$	$\longrightarrow$	2 mol $\text{H}_2\text{O}$
Mass (g):	4.0 g $\text{H}_2$	+	32.0 g $\text{O}_2$	$\longrightarrow$	36.0 g $\text{H}_2\text{O}$

The quantities 2 mol  $\text{H}_2$ , 1 mol  $\text{O}_2$ , and 2 mol  $\text{H}_2\text{O}$ , which are given by the coefficients in Equation 3.12, are called *stoichiometrically equivalent quantities*. The relationship between these quantities can be represented as

where the  $\approx$  symbol means “is stoichiometrically equivalent to.” In other words, Equation 3.12 shows 2 mol of  $\text{H}_2$  and 1 mol of  $\text{O}_2$  forming 2 mol of  $\text{H}_2\text{O}$ . These stoichiometric relations can be used to convert between quantities of reactants and products in a chemical reaction. For example, the number of moles of  $\text{H}_2\text{O}$  produced from 1.57 mol of  $\text{O}_2$  can be calculated as follows:

$$\text{Moles H}_2\text{O} = (1.57 \text{ mol O}_2) \left( \frac{2 \text{ mol H}_2\text{O}}{1 \text{ mol O}_2} \right) = 3.14 \text{ mol H}_2\text{O}$$

### GIVE IT SOME THOUGHT

When 1.57 mol  $\text{O}_2$  reacts with  $\text{H}_2$  to form  $\text{H}_2\text{O}$ , how many moles of  $\text{H}_2$  are consumed in the process?

As an additional example, consider the combustion of butane ( $\text{C}_4\text{H}_{10}$ ), the fuel in disposable cigarette lighters:

Let’s calculate the mass of  $\text{CO}_2$  produced when 1.00 g of  $\text{C}_4\text{H}_{10}$  is burned. The coefficients in Equation 3.13 tell how the amount of  $\text{C}_4\text{H}_{10}$  consumed is related to the amount of  $\text{CO}_2$  produced: 2 mol  $\text{C}_4\text{H}_{10} \approx 8 \text{ mol CO}_2$ . To use this relationship we must use the molar mass of  $\text{C}_4\text{H}_{10}$  to convert grams of  $\text{C}_4\text{H}_{10}$  to moles of  $\text{C}_4\text{H}_{10}$ . Because 1 mol  $\text{C}_4\text{H}_{10} = 58.0 \text{ g C}_4\text{H}_{10}$ , we have

$$\begin{aligned} \text{Moles C}_4\text{H}_{10} &= (1.00 \text{ g C}_4\text{H}_{10}) \left( \frac{1 \text{ mol C}_4\text{H}_{10}}{58.0 \text{ g C}_4\text{H}_{10}} \right) \\ &= 1.72 \times 10^{-2} \text{ mol C}_4\text{H}_{10} \end{aligned}$$

We can then use the stoichiometric factor from the balanced equation, 2 mol  $\text{C}_4\text{H}_{10} \approx 8 \text{ mol CO}_2$ , to calculate moles of  $\text{CO}_2$ :

$$\begin{aligned} \text{Moles CO}_2 &= (1.72 \times 10^{-2} \text{ mol C}_4\text{H}_{10}) \left( \frac{8 \text{ mol CO}_2}{2 \text{ mol C}_4\text{H}_{10}} \right) \\ &= 6.88 \times 10^{-2} \text{ mol CO}_2 \end{aligned}$$

Finally, we can calculate the mass of the  $\text{CO}_2$ , in grams, using the molar mass of  $\text{CO}_2$  (1 mol  $\text{CO}_2 = 44.0 \text{ g CO}_2$ ):

$$\begin{aligned}\text{Grams CO}_2 &= (6.88 \times 10^{-2} \text{ mol CO}_2) \left( \frac{44.0 \text{ g CO}_2}{1 \text{ mol CO}_2} \right) \\ &= 3.03 \text{ g CO}_2\end{aligned}$$

Thus, the conversion sequence is

These steps can be combined in a single sequence of factors:

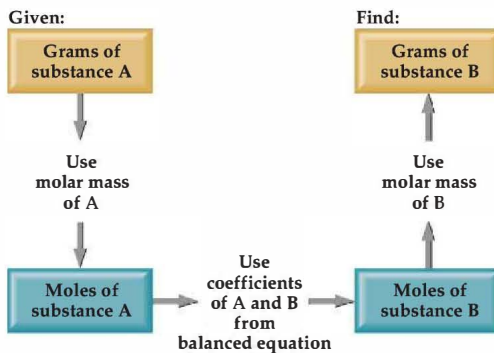

$$\begin{aligned}\text{Grams CO}_2 &= (1.00 \text{ g C}_4\text{H}_{10}) \left( \frac{1 \text{ mol C}_4\text{H}_{10}}{58.0 \text{ g C}_4\text{H}_{10}} \right) \left( \frac{8 \text{ mol CO}_2}{2 \text{ mol C}_4\text{H}_{10}} \right) \left( \frac{44.0 \text{ g CO}_2}{1 \text{ mol CO}_2} \right) \\ &= 3.03 \text{ g CO}_2\end{aligned}$$

Similarly, we can calculate the amount of  $\text{O}_2$  consumed or  $\text{H}_2\text{O}$  produced in this reaction. For example, to calculate the amount of  $\text{O}_2$  consumed, we again rely on the coefficients in the balanced equation to give us the appropriate stoichiometric factor: 2 mol  $\text{C}_4\text{H}_{10} \approx 13 \text{ mol O}_2$ :

$$\begin{aligned}\text{Grams O}_2 &= (1.00 \text{ g C}_4\text{H}_{10}) \left( \frac{1 \text{ mol C}_4\text{H}_{10}}{58.0 \text{ g C}_4\text{H}_{10}} \right) \left( \frac{13 \text{ mol O}_2}{2 \text{ mol C}_4\text{H}_{10}} \right) \left( \frac{32.0 \text{ g O}_2}{1 \text{ mol O}_2} \right) \\ &= 3.59 \text{ g O}_2\end{aligned}$$

Figure 3.13 summarizes the general approach used to calculate the quantities of substances consumed or produced in chemical reactions. The balanced chemical equation provides the relative numbers of moles of reactants and products in the reaction.

► **Figure 3.13** The procedure for calculating amounts of reactants or products in a reaction. The number of grams of a reactant consumed or of a product formed in a reaction can be calculated, starting with the number of grams of one of the other reactants or products. Notice how molar masses and the coefficients in the balanced equation are used.

### GIVE IT SOME THOUGHT

If 20.00 g of a compound reacts completely with 30.00 g of another compound in a combination reaction, how many grams of product were formed?

#### SAMPLE EXERCISE 3.16 | Calculating Amounts of Reactants and Products

How many grams of water are produced in the oxidation of 1.00 g of glucose,  $\text{C}_6\text{H}_{12}\text{O}_6$ ?

#### SOLUTION

**Analyze** We are given the mass of a reactant and are asked to determine the mass of a product in the given equation.

**Plan** The general strategy, as outlined in Figure 3.13, requires three steps. First, the amount of  $C_6H_{12}O_6$  must be converted from grams to moles. Second, we can use the balanced equation, which relates the moles of  $C_6H_{12}O_6$  to the moles of  $H_2O$ :  $1 \text{ mol } C_6H_{12}O_6 \approx 6 \text{ mol } H_2O$ . Third, we must convert the moles of  $H_2O$  to grams.

**Solve** First, use the molar mass of  $C_6H_{12}O_6$  to convert from grams  $C_6H_{12}O_6$  to moles  $C_6H_{12}O_6$ :

$$\text{Moles } C_6H_{12}O_6 = (1.00 \text{ g } C_6H_{12}O_6) \left( \frac{1 \text{ mol } C_6H_{12}O_6}{180.0 \text{ g } C_6H_{12}O_6} \right)$$

Second, use the balanced equation to convert moles of  $C_6H_{12}O_6$  to moles of  $H_2O$ :

$$\text{Moles } H_2O = (1.00 \text{ g } C_6H_{12}O_6) \left( \frac{1 \text{ mol } C_6H_{12}O_6}{180.0 \text{ g } C_6H_{12}O_6} \right) \left( \frac{6 \text{ mol } H_2O}{1 \text{ mol } C_6H_{12}O_6} \right)$$

Third, use the molar mass of  $H_2O$  to convert from moles of  $H_2O$  to grams of  $H_2O$ :

$$\begin{aligned} \text{Grams } H_2O &= (1.00 \text{ g } C_6H_{12}O_6) \left( \frac{1 \text{ mol } C_6H_{12}O_6}{180.0 \text{ g } C_6H_{12}O_6} \right) \left( \frac{6 \text{ mol } H_2O}{1 \text{ mol } C_6H_{12}O_6} \right) \left( \frac{18.0 \text{ g } H_2O}{1 \text{ mol } H_2O} \right) \\ &= 0.600 \text{ g } H_2O \end{aligned}$$

The steps can be summarized in a diagram like that in Figure 3.13:

**Check** An estimate of the magnitude of our answer,  $18/180 = 0.1$  and  $0.1 \times 6 = 0.6$ , agrees with the exact calculation. The units, grams  $H_2O$ , are correct. The initial data had three significant figures, so three significant figures for the answer is correct.

**Comment** An average person ingests 2 L of water daily and eliminates 2.4 L. The difference between 2 L and 2.4 L is produced in the metabolism of foodstuffs, such as in the oxidation of glucose. (*Metabolism* is a general term used to describe all the chemical processes of a living animal or plant.) The desert rat (kangaroo rat), on the other hand, apparently never drinks water. It survives on its metabolic water.

### PRACTICE EXERCISE

The decomposition of  $KClO_3$  is commonly used to prepare small amounts of  $O_2$  in the laboratory:  $2 KClO_3(s) \longrightarrow 2 KCl(s) + 3 O_2(g)$ . How many grams of  $O_2$  can be prepared from 4.50 g of  $KClO_3$ ?

**Answer:** 1.77 g

### SAMPLE EXERCISE 3.17 | Calculating Amounts of Reactants and Products

Solid lithium hydroxide is used in space vehicles to remove the carbon dioxide exhaled by astronauts. The lithium hydroxide reacts with gaseous carbon dioxide to form solid lithium carbonate and liquid water. How many grams of carbon dioxide can be absorbed by 1.00 g of lithium hydroxide?

#### SOLUTION

**Analyze** We are given a verbal description of a reaction and asked to calculate the number of grams of one reactant that reacts with 1.00 g of another.

**Plan** The verbal description of the reaction can be used to write a balanced equation:

We are given the grams of  $\text{LiOH}$  and asked to calculate grams of  $\text{CO}_2$ . We can accomplish this task by using the following sequence of conversions:

The conversion from grams of  $\text{LiOH}$  to moles of  $\text{LiOH}$  requires the molar mass of  $\text{LiOH}$  ( $6.94 + 16.00 + 1.01 = 23.95 \text{ g/mol}$ ). The conversion of moles of  $\text{LiOH}$  to moles of  $\text{CO}_2$  is based on the balanced chemical equation:  $2 \text{ mol LiOH} \approx 1 \text{ mol CO}_2$ . To convert the number of moles of  $\text{CO}_2$  to grams, we must use the molar mass of  $\text{CO}_2$ :  $12.01 + 2(16.00) = 44.01 \text{ g/mol}$ .

**Solve**

$$(1.00 \text{ g LiOH}) \left( \frac{1 \text{ mol LiOH}}{23.95 \text{ g LiOH}} \right) \left( \frac{1 \text{ mol CO}_2}{2 \text{ mol LiOH}} \right) \left( \frac{44.01 \text{ g CO}_2}{1 \text{ mol CO}_2} \right) = 0.919 \text{ g CO}_2$$

**Check** Notice that  $23.95 \approx 24$ ,  $24 \times 2 = 48$ , and  $44/48$  is slightly less than 1. The magnitude of the answer is reasonable based on the amount of starting LiOH; the significant figures and units are appropriate, too.

**■ PRACTICE EXERCISE**

Propane,  $\text{C}_3\text{H}_8$ , is a common fuel used for cooking and home heating. What mass of  $\text{O}_2$  is consumed in the combustion of 1.00 g of propane?

*Answer:* 3.64 g

*Chemistry and Life*

## GLUCOSE MONITORING

Over 20 million Americans have diabetes. In the world, the number approaches 172 million. Diabetes is a disorder of metabolism in which the body cannot produce or properly use the hormone insulin. One signal that a person is diabetic is that the concentration of glucose in her or his blood is higher than normal. Therefore, people who are diabetic need to measure their blood glucose concentrations regularly. Untreated diabetes can cause severe complications such as blindness and loss of limbs.

How does insulin relate to glucose? The body converts most of the food we eat into glucose. After digestion, glucose is delivered to cells via the bloodstream; cells need glucose to live. Insulin must be present for glucose to enter the cells. Normally, the body adjusts the concentration of insulin automatically, in concert with the glucose concentration after eating. However, in a diabetic person, little or no insulin is produced (Type 1 diabetes), or the cells cannot take up insulin properly (Type 2 diabetes). The result is that the blood glucose concentration is too high. People normally have a range of 70–120 mg glucose per deciliter of blood (about 4–6 mmol glucose per liter of blood). If a person has not eaten for 8 hours or more, he or she would be diagnosed as diabetic if the glucose levels were 126 mg/dL or higher. In the United States, diabetics monitor their blood glucose concentrations in mg/dL; in Europe, they use different units—millimoles glucose per liter of blood.

Glucose monitors work by the introduction of blood from a person, usually by a prick of the finger, onto a small strip of

paper that contains numerous chemicals that react specifically with glucose. Insertion of the strip into a small battery-operated reader gives the glucose concentration (Figure 3.14 ▼). The actual mechanism of the readout varies for different devices—it may be a small electrical current or a measure of light produced in a chemical reaction. Depending on the result, a diabetic person may need to receive an injection of insulin or simply stop eating sweets for a while.

▲ **Figure 3.14** Glucose meter. This is an example of a commercial glucose meter and its readout.

### 3.7 LIMITING REACTANTS

Suppose you wish to make several sandwiches using one slice of cheese and two slices of bread for each sandwich. Using Bd = bread, Ch = cheese, and  $\text{Bd}_2\text{Ch}$  = sandwich, the recipe for making a sandwich can be represented like a chemical equation:

If you have 10 slices of bread and 7 slices of cheese, you will be able to make only five sandwiches before you run out of bread. You will have 2 slices of cheese left over. The amount of available bread limits the number of sandwiches.

An analogous situation occurs in chemical reactions when one of the reactants is used up before the others. The reaction stops as soon as any one of the reactants is totally consumed, leaving the excess reactants as leftovers.

Suppose, for example, that we have a mixture of 10 mol H<sub>2</sub> and 7 mol O<sub>2</sub>, which react to form water:

Because 2 mol H<sub>2</sub> ≈ 1 mol O<sub>2</sub>, the number of moles of O<sub>2</sub> needed to react with all the H<sub>2</sub> is

$$\text{Moles O}_2 = (10 \text{ mol H}_2) \left( \frac{1 \text{ mol O}_2}{2 \text{ mol H}_2} \right) = 5 \text{ mol O}_2$$

Because 7 mol O<sub>2</sub> was available at the start of the reaction, 7 mol O<sub>2</sub> – 5 mol O<sub>2</sub> = 2 mol O<sub>2</sub> will still be present when all the H<sub>2</sub> is consumed. The example we have considered is depicted on a molecular level in Figure 3.15 ▶.

The reactant that is completely consumed in a reaction is called either the **limiting reactant** or *limiting reagent* because it determines, or limits, the amount of product formed. The other reactants are sometimes called either *excess reactants* or *excess reagents*. In our example, H<sub>2</sub> is the limiting reactant, which means that once all the H<sub>2</sub> has been consumed, the reaction stops. O<sub>2</sub> is the excess reactant, and some is left over when the reaction stops.

There are no restrictions on the starting amounts of the reactants in any reaction. Indeed, many reactions are carried out using an excess of one reagent. The quantities of reactants consumed and the quantities of products formed, however, are restricted by the quantity of the limiting reactant. When a combustion reaction takes place in the open air, oxygen is plentiful and is therefore the excess reactant. You may have had the unfortunate experience of running out of gasoline while driving. The car stops because you have run out of the limiting reactant in the combustion reaction, the fuel.

Before we leave our present example, let's summarize the data in a tabular form:

	2 H <sub>2</sub> (g)	+ O <sub>2</sub> (g)	→	2 H <sub>2</sub> O(g)
Initial quantities:	10 mol	7 mol		0 mol
Change (reaction):	-10 mol	-5 mol		+10 mol
Final quantities:	0 mol	2 mol		10 mol

The initial amounts of the reactants are what we started with (10 mol H<sub>2</sub> and 7 mol O<sub>2</sub>). The second line in the table (change) summarizes the amounts of the reactants consumed and the amount of the product formed in the reaction. These quantities are restricted by the quantity of the limiting reactant and depend on the coefficients in the balanced equation. The mole ratio H<sub>2</sub>: O<sub>2</sub>: H<sub>2</sub>O = 10:5:10 conforms to the ratio of the coefficients in the balanced equation, 2:1:2. The changes are negative for the reactants because they are consumed during the reaction and positive for the product because it is formed during the reaction. Finally, the quantities in the third line of the table (final quantities) depend on the initial quantities and their changes, and these entries are found by adding the entries for the initial quantity and change for each column. No amount of the limiting reactant (H<sub>2</sub>) remains at the end of the reaction. All that remains is 2 mol O<sub>2</sub> and 10 mol H<sub>2</sub>O.

▲ **Figure 3.15 Example illustrating a limiting reactant.** Because the H<sub>2</sub> is completely consumed, it is the limiting reagent in this case. Because there is a stoichiometric excess of O<sub>2</sub>, some is left over at the end of the reaction. The amount of H<sub>2</sub>O formed is related directly to the amount of H<sub>2</sub> consumed.

**SAMPLE EXERCISE 3.18** | Calculating the Amount of Product Formed from a Limiting Reactant

The most important commercial process for converting  $N_2$  from the air into nitrogen-containing compounds is based on the reaction of  $N_2$  and  $H_2$  to form ammonia ( $NH_3$ ):

How many moles of  $NH_3$  can be formed from 3.0 mol of  $N_2$  and 6.0 mol of  $H_2$ ?

**SOLUTION**

**Analyze** We are asked to calculate the number of moles of product,  $NH_3$ , given the quantities of each reactant,  $N_2$  and  $H_2$ , available in a reaction. Thus, this is a limiting reactant problem.

**Plan** If we assume that one reactant is completely consumed, we can calculate how much of the second reactant is needed in the reaction. By comparing the calculated quantity with the available amount, we can determine which reactant is limiting. We then proceed with the calculation, using the quantity of the limiting reactant.

**Solve** The number of moles of  $H_2$  needed for complete consumption of 3.0 mol of  $N_2$  is:

$$\text{Moles } H_2 = (3.0 \text{ mol } N_2) \left( \frac{3 \text{ mol } H_2}{1 \text{ mol } N_2} \right) = 9.0 \text{ mol } H_2$$

Because only 6.0 mol  $H_2$  is available, we will run out of  $H_2$  before the  $N_2$  is gone, and  $H_2$  will be the limiting reactant. We use the quantity of the limiting reactant,  $H_2$ , to calculate the quantity of  $NH_3$  produced:

$$\text{Moles } NH_3 = (6.0 \text{ mol } H_2) \left( \frac{2 \text{ mol } NH_3}{3 \text{ mol } H_2} \right) = 4.0 \text{ mol } NH_3$$

**Comment** The table on the right summarizes this example:

	$N_2(g)$	+ 3 $H_2(g)$	$\longrightarrow$	2 $NH_3(g)$
Initial quantities:	3.0 mol	6.0 mol		0 mol
Change (reaction):	-2.0 mol	-6.0 mol		+4.0 mol
Final quantities:	1.0 mol	0 mol		4.0 mol

Notice that we can calculate not only the number of moles of  $NH_3$  formed but also the number of moles of each of the reactants remaining after the reaction. Notice also that although the number of moles of  $H_2$  present at the beginning of the reaction is greater than the number of moles of  $N_2$  present, the  $H_2$  is nevertheless the limiting reactant because of its larger coefficient in the balanced equation.

**Check** The summarizing table shows that the mole ratio of reactants used and product formed conforms to the coefficients in the balanced equation, 1:3:2. Also, because  $H_2$  is the limiting reactant, it is completely consumed in the reaction, leaving 0 mol at the end. Because 6.0 mol  $H_2$  has two significant figures, our answer has two significant figures.

**PRACTICE EXERCISE**

Consider the reaction  $2 Al(s) + 3 Cl_2(g) \longrightarrow 2 AlCl_3(s)$ . A mixture of 1.50 mol of Al and 3.00 mol of  $Cl_2$  is allowed to react. (a) Which is the limiting reactant? (b) How many moles of  $AlCl_3$  are formed? (c) How many moles of the excess reactant remain at the end of the reaction?

**Answers:** (a) Al, (b) 1.50 mol, (c) 0.75 mol  $Cl_2$

**SAMPLE EXERCISE 3.19** | Calculating the Amount of Product Formed from a Limiting Reactant

Consider the following reaction that occurs in a fuel cell:

This reaction, properly done, produces energy in the form of electricity and water. Suppose a fuel cell is set up with 150 g of hydrogen gas and 1500 grams of oxygen gas (each measurement is given with two significant figures). How many grams of water can be formed?

**SOLUTION**

**Analyze** We are asked to calculate the amount of a product, given the amounts of two reactants, so this is a limiting reactant problem.

**Plan** We must first identify the limiting reagent. To do so, we can calculate the number of moles of each reactant and compare their ratio with that required by the balanced

equation. We then use the quantity of the limiting reagent to calculate the mass of water that forms.

**Solve** From the balanced equation, we have the following stoichiometric relations:

Using the molar mass of each substance, we can calculate the number of moles of each reactant:

$$\text{Moles H}_2 = (150 \text{ g H}_2) \left( \frac{1 \text{ mol H}_2}{2.00 \text{ g H}_2} \right) = 75 \text{ mol H}_2$$

$$\text{Moles O}_2 = (1500 \text{ g O}_2) \left( \frac{1 \text{ mol O}_2}{32.0 \text{ g O}_2} \right) = 47 \text{ mol O}_2$$

Thus, there are more moles of H<sub>2</sub> than O<sub>2</sub>. The coefficients in the balanced equation indicate, however, that the reaction requires 2 moles of H<sub>2</sub> for every 1 mole of O<sub>2</sub>. Therefore, to completely react all the O<sub>2</sub>, we would need  $2 \times 47 = 94$  moles of H<sub>2</sub>. Since there are only 75 moles of H<sub>2</sub>, H<sub>2</sub> is the limiting reagent. We therefore use the quantity of H<sub>2</sub> to calculate the quantity of product formed. We can begin this calculation with the grams of H<sub>2</sub>, but we can save a step by starting with the moles of H<sub>2</sub> that were calculated previously in the exercise:

$$\begin{aligned} \text{Grams H}_2\text{O} &= (75 \text{ moles H}_2) \left( \frac{2 \text{ mol H}_2\text{O}}{2 \text{ mol H}_2} \right) \left( \frac{18.0 \text{ g H}_2\text{O}}{1 \text{ mol H}_2\text{O}} \right) \\ &= 1400 \text{ g H}_2\text{O} \text{ (to two significant figures)} \end{aligned}$$

**Check** The magnitude of the answer seems reasonable. The units are correct, and the number of significant figures (two) corresponds to those in the numbers of grams of the starting materials.

**Comment** The quantity of the limiting reagent, H<sub>2</sub>, can also be used to determine the quantity of O<sub>2</sub> used (37.5 mol = 1200 g). The number of grams of the excess oxygen remaining at the end of the reaction equals the starting amount minus the amount consumed in the reaction, 1500 g – 1200 g = 300 g.

### PRACTICE EXERCISE

A strip of zinc metal with a mass of 2.00 g is placed in an aqueous solution containing 2.50 g of silver nitrate, causing the following reaction to occur:

(a) Which reactant is limiting? (b) How many grams of Ag will form? (c) How many grams of Zn(NO<sub>3</sub>)<sub>2</sub> will form? (d) How many grams of the excess reactant will be left at the end of the reaction?

**Answers:** (a) AgNO<sub>3</sub>, (b) 1.59 g, (c) 1.39 g, (d) 1.52 g Zn

## Theoretical Yields

The quantity of product that is calculated to form when all of the limiting reactant reacts is called the **theoretical yield**. The amount of product actually obtained in a reaction is called the *actual yield*. The actual yield is almost always less than (and can never be greater than) the theoretical yield. There are many reasons for this difference. Part of the reactants may not react, for example, or they may react in a way different from that desired (side reactions). In addition, it is not always possible to recover all of the product from the reaction mixture. The **percent yield** of a reaction relates the actual yield to the theoretical (calculated) yield:

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% \quad [3.14]$$

At about this time in your study of chemistry, you are likely to face your first hour-long examination. The best way to prepare for the exam is to study and do homework diligently and to make sure you get help from the instructor on any material that is unclear or confusing. (See the advice for learning and studying chemistry presented in the preface of the book.) We present here some general guidelines for taking tests.

Depending on the nature of your course, the exam could consist of a variety of different types of questions. Let's consider some of the more common types and how they can best be addressed.

- Multiple-choice questions** In large-enrollment courses, the most common kind of testing device is the multiple-choice question. You are given the problem and usually presented with four or five possible answers from which you must select the correct one. The first thing to realize is that the instructor has written the question so that all of the answer choices appear at first glance to be correct. (There would be little point in offering choices you could

tell were wrong even without knowing much about the concept being tested.) Thus, you should not jump to the conclusion that because one of the choices looks correct, it must be so.

If a multiple-choice question involves a calculation, perform the calculation, quickly double-check your work, and *only then* compare your answer with the choices. If you find a match, you have probably found the correct answer. Keep in mind, though, that your instructor has anticipated the most common errors one can make in solving a given problem and has probably listed the incorrect answers resulting from those errors. Always double-check your reasoning and make sure to use dimensional analysis to arrive at the correct answer, with the correct units.

In multiple-choice questions that do not involve calculations, if you are not sure of the correct choice, eliminate all the choices you know for sure to be incorrect. Additionally, the reasoning you used in eliminating incorrect choices will help you in reasoning about which choice is correct.

### SAMPLE EXERCISE 3.20 Calculating the Theoretical Yield and Percent Yield for a Reaction

Adipic acid,  $\text{H}_2\text{C}_6\text{H}_8\text{O}_4$ , is used to produce nylon. The acid is made commercially by a controlled reaction between cyclohexane ( $\text{C}_6\text{H}_{12}$ ) and  $\text{O}_2$ :

- Assume that you carry out this reaction starting with 25.0 g of cyclohexane and that cyclohexane is the limiting reactant. What is the theoretical yield of adipic acid?
- If you obtain 33.5 g of adipic acid from your reaction, what is the percent yield of adipic acid?

#### SOLUTION

**Analyze** We are given a chemical equation and the quantity of the limiting reactant (25.0 g of  $\text{C}_6\text{H}_{12}$ ). We are asked first to calculate the theoretical yield of a product ( $\text{H}_2\text{C}_6\text{H}_8\text{O}_4$ ) and then to calculate its percent yield if only 33.5 g of the substance is actually obtained.

**Plan** (a) The theoretical yield, which is the calculated quantity of adipic acid formed in the reaction, can be calculated using the following sequence of conversions:

(b) The percent yield is calculated by comparing the actual yield (33.5 g) to the theoretical yield using Equation 3.14.

#### Solve

$$\begin{aligned} \text{(a) Grams H}_2\text{C}_6\text{H}_8\text{O}_4 &= (25.0 \text{ g C}_6\text{H}_{12}) \left( \frac{1 \text{ mol C}_6\text{H}_{12}}{84.0 \text{ g C}_6\text{H}_{12}} \right) \left( \frac{2 \text{ mol H}_2\text{C}_6\text{H}_8\text{O}_4}{2 \text{ mol C}_6\text{H}_{12}} \right) \left( \frac{146.0 \text{ g H}_2\text{C}_6\text{H}_8\text{O}_4}{1 \text{ mol H}_2\text{C}_6\text{H}_8\text{O}_4} \right) \\ &= 43.5 \text{ g H}_2\text{C}_6\text{H}_8\text{O}_4 \end{aligned}$$

$$\text{(b) Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% = \frac{33.5 \text{ g}}{43.5 \text{ g}} \times 100\% = 77.0\%$$

**Check** Our answer in (a) has the appropriate magnitude, units, and significant figures. In (b) the answer is less than 100% as necessary.

2. *Calculations in which you must show your work* Your instructor may present you with a numerical problem in which you are to show your work in arriving at a solution. In questions of this kind, you may receive partial credit even if you do not arrive at the correct answer, depending on whether the instructor can follow your line of reasoning. It is important, therefore, to be as neat and organized as you can be, given the pressures of exam taking. It is helpful in approaching such questions to take a few moments to think about the direction you are going to take in solving the problem. You may even want to write a few words or a diagram on the test paper to indicate your approach. Then write out your calculations as neatly as you can. Show the units for every number you write down, and use dimensional analysis as much as you can, showing how units cancel.
3. *Questions requiring drawings* Sometimes a test question will require you to draw a chemical structure, a diagram related to chemical bonding, or a figure showing some kind of chemical process. Questions of this kind will

come later in the course, but it is useful to talk about them here. (You should review this box before each exam you take, to remind yourself of good exam-taking practices.) Be sure to label your drawing as completely as possible.

4. *Other types of questions* Other exam questions you might encounter include true-false questions and ones in which you are given a list and asked to indicate which members of the list match some criterion given in the question. Often students answer such questions incorrectly because, in their haste, they misunderstand the nature of the question. Whatever the form of the question, ask yourself this: What is the instructor testing here? What material am I supposed to know that this question covers?

Finally, if you find that you simply do not understand how to arrive at a reasoned response to a question, do not linger over the question. Put a check next to it and go on to the next one. If time permits, you can come back to the unanswered questions, but lingering over a question when nothing is coming to mind is wasting time you may need to finish the exam.

### ■ PRACTICE EXERCISE

Imagine that you are working on ways to improve the process by which iron ore containing  $\text{Fe}_2\text{O}_3$  is converted into iron. In your tests you carry out the following reaction on a small scale:

(a) If you start with 150 g of  $\text{Fe}_2\text{O}_3$  as the limiting reagent, what is the theoretical yield of Fe? (b) If the actual yield of Fe in your test was 87.9 g, what was the percent yield?  
*Answers:* (a) 105 g Fe, (b) 83.7%

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 3.1** The study of the quantitative relationships between chemical formulas and chemical equations is known as **stoichiometry**. One of the important concepts of stoichiometry is the law of conservation of mass, which states that the total mass of the products of a chemical reaction is the same as the total mass of the reactants. The same numbers of atoms of each type are present before and after a chemical reaction. A balanced **chemical equation** shows equal numbers of atoms of each element on each side of the equation. Equations are balanced by placing coefficients in front of the chemical formulas for the **reactants** and **products** of a reaction, *not* by changing the subscripts in chemical formulas.

**Section 3.2** Among the reaction types described in this chapter are (1) **combination reactions**, in which two reactants combine to form one product; (2) **decomposition reactions**, in which a single reactant forms two or more products; and (3) **combustion reactions** in oxygen, in

which a hydrocarbon or related compound reacts with  $\text{O}_2$  to form  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

**Section 3.3** Much quantitative information can be determined from chemical formulas and balanced chemical equations by using atomic weights. The **formula weight** of a compound equals the sum of the atomic weights of the atoms in its formula. If the formula is a molecular formula, the formula weight is also called the **molecular weight**. Atomic weights and formula weights can be used to determine the elemental composition of a compound.

**Section 3.4** A mole of any substance is **Avogadro's number** ( $6.02 \times 10^{23}$ ) of formula units of that substance. The mass of a mole of atoms, molecules, or ions (the **molar mass**) equals the formula weight of that material expressed in grams. The mass of one molecule of  $\text{H}_2\text{O}$ , for example, is 18 amu, so the mass of 1 mol of  $\text{H}_2\text{O}$  is 18 g. That is, the molar mass of  $\text{H}_2\text{O}$  is 18 g/mol.

**Section 3.5** The empirical formula of any substance can be determined from its percent composition by calculating the relative number of moles of each atom in 100 g of the substance. If the substance is molecular in nature, its molecular formula can be determined from the empirical formula if the molecular weight is also known.

**Sections 3.6 and 3.7** The mole concept can be used to calculate the relative quantities of reactants and products in chemical reactions. The coefficients in a balanced equation give the relative numbers of moles of the reactants and products. To calculate the number of grams of a

product from the number of grams of a reactant, first convert grams of reactant to moles of reactant. Then use the coefficients in the balanced equation to convert the number of moles of reactant to moles of product. Finally, convert moles of product to grams of product.

A **limiting reactant** is completely consumed in a reaction. When it is used up, the reaction stops, thus limiting the quantities of products formed. The **theoretical yield** of a reaction is the quantity of product calculated to form when all of the limiting reagent reacts. The actual yield of a reaction is always less than the theoretical yield. The **percent yield** compares the actual and theoretical yields.

## KEY SKILLS

- Balance chemical equations.
- Calculate molecular weights.
- Convert grams to moles and moles to grams using molar masses.
- Convert number of molecules to moles and moles to number of molecules using Avogadro's number.
- Calculate the empirical and molecular formula of a compound from percentage composition and molecular weight.
- Calculate amounts, in grams or moles, of reactants and products for a reaction.
- Calculate the percent yield of a reaction.

## KEY EQUATIONS

$$\% \text{ element} = \frac{\left( \begin{array}{c} \text{number of atoms} \\ \text{of that element} \end{array} \right) \left( \begin{array}{c} \text{atomic weight} \\ \text{of element} \end{array} \right)}{\text{formula weight of compound}} \times 100\% \quad [3.10]$$

This is the formula to calculate the mass percentage of each element in a compound. The sum of all the percentages of all the elements in a compound should add up to 100%.

$$\% \text{ yield} = \frac{\text{(actual yield)}}{\text{(theoretical yield)}} \times 100\% \quad [3.14]$$

This is the formula to calculate the percent yield of a reaction. The percent yield can never be more than 100%.

## VISUALIZING CONCEPTS

- 3.1** The reaction between reactant A (blue spheres) and reactant B (red spheres) is shown in the following diagram:

Based on this diagram, which equation best describes the reaction? [Section 3.1]

- (a)  $A_2 + B \longrightarrow A_2B$   
 (b)  $A_2 + 4B \longrightarrow 2AB_2$   
 (c)  $2A + B_4 \longrightarrow 2AB_2$   
 (d)  $A + B_2 \longrightarrow AB_2$
- 3.2** Under appropriate experimental conditions,  $H_2$  and  $CO$  undergo a combination reaction to form  $CH_3OH$ . The

drawing below represents a sample of  $H_2$ . Make a corresponding drawing of the  $CO$  needed to react completely with the  $H_2$ . How did you arrive at the number of  $CO$  molecules in your drawing? [Section 3.2]

- 3.3** The following diagram represents the collection of elements formed by a decomposition reaction. (a) If the blue spheres represent N atoms and the red ones represent O atoms, what was the empirical formula of the original compound? (b) Could you draw a diagram rep-

representing the molecules of the compound that had been decomposed? Why or why not? [Section 3.2]

- 3.4 The following diagram represents the collection of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  molecules formed by complete combustion of a hydrocarbon. What is the empirical formula of the hydrocarbon? [Section 3.2]

- 3.5 Glycine, an amino acid used by organisms to make proteins, is represented by the molecular model below.
- Write its molecular formula.
  - Determine its molar mass.
  - Calculate the mass of 3 moles of glycine.
  - Calculate the percent nitrogen by mass in glycine. [Sections 3.3 and 3.5]

- 3.6 The following diagram represents a high-temperature reaction between  $\text{CH}_4$  and  $\text{H}_2\text{O}$ . Based on this reaction,

how many moles of each product can be obtained starting with 4.0 mol  $\text{CH}_4$ ? [Section 3.6]

- 3.7 Nitrogen ( $\text{N}_2$ ) and hydrogen ( $\text{H}_2$ ) react to form ammonia ( $\text{NH}_3$ ). Consider the mixture of  $\text{N}_2$  and  $\text{H}_2$  shown in the accompanying diagram. The blue spheres represent N, and the white ones represent H. Draw a representation of the product mixture, assuming that the reaction goes to completion. How did you arrive at your representation? What is the limiting reactant in this case? [Section 3.7]

- 3.8 Nitrogen monoxide and oxygen react to form nitrogen dioxide. Consider the mixture of  $\text{NO}$  and  $\text{O}_2$  shown in the accompanying diagram. The blue spheres represent N, and the red ones represent O. (a) Draw a representation of the product mixture, assuming that the reaction goes to completion. What is the limiting reactant in this case? (b) How many  $\text{NO}_2$  molecules would you draw as products if the reaction had a percent yield of 75%? [Section 3.7]

## EXERCISES

### Balancing Chemical Equations

- 3.9 (a) What scientific principle or law is used in the process of balancing chemical equations? (b) In balancing equations, why should you not change subscripts in chemical formulas? (c) How would one write out liquid water, water vapor, aqueous sodium chloride, and solid sodium chloride in chemical equations?
- 3.10 (a) What is the difference between adding a subscript 2 to the end of the formula for CO to give  $\text{CO}_2$  and adding a coefficient in front of the formula to give  $2\text{CO}$ ?

(b) Is the following chemical equation, as written, consistent with the law of conservation of mass?

Why or why not?

- 3.11 Balance the following equations:

3.12 Balance the following equations:

3.13 Write balanced chemical equations to correspond to each of the following descriptions: (a) Solid calcium carbide,  $\text{CaC}_2$ , reacts with water to form an aqueous solution of calcium hydroxide and acetylene gas,  $\text{C}_2\text{H}_2$ . (b) When solid potassium chlorate is heated, it decom-

poses to form solid potassium chloride and oxygen gas. (c) Solid zinc metal reacts with sulfuric acid to form hydrogen gas and an aqueous solution of zinc sulfate. (d) When liquid phosphorus trichloride is added to water, it reacts to form aqueous phosphorous acid,  $\text{H}_3\text{PO}_3(\text{aq})$ , and aqueous hydrochloric acid. (e) When hydrogen sulfide gas is passed over solid hot iron(III) hydroxide, the resultant reaction produces solid iron(III) sulfide and gaseous water.

3.14 Write balanced chemical equations to correspond to each of the following descriptions: (a) When sulfur trioxide gas reacts with water, a solution of sulfuric acid forms. (b) Boron sulfide,  $\text{B}_2\text{S}_3(\text{s})$ , reacts violently with water to form dissolved boric acid,  $\text{H}_3\text{BO}_3$ , and hydrogen sulfide gas. (c) When an aqueous solution of lead(II) nitrate is mixed with an aqueous solution of sodium iodide, an aqueous solution of sodium nitrate and a yellow solid, lead iodide, are formed. (d) When solid mercury(II) nitrate is heated, it decomposes to form solid mercury(II) oxide, gaseous nitrogen dioxide, and oxygen. (e) Copper metal reacts with hot concentrated sulfuric acid solution to form aqueous copper(II) sulfate, sulfur dioxide gas, and water.

## Patterns of Chemical Reactivity

3.15 (a) When the metallic element sodium combines with the nonmetallic element bromine,  $\text{Br}_2(\text{l})$ , how can you determine the chemical formula of the product? How do you know whether the product is a solid, liquid, or gas at room temperature? Write the balanced chemical equation for the reaction. (b) When a hydrocarbon burns in air, what reactant besides the hydrocarbon is involved in the reaction? What products are formed? Write a balanced chemical equation for the combustion of benzene,  $\text{C}_6\text{H}_6(\text{l})$ , in air.

3.16 (a) Determine the chemical formula of the product formed when the metallic element calcium combines with the nonmetallic element oxygen,  $\text{O}_2$ . Write the balanced chemical equation for the reaction. (b) What products form when a compound containing C, H, and O is completely combusted in air? Write a balanced chemical equation for the combustion of acetone,  $\text{C}_3\text{H}_6\text{O}(\text{l})$ , in air.

3.17 Write a balanced chemical equation for the reaction that occurs when (a)  $\text{Mg}(\text{s})$  reacts with  $\text{Cl}_2(\text{g})$ ; (b) barium carbonate decomposes into barium oxide and carbon dioxide gas when heated; (c) the hydrocarbon styrene,  $\text{C}_8\text{H}_8(\text{l})$ , is combusted in air; (d) dimethylether,  $\text{CH}_3\text{OCH}_3(\text{g})$ , is combusted in air.

3.18 Write a balanced chemical equation for the reaction that occurs when (a) aluminum metal undergoes a combination reaction with  $\text{O}_2(\text{g})$ ; (b) copper(II) hydroxide decomposes into copper(II) oxide and water when heated; (c) heptane,  $\text{C}_7\text{H}_{16}(\text{l})$ , burns in air; (d) the gasoline additive MTBE (methyl tert-butyl ether),  $\text{C}_5\text{H}_{12}\text{O}(\text{l})$ , burns in air.

3.19 Balance the following equations, and indicate whether they are combination, decomposition, or combustion reactions:

3.20 Balance the following equations, and indicate whether they are combination, decomposition, or combustion reactions:

## Formula Weights

3.21 Determine the formula weights of each of the following compounds: (a) nitric acid,  $\text{HNO}_3$ ; (b)  $\text{KMnO}_4$ ; (c)  $\text{Ca}_3(\text{PO}_4)_2$ ; (d) quartz,  $\text{SiO}_2$ ; (e) gallium sulfide, (f) chromium(III) sulfate, (g) phosphorus trichloride.

3.22 Determine the formula weights of each of the following compounds: (a) nitrous oxide,  $\text{N}_2\text{O}$ , known as laughing

gas and used as an anesthetic in dentistry; (b) benzoic acid,  $\text{HC}_7\text{H}_5\text{O}_2$ , a substance used as a food preservative; (c)  $\text{Mg}(\text{OH})_2$ , the active ingredient in milk of magnesia; (d) urea,  $(\text{NH}_2)_2\text{CO}$ , a compound used as a nitrogen fertilizer; (e) isopentyl acetate,  $\text{CH}_3\text{CO}_2\text{C}_5\text{H}_{11}$ , responsible for the odor of bananas.

- 3.23 Calculate the percentage by mass of oxygen in the following compounds: (a) morphine,  $C_{17}H_{19}NO_3$ ; (b) codeine,  $C_{18}H_{21}NO_3$ ; (c) cocaine,  $C_{17}H_{21}NO_4$ ; (d) tetracycline,  $C_{22}H_{24}N_2O_8$ ; (e) digitoxin,  $C_{41}H_{64}O_{13}$ ; (f) vancomycin,  $C_{66}H_{75}Cl_2N_9O_{24}$ .
- 3.24 Calculate the percentage by mass of the indicated element in the following compounds: (a) carbon in acetylene,  $C_2H_2$ , a gas used in welding; (b) hydrogen in ascorbic acid,  $C_6H_7O_6$ , also known as vitamin C; (c) hydrogen in ammonium sulfate,  $(NH_4)_2SO_4$ , a substance used as a nitrogen fertilizer; (d) platinum in  $PtCl_2(NH_3)_2$ , a chemotherapy agent called cisplatin; (e) oxygen in the female sex hormone estradiol,  $C_{18}H_{24}O_2$ ; (f) carbon in capsaicin,  $C_{18}H_{27}NO_3$ , the compound that gives the hot taste to chili peppers.

- 3.25 Based on the following structural formulas, calculate the percentage of carbon by mass present in each compound:

- 3.26 Calculate the percentage of carbon by mass in each of the compounds represented by the following models:

## Avogadro's Number and the Mole

- 3.27 (a) What is Avogadro's number, and how is it related to the mole? (b) What is the relationship between the formula weight of a substance and its molar mass?
- 3.28 (a) What is the mass, in grams, of a mole of  $^{12}C$ ? (b) How many carbon atoms are present in a mole of  $^{12}C$ ?
- 3.29 Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing number of atoms: 0.50 mol  $H_2O$ , 23 g Na,  $6.0 \times 10^{23}$   $N_2$  molecules.
- 3.30 Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing number of atoms:  $3.0 \times 10^{23}$  molecules of  $H_2O_2$ , 2.0 mol  $CH_4$ , 32 g  $O_2$ .
- 3.31 What is the mass, in kilograms, of an Avogadro's number of people, if the average mass of a person is 160 lb? How does this compare with the mass of Earth,  $5.98 \times 10^{24}$  kg?
- 3.32 If Avogadro's number of pennies is divided equally among the 300 million men, women, and children in the United States, how many dollars would each receive? How does this compare with the gross domestic product of the United States, which was \$13.5 trillion in 2006? (The GDP is the total market value of the nation's goods and services.)
- 3.33 Calculate the following quantities:  
(a) mass, in grams, of 0.105 moles sucrose ( $C_{12}H_{22}O_{11}$ )  
(b) moles of  $Zn(NO_3)_2$  in 143.50 g of this substance  
(c) number of molecules in  $1.0 \times 10^{-6}$  mol  $CH_3CH_2OH$   
(d) number of N atoms in 0.410 mol  $NH_3$
- 3.34 Calculate the following quantities  
(a) mass, in grams, of  $5.76 \times 10^{-3}$  mol of CdS  
(b) number of moles of  $NH_4Cl$  in 112.6 g of this substance  
(c) number of molecules in  $1.305 \times 10^{-2}$  mol  $C_6H_6$   
(d) number of O atoms in  $4.88 \times 10^{-3}$  mol  $Al(NO_3)_3$
- 3.35 (a) What is the mass, in grams, of  $2.50 \times 10^{-3}$  mol of ammonium phosphate?  
(b) How many moles of chloride ions are in 0.2550 g of aluminum chloride?  
(c) What is the mass, in grams, of  $7.70 \times 10^{20}$  molecules of caffeine,  $C_8H_{10}N_4O_2$ ?  
(d) What is the molar mass of cholesterol if 0.00105 mol weighs 0.406 g?
- 3.36 (a) What is the mass, in grams, of 0.0714 mol of iron(III) sulfate?  
(b) How many moles of ammonium ions are in 8.776 g of ammonium carbonate?

- (c) What is the mass, in grams, of  $6.52 \times 10^{21}$  molecules of aspirin,  $C_9H_8O_4$ ?  
 (d) What is the molar mass of diazepam (Valium<sup>®</sup>) if 0.05570 mol weighs 15.86 g?
- 3.37** The molecular formula of allicin, the compound responsible for the characteristic smell of garlic, is  $C_6H_{10}OS_2$ .  
 (a) What is the molar mass of allicin? (b) How many moles of allicin are present in 5.00 mg of this substance? (c) How many molecules of allicin are in 5.00 mg of this substance? (d) How many S atoms are present in 5.00 mg of allicin?
- 3.38** The molecular formula of aspartame, the artificial sweetener marketed as NutraSweet<sup>®</sup>, is  $C_{14}H_{18}N_2O_5$ .  
 (a) What is the molar mass of aspartame? (b) How many moles of aspartame are present in 1.00 mg of aspartame? (c) How many molecules of aspartame are present in 1.00 mg of aspartame? (d) How many hydrogen atoms are present in 1.00 mg of aspartame?
- 3.39** A sample of glucose,  $C_6H_{12}O_6$ , contains  $1.250 \times 10^{21}$  carbon atoms. (a) How many atoms of hydrogen does it contain? (b) How many molecules of glucose does it contain? (c) How many moles of glucose does it contain? (d) What is the mass of this sample in grams?
- 3.40** A sample of the male sex hormone testosterone,  $C_{19}H_{28}O_2$ , contains  $7.08 \times 10^{20}$  hydrogen atoms. (a) How many atoms of carbon does it contain? (b) How many molecules of testosterone does it contain? (c) How many moles of testosterone does it contain? (d) What is the mass of this sample in grams?
- 3.41** The allowable concentration level of vinyl chloride,  $C_2H_3Cl$ , in the atmosphere in a chemical plant is  $2.0 \times 10^{-6}$  g/L. How many moles of vinyl chloride in each liter does this represent? How many molecules per liter?
- 3.42** At least 25  $\mu\text{g}$  of tetrahydrocannabinol (THC), the active ingredient in marijuana, is required to produce intoxication. The molecular formula of THC is  $C_{21}H_{30}O_2$ . How many moles of THC does this 25  $\mu\text{g}$  represent? How many molecules?

## Empirical Formulas

- 3.43** Give the empirical formula of each of the following compounds if a sample contains (a) 0.0130 mol C, 0.0390 mol H, and 0.0065 mol O; (b) 11.66 g iron and 5.01 g oxygen; (c) 40.0% C, 6.7% H, and 53.3% O by mass.
- 3.44** Determine the empirical formula of each of the following compounds if a sample contains (a) 0.104 mol K, 0.052 mol C, and 0.156 mol O; (b) 5.28 g Sn and 3.37 g F; (c) 87.5% N and 12.5% H by mass.
- 3.45** Determine the empirical formulas of the compounds with the following compositions by mass:  
 (a) 10.4% C, 27.8% S, and 61.7% Cl  
 (b) 21.7% C, 9.6% O, and 68.7% F  
 (c) 32.79% Na, 13.02% Al, and 54.19% F
- 3.46** Determine the empirical formulas of the compounds with the following compositions by mass:  
 (a) 55.3% K, 14.6% P, and 30.1% O  
 (b) 24.5% Na, 14.9% Si, and 60.6% F  
 (c) 62.1% C, 5.21% H, 12.1% N, and 20.7% O
- 3.47** What is the molecular formula of each of the following compounds?  
 (a) empirical formula  $CH_2$ , molar mass = 84 g/mol  
 (b) empirical formula  $NH_2Cl$ , molar mass = 51.5 g/mol
- 3.48** What is the molecular formula of each of the following compounds?  
 (a) empirical formula  $HCO_2$ , molar mass = 90.0 g/mol  
 (b) empirical formula  $C_2H_4O$ , molar mass = 88 g/mol
- 3.49** Determine the empirical and molecular formulas of each of the following substances:  
 (a) Styrene, a compound substance used to make Styrofoam<sup>®</sup> cups and insulation, contains 92.3% C and 7.7% H by mass and has a molar mass of 104 g/mol.  
 (b) Caffeine, a stimulant found in coffee, contains 49.5% C, 5.15% H, 28.9% N, and 16.5% O by mass and has a molar mass of 195 g/mol.  
 (c) Monosodium glutamate (MSG), a flavor enhancer in certain foods, contains 35.51% C, 4.77% H, 37.85% O, 8.29% N, and 13.60% Na, and has a molar mass of 169 g/mol.
- 3.50** Determine the empirical and molecular formulas of each of the following substances:  
 (a) Ibuprofen, a headache remedy, contains 75.69% C, 8.80% H, and 15.51% O by mass, and has a molar mass of 206 g/mol.  
 (b) Cadaverine, a foul smelling substance produced by the action of bacteria on meat, contains 58.55% C, 13.81% H, and 27.40% N by mass; its molar mass is 102.2 g/mol.  
 (c) Epinephrine (adrenaline), a hormone secreted into the bloodstream in times of danger or stress, contains 59.0% C, 7.1% H, 26.2% O, and 7.7% N by mass; its MW is about 180 amu.
- 3.51** (a) Combustion analysis of toluene, a common organic solvent, gives 5.86 mg of  $CO_2$  and 1.37 mg of  $H_2O$ . If the compound contains only carbon and hydrogen, what is its empirical formula? (b) Menthol, the substance we can smell in mentholated cough drops, is composed of C, H, and O. A 0.1005-g sample of menthol is combusted, producing 0.2829 g of  $CO_2$  and 0.1159 g of  $H_2O$ . What is the empirical formula for menthol? If menthol has a molar mass of 156 g/mol, what is its molecular formula?
- 3.52** (a) The characteristic odor of pineapple is due to ethyl butyrate, a compound containing carbon, hydrogen, and oxygen. Combustion of 2.78 mg of ethyl butyrate produces 6.32 mg of  $CO_2$  and 2.58 mg of  $H_2O$ . What is the empirical formula of the compound? (b) Nicotine, a component of tobacco, is composed of C, H, and N. A 5.250-mg sample of nicotine was combusted, producing 14.242 mg of  $CO_2$  and 4.083 mg of  $H_2O$ . What is the empirical formula for nicotine? If nicotine has a molar mass of  $160 \pm 5$  g/mol, what is its molecular formula?
- 3.53** Washing soda, a compound used to prepare hard water for washing laundry, is a hydrate, which means that a

certain number of water molecules are included in the solid structure. Its formula can be written as  $\text{Na}_2\text{CO}_3 \cdot x\text{H}_2\text{O}$ , where  $x$  is the number of moles of  $\text{H}_2\text{O}$  per mole of  $\text{Na}_2\text{CO}_3$ . When a 2.558-g sample of washing soda is heated at  $25^\circ\text{C}$ , all the water of hydration is lost, leaving 0.948 g of  $\text{Na}_2\text{CO}_3$ . What is the value of  $x$ ?

## Calculations Based on Chemical Equations

**3.55** Why is it essential to use balanced chemical equations when determining the quantity of a product formed from a given quantity of a reactant?

**3.56** What parts of balanced chemical equations give information about the relative numbers of moles of reactants and products involved in a reaction?

**3.57** Hydrofluoric acid,  $\text{HF}(aq)$ , cannot be stored in glass bottles because compounds called silicates in the glass are attacked by the  $\text{HF}(aq)$ . Sodium silicate ( $\text{Na}_2\text{SiO}_3$ ), for example, reacts as follows:

(a) How many moles of  $\text{HF}$  are needed to react with 0.300 mol of  $\text{Na}_2\text{SiO}_3$ ?

(b) How many grams of  $\text{NaF}$  form when 0.500 mol of  $\text{HF}$  reacts with excess  $\text{Na}_2\text{SiO}_3$ ?

(c) How many grams of  $\text{Na}_2\text{SiO}_3$  can react with 0.800 g of  $\text{HF}$ ?

**3.58** The fermentation of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) produces ethyl alcohol ( $\text{C}_2\text{H}_5\text{OH}$ ) and  $\text{CO}_2$ :

(a) How many moles of  $\text{CO}_2$  are produced when 0.400 mol of  $\text{C}_6\text{H}_{12}\text{O}_6$  reacts in this fashion?

(b) How many grams of  $\text{C}_6\text{H}_{12}\text{O}_6$  are needed to form 7.50 g of  $\text{C}_2\text{H}_5\text{OH}$ ?

(c) How many grams of  $\text{CO}_2$  form when 7.50 g of  $\text{C}_2\text{H}_5\text{OH}$  are produced?

**3.59** Several brands of antacids use  $\text{Al}(\text{OH})_3$  to react with stomach acid, which contains primarily  $\text{HCl}$ :

(a) Balance this equation.

(b) Calculate the number of grams of  $\text{HCl}$  that can react with 0.500 g of  $\text{Al}(\text{OH})_3$ .

(c) Calculate the number of grams of  $\text{AlCl}_3$  and the number of grams of  $\text{H}_2\text{O}$  formed when 0.500 g of  $\text{Al}(\text{OH})_3$  reacts.

(d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.

**3.60** An iron ore sample contains  $\text{Fe}_2\text{O}_3$  together with other substances. Reaction of the ore with  $\text{CO}$  produces iron metal:

(a) Balance this equation.

(b) Calculate the number of grams of  $\text{CO}$  that can react with 0.150 kg of  $\text{Fe}_2\text{O}_3$ .

(c) Calculate the number of grams of  $\text{Fe}$  and the number of grams of  $\text{CO}_2$  formed when 0.150 kg of  $\text{Fe}_2\text{O}_3$  reacts.

**3.54** Epsom salts, a strong laxative used in veterinary medicine, is a hydrate, which means that a certain number of water molecules are included in the solid structure. The formula for Epsom salts can be written as  $\text{MgSO}_4 \cdot x\text{H}_2\text{O}$ , where  $x$  indicates the number of moles of  $\text{H}_2\text{O}$  per mole of  $\text{MgSO}_4$ . When 5.061 g of this hydrate is heated to  $250^\circ\text{C}$ , all the water of hydration is lost, leaving 2.472 g of  $\text{MgSO}_4$ . What is the value of  $x$ ?

(d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.

**3.61** Aluminum sulfide reacts with water to form aluminum hydroxide and hydrogen sulfide. (a) Write the balanced chemical equation for this reaction. (b) How many grams of aluminum hydroxide are obtained from 14.2 g of aluminum sulfide?

**3.62** Calcium hydride reacts with water to form calcium hydroxide and hydrogen gas. (a) Write a balanced chemical equation for the reaction. (b) How many grams of calcium hydride are needed to form 8.500 g of hydrogen?

**3.63** Automotive air bags inflate when sodium azide,  $\text{NaN}_3$ , rapidly decomposes to its component elements:

(a) How many moles of  $\text{N}_2$  are produced by the decomposition of 1.50 mol of  $\text{NaN}_3$ ?

(b) How many grams of  $\text{NaN}_3$  are required to form 10.0 g of nitrogen gas?

(c) How many grams of  $\text{NaN}_3$  are required to produce 10.0  $\text{ft}^3$  of nitrogen gas, about the size of an automotive air bag, if the gas has a density of 1.25 g/L?

**3.64** The complete combustion of octane,  $\text{C}_8\text{H}_{18}$ , the main component of gasoline, proceeds as follows:

(a) How many moles of  $\text{O}_2$  are needed to burn 1.25 mol of  $\text{C}_8\text{H}_{18}$ ?

(b) How many grams of  $\text{O}_2$  are needed to burn 10.0 g of  $\text{C}_8\text{H}_{18}$ ?

(c) Octane has a density of 0.692 g/mL at  $20^\circ\text{C}$ . How many grams of  $\text{O}_2$  are required to burn 1.00 gal of  $\text{C}_8\text{H}_{18}$ ?

**3.65** A piece of aluminum foil 1.00 cm square and 0.550 mm thick is allowed to react with bromine to form aluminum bromide as shown in the accompanying photo.

(a) How many moles of aluminum were used? (The density of aluminum is  $2.699 \text{ g/cm}^3$ .) (b) How many grams of aluminum bromide form, assuming the aluminum reacts completely?

3.66 Detonation of nitroglycerin proceeds as follows:

(a) If a sample containing 2.00 mL of nitroglycerin (density =  $1.592 \text{ g/mL}$ ) is detonated, how many total moles of gas are produced? (b) If each mole of gas occupies 55 L under the conditions of the explosion, how many liters of gas are produced? (c) How many grams of  $\text{N}_2$  are produced in the detonation?

## Limiting Reactants; Theoretical Yields

3.67 (a) Define the terms *limiting reactant* and *excess reactant*. (b) Why are the amounts of products formed in a reaction determined only by the amount of the limiting reactant? (c) Why should you base your choice of what compound is the limiting reactant on its number of initial moles, not on its initial mass in grams?

3.68 (a) Define the terms *theoretical yield*, *actual yield*, and *percent yield*. (b) Why is the actual yield in a reaction almost always less than the theoretical yield? (c) Can a reaction ever have 110% actual yield?

3.69 A manufacturer of bicycles has 4815 wheels, 2305 frames, and 2255 handlebars. (a) How many bicycles can be manufactured using these parts? (b) How many parts of each kind are left over? (c) Which part limits the production of bicycles?

3.70 A bottling plant has 121,515 bottles with a capacity of 355 mL, 122,500 caps, and 40,875 L of beverage. (a) How many bottles can be filled and capped? (b) How much of each item is left over? (c) Which component limits the production?

3.71 Sodium hydroxide reacts with carbon dioxide as follows:

Which reagent is the limiting reactant when 1.85 mol NaOH and 1.00 mol  $\text{CO}_2$  are allowed to react? How many moles of  $\text{Na}_2\text{CO}_3$  can be produced? How many moles of the excess reactant remain after the completion of the reaction?

3.72 Aluminum hydroxide reacts with sulfuric acid as follows:

Which reagent is the limiting reactant when 0.500 mol  $\text{Al}(\text{OH})_3$  and 0.500 mol  $\text{H}_2\text{SO}_4$  are allowed to react? How many moles of  $\text{Al}_2(\text{SO}_4)_3$  can form under these conditions? How many moles of the excess reactant remain after the completion of the reaction?

3.73 The fizz produced when an Alka-Seltzer<sup>®</sup> tablet is dissolved in water is due to the reaction between sodium bicarbonate ( $\text{NaHCO}_3$ ) and citric acid ( $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$ ):

In a certain experiment 1.00 g of sodium bicarbonate and 1.00 g of citric acid are allowed to react. (a) Which is the limiting reactant? (b) How many grams of carbon dioxide form? (c) How many grams of the excess reac-

tant remain after the limiting reactant is completely consumed?

3.74 One of the steps in the commercial process for converting ammonia to nitric acid is the conversion of  $\text{NH}_3$  to NO:

In a certain experiment, 1.50 g of  $\text{NH}_3$  reacts with 2.75 g of  $\text{O}_2$ . (a) Which is the limiting reactant? (b) How many grams of NO and of  $\text{H}_2\text{O}$  form? (c) How many grams of the excess reactant remain after the limiting reactant is completely consumed? (d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.

3.75 Solutions of sodium carbonate and silver nitrate react to form solid silver carbonate and a solution of sodium nitrate. A solution containing 3.50 g of sodium carbonate is mixed with one containing 5.00 g of silver nitrate. How many grams of sodium carbonate, silver nitrate, silver carbonate, and sodium nitrate are present after the reaction is complete?

3.76 Solutions of sulfuric acid and lead(II) acetate react to form solid lead(II) sulfate and a solution of acetic acid. If 7.50 g of sulfuric acid and 7.50 g of lead(II) acetate are mixed, calculate the number of grams of sulfuric acid, lead(II) acetate, lead(II) sulfate, and acetic acid present in the mixture after the reaction is complete.

3.77 When benzene ( $\text{C}_6\text{H}_6$ ) reacts with bromine ( $\text{Br}_2$ ), bromobenzene ( $\text{C}_6\text{H}_5\text{Br}$ ) is obtained:

(a) What is the theoretical yield of bromobenzene in this reaction when 30.0 g of benzene reacts with 65.0 g of bromine? (b) If the actual yield of bromobenzene was 42.3 g, what was the percentage yield?

3.78 When ethane ( $\text{C}_2\text{H}_6$ ) reacts with chlorine ( $\text{Cl}_2$ ), the main product is  $\text{C}_2\text{H}_5\text{Cl}$ ; but other products containing Cl, such as  $\text{C}_2\text{H}_4\text{Cl}_2$ , are also obtained in small quantities. The formation of these other products reduces the yield

of  $C_2H_5Cl$ . (a) Calculate the theoretical yield of  $C_2H_5Cl$  when 125 g of  $C_2H_6$  reacts with 255 g of  $Cl_2$ , assuming that  $C_2H_6$  and  $Cl_2$  react only to form  $C_2H_5Cl$  and  $HCl$ . (b) Calculate the percent yield of  $C_2H_5Cl$  if the reaction produces 206 g of  $C_2H_5Cl$ .

- 3.79 Hydrogen sulfide is an impurity in natural gas that must be removed. One common removal method is called the Claus process, which relies on the reaction:

## ADDITIONAL EXERCISES

- 3.81 Write the balanced chemical equations for (a) the complete combustion of acetic acid ( $CH_3COOH$ ), the main active ingredient in vinegar; (b) the decomposition of solid calcium hydroxide into solid calcium(II) oxide (lime) and water vapor; (c) the combination reaction between nickel metal and chlorine gas.
- 3.82 The effectiveness of nitrogen fertilizers depends on both their ability to deliver nitrogen to plants and the amount of nitrogen they can deliver. Four common nitrogen-containing fertilizers are ammonia, ammonium nitrate, ammonium sulfate, and urea  $[(NH_2)_2CO]$ . Rank these fertilizers in terms of the mass percentage nitrogen they contain.
- 3.83 (a) Diamond is a natural form of pure carbon. How many moles of carbon are in a 1.25-carat diamond (1 carat = 0.200 g)? How many atoms are in this diamond? (b) The molecular formula of acetylsalicylic acid (aspirin), one of the most common pain relievers, is  $C_9H_8O_4$ . How many moles of  $C_9H_8O_4$  are in a 0.500-g tablet of aspirin? How many molecules of  $C_9H_8O_4$  are in this tablet?
- 3.84 (a) One molecule of the antibiotic known as penicillin G has a mass of  $5.342 \times 10^{-21}$  g. What is the molar mass of penicillin G? (b) Hemoglobin, the oxygen-carrying protein in red blood cells, has four iron atoms per molecule and contains 0.340% iron by mass. Calculate the molar mass of hemoglobin.
- 3.85 Very small crystals composed of 1000 to 100,000 atoms, called quantum dots, are being investigated for use in electronic devices.
- (a) A quantum dot was made of solid silicon in the shape of a sphere, with a diameter of 4 nm. Calculate the mass of the quantum dot, using the density of silicon ( $2.3 \text{ g/cm}^3$ ).
- (b) How many silicon atoms are in the quantum dot?
- (c) The density of germanium is  $5.325 \text{ g/cm}^3$ . If you made a 4 nm quantum dot of germanium, how many Ge atoms would it contain? Assume the dot is spherical.
- 3.86 Serotonin is a compound that conducts nerve impulses in the brain. It contains 68.2 mass percent C, 6.86 mass percent H, 15.9 mass percent N, and 9.08 mass percent O. Its molar mass is 176 g/mol. Determine its molecular formula.
- 3.87 The koala dines exclusively on eucalyptus leaves. Its digestive system detoxifies the eucalyptus oil, a poison to other animals. The chief constituent in eucalyptus oil is a substance called eucalyptol, which contains 77.87% C,

Under optimal conditions the Claus process gives 98% yield of  $S_8$  from  $H_2S$ . If you started with 30.0 grams of  $H_2S$  and 50.0 grams of  $O_2$ , how many grams of  $S_8$  would be produced, assuming 98% yield?

- 3.80 When hydrogen sulfide gas is bubbled into a solution of sodium hydroxide, the reaction forms sodium sulfide and water. How many grams of sodium sulfide are formed if 1.50 g of hydrogen sulfide is bubbled into a solution containing 2.00 g of sodium hydroxide, assuming that the sodium sulfide is made in 92.0% yield?

11.76% H, and the remainder O. (a) What is the empirical formula for this substance? (b) A mass spectrum of eucalyptol shows a peak at about 154 amu. What is the molecular formula of the substance?

- 3.88 Vanillin, the dominant flavoring in vanilla, contains C, H, and O. When 1.05 g of this substance is completely combusted, 2.43 g of  $CO_2$  and 0.50 g of  $H_2O$  are produced. What is the empirical formula of vanillin?
- [3.89] An organic compound was found to contain only C, H, and Cl. When a 1.50-g sample of the compound was completely combusted in air, 3.52 g of  $CO_2$  was formed. In a separate experiment the chlorine in a 1.00-g sample of the compound was converted to 1.27 g of  $AgCl$ . Determine the empirical formula of the compound.
- [3.90] An oxybromate compound,  $KBrO_x$ , where  $x$  is unknown, is analyzed and found to contain 52.92% Br. What is the value of  $x$ ?
- [3.91] An element X forms an iodide ( $XI_3$ ) and a chloride ( $XC l_3$ ). The iodide is quantitatively converted to the chloride when it is heated in a stream of chlorine:

If 0.5000 g of  $XI_3$  is treated, 0.2360 g of  $XCl_3$  is obtained. (a) Calculate the atomic weight of the element X. (b) Identify the element X.

- 3.92 If 1.5 mol of each of the following compounds is completely combusted in oxygen, which one will produce the largest number of moles of  $H_2O$ ? Which will produce the least? Explain.  $C_2H_5OH$ ,  $C_3H_8$ ,  $CH_3CH_2COCH_3$ .
- 3.93 A method used by the U.S. Environmental Protection Agency (EPA) for determining the concentration of ozone in air is to pass the air sample through a "bubbler" containing sodium iodide, which removes the ozone according to the following equation:

- (a) How many moles of sodium iodide are needed to remove  $5.95 \times 10^{-6}$  mol of  $O_3$ ? (b) How many grams of sodium iodide are needed to remove 1.3 mg of  $O_3$ ?
- 3.94 A chemical plant uses electrical energy to decompose aqueous solutions of  $NaCl$  to give  $Cl_2$ ,  $H_2$ , and  $NaOH$ :

If the plant produces  $1.5 \times 10^6$  kg (1500 metric tons) of  $Cl_2$  daily, estimate the quantities of  $H_2$  and  $NaOH$  produced.

- 3.95 The fat stored in the hump of a camel is a source of both energy and water. Calculate the mass of  $\text{H}_2\text{O}$  produced by metabolism of 1.0 kg of fat, assuming the fat consists entirely of tristearin ( $\text{C}_{57}\text{H}_{110}\text{O}_6$ ), a typical animal fat, and assuming that during metabolism, tristearin reacts with  $\text{O}_2$  to form only  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .
- [3.96] When hydrocarbons are burned in a limited amount of air, both  $\text{CO}$  and  $\text{CO}_2$  form. When 0.450 g of a particular hydrocarbon was burned in air, 0.467 g of  $\text{CO}$ , 0.733 g of  $\text{CO}_2$ , and 0.450 g of  $\text{H}_2\text{O}$  were formed. (a) What is the empirical formula of the compound? (b) How many grams of  $\text{O}_2$  were used in the reaction? (c) How many grams would have been required for complete combustion?
- 3.97 A mixture of  $\text{N}_2(\text{g})$  and  $\text{H}_2(\text{g})$  reacts in a closed container to form ammonia,  $\text{NH}_3(\text{g})$ . The reaction ceases before either reactant has been totally consumed. At this stage 3.0 mol  $\text{N}_2$ , 3.0 mol  $\text{H}_2$ , and 3.0 mol  $\text{NH}_3$  are present. How many moles of  $\text{N}_2$  and  $\text{H}_2$  were present originally?
- [3.98] A mixture containing  $\text{KClO}_3$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{KHCO}_3$ , and  $\text{KCl}$  was heated, producing  $\text{CO}_2$ ,  $\text{O}_2$ , and  $\text{H}_2\text{O}$  gases according to the following equations:
- $$2 \text{KClO}_3(\text{s}) \longrightarrow 2 \text{KCl}(\text{s}) + 3 \text{O}_2(\text{g})$$
- $$2 \text{KHCO}_3(\text{s}) \longrightarrow \text{K}_2\text{O}(\text{s}) + \text{H}_2\text{O}(\text{g}) + 2 \text{CO}_2(\text{g})$$
- $$\text{K}_2\text{CO}_3(\text{s}) \longrightarrow \text{K}_2\text{O}(\text{s}) + \text{CO}_2(\text{g})$$

## INTEGRATIVE EXERCISES

(These exercises require skills from earlier chapters as well as skills from the present chapter.)

- 3.101 Consider a sample of calcium carbonate in the form of a cube measuring 2.005 in. on each edge. If the sample has a density of 2.71  $\text{g}/\text{cm}^3$ , how many oxygen atoms does it contain?
- 3.102 (a) You are given a cube of silver metal that measures 1.000 cm on each edge. The density of silver is 10.5  $\text{g}/\text{cm}^3$ . How many atoms are in this cube? (b) Because atoms are spherical, they cannot occupy all of the space of the cube. The silver atoms pack in the solid in such a way that 74% of the volume of the solid is actually filled with the silver atoms. Calculate the volume of a single silver atom. (c) Using the volume of a silver atom and the formula for the volume of a sphere, calculate the radius in angstroms of a silver atom.
- 3.103 (a) If an automobile travels 225 mi with a gas mileage of 20.5 mi/gal, how many kilograms of  $\text{CO}_2$  are produced? Assume that the gasoline is composed of octane,  $\text{C}_8\text{H}_{18}(\text{l})$ , whose density is 0.69  $\text{g}/\text{mL}$ . (b) Repeat the calculation for a truck that has a gas mileage of 5 mi/gal.
- 3.104 In 1865 a chemist reported that he had reacted a weighed amount of pure silver with nitric acid and had recovered all the silver as pure silver nitrate. The mass ratio of silver to silver nitrate was found to be 0.634985. Using only this ratio and the presently accepted values for the atomic weights of silver and oxygen, calculate the atomic weight of nitrogen. Compare this calculated atomic weight with the currently accepted value.
- 3.105 A particular coal contains 2.5% sulfur by mass. When this coal is burned at a power plant, the sulfur is converted into sulfur dioxide gas, which is a pollutant. To reduce sulfur dioxide emissions, calcium oxide (lime) is used. The sulfur dioxide reacts with calcium oxide to form solid calcium sulfite. (a) Write the balanced chemical equation for the reaction. (b) If the coal is burned in a power plant that uses 2000 tons of coal per day, what mass of calcium oxide is required daily to eliminate the sulfur dioxide? (c) How many grams of calcium sulfite are produced daily by this power plant?
- 3.106 Copper is an excellent electrical conductor widely used in making electric circuits. In producing a printed circuit board for the electronics industry, a layer of copper is laminated on a plastic board. A circuit pattern is then printed on the board using a chemically resistant polymer. The board is then exposed to a chemical bath that reacts with the exposed copper, leaving the desired copper circuit, which has been protected by the overlying polymer. Finally, a solvent removes the polymer. One reaction used to remove the exposed copper from the circuit board is
- $$\text{Cu}(\text{s}) + \text{Cu}(\text{NH}_3)_4\text{Cl}_2(\text{aq}) + 4 \text{NH}_3(\text{aq}) \longrightarrow 2 \text{Cu}(\text{NH}_3)_4\text{Cl}(\text{aq})$$
- A plant needs to produce 5000 circuit boards, each with a surface area measuring 2.0 in.  $\times$  3.0 in. The boards are covered with a 0.65-mm layer of copper. In subsequent processing, 85% of the copper is removed. Copper has a density of 8.96  $\text{g}/\text{cm}^3$ . Calculate the masses of  $\text{Cu}(\text{NH}_3)_4\text{Cl}_2$  and  $\text{NH}_3$  needed to produce the circuit boards, assuming that the reaction used gives a 97% yield.
- 3.107 Hydrogen cyanide,  $\text{HCN}$ , is a poisonous gas. The lethal dose is approximately 300 mg  $\text{HCN}$  per kilogram of air

The  $\text{KCl}$  does not react under the conditions of the reaction. If 100.0 g of the mixture produces 1.80 g of  $\text{H}_2\text{O}$ , 13.20 g of  $\text{CO}_2$ , and 4.00 g of  $\text{O}_2$ , what was the composition of the original mixture? (Assume complete decomposition of the mixture.)

- 3.99 When a mixture of 10.0 g of acetylene ( $\text{C}_2\text{H}_2$ ) and 10.0 g of oxygen ( $\text{O}_2$ ) is ignited, the resultant combustion reaction produces  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . (a) Write the balanced chemical equation for this reaction. (b) Which is the limiting reactant? (c) How many grams of  $\text{C}_2\text{H}_2$ ,  $\text{O}_2$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$  are present after the reaction is complete?
- 3.100 Aspirin ( $\text{C}_9\text{H}_8\text{O}_4$ ) is produced from salicylic acid ( $\text{C}_7\text{H}_6\text{O}_3$ ) and acetic anhydride ( $\text{C}_4\text{H}_6\text{O}_3$ ):

(a) How much salicylic acid is required to produce  $1.5 \times 10^2$  kg of aspirin, assuming that all of the salicylic acid is converted to aspirin? (b) How much salicylic acid would be required if only 80% of the salicylic acid is converted to aspirin? (c) What is the theoretical yield of aspirin if 185 kg of salicylic acid is allowed to react with 125 kg of acetic anhydride? (d) If the situation described in part (c) produces 182 kg of aspirin, what is the percentage yield?

when inhaled. (a) Calculate the amount of HCN that gives the lethal dose in a small laboratory room measuring  $12 \times 15 \times 8.0$  ft. The density of air at  $26^\circ\text{C}$  is  $0.00118\text{ g/cm}^3$ . (b) If the HCN is formed by reaction of NaCN with an acid such as  $\text{H}_2\text{SO}_4$ , what mass of NaCN gives the lethal dose in the room?

(c) HCN forms when synthetic fibers containing Orlon<sup>®</sup> or Acrilan<sup>®</sup> burn. Acrilan<sup>®</sup> has an empirical formula of  $\text{CH}_2\text{CHCN}$ , so HCN is 50.9% of the formula by mass. A rug measures  $12 \times 15$  ft and contains 30 oz of Acrilan<sup>®</sup> fibers per square yard of carpet. If the rug burns, will a lethal dose of HCN be generated in the room? Assume that the yield of HCN from the fibers is 20% and that the carpet is 50% consumed.

- 3.108 The source of oxygen that drives the internal combustion engine in an automobile is air. Air is a mixture of gases, which are principally  $\text{N}_2$  (~79%) and  $\text{O}_2$  (~20%).

In the cylinder of an automobile engine, nitrogen can react with oxygen to produce nitric oxide gas, NO. As NO is emitted from the tailpipe of the car, it can react with more oxygen to produce nitrogen dioxide gas. (a) Write balanced chemical equations for both reactions. (b) Both nitric oxide and nitrogen dioxide are pollutants that can lead to acid rain and global warming; collectively, they are called "NO<sub>x</sub>" gases. In 2004, the United States emitted an estimated 19 million tons of nitrogen dioxide into the atmosphere. How many grams of nitrogen dioxide is this? (c) The production of NO<sub>x</sub> gases is an unwanted side reaction of the main engine combustion process that turns octane,  $\text{C}_8\text{H}_{18}$ , into  $\text{CO}_2$  and water. If 85% of the oxygen in an engine is used to combust octane, and the remainder used to produce nitrogen dioxide, calculate how many grams of nitrogen dioxide would be produced during the combustion of 500 grams of octane.

CHAPTER  
4

AQUEOUS REACTIONS  
AND SOLUTION  
STOICHIOMETRY

A VIEW OF THE PACIFIC OCEAN along the California coastline.

## WHAT'S AHEAD

---

### 4.1 General Properties of Aqueous Solutions

We begin by examining the nature of the substances dissolved in water, whether they exist in water as ions, molecules, or some mixture of the two. This information is necessary to understand the nature of reactants in aqueous solutions.

### 4.2 Precipitation Reactions

We will identify reactions in which soluble reactants yield an insoluble product.

### 4.3 Acid–Base Reactions

We will explore reactions in which protons,  $H^+$  ions, are transferred between reactants.

### 4.4 Oxidation-Reduction Reactions

We will examine reactions in which electrons are transferred between reactants.

### 4.5 Concentrations of Solutions

We will recognize that the amount of a compound in a given volume of a solution is called its *concentration*. Concentration can be expressed in a number of ways, the most usual of which is moles of compound per liter of solution (*molarity*).

### 4.6 Solution Stoichiometry and Chemical Analysis

We will use what we have learned about stoichiometry and concentration to calculate the amounts or concentrations of substances in solution.

**THE WATERS OF THE PACIFIC OCEAN**, seen in this chapter-opening photograph of the California coast, are part of the World Ocean that covers almost two-thirds of our planet. Water has been the key to much of Earth's evolutionary history. Life itself almost certainly originated in water, and the

need for water by all forms of life has helped determine diverse biological structures. Your own body is about 60% water by mass. We will see repeatedly throughout this text that water possesses many unusual properties essential to supporting life on Earth.

The waters of the World Ocean may not appear to be any different from those of Lake Tahoe or the water that flows from your kitchen faucet, but a taste of seawater is all it takes to demonstrate that there is an important difference. Water has an exceptional ability to dissolve a wide variety of substances. Water on Earth—whether it is drinking water from the tap, water from a clear mountain stream, or seawater—invariably contains a variety of dissolved substances. A solution in which water is the dissolving medium is called an **aqueous solution**. Seawater is different from what we call “freshwater” because it has a much higher total concentration of dissolved ionic substances.

Water is the medium for most of the chemical reactions that take place within us and around us. Nutrients dissolved in blood are carried to our cells, where they enter into reactions that help keep us alive. Automobile parts rust

▲ **Figure 4.1 Limestone cave.** When  $\text{CO}_2$  dissolves in water, the resulting solution is slightly acidic. Limestone caves are formed by the dissolving action of this acidic solution acting on  $\text{CaCO}_3$  in the limestone.

when they come into frequent contact with aqueous solutions that contain various dissolved substances. Spectacular limestone caves (Figure 4.1 ◀) are formed by the dissolving action of underground water containing carbon dioxide,  $\text{CO}_2(aq)$ :

In Chapter 3 we saw a few simple types of chemical reactions and their descriptions. In this chapter we continue to examine chemical reactions by focusing on aqueous solutions. A great deal of important chemistry occurs in aqueous solutions, so we need to learn the vocabulary and concepts used to describe and understand this chemistry. In addition, we will extend the concepts of stoichiometry that we learned in Chapter 3 by considering how solution concentrations are expressed and used.

## 4.1 GENERAL PROPERTIES OF AQUEOUS SOLUTIONS

Recall that a *solution* is a homogeneous mixture of two or more substances. ⇌ (Section 1.2) The substance present in the greatest quantity is usually called the **solvent**. The other substances in the solution are called the **solutes**; they are said to be dissolved in the solvent. When a small amount of sodium chloride ( $\text{NaCl}$ ) is dissolved in a large quantity of water, for example, the water is the solvent and the sodium chloride is the solute.

### Electrolytic Properties

Imagine preparing two aqueous solutions—one by dissolving a teaspoon of table salt (sodium chloride) in a cup of water and the other by dissolving a teaspoon of table sugar (sucrose) in a cup of water. Both solutions are clear and colorless. How do they differ? One way, which might not be immediately obvious, is in their electrical conductivity: The salt solution is a good conductor of electricity; the sugar solution is not.

Whether a solution conducts electricity can be determined by using a device such as that shown in Figure 4.2 ▶. To light the bulb, an electric current must flow between the two electrodes that are immersed in the solution. Although water itself is a poor conductor of electricity, the presence of ions causes aqueous solutions to become good conductors. Ions carry electrical charge from one electrode to the other, completing the electrical circuit. Thus, the conductivity of  $\text{NaCl}$  solutions indicates the presence of ions in the solution. The lack of conductivity of sucrose solutions indicates the absence of ions. When  $\text{NaCl}$  dissolves in water, the solution contains  $\text{Na}^+$  and  $\text{Cl}^-$  ions, each surrounded by water molecules. When sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) dissolves in water, the solution contains only neutral sucrose molecules surrounded by water molecules.

A substance (such as  $\text{NaCl}$ ) whose aqueous solutions contain ions is called an **electrolyte**. A substance (such as  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) that does not form ions in solution is called a **nonelectrolyte**. The difference between  $\text{NaCl}$  and  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  arises largely because  $\text{NaCl}$  is ionic, whereas  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  is molecular.

### Ionic Compounds in Water

Recall from Section 2.7 and especially Figure 2.23 that solid  $\text{NaCl}$  consists of an orderly arrangement of  $\text{Na}^+$  and  $\text{Cl}^-$  ions. When  $\text{NaCl}$  dissolves in water, each ion separates from the solid structure and disperses throughout the solution, as shown in Figure 4.3(a) ▶. The ionic solid *dissociates* into its component ions as it dissolves.

### ELECTROLYTIC PROPERTIES

One way to differentiate two aqueous solutions is to employ a device that measures their electrical conductivities. The ability of a solution to conduct electricity depends on the number of ions it contains. An electrolyte solution contains ions that serve as charge carriers, causing the bulb to light.

▲ **Figure 4.2** Measuring ion concentrations using conductivity.

▲ **Figure 4.3** Dissolution in water. (a) When an ionic compound dissolves in water,  $\text{H}_2\text{O}$  molecules separate, surround, and disperse the ions into the liquid. (b) Methanol,  $\text{CH}_3\text{OH}$ , a molecular compound, dissolves without forming ions. The methanol molecules contain black spheres, which represent carbon atoms. In both parts (a) and (b) the water molecules have been moved apart so that the solute particles can be seen more clearly.

Water is a very effective solvent for ionic compounds. Although water is an electrically neutral molecule, one end of the molecule (the O atom) is rich in electrons and has a partial negative charge, denoted by  $\delta^-$ . The other end (the H atoms) has a partial positive charge, denoted by  $\delta^+$  as shown in the margin. Positive ions (cations) are attracted by the negative end of  $\text{H}_2\text{O}$ , and negative ions (anions) are attracted by the positive end.

As an ionic compound dissolves, the ions become surrounded by  $\text{H}_2\text{O}$  molecules, as shown in Figure 4.3(a). The ions are said to be solvated. We denote these ions in chemical equations by writing them as  $\text{Na}^+(\text{aq})$  and  $\text{Cl}^-(\text{aq})$ , where “aq” is an abbreviation for “aqueous.” [↔ \(Section 3.1\)](#) The **solvation** process helps stabilize the ions in solution and prevents cations and anions from recombining. Furthermore, because the ions and their shells of surrounding water molecules are free to move about, the ions become dispersed uniformly throughout the solution.

We can usually predict the nature of the ions present in a solution of an ionic compound from the chemical name of the substance. Sodium sulfate ( $\text{Na}_2\text{SO}_4$ ), for example, dissociates into sodium ions ( $\text{Na}^+$ ) and sulfate ions ( $\text{SO}_4^{2-}$ ). You must remember the formulas and charges of common ions (Tables 2.4 and 2.5) to understand the forms in which ionic compounds exist in aqueous solution.

### GIVE IT SOME THOUGHT

What dissolved species are present in a solution of (a) KCN, (b)  $\text{NaClO}_4$ ?

## Molecular Compounds in Water

When a molecular compound dissolves in water, the solution usually consists of intact molecules dispersed throughout the solution. Consequently, most molecular compounds are nonelectrolytes. As we have seen, table sugar (sucrose) is an example of a nonelectrolyte. As another example, a solution of methanol ( $\text{CH}_3\text{OH}$ ) in water consists entirely of  $\text{CH}_3\text{OH}$  molecules dispersed throughout the water [Figure 4.3(b)].

A few molecular substances, however, have aqueous solutions that contain ions. Acids are the most important of these solutions. For example, when  $\text{HCl}(\text{g})$  dissolves in water to form hydrochloric acid,  $\text{HCl}(\text{aq})$ , it *ionizes*; that is, it dissociates into  $\text{H}^+(\text{aq})$  and  $\text{Cl}^-(\text{aq})$  ions.

## Strong and Weak Electrolytes

Two categories of electrolytes—strong and weak—differ in the extent to which they conduct electricity. **Strong electrolytes** are those solutes that exist in solution completely or nearly completely as ions. Essentially all soluble ionic compounds (such as NaCl) and a few molecular compounds (such as HCl) are strong electrolytes. **Weak electrolytes** are those solutes that exist in solution mostly in the form of molecules with only a small fraction in the form of ions. For example, in a solution of acetic acid ( $\text{CH}_3\text{COOH}$ ) most of the solute is present as  $\text{CH}_3\text{COOH}(\text{aq})$  molecules. Only a small fraction (about 1%) of the  $\text{CH}_3\text{COOH}$  is present as  $\text{H}^+(\text{aq})$  and  $\text{CH}_3\text{COO}^-(\text{aq})$  ions.\*

We must be careful not to confuse the extent to which an electrolyte dissolves with whether it is strong or weak. For example,  $\text{CH}_3\text{COOH}$  is extremely soluble in water but is a weak electrolyte.  $\text{Ba}(\text{OH})_2$ , on the other hand, is not very soluble, but the amount of the substance that does dissolve dissociates almost completely. Thus,  $\text{Ba}(\text{OH})_2$  is a strong electrolyte.

\*The chemical formula of acetic acid is sometimes written as  $\text{HC}_2\text{H}_3\text{O}_2$  with the acidic H written in front of the chemical formula, so the formula looks like that of other common acids such as HCl. The formula  $\text{CH}_3\text{COOH}$  conforms to the molecular structure of acetic acid, with the acidic H on the O atom at the end of the formula.

When a weak electrolyte such as acetic acid ionizes in solution, we write the reaction in the following manner:

The half-arrows in both directions mean that the reaction is significant in both directions. At any given moment some  $\text{CH}_3\text{COOH}$  molecules are ionizing to form  $\text{H}^+$  and  $\text{CH}_3\text{COO}^-$  ions. At the same time,  $\text{H}^+$  and  $\text{CH}_3\text{COO}^-$  ions are recombining to form  $\text{CH}_3\text{COOH}$ . The balance between these opposing processes determines the relative numbers of ions and neutral molecules. This balance produces a state of **chemical equilibrium** in which the relative numbers of each type of ion or molecule in the reaction are constant over time. This equilibrium condition varies from one weak electrolyte to another. Chemical equilibria are extremely important. We will devote Chapters 15–17 to examining them in detail.

Chemists use half-arrows in both directions to represent the ionization of weak electrolytes and a single arrow to represent the ionization of strong electrolytes. Because HCl is a strong electrolyte, we write the equation for the ionization of HCl as follows:

The absence of a reverse arrow indicates that the  $\text{H}^+$  and  $\text{Cl}^-$  ions have no tendency to recombine in water to form HCl molecules.

In the following sections we will look more closely at how we can use the composition of a compound to predict whether it is a strong electrolyte, weak electrolyte, or nonelectrolyte. For the moment, you need only to remember that *soluble ionic compounds are strong electrolytes*. We identify ionic compounds as those composed of metals and nonmetals—such as NaCl,  $\text{FeSO}_4$ , and  $\text{Al}(\text{NO}_3)_3$ —or compounds containing the ammonium ion,  $\text{NH}_4^+$ —such as  $\text{NH}_4\text{Br}$  and  $(\text{NH}_4)_2\text{CO}_3$ .

### GIVE IT SOME THOUGHT

Which solute will cause the lightbulb in the experiment shown in Figure 4.2 to glow more brightly,  $\text{CH}_3\text{OH}$  or  $\text{MgBr}_2$ ?

#### SAMPLE EXERCISE 4.1 Relating Relative Numbers of Anions and Cations to Chemical Formulas

The diagram on the right represents an aqueous solution of one of the following compounds:  $\text{MgCl}_2$ , KCl, or  $\text{K}_2\text{SO}_4$ . Which solution does the drawing best represent?

#### SOLUTION

**Analyze:** We are asked to associate the charged spheres in the diagram with ions present in a solution of an ionic substance.

**Plan:** We examine the ionic substances given in the problem to determine the relative numbers and charges of the ions that each contains. We then correlate these charged ionic species with the ones shown in the diagram.

**Solve:** The diagram shows twice as many cations as anions, consistent with the formulation  $\text{K}_2\text{SO}_4$ .

**Check:** Notice that the total net charge in the diagram is zero, as it must be if it is to represent an ionic substance.

#### PRACTICE EXERCISE

If you were to draw diagrams (such as that shown on the right) representing aqueous solutions of each of the following ionic compounds, how many anions would you show if the diagram contained six cations? (a)  $\text{NiSO}_4$ , (b)  $\text{Ca}(\text{NO}_3)_2$ , (c)  $\text{Na}_3\text{PO}_4$ , (d)  $\text{Al}_2(\text{SO}_4)_3$

**Answers:** (a) 6, (b) 12, (c) 2, (d) 9

## 4.2 PRECIPITATION REACTIONS

Figure 4.4▼ shows two clear solutions being mixed. One solution contains lead nitrate,  $\text{Pb}(\text{NO}_3)_2$ , and the other contains potassium iodide (KI). The reaction between these two solutes produces an insoluble yellow product. Reactions that result in the formation of an insoluble product are called **precipitation reactions**. A **precipitate** is an insoluble solid formed by a reaction in solution. In Figure 4.4 the precipitate is lead iodide ( $\text{PbI}_2$ ), a compound that has a very low solubility in water:

The other product of this reaction, potassium nitrate ( $\text{KNO}_3$ ), remains in solution.

Precipitation reactions occur when certain pairs of oppositely charged ions attract each other so strongly that they form an insoluble ionic solid. To predict whether certain combinations of ions form insoluble compounds, we must consider some guidelines concerning the solubilities of common ionic compounds.

### Solubility Guidelines for Ionic Compounds

The **solubility** of a substance at a given temperature is the amount of the substance that can be dissolved in a given quantity of solvent at the given temperature.

▼ **Figure 4.4** A precipitation reaction.

TABLE 4.1 ■ Solubility Guidelines for Common Ionic Compounds in Water

Soluble Ionic Compounds		Important Exceptions
Compounds containing	$\text{NO}_3^-$	None
	$\text{CH}_3\text{COO}^-$	None
	$\text{Cl}^-$	Compounds of $\text{Ag}^+$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$
	$\text{Br}^-$	Compounds of $\text{Ag}^+$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$
	$\text{I}^-$	Compounds of $\text{Ag}^+$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$
	$\text{SO}_4^{2-}$	Compounds of $\text{Sr}^{2+}$ , $\text{Ba}^{2+}$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$
Insoluble Ionic Compounds		Important Exceptions
Compounds containing	$\text{S}^{2-}$	Compounds of $\text{NH}_4^+$ , the alkali metal cations, and $\text{Ca}^{2+}$ , $\text{Sr}^{2+}$ , and $\text{Ba}^{2+}$
	$\text{CO}_3^{2-}$	Compounds of $\text{NH}_4^+$ and the alkali metal cations
	$\text{PO}_4^{3-}$	Compounds of $\text{NH}_4^+$ and the alkali metal cations
	$\text{OH}^-$	Compounds of the alkali metal cations, and $\text{NH}_4^+$ , $\text{Ca}^{2+}$ , $\text{Sr}^{2+}$ , and $\text{Ba}^{2+}$

For instance, only  $1.2 \times 10^{-3}$  mol of  $\text{PbI}_2$  dissolves in a liter of water at 25 °C. In our discussions, any substance with a solubility less than 0.01 mol/L will be referred to as *insoluble*. In those cases the attraction between the oppositely charged ions in the solid is too great for the water molecules to separate the ions to any significant extent; the substance remains largely undissolved.

Unfortunately, there are no rules based on simple physical properties such as ionic charge to guide us in predicting whether a particular ionic compound will be soluble. Experimental observations, however, have led to guidelines for predicting solubility for ionic compounds. For example, experiments show that all common ionic compounds that contain the nitrate anion,  $\text{NO}_3^-$ , are soluble in water. Table 4.1 summarizes the solubility guidelines for common ionic compounds. The table is organized according to the anion in the compound, but it also reveals many important facts about cations. Note that *all common ionic compounds of the alkali metal ions (group 1A of the periodic table) and of the ammonium ion ( $\text{NH}_4^+$ ) are soluble in water.*

#### ■ SAMPLE EXERCISE 4.2 | Using Solubility Rules

Classify the following ionic compounds as soluble or insoluble in water: (a) sodium carbonate ( $\text{Na}_2\text{CO}_3$ ), (b) lead sulfate ( $\text{PbSO}_4$ ).

#### SOLUTION

**Analyze:** We are given the names and formulas of two ionic compounds and asked to predict whether they are soluble or insoluble in water.

**Plan:** We can use Table 4.1 to answer the question. Thus, we need to focus on the anion in each compound because the table is organized by anions.

#### Solve:

(a) According to Table 4.1, most carbonates are insoluble. But carbonates of the alkali metal cations (such as sodium ion) are an exception to this rule and are soluble. Thus,  $\text{Na}_2\text{CO}_3$  is soluble in water.

(b) Table 4.1 indicates that although most sulfates are water soluble, the sulfate of  $\text{Pb}^{2+}$  is an exception. Thus,  $\text{PbSO}_4$  is insoluble in water.

#### ■ PRACTICE EXERCISE

Classify the following compounds as soluble or insoluble in water: (a) cobalt(II) hydroxide, (b) barium nitrate, (c) ammonium phosphate.

**Answers:** (a) insoluble, (b) soluble, (c) soluble

To predict whether a precipitate forms when we mix aqueous solutions of two strong electrolytes, we must (1) note the ions present in the reactants, (2) consider the possible combinations of the cations and anions, and (3) use Table 4.1 to determine if any of these combinations is insoluble. For example, will a precipitate form when solutions of  $\text{Mg}(\text{NO}_3)_2$  and  $\text{NaOH}$  are mixed? Both  $\text{Mg}(\text{NO}_3)_2$  and  $\text{NaOH}$  are soluble ionic compounds and strong electrolytes. Mixing  $\text{Mg}(\text{NO}_3)_2(\text{aq})$  and  $\text{NaOH}(\text{aq})$  first produces a solution containing  $\text{Mg}^{2+}$ ,  $\text{NO}_3^-$ ,  $\text{Na}^+$ , and  $\text{OH}^-$  ions. Will either of the cations interact with either of the anions to form an insoluble compound? In addition to the reactants, the other possible interactions are  $\text{Mg}^{2+}$  with  $\text{OH}^-$  and  $\text{Na}^+$  with  $\text{NO}_3^-$ . From Table 4.1 we see that hydroxides are generally insoluble. Because  $\text{Mg}^{2+}$  is not an exception,  $\text{Mg}(\text{OH})_2$  is insoluble and will thus form a precipitate.  $\text{NaNO}_3$ , however, is soluble, so  $\text{Na}^+$  and  $\text{NO}_3^-$  will remain in solution. The balanced equation for the precipitation reaction is

### Exchange (Metathesis) Reactions

Notice in Equation 4.5 that the cations in the two reactants exchange anions— $\text{Mg}^{2+}$  ends up with  $\text{OH}^-$ , and  $\text{Na}^+$  ends up with  $\text{NO}_3^-$ . The chemical formulas of the products are based on the charges of the ions—two  $\text{OH}^-$  ions are needed to give a neutral compound with  $\text{Mg}^{2+}$ , and one  $\text{NO}_3^-$  ion is needed to give a neutral compound with  $\text{Na}^+$ .  $\rightleftharpoons$  (Section 2.7) The equation can be balanced only after the chemical formulas of the products have been determined.

Reactions in which positive ions and negative ions appear to exchange partners conform to the following general equation:

Such reactions are called **exchange reactions**, or **metathesis reactions** (meh-TATH-eh-sis, which is the Greek word for “to transpose”). Precipitation reactions conform to this pattern, as do many acid–base reactions, as we will see in Section 4.3.

To complete and balance a metathesis equation, we follow these steps:

1. Use the chemical formulas of the reactants to determine the ions that are present.
2. Write the chemical formulas of the products by combining the cation from one reactant with the anion of the other. (Use the charges of the ions to determine the subscripts in the chemical formulas.)
3. Finally, balance the equation.

#### **SAMPLE EXERCISE 4.3** | Predicting a Metathesis Reaction

- (a) Predict the identity of the precipitate that forms when solutions of  $\text{BaCl}_2$  and  $\text{K}_2\text{SO}_4$  are mixed.
- (b) Write the balanced chemical equation for the reaction.

#### **SOLUTION**

**Analyze:** We are given two ionic reactants and asked to predict the insoluble product that they form.

**Plan:** We need to write down the ions present in the reactants and to exchange the anions between the two cations. Once we have written the chemical formulas for these products, we can use Table 4.1 to determine which is insoluble in water. Knowing the products also allows us to write the equation for the reaction.

#### **Solve:**

(a) The reactants contain  $\text{Ba}^{2+}$ ,  $\text{Cl}^-$ ,  $\text{K}^+$ , and  $\text{SO}_4^{2-}$  ions. If we exchange the anions, we will have  $\text{BaSO}_4$  and  $\text{KCl}$ . According to Table 4.1, most compounds of  $\text{SO}_4^{2-}$  are soluble but those of  $\text{Ba}^{2+}$  are not. Thus,  $\text{BaSO}_4$  is insoluble and will precipitate from solution.  $\text{KCl}$ , on the other hand, is soluble.

(b) From part (a) we know the chemical formulas of the products,  $\text{BaSO}_4$  and  $\text{KCl}$ . The balanced equation with phase labels shown is

### ■ PRACTICE EXERCISE

(a) What compound precipitates when solutions of  $\text{Fe}_2(\text{SO}_4)_3$  and  $\text{LiOH}$  are mixed? (b) Write a balanced equation for the reaction. (c) Will a precipitate form when solutions of  $\text{Ba}(\text{NO}_3)_2$  and  $\text{KOH}$  are mixed?

**Answers:** (a)  $\text{Fe}(\text{OH})_3$ ; (b)  $\text{Fe}_2(\text{SO}_4)_3(aq) + 6 \text{LiOH}(aq) \longrightarrow 2 \text{Fe}(\text{OH})_3(s) + 3 \text{Li}_2\text{SO}_4(aq)$ ; (c) no (both possible products are water soluble)

## Ionic Equations

In writing chemical equations for reactions in aqueous solution, it is often useful to indicate explicitly whether the dissolved substances are present predominantly as ions or as molecules. Let's reconsider the precipitation reaction between  $\text{Pb}(\text{NO}_3)_2$  and 2  $\text{KI}$ , shown previously in Figure 4.4:

An equation written in this fashion, showing the complete chemical formulas of the reactants and products, is called a **molecular equation** because it shows the chemical formulas of the reactants and products without indicating their ionic character. Because  $\text{Pb}(\text{NO}_3)_2$ ,  $\text{KI}$ , and  $\text{KNO}_3$  are all soluble ionic compounds and therefore strong electrolytes, we can write the chemical equation to indicate explicitly the ions that are in the solution:

An equation written in this form, with all soluble strong electrolytes shown as ions, is called a **complete ionic equation**.

Notice that  $\text{K}^+(aq)$  and  $\text{NO}_3^-(aq)$  appear on both sides of Equation 4.7. Ions that appear in identical forms among both the reactants and products of a complete ionic equation are called **spectator ions**. These ions are present but play no direct role in the reaction. When spectator ions are omitted from the equation (they cancel out like algebraic quantities), we are left with the **net ionic equation**:

A net ionic equation includes only the ions and molecules directly involved in the reaction. Charge is conserved in reactions, so the sum of the charges of the ions must be the same on both sides of a balanced net ionic equation. In this case the 2+ charge of the cation and the two 1- charges of the anions add to give zero, the charge of the electrically neutral product. *If every ion in a complete ionic equation is a spectator, then no reaction occurs.*

### GIVE IT SOME THOUGHT

Are any spectator ions shown in the following chemical equation?

Net ionic equations are widely used to illustrate the similarities between large numbers of reactions involving electrolytes. For example, Equation 4.8 expresses the essential feature of the precipitation reaction between any strong electrolyte containing  $\text{Pb}^{2+}$  and any strong electrolyte containing  $\text{I}^-$ : The  $\text{Pb}^{2+}(aq)$  and  $\text{I}^-(aq)$  ions combine to form a precipitate of  $\text{PbI}_2$ . Thus, a net ionic equation demonstrates that more than one set of reactants can lead to the same net reaction. For example, aqueous solutions of  $\text{KI}$  and  $\text{MgI}_2$  share many chemical similarities because both contain  $\text{I}^-$  ions. The complete equation, on the other hand, identifies the actual reactants that participate in a reaction.

The following steps summarize the procedure for writing net ionic equations:

1. Write a balanced molecular equation for the reaction.
2. Rewrite the equation to show the ions that form in solution when each soluble strong electrolyte dissociates into its component ions. *Only strong electrolytes dissolved in aqueous solution are written in ionic form.*
3. Identify and cancel spectator ions.

#### ■ SAMPLE EXERCISE 4.4 | Writing a Net Ionic Equation

Write the net ionic equation for the precipitation reaction that occurs when solutions of calcium chloride and sodium carbonate are mixed.

#### SOLUTION

**Analyze:** Our task is to write a net ionic equation for a precipitation reaction, given the names of the reactants present in solution.

**Plan:** We first need to write the chemical formulas of the reactants and products and then determine which product is insoluble. We then write and balance the molecular equation. Next, we write each soluble strong electrolyte as separated ions to obtain the complete ionic equation. Finally, we eliminate the spectator ions to obtain the net ionic equation.

**Solve:** Calcium chloride is composed of calcium ions,  $\text{Ca}^{2+}$ , and chloride ions,  $\text{Cl}^-$ ; hence an aqueous solution of the substance is  $\text{CaCl}_2(\text{aq})$ . Sodium carbonate is composed of  $\text{Na}^+$  ions and  $\text{CO}_3^{2-}$  ions; hence an aqueous solution of the compound is  $\text{Na}_2\text{CO}_3(\text{aq})$ . In the molecular equations for precipitation reactions, the anions and cations appear to exchange partners. Thus, we put  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  together to give  $\text{CaCO}_3$  and  $\text{Na}^+$  and  $\text{Cl}^-$  together to give  $\text{NaCl}$ . According to the solubility guidelines in Table 4.1,  $\text{CaCO}_3$  is insoluble and  $\text{NaCl}$  is soluble. The balanced molecular equation is

In a complete ionic equation, *only* dissolved strong electrolytes (such as soluble ionic compounds) are written as separate ions. As the (aq) designations remind us,  $\text{CaCl}_2$ ,  $\text{Na}_2\text{CO}_3$ , and  $\text{NaCl}$  are all dissolved in the solution. Furthermore, they are all strong electrolytes.  $\text{CaCO}_3$  is an ionic compound, but it is not soluble. We do not write the formula of any insoluble compound as its component ions. Thus, the complete ionic equation is

$\text{Cl}^-$  and  $\text{Na}^+$  are spectator ions. Canceling them gives the following net ionic equation:

**Check:** We can check our result by confirming that both the elements and the electric charge are balanced. Each side has one Ca, one C, and three O, and the net charge on each side equals 0.

**Comment:** If none of the ions in an ionic equation is removed from solution or changed in some way, then they all are spectator ions and a reaction does not occur.

#### ■ PRACTICE EXERCISE

Write the net ionic equation for the precipitation reaction that occurs when aqueous solutions of silver nitrate and potassium phosphate are mixed.

**Answers:**  $3 \text{Ag}^+(\text{aq}) + \text{PO}_4^{3-}(\text{aq}) \longrightarrow \text{Ag}_3\text{PO}_4(\text{s})$

▲ **Figure 4.5** Some common household acids (left) and bases (right).

## 4.3 ACID-BASE REACTIONS

Many acids and bases are industrial and household substances (Figure 4.5 ◀), and some are important components of biological fluids. Hydrochloric acid, for example, is an important industrial chemical and the main constituent of gastric juice in your stomach. Acids and bases are also common electrolytes.

## Acids

**Acids** are substances that ionize in aqueous solutions to form hydrogen ions, thereby increasing the concentration of  $\text{H}^+(aq)$  ions. Because a hydrogen atom consists of a proton and an electron,  $\text{H}^+$  is simply a proton. Thus, acids are often called proton donors. Molecular models of three common acids,  $\text{HCl}$ ,  $\text{HNO}_3$  and  $\text{CH}_3\text{COOH}$ , are shown in the margin.

Just as cations are surrounded and bound by water molecules (see Figure 4.3[a]), the proton is also solvated by water molecules. The nature of the proton in water is discussed in detail in Section 16.2. In writing chemical equations involving the proton in water, we represent it simply as  $\text{H}^+(aq)$ .

Molecules of different acids can ionize to form different numbers of  $\text{H}^+$  ions. Both  $\text{HCl}$  and  $\text{HNO}_3$  are *monoprotic* acids, which yield one  $\text{H}^+$  per molecule of acid. Sulfuric acid,  $\text{H}_2\text{SO}_4$ , is a *diprotic* acid, one that yields two  $\text{H}^+$  per molecule of acid. The ionization of  $\text{H}_2\text{SO}_4$  and other diprotic acids occurs in two steps:

Although  $\text{H}_2\text{SO}_4$  is a strong electrolyte, only the first ionization is complete. Thus, aqueous solutions of sulfuric acid contain a mixture of  $\text{H}^+(aq)$ ,  $\text{HSO}_4^-(aq)$ , and  $\text{SO}_4^{2-}(aq)$ .

The molecule  $\text{CH}_3\text{COOH}$  (acetic acid) that we have mentioned frequently is the primary component in vinegar. Acetic acid has four hydrogens, but only one of them is capable of being ionized in water. Only the hydrogen that is bound to oxygen in the  $\text{COOH}$  group will ionize in water; the other hydrogens are bound to carbon and do not break their  $\text{C}-\text{H}$  bonds in water. We will discuss acids much more in Chapter 16.

### GIVE IT SOME THOUGHT

The structural formula of citric acid, a main component of citrus fruits, is shown here:

How many  $\text{H}^+(aq)$  can be generated by each citric acid molecule when citric acid is dissolved in water?

## Bases

**Bases** are substances that accept (react with)  $\text{H}^+$  ions. Bases produce hydroxide ions ( $\text{OH}^-$ ) when they dissolve in water. Ionic hydroxide compounds such as  $\text{NaOH}$ ,  $\text{KOH}$ , and  $\text{Ca}(\text{OH})_2$  are among the most common bases. When dissolved in water, they dissociate into their component ions, introducing  $\text{OH}^-$  ions into the solution.

Compounds that do not contain  $\text{OH}^-$  ions can also be bases. For example, ammonia ( $\text{NH}_3$ ) is a common base. When added to water, it accepts an  $\text{H}^+$  ion from the water molecule and thereby produces an  $\text{OH}^-$  ion (Figure 4.6 ▶):

Ammonia is a weak electrolyte because only a small fraction of the  $\text{NH}_3$  (about 1%) forms  $\text{NH}_4^+$  and  $\text{OH}^-$  ions.

**▲ Figure 4.6 Hydrogen ion transfer.** An  $\text{H}_2\text{O}$  molecule acts as a proton donor (acid), and  $\text{NH}_3$  as a proton acceptor (base). Only a fraction of the  $\text{NH}_3$  reacts with  $\text{H}_2\text{O}$ ;  $\text{NH}_3$  is a weak electrolyte.

TABLE 4.2 ■ Common Strong Acids and Bases

Strong Acids	Strong Bases
Hydrochloric, HCl	Group 1A metal hydroxides (LiOH, NaOH, KOH, RbOH, CsOH)
Hydrobromic, HBr	Heavy group 2A metal hydroxides [Ca(OH) <sub>2</sub> , Sr(OH) <sub>2</sub> , Ba(OH) <sub>2</sub> ]
Hydroiodic, HI	
Chloric, HClO <sub>3</sub>	
Perchloric, HClO <sub>4</sub>	
Nitric, HNO <sub>3</sub>	
Sulfuric, H <sub>2</sub> SO <sub>4</sub>	

### Strong and Weak Acids and Bases

Acids and bases that are strong electrolytes (completely ionized in solution) are called **strong acids** and **strong bases**. Those that are weak electrolytes (partly ionized) are called **weak acids** and **weak bases**. Strong acids are more reactive than weak acids when the reactivity depends only on the concentration of  $\text{H}^+(\text{aq})$ . The reactivity of an acid, however, can depend on the anion as well as on  $\text{H}^+(\text{aq})$ . For example, hydrofluoric acid (HF) is a weak acid (only partly ionized in aqueous solution), but it is very reactive and vigorously attacks many substances, including glass. This reactivity is due to the combined action of  $\text{H}^+(\text{aq})$  and  $\text{F}^-(\text{aq})$ .

Table 4.2▲ lists the common strong acids and bases. You should commit these to memory. As you examine this table, notice that some of the most common acids, such as HCl, HNO<sub>3</sub>, and H<sub>2</sub>SO<sub>4</sub>, are strong. (For H<sub>2</sub>SO<sub>4</sub>, as we noted earlier, only the first proton completely ionizes.) Three of the strong acids are the hydrogen compounds of the halogen family. (HF, however, is a weak acid.) The list of strong acids is very short. Most acids are weak. The only common strong bases are the hydroxides of  $\text{Li}^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Rb}^+$ , and  $\text{Cs}^+$  (the alkali metals, group 1A) and the hydroxides of  $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ , and  $\text{Ba}^{2+}$  (the heavy alkaline earths, group 2A). These are the common soluble metal hydroxides. Most other metal hydroxides are insoluble in water. The most common weak base is  $\text{NH}_3$ , which reacts with water to form  $\text{OH}^-$  ions (Equation 4.11).

### GIVE IT SOME THOUGHT

Which of the following is a strong acid:  $\text{H}_2\text{SO}_3$ , HBr,  $\text{CH}_3\text{COOH}$ ?

### SAMPLE EXERCISE 4.5 | Comparing Acid Strengths

The following diagrams represent aqueous solutions of three acids (HX, HY, and HZ) with water molecules omitted for clarity. Rank them from strongest to weakest.

**SOLUTION**

**Analyze:** We are asked to rank three acids from strongest to weakest, based on schematic drawings of their solutions.

**Plan:** We can examine the drawings to determine the relative numbers of uncharged molecular species present. The strongest acid is the one with the most  $\text{H}^+$  ions and fewest undissociated acid molecules in solution. The weakest acid is the one with the largest number of undissociated molecules.

**Solve:** The order is  $\text{HY} > \text{HZ} > \text{HX}$ . HY is a strong acid because it is totally ionized (no HY molecules in solution), whereas both HX and HZ are weak acids, whose solutions consist of a mixture of molecules and ions. Because HZ contains more  $\text{H}^+$  ions and fewer molecules than HX, it is a stronger acid.

**PRACTICE EXERCISE**

Imagine a diagram showing 10  $\text{Na}^+$  ions and 10  $\text{OH}^-$  ions. If this solution were mixed with the one pictured on the previous page for HY, what would the diagram look like that represents the solution after any possible reaction? ( $\text{H}^+$  ions will react with  $\text{OH}^-$  ions to form  $\text{H}_2\text{O}$ .)

**Answer:** The final diagram would show 10  $\text{Na}^+$  ions, 2  $\text{OH}^-$  ions, 8  $\text{Y}^-$  ions, and 8  $\text{H}_2\text{O}$  molecules.

## Identifying Strong and Weak Electrolytes

If we remember the common strong acids and bases (Table 4.2) and also remember that  $\text{NH}_3$  is a weak base, we can make reasonable predictions about the electrolytic strength of a great number of water-soluble substances. Table 4.3  $\blacktriangledown$  summarizes our observations about electrolytes. To classify a soluble substance as a strong electrolyte, weak electrolyte, or nonelectrolyte, we simply work our way down and across this table. We first ask ourselves whether the substance is ionic or molecular. If it is ionic, it is a strong electrolyte. The second column of Table 4.3 tells us that all ionic compounds are strong electrolytes. If the substance we want to classify is molecular, we ask whether it is an acid or a base. (Does it have H first in the chemical formula or contain a COOH group?) If it is an acid, we rely on the memorized list from Table 4.2 to determine whether it is a strong or weak electrolyte: All strong acids are strong electrolytes, and all weak acids are weak electrolytes. If an acid is not listed in Table 4.2, it is probably a weak acid and therefore a weak electrolyte. For example,  $\text{H}_3\text{PO}_4$ ,  $\text{H}_2\text{SO}_3$ , and  $\text{HC}_7\text{H}_5\text{O}_2$  are not listed in Table 4.2 and are weak acids. If the substance we want to classify is a base, we again turn to Table 4.2 to determine whether it is one of the listed strong bases.  $\text{NH}_3$  is the only molecular base that we consider in this chapter, and Table 4.3 tells us it is a weak electrolyte. (There are compounds called amines that are related to  $\text{NH}_3$  and are also molecular bases, but we will not consider them until Chapter 16.) Finally, any molecular substance that we encounter in this chapter that is not an acid or  $\text{NH}_3$  is probably a nonelectrolyte.

**TABLE 4.3** ■ Summary of the Electrolytic Behavior of Common Soluble Ionic and Molecular Compounds

	Strong Electrolyte	Weak Electrolyte	Nonelectrolyte
<b>Ionic</b>	All	None	None
<b>Molecular</b>	Strong acids (see Table 4.2)	Weak acids Weak bases	All other compounds

**SAMPLE EXERCISE 4.6** | Identifying Strong, Weak, and Nonelectrolytes

Classify each of the following dissolved substances as a strong electrolyte, weak electrolyte, or nonelectrolyte:  $\text{CaCl}_2$ ,  $\text{HNO}_3$ ,  $\text{C}_2\text{H}_5\text{OH}$  (ethanol),  $\text{HCOOH}$  (formic acid),  $\text{KOH}$ .

**SOLUTION**

**Analyze:** We are given several chemical formulas and asked to classify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte.

**Plan:** The approach we take is outlined in Table 4.3. We can predict whether a substance is ionic or molecular based on its composition. As we saw in Section 2.7, most ionic compounds we encounter in this text are composed of a metal and a nonmetal, whereas most molecular compounds are composed only of nonmetals.

**Solve:** Two compounds fit the criteria for ionic compounds:  $\text{CaCl}_2$  and  $\text{KOH}$ . Because Table 4.3 tells us that all ionic compounds are strong electrolytes, that is how we classify these two substances. The three remaining compounds are molecular. Two,  $\text{HNO}_3$  and  $\text{HCOOH}$ , are acids. Nitric acid,  $\text{HNO}_3$ , is a common strong acid, as shown in Table 4.2, and therefore is a strong electrolyte. Because most acids are weak acids, our best guess would be that  $\text{HCOOH}$  is a weak acid (weak electrolyte). This is correct. The remaining molecular compound,  $\text{C}_2\text{H}_5\text{OH}$ , is neither an acid nor a base, so it is a nonelectrolyte.

**Comment:** Although  $\text{C}_2\text{H}_5\text{OH}$  has an OH group, it is not a metal hydroxide; thus, it is not a base. Rather, it is a member of a class of organic compounds that have C—OH bonds, which are known as alcohols.  $\infty$  (Section 2.9). The COOH group is called the “carboxylic acid group” (Chapter 16). Molecules that have this group are all weak acids.

**PRACTICE EXERCISE**

Consider solutions in which 0.1 mol of each of the following compounds is dissolved in 1 L of water:  $\text{Ca}(\text{NO}_3)_2$  (calcium nitrate),  $\text{C}_6\text{H}_{12}\text{O}_6$  (glucose),  $\text{CH}_3\text{COONa}$  (sodium acetate), and  $\text{CH}_3\text{COOH}$  (acetic acid). Rank the solutions in order of increasing electrical conductivity, based on the fact that the greater the number of ions in solution, the greater the conductivity.

**Answers:**  $\text{C}_6\text{H}_{12}\text{O}_6$  (nonelectrolyte) <  $\text{CH}_3\text{COOH}$  (weak electrolyte, existing mainly in the form of molecules with few ions) <  $\text{CH}_3\text{COONa}$  (strong electrolyte that provides two ions,  $\text{Na}^+$  and  $\text{CH}_3\text{COO}^-$ ) <  $\text{Ca}(\text{NO}_3)_2$  (strong electrolyte that provides three ions,  $\text{Ca}^{2+}$  and  $2\text{NO}_3^-$ )

**▲ Figure 4.7** The acid–base indicator bromthymol blue. The indicator is blue in basic solution and yellow in acidic solution. The left flask shows the indicator in the presence of a base, aqueous ammonia (labeled as ammonium hydroxide). The right flask shows the indicator in the presence of hydrochloric acid,  $\text{HCl}$ .

## Neutralization Reactions and Salts

The properties of acidic solutions are quite different from those of basic solutions. Acids have a sour taste, whereas bases have a bitter taste.\* Acids can change the colors of certain dyes in a specific way that differs from the effect of a base (Figure 4.7◀). The dye known as litmus, for example, is changed from blue to red by an acid and from red to blue by a base. In addition, acidic and basic solutions differ in chemical properties in several important ways that we will explore in this chapter and in later chapters.

When a solution of an acid and a solution of a base are mixed, a **neutralization reaction** occurs. The products of the reaction have none of the characteristic properties of either the acidic solution or the basic solution. For example, when hydrochloric acid is mixed with a solution of sodium hydroxide, the following reaction occurs:

Water and table salt,  $\text{NaCl}$ , are the products of the reaction. By analogy to this reaction, the term **salt** has come to mean any ionic compound whose cation comes from a base (for example,  $\text{Na}^+$  from  $\text{NaOH}$ ) and whose anion comes from an acid (for example,  $\text{Cl}^-$  from  $\text{HCl}$ ). In general, a *neutralization reaction between an acid and a metal hydroxide produces water and a salt*.

\*Tasting chemical solutions is not a good practice. However, we have all had acids such as ascorbic acid (vitamin C), acetylsalicylic acid (aspirin), and citric acid (in citrus fruits) in our mouths, and we are familiar with their characteristic sour taste. Soaps, which are basic, have the characteristic bitter taste of bases.

▲ **Figure 4.8 Reaction of  $\text{Mg}(\text{OH})_2(\text{s})$  with acid.** (a) Milk of magnesia is a suspension of magnesium hydroxide,  $\text{Mg}(\text{OH})_2(\text{s})$ , in water. (b) The magnesium hydroxide dissolves upon the addition of hydrochloric acid,  $\text{HCl}(\text{aq})$ . (c) The final clear solution contains soluble  $\text{MgCl}_2(\text{aq})$ , as shown in Equation 4.15.

Because  $\text{HCl}$ ,  $\text{NaOH}$ , and  $\text{NaCl}$  are all soluble strong electrolytes, the complete ionic equation associated with Equation 4.12 is

Therefore, the net ionic equation is

Equation 4.14 summarizes the essential feature of the neutralization reaction between any strong acid and any strong base:  $\text{H}^+(\text{aq})$  and  $\text{OH}^-(\text{aq})$  ions combine to form  $\text{H}_2\text{O}$ .

Figure 4.8▲ shows the reaction between hydrochloric acid and the base  $\text{Mg}(\text{OH})_2$ , which is insoluble in water. A milky white suspension of  $\text{Mg}(\text{OH})_2$  called milk of magnesia is seen dissolving as the neutralization reaction occurs:

*Molecular equation:*

*Net ionic equation:*

Notice that the  $\text{OH}^-$  ions (this time in a solid reactant) and  $\text{H}^+$  ions combine to form  $\text{H}_2\text{O}$ . Because the ions exchange partners, neutralization reactions between acids and metal hydroxides are also metathesis reactions.

#### ■ SAMPLE EXERCISE 4.7 | Writing Chemical Equations for a Neutralization Reaction

(a) Write a balanced molecular equation for the reaction between aqueous solutions of acetic acid ( $\text{CH}_3\text{COOH}$ ) and barium hydroxide,  $\text{Ba}(\text{OH})_2$ . (b) Write the net ionic equation for this reaction.

#### SOLUTION

**Analyze:** We are given the chemical formulas for an acid and a base and asked to write a balanced molecular equation and then a net ionic equation for their neutralization reaction.

**Plan:** As Equation 4.12 and the italicized statement that follows it indicate, neutralization reactions form two products,  $\text{H}_2\text{O}$  and a salt. We examine the cation of the base and the anion of the acid to determine the composition of the salt.

**Solve:**

(a) The salt will contain the cation of the base ( $\text{Ba}^{2+}$ ) and the anion of the acid ( $\text{CH}_3\text{COO}^-$ ). Thus, the formula of the salt is  $\text{Ba}(\text{CH}_3\text{COO})_2$ . According to the solubility guidelines in Table 4.1, this compound is soluble. The unbalanced molecular equation for the neutralization reaction is

To balance this molecular equation, we must provide two molecules of  $\text{CH}_3\text{COOH}$  to furnish the two  $\text{CH}_3\text{COO}^-$  ions and to supply the two  $\text{H}^+$  ions needed to combine with the two  $\text{OH}^-$  ions of the base. The balanced molecular equation is

(b) To write the net ionic equation, we must determine whether each compound in aqueous solution is a strong electrolyte.  $\text{CH}_3\text{COOH}$  is a weak electrolyte (weak acid),  $\text{Ba}(\text{OH})_2$  is a strong electrolyte, and  $\text{Ba}(\text{CH}_3\text{COO})_2$  is also a strong electrolyte (ionic compound). Thus, the complete ionic equation is

Eliminating the spectator ions gives

Simplifying the coefficients gives the net ionic equation:

**Check:** We can determine whether the molecular equation is correctly balanced by counting the number of atoms of each kind on both sides of the arrow. (There are 10 H, 6 O, 4 C, and 1 Ba on each side.) However, it is often easier to check equations by counting groups: There are 2  $\text{CH}_3\text{COO}$  groups, as well as 1 Ba, and 4 additional H atoms and 2 additional O atoms on each side of the equation. The net ionic equation checks out because the numbers of each kind of element and the net charge are the same on both sides of the equation.

### PRACTICE EXERCISE

(a) Write a balanced molecular equation for the reaction of carbonic acid ( $\text{H}_2\text{CO}_3$ ) and potassium hydroxide (KOH). (b) Write the net ionic equation for this reaction.

**Answers:** (a)  $\text{H}_2\text{CO}_3(aq) + 2 \text{KOH}(aq) \longrightarrow 2 \text{H}_2\text{O}(l) + \text{K}_2\text{CO}_3(aq)$ ; (b)  $\text{H}_2\text{CO}_3(aq) + 2 \text{OH}^-(aq) \longrightarrow 2 \text{H}_2\text{O}(l) + \text{CO}_3^{2-}(aq)$ . ( $\text{H}_2\text{CO}_3$  is a weak acid and therefore a weak electrolyte, whereas KOH, a strong base, and  $\text{K}_2\text{CO}_3$ , an ionic compound, are strong electrolytes.)

## Acid–Base Reactions with Gas Formation

Many bases besides  $\text{OH}^-$  react with  $\text{H}^+$  to form molecular compounds. Two of these that you might encounter in the laboratory are the sulfide ion and the carbonate ion. Both of these anions react with acids to form gases that have low solubilities in water. Hydrogen sulfide ( $\text{H}_2\text{S}$ ), the substance that gives rotten eggs their foul odor, forms when an acid such as  $\text{HCl}(aq)$  reacts with a metal sulfide such as  $\text{Na}_2\text{S}$ :

Carbonates and bicarbonates react with acids to form  $\text{CO}_2$  gas. Reaction of  $\text{CO}_3^{2-}$  or  $\text{HCO}_3^-$  with an acid first gives carbonic acid ( $\text{H}_2\text{CO}_3$ ). For example, when hydrochloric acid is added to sodium bicarbonate, the following reaction occurs:

Carbonic acid is unstable. If carbonic acid is present in solution in sufficient concentrations, it decomposes to form  $\text{H}_2\text{O}$  and  $\text{CO}_2$ , which escapes from the solution as a gas.

The decomposition of  $\text{H}_2\text{CO}_3$  produces bubbles of  $\text{CO}_2$  gas, as shown in Figure 4.9. The overall reaction is summarized by the following equations:

*Molecular equation:*

▲ **Figure 4.9** Carbonates react with acids to form carbon dioxide gas.

Here  $\text{NaHCO}_3$  (white solid) reacts with hydrochloric acid. The bubbles contain  $\text{CO}_2$ .

## Chemistry Put to Work ANTACIDS

Your stomach secretes acids to help digest foods. These acids, which include hydrochloric acid, contain about 0.1 mol of  $H^+$  per liter of solution. The stomach and digestive tract are normally protected from the corrosive effects of stomach acid by a mucosal lining. Holes can develop in this lining, however, allowing the acid to attack the underlying tissue, causing painful damage. These holes, known as ulcers, can be caused by the secretion of excess acids or by a weakness in the digestive lining. Studies indicate, however, that many ulcers are caused by bacterial infection. Between 10 and 20% of Americans suffer from ulcers at some point in their lives. Many others experience occasional indigestion or heartburn that is due to digestive acids entering the esophagus.

We can address the problem of excess stomach acid in two simple ways: (1) removing the excess acid, or (2) decreasing the production of acid. Those substances that remove ex-

cess acid are called *antacids*, whereas those that decrease the production of acid are called *acid inhibitors*. Figure 4.10 shows several common, over-the-counter antacids.

Antacids are simple bases that neutralize digestive acids. They are able to neutralize acids because they contain hydroxide, carbonate, or bicarbonate ions. Table 4.4 lists the active ingredients in some antacids.

The newer generation of antiulcer drugs, such as Tagamet® and Zantac®, are acid inhibitors. They act on acid-producing cells in the lining of the stomach. Formulations that control acid in this way are now available as over-the-counter drugs.

*Related Exercise: 4.95*

TABLE 4.4 ■ Some Common Antacids

Commercial Name	Acid-Neutralizing Agents
Alka-Seltzer®	$NaHCO_3$
Amphojel®	$Al(OH)_3$
Di-Gel®	$Mg(OH)_2$ and $CaCO_3$
Milk of Magnesia	$Mg(OH)_2$
Maalox®	$Mg(OH)_2$ and $Al(OH)_3$
Mylanta®	$Mg(OH)_2$ and $Al(OH)_3$
Roloids®	$NaAl(OH)_2CO_3$
Tums®	$CaCO_3$

▲ **Figure 4.10 Antacids.** These products all serve as acid-neutralizing agents in the stomach.

Both  $NaHCO_3$  and  $Na_2CO_3$  are used as acid neutralizers in acid spills. The bicarbonate or carbonate salt is added until the fizzing due to the formation of  $CO_2(g)$  stops. Sometimes sodium bicarbonate is used as an antacid to soothe an upset stomach. In that case the  $HCO_3^-$  reacts with stomach acid to form  $CO_2(g)$ . The fizz when Alka-Seltzer® tablets are added to water arises from the reaction of sodium bicarbonate and citric acid.

### GIVE IT SOME THOUGHT

By analogy to examples already given in the text, predict what gas forms when  $Na_2SO_3(s)$  is treated with  $HCl(aq)$ .

## 4.4 OXIDATION-REDUCTION REACTIONS

In precipitation reactions, cations and anions come together to form an insoluble ionic compound. In neutralization reactions  $H^+$  ions and  $OH^-$  ions come together to form  $H_2O$  molecules. Now let's consider a third important kind of reaction, one in which electrons are transferred between reactants. Such reactions are called **oxidation-reduction**, or *redox*, reactions.

► **Figure 4.11 Corrosion of iron.**

Corrosion of iron is caused by chemical attack of oxygen and water on exposed metal surfaces. Corrosion is even more rapid in salt water.

**Oxidation and Reduction**

The corrosion of iron (rusting) and of other metals, such as the corrosion of the terminals of an automobile battery, are familiar processes. What we call *corrosion* is the conversion of a metal into a metal compound by a reaction between the metal and some substance in its environment. Rusting, as shown in Figure 4.11 ▲, involves the reaction of oxygen with iron in the presence of water.

When a metal corrodes, it loses electrons and forms cations. Calcium, for example, is vigorously attacked by acids to form calcium ions:

When an atom, ion, or molecule has become more positively charged (that is, when it has lost electrons), we say that it has been oxidized. *Loss of electrons by a substance is called oxidation.* Thus, Ca, which has no net charge, is oxidized (undergoes oxidation) in Equation 4.23, forming  $\text{Ca}^{2+}$ .

The term oxidation is used because the first reactions of this sort to be studied thoroughly were reactions with oxygen. Many metals react directly with  $\text{O}_2$  in air to form metal oxides. In these reactions the metal loses electrons to oxygen, forming an ionic compound of the metal ion and oxide ion. For example, when calcium metal is exposed to air, the bright metallic surface of the metal tarnishes as  $\text{CaO}$  forms:

As Ca is oxidized in Equation 4.24, oxygen is transformed from neutral  $\text{O}_2$  to two  $\text{O}^{2-}$  ions (Figure 4.12 ▼). When an atom, ion, or molecule has become more negatively charged (gained electrons), we say that it is *reduced*.

▲ **Figure 4.12 Oxidation of calcium metal by molecular oxygen.** The oxidation involves transfer of electrons from the metal to  $\text{O}_2$ , eventually leading to formation of  $\text{CaO}$ .

The gain of electrons by a substance is called **reduction**. When one reactant loses electrons (that is, when it is *oxidized*), another reactant must gain them. The oxidation of one substance is always accompanied by the reduction of another as electrons are transferred between them.

## Oxidation Numbers

Before we can properly identify an oxidation-reduction reaction, we must have a kind of bookkeeping system—a way of keeping track of the electrons gained by the substance reduced and those lost by the substance oxidized. The concept of oxidation numbers (also called *oxidation states*) was devised as a way of doing this. Each atom in a neutral molecule or charged species is assigned an **oxidation number**, which is the actual charge for a monatomic ion. Otherwise, the oxidation number is the hypothetical charge assigned to the atom, assuming that the electrons are *completely* held by one atom or the other. The oxidation numbers of certain atoms change in an oxidation-reduction reaction. Oxidation occurs when the oxidation number increases, whereas reduction occurs when the oxidation number decreases.

We use the following rules for assigning oxidation numbers:

1. For an atom in its **elemental form**, the oxidation number is always zero.  
Thus, each H atom in the  $\text{H}_2$  molecule has an oxidation number of 0, and each P atom in the  $\text{P}_4$  molecule has an oxidation number of 0.
2. For any **monatomic ion** the oxidation number equals the charge on the ion.  
Thus,  $\text{K}^+$  has an oxidation number of +1,  $\text{S}^{2-}$  has an oxidation number of -2, and so forth. The alkali metal ions (group 1A) always have a 1+ charge, and therefore the alkali metals always have an oxidation number of +1 in their compounds. Similarly, the alkaline earth metals (group 2A) are always +2, and aluminum (group 3A) is always +3 in its compounds. (In writing oxidation numbers, we will write the sign before the number to distinguish them from the actual electronic charges, which we write with the number first.)
3. **Nonmetals** usually have negative oxidation numbers, although they can sometimes be positive:
  - (a) The oxidation number of **oxygen** is usually -2 in both ionic and molecular compounds. The major exception is in compounds called peroxides, which contain the  $\text{O}_2^{2-}$  ion, giving each oxygen an oxidation number of -1.
  - (b) The oxidation number of **hydrogen** is usually +1 when bonded to nonmetals and -1 when bonded to metals.
  - (c) The oxidation number of **fluorine** is -1 in all compounds. The other **halogens** have an oxidation number of -1 in most binary compounds. When combined with oxygen, as in oxyanions, however, they have positive oxidation states.
4. The **sum of the oxidation numbers** of all atoms in a neutral compound is zero. The sum of the oxidation numbers in a polyatomic ion equals the charge of the ion. For example, in the hydronium ion,  $\text{H}_3\text{O}^+$ , the oxidation number of each hydrogen is +1 and that of oxygen is -2. Thus, the sum of the oxidation numbers is  $3(+1) + (-2) = +1$ , which equals the net charge of the ion. This rule is very useful in obtaining the oxidation number of one atom in a compound or ion if you know the oxidation numbers of the other atoms, as illustrated in Sample Exercise 4.8.

### GIVE IT SOME THOUGHT

- (a) What noble gas element has the same number of electrons as the fluoride ion?
- (b) What is the oxidation number of that noble gas?

**SAMPLE EXERCISE 4.8** | Determining Oxidation Numbers

Determine the oxidation number of sulfur in each of the following: (a)  $\text{H}_2\text{S}$ , (b)  $\text{S}_8$ , (c)  $\text{SCl}_2$ , (d)  $\text{Na}_2\text{SO}_3$ , (e)  $\text{SO}_4^{2-}$ .

**SOLUTION**

**Analyze:** We are asked to determine the oxidation number of sulfur in two molecular species, in the elemental form, and in two ionic substances.

**Plan:** In each species the sum of oxidation numbers of all the atoms must equal the charge on the species. We will use the rules outlined above to assign oxidation numbers.

**Solve:**

(a) When bonded to a nonmetal, hydrogen has an oxidation number of +1 (rule 3b). Because the  $\text{H}_2\text{S}$  molecule is neutral, the sum of the oxidation numbers must equal zero (rule 4). Letting  $x$  equal the oxidation number of S, we have  $2(+1) + x = 0$ . Thus, S has an oxidation number of  $-2$ .

(b) Because this is an elemental form of sulfur, the oxidation number of S is 0 (rule 1).

(c) Because this is a binary compound, we expect chlorine to have an oxidation number of  $-1$  (rule 3c). The sum of the oxidation numbers must equal zero (rule 4). Letting  $x$  equal the oxidation number of S, we have  $x + 2(-1) = 0$ . Consequently, the oxidation number of S must be  $+2$ .

(d) Sodium, an alkali metal, always has an oxidation number of  $+1$  in its compounds (rule 2). Oxygen has a common oxidation state of  $-2$  (rule 3a). Letting  $x$  equal the oxidation number of S, we have  $2(+1) + x + 3(-2) = 0$ . Therefore, the oxidation number of S in this compound is  $+4$ .

(e) The oxidation state of O is  $-2$  (rule 3a). The sum of the oxidation numbers equals  $-2$ , the net charge of the  $\text{SO}_4^{2-}$  ion (rule 4). Thus, we have  $x + 4(-2) = -2$ . From this relation we conclude that the oxidation number of S in this ion is  $+6$ .

**Comment:** These examples illustrate that the oxidation number of a given element depends on the compound in which it occurs. The oxidation numbers of sulfur, as seen in these examples, range from  $-2$  to  $+6$ .

**PRACTICE EXERCISE**

What is the oxidation state of the boldfaced element in each of the following: (a)  $\text{P}_2\text{O}_5$ , (b)  $\text{NaH}$ , (c)  $\text{Cr}_2\text{O}_7^{2-}$ , (d)  $\text{SnBr}_4$ , (e)  $\text{BaO}_2$ ?

**Answers:** (a)  $+5$ , (b)  $-1$ , (c)  $+6$ , (d)  $+4$ , (e)  $-1$

## Oxidation of Metals by Acids and Salts

There are many kinds of redox reactions. For example, combustion reactions are redox reactions because elemental oxygen is converted to compounds of oxygen.  $\rightleftharpoons$  (Section 3.2) In this chapter we consider the redox reactions between metals and either acids or salts. In Chapter 20 we will examine more complex kinds of redox reactions.

The reaction of a metal with either an acid or a metal salt conforms to the following general pattern:

These reactions are called **displacement reactions** because the ion in solution is displaced or replaced through oxidation of an element.

Many metals undergo displacement reactions with acids, producing salts and hydrogen gas. For example, magnesium metal reacts with hydrochloric acid to form magnesium chloride and hydrogen gas (Figure 4.13  $\blacktriangleright$ ).

### SAMPLE EXERCISE 4.9 | Writing Molecular and Net Ionic Equations for Oxidation-Reduction Reactions

Write the balanced molecular and net ionic equations for the reaction of aluminum with hydrobromic acid.

#### SOLUTION

**Analyze:** We must write two equations—molecular and net ionic—for the redox reaction between a metal and an acid.

**Plan:** Metals react with acids to form salts and  $\text{H}_2$  gas. To write the balanced equations, we must write the chemical formulas for the two reactants and then determine the formula of the salt. The salt is composed of the cation formed by the metal and the anion of the acid.

**Solve:** The formulas of the given reactants are Al and HBr. The cation formed by Al is  $\text{Al}^{3+}$ , and the anion from hydrobromic acid is  $\text{Br}^-$ . Thus, the salt formed in the reaction is  $\text{AlBr}_3$ . Writing the reactants and products and then balancing the equation gives this molecular equation:

Both HBr and  $\text{AlBr}_3$  are soluble strong electrolytes. Thus, the complete ionic equation is

Because  $\text{Br}^-$  is a spectator ion, the net ionic equation is

**Comment:** The substance oxidized is the aluminum metal because its oxidation state changes from 0 in the metal to +3 in the cation, thereby increasing in oxidation number. The  $\text{H}^+$  is reduced because its oxidation state changes from +1 in the acid to 0 in  $\text{H}_2$ .

#### PRACTICE EXERCISE

(a) Write the balanced molecular and net ionic equations for the reaction between magnesium and cobalt(II) sulfate. (b) What is oxidized and what is reduced in the reaction?

**Answers:** (a)  $\text{Mg}(s) + \text{CoSO}_4(aq) \longrightarrow \text{MgSO}_4(aq) + \text{Co}(s)$ ;

$\text{Mg}(s) + \text{Co}^{2+}(aq) \longrightarrow \text{Mg}^{2+}(aq) + \text{Co}(s)$ ; (b) Mg is oxidized and  $\text{Co}^{2+}$  is reduced.

## The Activity Series

Can we predict whether a certain metal will be oxidized either by an acid or by a particular salt? This question is of practical importance as well as chemical interest. According to Equation 4.28, for example, it would be unwise to store a solution of nickel nitrate in an iron container because the solution would dissolve the container. When a metal is oxidized, it reacts to form various compounds. Extensive oxidation can lead to the failure of metal machinery parts or the deterioration of metal structures.

Different metals vary in the ease with which they are oxidized. Zn is oxidized by aqueous solutions of  $\text{Cu}^{2+}$ , for example, but Ag is not. Zn, therefore, loses electrons more readily than Ag; that is, Zn is easier to oxidize than Ag.

A list of metals arranged in order of decreasing ease of oxidation is called an **activity series**. Table 4.5 gives the activity series in aqueous solution for many of the most common metals. Hydrogen is also included in the table. The metals at the top of the table, such as the alkali metals and the alkaline earth metals, are most easily oxidized; that is, they react most readily to form compounds. They are called the *active metals*. The metals at the bottom of the activity series, such as the transition elements from groups 8B and 1B, are very stable and form compounds less readily. These metals, which are used to make coins and jewelry, are called *noble metals* because of their low reactivity.

The activity series can be used to predict the outcome of reactions between metals and either metal salts or acids. *Any metal on the list can be oxidized by the ions of elements below it.* For example, copper is above silver in the series.

TABLE 4.5 ■ Activity Series of Metals in Aqueous Solution

Metal	Oxidation Reaction
Lithium	$\text{Li}(s) \longrightarrow \text{Li}^+(aq) + e^-$
Potassium	$\text{K}(s) \longrightarrow \text{K}^+(aq) + e^-$
Barium	$\text{Ba}(s) \longrightarrow \text{Ba}^{2+}(aq) + 2e^-$
Calcium	$\text{Ca}(s) \longrightarrow \text{Ca}^{2+}(aq) + 2e^-$
Sodium	$\text{Na}(s) \longrightarrow \text{Na}^+(aq) + e^-$
Magnesium	$\text{Mg}(s) \longrightarrow \text{Mg}^{2+}(aq) + 2e^-$
Aluminum	$\text{Al}(s) \longrightarrow \text{Al}^{3+}(aq) + 3e^-$
Manganese	$\text{Mn}(s) \longrightarrow \text{Mn}^{2+}(aq) + 2e^-$
Zinc	$\text{Zn}(s) \longrightarrow \text{Zn}^{2+}(aq) + 2e^-$
Chromium	$\text{Cr}(s) \longrightarrow \text{Cr}^{3+}(aq) + 3e^-$
Iron	$\text{Fe}(s) \longrightarrow \text{Fe}^{2+}(aq) + 2e^-$
Cobalt	$\text{Co}(s) \longrightarrow \text{Co}^{2+}(aq) + 2e^-$
Nickel	$\text{Ni}(s) \longrightarrow \text{Ni}^{2+}(aq) + 2e^-$
Tin	$\text{Sn}(s) \longrightarrow \text{Sn}^{2+}(aq) + 2e^-$
Lead	$\text{Pb}(s) \longrightarrow \text{Pb}^{2+}(aq) + 2e^-$
Hydrogen	$\text{H}_2(g) \longrightarrow 2\text{H}^+(aq) + 2e^-$
Copper	$\text{Cu}(s) \longrightarrow \text{Cu}^{2+}(aq) + 2e^-$
Silver	$\text{Ag}(s) \longrightarrow \text{Ag}^+(aq) + e^-$
Mercury	$\text{Hg}(l) \longrightarrow \text{Hg}^{2+}(aq) + 2e^-$
Platinum	$\text{Pt}(s) \longrightarrow \text{Pt}^{2+}(aq) + 2e^-$
Gold	$\text{Au}(s) \longrightarrow \text{Au}^{3+}(aq) + 3e^-$

Thus, copper metal will be oxidized by silver ions, as pictured in Figure 4.14 ▼:

The oxidation of copper to copper ions is accompanied by the reduction of silver ions to silver metal. The silver metal is evident on the surface of the copper wires in Figure 4.14(b) and 4.14(c). The copper(II) nitrate produces a blue color in the solution, which is most evident in part (c).

◀ **Figure 4.14 Reaction of copper with silver ion.**

When copper metal is placed in a solution of silver nitrate, a redox reaction occurs, forming silver metal and a blue solution of copper(II) nitrate.

## GIVE IT SOME THOUGHT

Which is the more easily reduced,  $\text{Mg}^{2+}(\text{aq})$  or  $\text{Ni}^{2+}(\text{aq})$ ?

Only those metals above hydrogen in the activity series are able to react with acids to form  $\text{H}_2$ . For example, Ni reacts with  $\text{HCl}(\text{aq})$  to form  $\text{H}_2$ :

Because elements below hydrogen in the activity series are not oxidized by  $\text{H}^+$ , Cu does not react with  $\text{HCl}(\text{aq})$ . Interestingly, copper does react with nitric acid, as shown previously in Figure 1.11. This reaction, however, is not a simple oxidation of Cu by the  $\text{H}^+$  ions of the acid. Instead, the metal is oxidized to  $\text{Cu}^{2+}$  by the nitrate ion of the acid, accompanied by the formation of brown nitrogen dioxide,  $\text{NO}_2(\text{g})$ :

What substance is reduced as copper is oxidized in Equation 4.32? In this case the  $\text{NO}_2$  results from the reduction of  $\text{NO}_3^-$ . We will examine reactions of this type in more detail in Chapter 20.

#### SAMPLE EXERCISE 4.10 Determining When an Oxidation-Reduction Reaction Can Occur

Will an aqueous solution of iron(II) chloride oxidize magnesium metal? If so, write the balanced molecular and net ionic equations for the reaction.

#### SOLUTION

**Analyze:** We are given two substances—an aqueous salt,  $\text{FeCl}_2$ , and a metal, Mg—and asked if they react with each other.

**Plan:** A reaction will occur if Mg is above Fe in the activity series, Table 4.5. If the reaction occurs, the  $\text{Fe}^{2+}$  ion in  $\text{FeCl}_2$  will be reduced to Fe, and the elemental Mg will be oxidized to  $\text{Mg}^{2+}$ .

**Solve:** Because Mg is above Fe in the table, the reaction will occur. To write the formula for the salt that is produced in the reaction, we must remember the charges on common ions. Magnesium is always present in compounds as  $\text{Mg}^{2+}$ ; the chloride ion is  $\text{Cl}^-$ . The magnesium salt formed in the reaction is  $\text{MgCl}_2$ , meaning the balanced molecular equation is

Both  $\text{FeCl}_2$  and  $\text{MgCl}_2$  are soluble strong electrolytes and can be written in ionic form.  $\text{Cl}^-$  then, is a spectator ion in the reaction. The net ionic equation is

The net ionic equation shows that Mg is oxidized and  $\text{Fe}^{2+}$  is reduced in this reaction.

**Check:** Note that the net ionic equation is balanced with respect to both charge and mass.

#### PRACTICE EXERCISE

Which of the following metals will be oxidized by  $\text{Pb}(\text{NO}_3)_2$ : Zn, Cu, Fe?

**Answer:** Zn and Fe

## 4.5 CONCENTRATIONS OF SOLUTIONS

The behavior of solutions often depends on the nature of the solutes and their concentrations. Scientists use the term **concentration** to designate the amount of solute dissolved in a given quantity of solvent or quantity of solution. The concept of concentration is intuitive: The greater the amount of solute dissolved in a certain amount of solvent, the more concentrated the resulting solution. In chemistry we often need to express the concentrations of solutions quantitatively.

## A Closer Look THE AURA OF GOLD

Gold has been known since the earliest records of human existence. Throughout history people have cherished gold, have fought for it, and have died for it.

The physical and chemical properties of gold serve to make it a special metal. First, its intrinsic beauty and rarity make it precious. Second, gold is soft and can be easily formed into artistic objects, jewelry, and coins (Figure 4.15). Third, gold is one of the least active metals (Table 4.5). It is not oxidized in air and does not react with water. It is unreactive toward basic solutions and nearly all acidic solutions. As a result, gold can be found in nature as a pure element rather than combined with oxygen or other elements, which accounts for its early discovery.

Many of the early studies of the reactions of gold arose from the practice of alchemy, in which people attempted to turn cheap metals, such as lead, into gold. Alchemists discovered that gold can be dissolved in a 3:1 mixture of concentrated hydrochloric and nitric acids, known as aqua regia (“royal water”). The action of nitric acid on gold is similar to that on copper (Equation 4.32) in that the nitrate ion, rather than  $H^+$ , oxidizes the metal to  $Au^{3+}$ . The  $Cl^-$  ions interact with  $Au^{3+}$  to form highly stable  $AuCl_4^-$  ions. The net ionic equation for the reaction of gold with aqua regia is

All the gold ever mined would easily fit in a cube 19 m on a side and weighing about  $1.1 \times 10^8$  kg (125,000 tons). More than 90% of this amount has been produced since the beginning

of the California gold rush of 1848. Each year, worldwide production of gold amounts to about  $1.8 \times 10^6$  kg (2000 tons). By contrast, over  $1.5 \times 10^{10}$  kg (16 million tons) of aluminum are produced annually. Gold is used mainly in jewelry (73%), coins (10%), and electronics (9%). Its use in electronics relies on its excellent conductivity and its corrosion resistance. Gold is used, for example, to plate contacts in electrical switches, relays, and connections. A typical touch-tone telephone contains 33 gold-plated contacts. Gold is also used in computers and other microelectronic devices where fine gold wire is used to link components.

Because of its resistance to corrosion by acids and other substances found in saliva, gold is an ideal metal for dental crowns and caps, which accounts for about 3% of the annual use of the element. The pure metal is too soft to use in dentistry, so it is combined with other metals to form alloys.

## Strategies in Chemistry ANALYZING CHEMICAL REACTIONS

In this chapter you have been introduced to a great number of chemical reactions. A major difficulty that students face in trying to master material of this sort is gaining a “feel” for what happens when chemicals are allowed to react. In fact, you might marvel at the ease with which your professor or teaching assistant can figure out the results of a chemical reaction. One of our goals in this textbook is to help you become more adept at predicting the outcomes of reactions. The key to gaining this “chemical intuition” is understanding how to categorize reactions.

Attempting to memorize the many individual reactions in chemistry would be a futile task. It is far more fruitful to try to recognize patterns to determine the general category of a reaction, such as metathesis or oxidation-reduction. Thus, when you are faced with the challenge of predicting the outcome of a chemical reaction, ask yourself the following pertinent questions:

- What are the reactants in the reaction?
- Are they electrolytes or nonelectrolytes?
- Are they acids and bases?
- If the reactants are electrolytes, will metathesis produce a precipitate? Water? A gas?

- If metathesis cannot occur, can the reactants possibly engage in an oxidation-reduction reaction? This requires that there be both a reactant that can be oxidized and one that can be reduced.

By asking questions such as these, you should be able to predict what might happen during the reaction. You might not always be entirely correct, but if you keep your wits about you, you will not be far off. As you gain experience with chemical reactions, you will begin to look for reactants that might not be immediately obvious, such as water from the solution or oxygen from the atmosphere.

One of the greatest tools available to us in chemistry is experimentation. If you perform an experiment in which two solutions are mixed, you can make observations that help you understand what is happening. For example, using the information in Table 4.1 to predict whether a precipitate will form is not nearly as exciting as actually seeing the precipitate form, as in Figure 4.4. Careful observations in the laboratory portion of the course will make your lecture material easier to master.

▲ **Figure 4.16 Procedure for preparation of 0.250 L of 1.00 M solution of  $\text{CuSO}_4$ .** (a) Weigh out 0.250 mol (39.9 g) of  $\text{CuSO}_4$  (formula weight = 159.6 amu).

(b) Put the  $\text{CuSO}_4$  (solute) into a 250-mL volumetric flask, and add a small quantity of water. (c) Dissolve the solute by swirling the flask. (d) Add more water until the solution just reaches the calibration mark etched on the neck of the flask. Shake the stoppered flask to ensure complete mixing.

## Molarity

**Molarity** (symbol  $M$ ) expresses the concentration of a solution as the number of moles of solute in a liter of solution (soln):

$$\text{Molarity} = \frac{\text{moles solute}}{\text{volume of solution in liters}} \quad [4.33]$$

A 1.00 molar solution (written 1.00  $M$ ) contains 1.00 mol of solute in every liter of solution. Figure 4.16 ▲ shows the preparation of 250.0 mL of a 1.00  $M$  solution of  $\text{CuSO}_4$  by using a volumetric flask that is calibrated to hold exactly 250.0 mL. First, 0.250 mol of  $\text{CuSO}_4$  (39.9 g) is weighed out and placed in the volumetric flask. Water is added to dissolve the salt, and the resultant solution is diluted to a total volume of 250.0 mL. The molarity of the solution is  $(0.250 \text{ mol } \text{CuSO}_4)/(0.250 \text{ L soln}) = 1.00 M$ .

### GIVE IT SOME THOUGHT

Which is more concentrated, a  $1.00 \times 10^{-2} M$  solution of sucrose or a  $1.00 \times 10^{-4} M$  solution of sucrose?

#### SAMPLE EXERCISE 4.11 | Calculating Molarity

Calculate the molarity of a solution made by dissolving 23.4 g of sodium sulfate ( $\text{Na}_2\text{SO}_4$ ) in enough water to form 125 mL of solution.

#### SOLUTION

**Analyze:** We are given the number of grams of solute (23.4 g), its chemical formula ( $\text{Na}_2\text{SO}_4$ ), and the volume of the solution (125 mL). We are asked to calculate the molarity of the solution.

**Plan:** We can calculate molarity using Equation 4.33. To do so, we must convert the number of grams of solute to moles and the volume of the solution from milliliters to liters.

**Solve:** The number of moles of  $\text{Na}_2\text{SO}_4$  is obtained by using its molar mass:

$$\text{Moles } \text{Na}_2\text{SO}_4 = (23.4 \text{ g } \text{Na}_2\text{SO}_4) \left( \frac{1 \text{ mol } \text{Na}_2\text{SO}_4}{142 \text{ g } \text{Na}_2\text{SO}_4} \right) = 0.165 \text{ mol } \text{Na}_2\text{SO}_4$$

Converting the volume of the solution to liters:

$$\text{Liters soln} = (125 \text{ mL}) \left( \frac{1 \text{ L}}{1000 \text{ mL}} \right) = 0.125 \text{ L}$$

Thus, the molarity is

$$\text{Molarity} = \frac{0.165 \text{ mol } \text{Na}_2\text{SO}_4}{0.125 \text{ L soln}} = 1.32 \frac{\text{mol } \text{Na}_2\text{SO}_4}{\text{L soln}} = 1.32 M$$

**Check:** Because the numerator is only slightly larger than the denominator, it is reasonable for the answer to be a little over 1  $M$ . The units (mol/L) are appropriate for molarity, and three significant figures are appropriate for the answer because each of the initial pieces of data had three significant figures.

**PRACTICE EXERCISE**

Calculate the molarity of a solution made by dissolving 5.00 g of glucose ( $C_6H_{12}O_6$ ) in sufficient water to form exactly 100 mL of solution.

*Answer:* 0.278 M

## Expressing the Concentration of an Electrolyte

When an ionic compound dissolves, the relative concentrations of the ions introduced into the solution depend on the chemical formula of the compound. For example, a 1.0 M solution of NaCl is 1.0 M in  $Na^+$  ions and 1.0 M in  $Cl^-$  ions. Similarly, a 1.0 M solution of  $Na_2SO_4$  is 2.0 M in  $Na^+$  ions and 1.0 M in  $SO_4^{2-}$  ions. Thus, the concentration of an electrolyte solution can be specified either in terms of the compound used to make the solution (1.0 M  $Na_2SO_4$ ) or in terms of the ions that the solution contains (2.0 M  $Na^+$  and 1.0 M  $SO_4^{2-}$ ).

**SAMPLE EXERCISE 4.12 | Calculating Molar Concentrations of Ions**

What are the molar concentrations of each of the ions present in a 0.025 M aqueous solution of calcium nitrate?

**SOLUTION**

**Analyze:** We are given the concentration of the ionic compound used to make the solution and asked to determine the concentrations of the ions in the solution.

**Plan:** We can use the subscripts in the chemical formula of the compound to determine the relative concentrations of the ions.

**Solve:** Calcium nitrate is composed of calcium ions ( $Ca^{2+}$ ) and nitrate ions ( $NO_3^-$ ), so its chemical formula is  $Ca(NO_3)_2$ . Because there are two  $NO_3^-$  ions for each  $Ca^{2+}$  ion in the compound, each mole of  $Ca(NO_3)_2$  that dissolves dissociates into 1 mol of  $Ca^{2+}$  and 2 mol of  $NO_3^-$ . Thus, a solution that is 0.025 M in  $Ca(NO_3)_2$  is 0.025 M in  $Ca^{2+}$  and  $2 \times 0.025 M = 0.050 M$  in  $NO_3^-$ :

$$\frac{\text{mol } NO_3^-}{L} = \left( \frac{0.025 \text{ mol } Ca(NO_3)_2}{L} \right) \left( \frac{2 \text{ mol } NO_3^-}{1 \text{ mol } Ca(NO_3)_2} \right) = 0.050 M$$

**Check:** The concentration of  $NO_3^-$  ions is twice that of  $Ca^{2+}$  ions, as the subscript 2 after the  $NO_3^-$  in the chemical formula  $Ca(NO_3)_2$  suggests it should be.

**PRACTICE EXERCISE**

What is the molar concentration of  $K^+$  ions in a 0.015 M solution of potassium carbonate?

*Answer:* 0.030 M  $K^+$

## Interconverting Molarity, Moles, and Volume

The definition of molarity (Equation 4.33) contains three quantities—molarity, moles solute, and liters of solution. If we know any two of these, we can calculate the third. For example, if we know the molarity of a solution, we can calculate the number of moles of solute in a given volume. Molarity, therefore, is a conversion factor between volume of solution and moles of solute. Calculation of the number of moles of  $HNO_3$  in 2.0 L of 0.200 M  $HNO_3$  solution illustrates the conversion of volume to moles:

$$\begin{aligned} \text{moles } HNO_3 &= (2.0 \text{ L soln}) \left( \frac{0.200 \text{ mol } HNO_3}{1 \text{ L soln}} \right) \\ &= 0.40 \text{ mol } HNO_3 \end{aligned}$$

Dimensional analysis can be used in this conversion if we express molarity as moles/liter soln. To obtain moles, therefore, we multiply liters and molarity: moles = liters  $\times$  molarity =  $\cancel{\text{liters}} \times \text{moles}/\cancel{\text{liter}}$ .

To illustrate the conversion of moles to volume, let's calculate the volume of 0.30 M  $\text{HNO}_3$  solution required to supply 2.0 mol of  $\text{HNO}_3$ :

$$\text{Liters soln} = (2.0 \text{ mol HNO}_3) \left( \frac{1 \text{ L soln}}{0.30 \text{ mol HNO}_3} \right) = 6.7 \text{ L soln}$$

In this case we must use the reciprocal of molarity in the conversion:  $\text{liters} = \text{moles} \times 1/M = \text{moles} \times \text{liters/mole}$ .

### ■ SAMPLE EXERCISE 4.13 | Using Molarity to Calculate Grams of Solute

How many grams of  $\text{Na}_2\text{SO}_4$  are required to make 0.350 L of 0.500 M  $\text{Na}_2\text{SO}_4$ ?

#### SOLUTION

**Analyze:** We are given the volume of the solution (0.350 L), its concentration (0.500 M), and the identity of the solute  $\text{Na}_2\text{SO}_4$  and asked to calculate the number of grams of the solute in the solution.

**Plan:** We can use the definition of molarity (Equation 4.33) to determine the number of moles of solute, and then convert moles to grams using the molar mass of the solute.

$$M_{\text{Na}_2\text{SO}_4} = \frac{\text{moles Na}_2\text{SO}_4}{\text{liters soln}}$$

**Solve:** Calculating the moles of  $\text{Na}_2\text{SO}_4$  using the molarity and volume of solution gives

$$\begin{aligned} M_{\text{Na}_2\text{SO}_4} &= \frac{\text{moles Na}_2\text{SO}_4}{\text{liters soln}} \\ \text{moles Na}_2\text{SO}_4 &= \text{liters soln} \times M_{\text{Na}_2\text{SO}_4} \\ &= (0.350 \text{ L soln}) \left( \frac{0.500 \text{ mol Na}_2\text{SO}_4}{1 \text{ L soln}} \right) \\ &= 0.175 \text{ mol Na}_2\text{SO}_4 \end{aligned}$$

Because each mole of  $\text{Na}_2\text{SO}_4$  weighs 142 g, the required number of grams of  $\text{Na}_2\text{SO}_4$  is

$$\text{grams Na}_2\text{SO}_4 = (0.175 \text{ mol Na}_2\text{SO}_4) \left( \frac{142 \text{ g Na}_2\text{SO}_4}{1 \text{ mol Na}_2\text{SO}_4} \right) = 24.9 \text{ g Na}_2\text{SO}_4$$

**Check:** The magnitude of the answer, the units, and the number of significant figures are all appropriate.

#### ■ PRACTICE EXERCISE

(a) How many grams of  $\text{Na}_2\text{SO}_4$  are there in 15 mL of 0.50 M  $\text{Na}_2\text{SO}_4$ ? (b) How many milliliters of 0.50 M  $\text{Na}_2\text{SO}_4$  solution are needed to provide 0.038 mol of this salt?

**Answers:** (a) 1.1 g, (b) 76 mL

## Dilution

Solutions that are used routinely in the laboratory are often purchased or prepared in concentrated form (called *stock solutions*). Hydrochloric acid, for example, is purchased as a 12 M solution (concentrated HCl). Solutions of lower concentrations can then be obtained by adding water, a process called **dilution**.\*

Let's look at how to prepare a dilute solution from a concentrated one. Suppose we wanted to prepare 250.0 mL (that is, 0.2500 L) of 0.100 M  $\text{CuSO}_4$  solution by diluting a stock solution containing 1.00 M  $\text{CuSO}_4$ . When solvent is added to dilute a solution, the number of moles of solute remains unchanged.

$$\text{Moles solute before dilution} = \text{moles solute after dilution} \quad [4.34]$$

\*In diluting a concentrated acid or base, the acid or base should be added to water and then further diluted by adding more water. Adding water directly to concentrated acid or base can cause spattering because of the intense heat generated.

For a long time it was thought that dehydration was a potential danger for people engaged in extended vigorous activity. Thus, athletes were encouraged to drink lots of water while engaged in active sport. The trend toward extensive hydration has spread throughout society; many people carry water bottles everywhere and dutifully keep well hydrated.

It turns out, though, that in some circumstances, drinking too much water is a greater danger than not drinking enough. Excess water consumption can lead to *hyponatremia*, a condition in which the concentration of sodium ion in the blood is too low. In the past decade at least four marathon runners have died from hyponatremia-related trauma, and dozens more have become seriously ill. For example, a first-time marathoner named Hillary Bellamy, running in the Marine Corps marathon in 2003, collapsed near mile 22 and died the next day. One physician who treated her said that she died from hyponatremia-induced brain swelling, the result of drinking too much water before and during the race.

The normal blood sodium level is 135 to 145 mM (*millimolar*). When that level drops to as low as 125 mM, dizziness and confusion set in. A concentration below 120 mM can be critical. Low sodium level in the blood causes brain tissue to swell. Dangerously low levels can occur in a marathon runner or other active athlete who is sweating out salt at the same time that excessive salt-free water is being drunk to compensate for water loss. The condition affects women more than men because of their generally different body composition and patterns of metabolism. Drinking a sport drink, such as Gatorade, which contains some electrolytes, helps to prevent hyponatremia (Figure 4.17 ►).

Contrary to popular belief, dehydration is not as likely as overhydration to present a life-threatening situation, though it can contribute to heat stroke when the temperature is high. Athletes frequently lose several pounds in the course of extreme workouts, all in the form of water loss, with no lasting adverse effects. When, for instance, Amby Burfoot ran in the Boston Marathon in 1968, his body weight went from 138 to 129 pounds during the race. He lost 6.5% of his body weight while winning the men's competition that year. Weight losses of this magnitude are typical of elite marathon runners, who produce tremendous amounts of heat and sweat and cannot afford to slow down for much drinking.

*Related Exercises: 4.63, 4.64*

▲ **Figure 4.17 Water stations.** To help prevent overhydration, the number of water stations such as this one has been reduced in many marathon events.

Because we know both the volume and concentration of the dilute solution, we can calculate the number of moles of  $\text{CuSO}_4$  it contains.

$$\begin{aligned} \text{moles CuSO}_4 \text{ in dil soln} &= (0.2500 \text{ L soln}) \left( 0.100 \frac{\text{mol CuSO}_4}{\text{L soln}} \right) \\ &= 0.0250 \text{ mol CuSO}_4 \end{aligned}$$

Now we can calculate the volume of the concentrated solution needed to provide 0.0250 mol  $\text{CuSO}_4$ :

$$\text{Liters of conc soln} = (0.0250 \text{ mol CuSO}_4) \left( \frac{1 \text{ L soln}}{1.00 \text{ mol CuSO}_4} \right) = 0.0250 \text{ L}$$

Thus, this dilution is achieved by withdrawing 0.0250 L (that is, 25.0 mL) of the 1.00 M solution using a pipet, adding it to a 250-mL volumetric flask, and then diluting it to a final volume of 250.0 mL, as shown in Figure 4.18 ▼. Notice that the diluted solution is less intensely colored than the concentrated one.

In laboratory situations, calculations of this sort are often made very quickly with a simple equation that can be derived by remembering that the number of moles of solute is the same in both the concentrated and dilute solutions and that moles = molarity  $\times$  liters:

$$\begin{aligned} \text{moles solute in conc soln} &= \text{moles solute in dil soln} \\ M_{\text{conc}} \times V_{\text{conc}} &= M_{\text{dil}} \times V_{\text{dil}} \end{aligned} \quad [4.35]$$

► **Figure 4.18** Procedure for preparing 250 mL of 0.100 M  $\text{CuSO}_4$  by dilution of 1.00 M  $\text{CuSO}_4$ . (a) Draw 25.0 mL of the 1.00 M solution into a pipet. (b) Add this to a 250-mL volumetric flask. (c) Add water to dilute the solution to a total volume of 250 mL.

### GIVE IT SOME THOUGHT

How is the molarity of a 0.50 M KBr solution changed when water is added to double its volume?

The molarity of the more concentrated stock solution ( $M_{\text{conc}}$ ) is always larger than the molarity of the dilute solution ( $M_{\text{dil}}$ ). Because the volume of the solution increases upon dilution,  $V_{\text{dil}}$  is always larger than  $V_{\text{conc}}$ . Although Equation 4.35 is derived in terms of liters, any volume unit can be used as long as that same unit is used on both sides of the equation. For example, in the calculation we did for the  $\text{CuSO}_4$  solution, we have

$$(1.00 M)(V_{\text{conc}}) = (0.100 M)(250. \text{ mL})$$

Solving for  $V_{\text{conc}}$  gives  $V_{\text{conc}} = 25.0 \text{ mL}$  as before.

#### SAMPLE EXERCISE 4.14 | Preparing a Solution by Dilution

How many milliliters of 3.0 M  $\text{H}_2\text{SO}_4$  are needed to make 450 mL of 0.10 M  $\text{H}_2\text{SO}_4$ ?

#### SOLUTION

**Analyze:** We need to dilute a concentrated solution. We are given the molarity of a more concentrated solution (3.0 M) and the volume and molarity of a more dilute one containing the same solute (450 mL of 0.10 M solution). We must calculate the volume of the concentrated solution needed to prepare the dilute solution.

**Plan:** We can calculate the number of moles of solute,  $\text{H}_2\text{SO}_4$ , in the dilute solution and then calculate the volume of the concentrated solution needed to supply this amount of solute. Alternatively, we can directly apply Equation 4.35. Let's compare the two methods.

**Solve:** Calculating the moles of  $\text{H}_2\text{SO}_4$  in the dilute solution:

$$\begin{aligned} \text{moles } \text{H}_2\text{SO}_4 \text{ in dilute solution} &= (0.450 \text{ L soln}) \left( \frac{0.10 \text{ mol } \text{H}_2\text{SO}_4}{1 \text{ L soln}} \right) \\ &= 0.045 \text{ mol } \text{H}_2\text{SO}_4 \end{aligned}$$

Calculating the volume of the concentrated solution that contains 0.045 mol  $\text{H}_2\text{SO}_4$ :

$$\text{L conc soln} = (0.045 \text{ mol } \text{H}_2\text{SO}_4) \left( \frac{1 \text{ L soln}}{3.0 \text{ mol } \text{H}_2\text{SO}_4} \right) = 0.015 \text{ L soln}$$

Converting liters to milliliters gives 15 mL.

If we apply Equation 4.35, we get the same result:

$$(3.0 M)(V_{\text{conc}}) = (0.10 M)(450 \text{ mL})$$

$$(V_{\text{conc}}) = \frac{(0.10 M)(450 \text{ mL})}{3.0 M} = 15 \text{ mL}$$

Either way, we see that if we start with 15 mL of 3.0 M H<sub>2</sub>SO<sub>4</sub> and dilute it to a total volume of 450 mL, the desired 0.10 M solution will be obtained.

**Check:** The calculated volume seems reasonable because a small volume of concentrated solution is used to prepare a large volume of dilute solution.

### ■ PRACTICE EXERCISE

- (a) What volume of 2.50 M lead(II) nitrate solution contains 0.0500 mol of Pb<sup>2+</sup>?  
 (b) How many milliliters of 5.0 M K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution must be diluted to prepare 250 mL of 0.10 M solution? (c) If 10.0 mL of a 10.0 M stock solution of NaOH is diluted to 250 mL, what is the concentration of the resulting stock solution?

**Answers:** (a) 0.0200 L = 20.0 mL, (b) 5.0 mL, (c) 0.40 M

## 4.6 SOLUTION STOICHIOMETRY AND CHEMICAL ANALYSIS

Imagine that you have to determine the concentrations of several ions in a sample of lake water. Although many instrumental methods have been developed for such analyses, chemical reactions such as those discussed in this chapter continue to be used. In Chapter 3 we learned that if you know the chemical equation and the amount of one reactant consumed in the reaction, you can calculate the quantities of other reactants and products. In this section we briefly explore such analyses of solutions.

Recall that the coefficients in a balanced equation give the relative number of moles of reactants and products. ∞ (Section 3.6) To use this information, we must convert the quantities of substances involved in a reaction into moles. When we are dealing with grams of substances, as we were in Chapter 3, we use the molar mass to achieve this conversion. When we are working with solutions of known molarity, however, we use molarity and volume to determine the number of moles (moles solute =  $M \times L$ ). Figure 4.19 ▼ summarizes this approach to using stoichiometry.

▲ **Figure 4.19 Problem-solving procedure.** Outline of the procedure used to solve stoichiometry problems that involve measured (laboratory) units of mass, solution concentration (molarity), or volume.

### ■ SAMPLE EXERCISE 4.15 Using Mass Relations in a Neutralization Reaction

How many grams of  $\text{Ca}(\text{OH})_2$  are needed to neutralize 25.0 mL of 0.100 M  $\text{HNO}_3$ ?

#### SOLUTION

**Analyze:** The reactants are an acid,  $\text{HNO}_3$ , and a base,  $\text{Ca}(\text{OH})_2$ . The volume and molarity of  $\text{HNO}_3$  are given, and we are asked how many grams of  $\text{Ca}(\text{OH})_2$  are needed to neutralize this quantity of  $\text{HNO}_3$ .

**Plan:** We can use the molarity and volume of the  $\text{HNO}_3$  solution to calculate the number of moles of  $\text{HNO}_3$ . We then use the balanced equation to relate the moles of  $\text{HNO}_3$  to moles of  $\text{Ca}(\text{OH})_2$ . Finally, we can convert moles of  $\text{Ca}(\text{OH})_2$  to grams. These steps can be summarized as follows:

**Solve:** The product of the molar concentration of a solution and its volume in liters gives the number of moles of solute:

$$\begin{aligned} \text{moles HNO}_3 &= \text{L}_{\text{HNO}_3} \times M_{\text{HNO}_3} = (0.0250 \text{ L}) \left( 0.100 \frac{\text{mol HNO}_3}{\text{L}} \right) \\ &= 2.50 \times 10^{-3} \text{ mol HNO}_3 \end{aligned}$$

Because this is an acid–base neutralization reaction,  $\text{HNO}_3$  and  $\text{Ca}(\text{OH})_2$  react to form  $\text{H}_2\text{O}$  and the salt containing  $\text{Ca}^{2+}$  and  $\text{NO}_3^-$ :

Thus, 2 mol  $\text{HNO}_3 \approx$  1 mol  $\text{Ca}(\text{OH})_2$ . Therefore,

$$\begin{aligned} \text{grams Ca}(\text{OH})_2 &= (2.50 \times 10^{-3} \text{ mol HNO}_3) \left( \frac{1 \text{ mol Ca}(\text{OH})_2}{2 \text{ mol HNO}_3} \right) \left( \frac{74.1 \text{ g Ca}(\text{OH})_2}{1 \text{ mol Ca}(\text{OH})_2} \right) \\ &= 0.0926 \text{ g Ca}(\text{OH})_2 \end{aligned}$$

**Check:** The size of the answer is reasonable. A small volume of dilute acid will require only a small amount of base to neutralize it.

#### ■ PRACTICE EXERCISE

(a) How many grams of  $\text{NaOH}$  are needed to neutralize 20.0 mL of 0.150 M  $\text{H}_2\text{SO}_4$  solution? (b) How many liters of 0.500 M  $\text{HCl}(\text{aq})$  are needed to react completely with 0.100 mol of  $\text{Pb}(\text{NO}_3)_2(\text{aq})$ , forming a precipitate of  $\text{PbCl}_2(\text{s})$ ?

**Answers:** (a) 0.240 g, (b) 0.400 L

## Titration

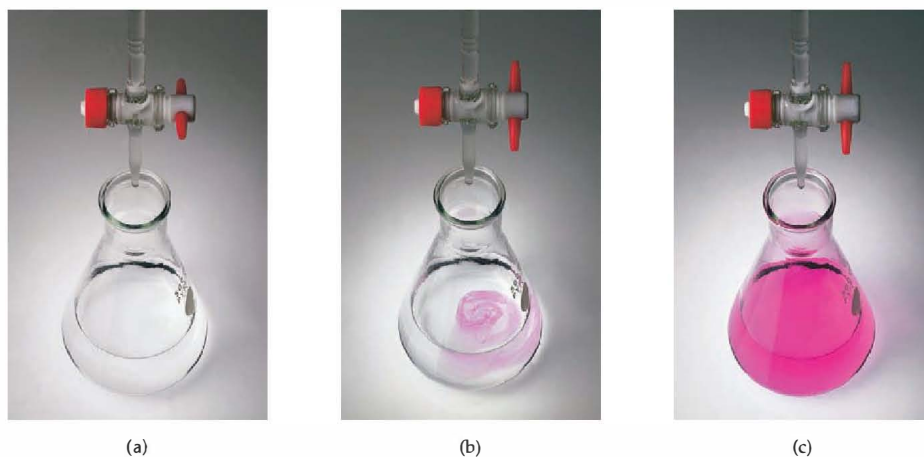

To determine the concentration of a particular solute in a solution, chemists often carry out a **titration**, which involves combining a sample of the solution with a reagent solution of known concentration, called a **standard solution**. Titrations can be conducted using acid–base, precipitation, or oxidation–reduction reactions. Suppose we have an  $\text{HCl}$  solution of unknown concentration and an  $\text{NaOH}$  solution we know to be 0.100 M. To determine the concentration of the  $\text{HCl}$  solution, we take a specific volume of that solution, say 20.00 mL. We then slowly add the standard  $\text{NaOH}$  solution to it until the neutralization reaction between the  $\text{HCl}$  and  $\text{NaOH}$  is complete. The point at which stoichiometrically equivalent quantities are brought together is known as the **equivalence point** of the titration.

### GIVE IT SOME THOUGHT

25.00 mL of a 0.100 M  $\text{HBr}$  solution is titrated with a 0.200 M  $\text{NaOH}$  solution. How many mL of the  $\text{NaOH}$  solution are required to reach the equivalence point?

To titrate an unknown with a standard solution, there must be some way to determine when the equivalence point of the titration has been reached. In acid–base titrations, dyes known as acid–base **indicators** are used for this purpose.

▲ **Figure 4.20** Change in appearance of a solution containing phenolphthalein indicator as base is added. Before the end point, the solution is colorless (a). As the end point is approached, a pale pink color forms where the base is added (b). At the end point, this pale pink color extends throughout the solution after mixing. As even more base is added, the intensity of the pink color increases (c).

For example, the dye known as phenolphthalein is colorless in acidic solution but is pink in basic solution. If we add phenolphthalein to an unknown solution of acid, the solution will be colorless, as seen in Figure 4.20(a) ▲. We can then add standard base from a buret until the solution barely turns from colorless to pink, as seen in Figure 4.20(b). This color change indicates that the acid has been neutralized and the drop of base that caused the solution to become colored has no acid to react with. The solution therefore becomes basic, and the dye turns pink. The color change signals the *end point* of the titration, which usually coincides very nearly with the equivalence point. Care must be taken to choose indicators whose end points correspond to the equivalence point of the titration. We will consider this matter in Chapter 17. The titration procedure is summarized in Figure 4.21 ▼.

◀ **Figure 4.21** Procedure for titrating an acid against a standardized solution of NaOH.

(a) A known quantity of acid is added to a flask. (b) An acid–base indicator is added, and standardized NaOH is added from a buret. (c) The equivalence point is signaled by a color change in the indicator.

**SAMPLE EXERCISE 4.16** | Determining the Quantity of Solute by Titration

The quantity of  $\text{Cl}^-$  in a municipal water supply is determined by titrating the sample with  $\text{Ag}^+$ . The reaction taking place during the titration is

The end point in this type of titration is marked by a change in color of a special type of indicator. (a) How many grams of chloride ion are in a sample of the water if 20.2 mL of 0.100 M  $\text{Ag}^+$  is needed to react with all the chloride in the sample? (b) If the sample has a mass of 10.0 g, what percent  $\text{Cl}^-$  does it contain?

**SOLUTION**

**Analyze:** We are given the volume (20.2 mL) and molarity (0.100 M) of a solution of  $\text{Ag}^+$  and the chemical equation for reaction of this ion with  $\text{Cl}^-$ . We are asked first to calculate the number of grams of  $\text{Cl}^-$  in the sample and, second, to calculate the mass percent of  $\text{Cl}^-$  in the sample.

**(a) Plan:** We begin by using the volume and molarity of  $\text{Ag}^+$  to calculate the number of moles of  $\text{Ag}^+$  used in the titration. We can then use the balanced equation to determine the moles of  $\text{Cl}^-$  in the sample and from that the grams of  $\text{Cl}^-$ .

**Solve:**

$$\begin{aligned} \text{moles Ag}^+ &= (20.2 \text{ mL solution}) \left( \frac{1 \text{ L solution}}{1000 \text{ mL solution}} \right) \left( 0.100 \frac{\text{mol Ag}^+}{\text{L solution}} \right) \\ &= 2.02 \times 10^{-3} \text{ mol Ag}^+ \end{aligned}$$

From the balanced equation we see that 1 mol  $\text{Ag}^+ \approx$  1 mol  $\text{Cl}^-$ . Using this information and the molar mass of Cl, we have

$$\begin{aligned} \text{grams Cl}^- &= (2.02 \times 10^{-3} \text{ mol Ag}^+) \left( \frac{1 \text{ mol Cl}^-}{1 \text{ mol Ag}^+} \right) \left( \frac{35.5 \text{ g Cl}^-}{1 \text{ mol Cl}^-} \right) \\ &= 7.17 \times 10^{-2} \text{ g Cl}^- \end{aligned}$$

**(b) Plan:** To calculate the percentage of  $\text{Cl}^-$  in the sample, we compare the number of grams of  $\text{Cl}^-$  in the sample,  $7.17 \times 10^{-2}$  g, with the original mass of the sample, 10.0 g.

$$\text{Solve: Percent Cl}^- = \frac{7.17 \times 10^{-2} \text{ g}}{10.0 \text{ g}} \times 100\% = 0.717\% \text{ Cl}^-$$

**Comment:** Chloride ion is one of the most common ions in water and sewage. Ocean water contains 1.92%  $\text{Cl}^-$ . Whether water containing  $\text{Cl}^-$  tastes salty depends on the other ions present. If the only accompanying ions are  $\text{Na}^+$ , a salty taste may be detected with as little as 0.03%  $\text{Cl}^-$ .

**PRACTICE EXERCISE**

A sample of an iron ore is dissolved in acid, and the iron is converted to  $\text{Fe}^{2+}$ . The sample is then titrated with 47.20 mL of 0.02240 M  $\text{MnO}_4^-$  solution. The oxidation-reduction reaction that occurs during titration is as follows:

(a) How many moles of  $\text{MnO}_4^-$  were added to the solution? (b) How many moles of  $\text{Fe}^{2+}$  were in the sample? (c) How many grams of iron were in the sample? (d) If the sample had a mass of 0.8890 g, what is the percentage of iron in the sample?

**Answers:** (a)  $1.057 \times 10^{-3}$  mol  $\text{MnO}_4^-$  (b)  $5.286 \times 10^{-3}$  mol  $\text{Fe}^{2+}$ , (c) 0.2952 g, (d) 33.21%

**SAMPLE EXERCISE 4.17** | Determining Solution Concentration Via an Acid–Base Titration

One commercial method used to peel potatoes is to soak them in a solution of NaOH for a short time, remove them from the NaOH, and spray off the peel. The concentration of NaOH is normally in the range of 3 to 6 M. The NaOH is analyzed periodically. In one such analysis, 45.7 mL of 0.500 M  $\text{H}_2\text{SO}_4$  is required to neutralize a 20.0-mL sample of NaOH solution. What is the concentration of the NaOH solution?

**SOLUTION**

**Analyze:** We are given the volume (45.7 mL) and molarity (0.500 M) of an  $\text{H}_2\text{SO}_4$  solution that reacts completely with a 20.0-mL sample of NaOH. We are asked to calculate the molarity of the NaOH solution.

**Plan:** We can use the volume and molarity of the  $\text{H}_2\text{SO}_4$  to calculate the number of moles of this substance. Then, we can use this quantity and the balanced equation for the reaction to calculate the number of moles of NaOH. Finally, we can use the moles of NaOH and the volume of this solution to calculate molarity.

**Solve:** The number of moles of  $\text{H}_2\text{SO}_4$  is given by the product of the volume and molarity of this solution:

$$\begin{aligned}\text{moles H}_2\text{SO}_4 &= (45.7 \text{ mL soln}) \left( \frac{1 \text{ L soln}}{1000 \text{ mL soln}} \right) \left( 0.500 \frac{\text{mol H}_2\text{SO}_4}{\text{L soln}} \right) \\ &= 2.28 \times 10^{-2} \text{ mol H}_2\text{SO}_4\end{aligned}$$

Acids react with metal hydroxides to form water and a salt. Thus, the balanced equation for the neutralization reaction is

According to the balanced equation, 1 mol  $\text{H}_2\text{SO}_4 \approx 2$  mol NaOH. Therefore,

$$\begin{aligned}\text{moles NaOH} &= (2.28 \times 10^{-2} \text{ mol H}_2\text{SO}_4) \left( \frac{2 \text{ mol NaOH}}{1 \text{ mol H}_2\text{SO}_4} \right) \\ &= 4.56 \times 10^{-2} \text{ mol NaOH}\end{aligned}$$

Knowing the number of moles of NaOH present in 20.0 mL of solution allows us to calculate the molarity of this solution:

$$\begin{aligned}\text{Molarity NaOH} &= \frac{\text{mol NaOH}}{\text{L soln}} = \left( \frac{4.56 \times 10^{-2} \text{ mol NaOH}}{20.0 \text{ mL soln}} \right) \left( \frac{1000 \text{ mL soln}}{1 \text{ L soln}} \right) \\ &= 2.28 \frac{\text{mol NaOH}}{\text{L soln}} = 2.28 \text{ M}\end{aligned}$$

**PRACTICE EXERCISE**

What is the molarity of an NaOH solution if 48.0 mL is needed to neutralize 35.0 mL of 0.144 M  $\text{H}_2\text{SO}_4$ ?

**Answers:** 0.210 M

**SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together**

Note: Integrative exercises require skills from earlier chapters as well as ones from the present chapter.

A sample of 70.5 mg of potassium phosphate is added to 15.0 mL of 0.050 M silver nitrate, resulting in the formation of a precipitate. (a) Write the molecular equation for the reaction. (b) What is the limiting reactant in the reaction? (c) Calculate the theoretical yield, in grams, of the precipitate that forms.

**SOLUTION**

(a) Potassium phosphate and silver nitrate are both ionic compounds. Potassium phosphate contains  $\text{K}^+$  and  $\text{PO}_4^{3-}$  ions, so its chemical formula is  $\text{K}_3\text{PO}_4$ . Silver nitrate contains  $\text{Ag}^+$  and  $\text{NO}_3^-$  ions, so its chemical formula is  $\text{AgNO}_3$ . Because both reactants are strong electrolytes, the solution contains  $\text{K}^+$ ,  $\text{PO}_4^{3-}$ ,  $\text{Ag}^+$ , and  $\text{NO}_3^-$  ions before the reaction occurs. According to the solubility guidelines in Table 4.1,  $\text{Ag}^+$  and  $\text{PO}_4^{3-}$  form an insoluble compound, so  $\text{Ag}_3\text{PO}_4$  will precipitate from the solution. In contrast,  $\text{K}^+$  and  $\text{NO}_3^-$  will remain in solution because  $\text{KNO}_3$  is water soluble. Thus, the balanced molecular equation for the reaction is

(b) To determine the limiting reactant, we must examine the number of moles of each reactant.  $\infty$  (Section 3.7) The number of moles of  $\text{K}_3\text{PO}_4$  is calculated from the mass of the sample using the molar mass as a conversion factor.  $\infty$  (Section 3.4)

The molar mass of  $K_3PO_4$  is  $3(39.1) + 31.0 + 4(16.0) = 212.3$  g/mol. Converting milligrams to grams and then to moles, we have

$$(70.5 \text{ mg } K_3PO_4) \left( \frac{10^{-3} \text{ g } K_3PO_4}{1 \text{ mg } K_3PO_4} \right) \left( \frac{1 \text{ mol } K_3PO_4}{212.3 \text{ g } K_3PO_4} \right) = 3.32 \times 10^{-4} \text{ mol } K_3PO_4$$

We determine the number of moles of  $AgNO_3$  from the volume and molarity of the solution.  $\Leftrightarrow$  (Section 4.5) Converting milliliters to liters and then to moles, we have

$$(15.0 \text{ mL}) \left( \frac{10^{-3} \text{ L}}{1 \text{ mL}} \right) \left( \frac{0.050 \text{ mol } AgNO_3}{\text{L}} \right) = 7.5 \times 10^{-4} \text{ mol } AgNO_3$$

Comparing the amounts of the two reactants, we find that there are  $(7.5 \times 10^{-4}) / (3.32 \times 10^{-4}) = 2.3$  times as many moles of  $AgNO_3$  as there are moles of  $K_3PO_4$ . According to the balanced equation, however, 1 mol  $K_3PO_4$  requires 3 mol of  $AgNO_3$ . Thus, there is insufficient  $AgNO_3$  to consume the  $K_3PO_4$ , and  $AgNO_3$  is the limiting reactant.

(c) The precipitate is  $Ag_3PO_4$ , whose molar mass is  $3(107.9) + 31.0 + 4(16.0) = 418.7$  g/mol. To calculate the number of grams of  $Ag_3PO_4$  that could be produced in this reaction (the theoretical yield), we use the number of moles of the limiting reactant, converting mol  $AgNO_3 \Rightarrow$  mol  $Ag_3PO_4 \Rightarrow$  g  $Ag_3PO_4$ . We use the coefficients in the balanced equation to convert moles of  $AgNO_3$  to moles  $Ag_3PO_4$ , and we use the molar mass of  $Ag_3PO_4$  to convert the number of moles of this substance to grams.

$$(7.5 \times 10^{-4} \text{ mol } AgNO_3) \left( \frac{1 \text{ mol } Ag_3PO_4}{3 \text{ mol } AgNO_3} \right) \left( \frac{418.7 \text{ g } Ag_3PO_4}{1 \text{ mol } Ag_3PO_4} \right) = 0.10 \text{ g } Ag_3PO_4$$

The answer has only two significant figures because the quantity of  $AgNO_3$  is given to only two significant figures.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 4.1** Solutions in which water is the dissolving medium are called **aqueous solutions**. The component of the solution that is in the greater quantity is the **solvent**. The other components are **solutes**.

Any substance whose aqueous solution contains ions is called an **electrolyte**. Any substance that forms a solution containing no ions is a **nonelectrolyte**. Electrolytes that are present in solution entirely as ions are **strong electrolytes**, whereas those that are present partly as ions and partly as molecules are **weak electrolytes**. Ionic compounds dissociate into ions when they dissolve, and they are strong electrolytes. The solubility of ionic substances is made possible by **solvation**, the interaction of ions with polar solvent molecules. Most molecular compounds are nonelectrolytes, although some are weak electrolytes, and a few are strong electrolytes. When representing the ionization of a weak electrolyte in solution, half-arrows in both directions are used, indicating that the forward and reverse reactions can achieve a chemical balance called a **chemical equilibrium**.

**Section 4.2** **Precipitation reactions** are those in which an insoluble product, called a **precipitate**, forms. Solubility guidelines help determine whether or not an ionic compound will be soluble in water. (The **solubility** of a substance is the amount that dissolves in a given quantity of solvent.) Reactions such as precipitation reactions, in which cations and anions appear to exchange partners, are called **exchange reactions**, or **metathesis reactions**.

Chemical equations can be written to show whether dissolved substances are present in solution predominantly as ions or molecules. When the complete chemical formulas of all reactants and products are used, the equation is called a **molecular equation**. A **complete ionic equation** shows all dissolved strong electrolytes as their component ions. In a **net ionic equation**, those ions that go through the reaction unchanged (**spectator ions**) are omitted.

**Section 4.3** Acids and bases are important electrolytes. **Acids** are proton donors; they increase the concentration of  $H^+(aq)$  in aqueous solutions to which they are added.

**Bases** are proton acceptors; they increase the concentration of  $\text{OH}^-(aq)$  in aqueous solutions. Those acids and bases that are strong electrolytes are called **strong acids** and **strong bases**, respectively. Those that are weak electrolytes are **weak acids** and **weak bases**. When solutions of acids and bases are mixed, a **neutralization reaction** results. The neutralization reaction between an acid and a metal hydroxide produces water and a **salt**. Gases can also be formed as a result of acid–base reactions. The reaction of a sulfide with an acid forms  $\text{H}_2\text{S}(g)$ ; the reaction between a carbonate and an acid forms  $\text{CO}_2(g)$ .

**Section 4.4** **Oxidation** is the loss of electrons by a substance, whereas **reduction** is the gain of electrons by a substance. **Oxidation numbers** keep track of electrons during chemical reactions and are assigned to atoms using specific rules. The oxidation of an element results in an increase in its oxidation number, whereas reduction is accompanied by a decrease in oxidation number. Oxidation is always accompanied by reduction, giving **oxidation-reduction**, or redox, **reactions**.

Many metals are oxidized by  $\text{O}_2$ , acids, and salts. The redox reactions between metals and acids and between metals and salts are called **displacement reactions**. The products of these displacement reactions are always an element ( $\text{H}_2$  or a metal) and a salt. Comparing such reactions allows us to rank metals according to their ease of oxidation. A list of metals arranged in order of decreasing

ease of oxidation is called an **activity series**. Any metal on the list can be oxidized by ions of metals (or  $\text{H}^+$ ) below it in the series.

**Section 4.5** The composition of a solution expresses the relative quantities of solvent and solutes that it contains. One of the common ways to express the **concentration** of a solute in a solution is in terms of molarity. The **molarity** of a solution is the number of moles of solute per liter of solution. Molarity makes it possible to interconvert solution volume and number of moles of solute. Solutions of known molarity can be formed either by weighing out the solute and diluting it to a known volume or by the **dilution** of a more concentrated solution of known concentration (a stock solution). Adding solvent to the solution (the process of dilution) decreases the concentration of the solute without changing the number of moles of solute in the solution ( $M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}}$ ).

**Section 4.6** In the process called **titration**, we combine a solution of known concentration (a **standard solution**) with a solution of unknown concentration to determine the unknown concentration or the quantity of solute in the unknown. The point in the titration at which stoichiometrically equivalent quantities of reactants are brought together is called the **equivalence point**. An **indicator** can be used to show the end point of the titration, which coincides closely with the equivalence point.

## KEY SKILLS

---

- Recognize compounds as acids or bases, and as strong, weak, or nonelectrolytes.
- Recognize reactions as acid–base, precipitation, metathesis, or redox.
- Be able to calculate moles or grams of substances in solution using molarity.
- Understand how to carry out a dilution to achieve a desired solution concentration.
- Understand how to perform and interpret the results of a titration.

## KEY EQUATIONS

---

$$\bullet \text{ Molarity} = \frac{\text{moles solute}}{\text{volume of solution in liters}} \quad [4.33]$$

$$\bullet M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}} \quad [4.35]$$

Molarity is the most commonly used unit of concentration in chemistry.

When adding solvent to a concentrated solution to make a dilute solution, molarities and volumes of both concentrated and dilute solutions can be calculated if three of the quantities are known.

## VISUALIZING CONCEPTS

- 4.1 Which of the following schematic drawings best describes a solution of  $\text{Li}_2\text{SO}_4$  in water (water molecules not shown for simplicity)? [Section 4.1]

(a)

(b)

(c)

- 4.2 Methanol,  $\text{CH}_3\text{OH}$ , and hydrogen chloride,  $\text{HCl}$ , are both molecular substances, yet an aqueous solution of methanol does not conduct an electrical current, whereas a solution of  $\text{HCl}$  does conduct. Account for this difference. [Section 4.1]

- 4.3 Aqueous solutions of three different substances, AX, AY, and AZ, are represented by the three diagrams below. Identify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte. [Section 4.1]

(a)

(b)

(c)

- 4.4 A 0.1 M solution of acetic acid,  $\text{CH}_3\text{COOH}$ , causes the lightbulb in the apparatus of Figure 4.2 to glow about as brightly as a 0.001 M solution of  $\text{HBr}$ . How do you account for this fact? [Section 4.1]

- 4.5 You are presented with three white solids, A, B, and C, which are glucose (a sugar substance),  $\text{NaOH}$ , and  $\text{AgBr}$ . Solid A dissolves in water to form a conducting solution. B is not soluble in water. C dissolves in water to form a nonconducting solution. Identify A, B, and C. [Section 4.2]

- 4.6 We have seen that ions in aqueous solution are stabilized by the attractions between the ions and the water molecules. Why then do some pairs of ions in solution form precipitates? [Section 4.2]

- 4.7 Which of the following ions will *always* be a spectator ion in a precipitation reaction? (a)  $\text{Cl}^-$ , (b)  $\text{NO}_3^-$ , (c)  $\text{NH}_4^+$ , (d)  $\text{S}^{2-}$ , (e)  $\text{SO}_4^{2-}$ . Explain briefly. [Section 4.2]

- 4.8 The labels have fallen off two bottles, one containing  $\text{Mg}(\text{NO}_3)_2$  and the other containing  $\text{Pb}(\text{NO}_3)_2$ . You have a bottle of dilute  $\text{H}_2\text{SO}_4$ . How could you use it to test a portion of each solution to identify which solution is which? [Section 4.2]

- 4.9 Explain how a redox reaction involves electrons in the same way that an acid–base reaction involves protons. [Sections 4.3 and 4.4]

- 4.10 If you want to double the concentration of a solution, how could you do it? [Section 4.5]

## EXERCISES

## Electrolytes

- 4.11 When asked what causes electrolyte solutions to conduct electricity, a student responds that it is due to the movement of electrons through the solution. Is the student correct? If not, what is the correct response?
- 4.12 When methanol,  $\text{CH}_3\text{OH}$ , is dissolved in water, a nonconducting solution results. When acetic acid,  $\text{CH}_3\text{COOH}$ , dissolves in water, the solution is weakly conducting and acidic in nature. Describe what happens upon dissolution in the two cases, and account for the different results.
- 4.13 We have learned in this chapter that many ionic solids dissolve in water as strong electrolytes, that is, as separated ions in solution. What properties of water facilitate this process?
- 4.14 What does it mean to say that ions are hydrated when an ionic substance dissolves in water?
- 4.15 Specify what ions are present in solution upon dissolving each of the following substances in water: (a)  $\text{ZnCl}_2$ , (b)  $\text{HNO}_3$ , (c)  $(\text{NH}_4)_2\text{SO}_4$ , (d)  $\text{Ca}(\text{OH})_2$ .
- 4.16 Specify what ions are present upon dissolving each of the following substances in water: (a)  $\text{MgI}_2$ , (b)  $\text{Al}(\text{NO}_3)_3$ , (c)  $\text{HClO}_4$ , (d)  $\text{NaCH}_3\text{COO}$ .
- 4.17 Formic acid,  $\text{HCOOH}$ , is a weak electrolyte. What solute particles are present in an aqueous solution of this compound? Write the chemical equation for the ionization of  $\text{HCOOH}$ .
- 4.18 Acetone,  $\text{CH}_3\text{COCH}_3$ , is a nonelectrolyte; hypochlorous acid,  $\text{HClO}$ , is a weak electrolyte; and ammonium chloride,  $\text{NH}_4\text{Cl}$ , is a strong electrolyte. (a) What are the solute particles present in aqueous solutions of each compound? (b) If 0.1 mol of each compound is dissolved in solution, which one contains 0.2 mol of solute particles, which contains 0.1 mol of solute particles, and which contains somewhere between 0.1 and 0.2 mol of solute particles?

## Precipitation Reactions and Net Ionic Equations

- 4.19 Using solubility guidelines, predict whether each of the following compounds is soluble or insoluble in water: (a)  $\text{NiCl}_2$ , (b)  $\text{Ag}_2\text{S}$ , (c)  $\text{Cs}_3\text{PO}_4$ , (d)  $\text{SrCO}_3$ , (e)  $\text{PbSO}_4$ .
- 4.20 Predict whether each of the following compounds is soluble in water: (a)  $\text{Ni}(\text{OH})_2$ , (b)  $\text{PbBr}_2$ , (c)  $\text{Ba}(\text{NO}_3)_2$ , (d)  $\text{AlPO}_4$ , (e)  $\text{AgCH}_3\text{COO}$ .
- 4.21 Will precipitation occur when the following solutions are mixed? If so, write a balanced chemical equation for the reaction. (a)  $\text{Na}_2\text{CO}_3$  and  $\text{AgNO}_3$ , (b)  $\text{NaNO}_3$  and  $\text{NiSO}_4$ , (c)  $\text{FeSO}_4$  and  $\text{Pb}(\text{NO}_3)_2$ .
- 4.22 Identify the precipitate (if any) that forms when the following solutions are mixed, and write a balanced equation for each reaction. (a)  $\text{Ni}(\text{NO}_3)_2$  and  $\text{NaOH}$ , (b)  $\text{NaOH}$  and  $\text{K}_2\text{SO}_4$ , (c)  $\text{Na}_2\text{S}$  and  $\text{Cu}(\text{CH}_3\text{COO})_2$ .
- 4.23 Name the spectator ions in any reactions that may be involved when each of the following pairs of solutions are mixed.  
 (a)  $\text{Na}_2\text{CO}_3(\text{aq})$  and  $\text{MgSO}_4(\text{aq})$   
 (b)  $\text{Pb}(\text{NO}_3)_2(\text{aq})$  and  $\text{Na}_2\text{S}(\text{aq})$   
 (c)  $(\text{NH}_4)_3\text{PO}_4(\text{aq})$  and  $\text{CaCl}_2(\text{aq})$
- 4.24 Write balanced net ionic equations for the reactions that occur in each of the following cases. Identify the spectator ion or ions in each reaction.
- (a)  $\text{Cr}_2(\text{SO}_4)_3(\text{aq}) + (\text{NH}_4)_2\text{CO}_3(\text{aq}) \longrightarrow$   
 (b)  $\text{Ba}(\text{NO}_3)_2(\text{aq}) + \text{K}_2\text{SO}_4(\text{aq}) \longrightarrow$   
 (c)  $\text{Fe}(\text{NO}_3)_2(\text{aq}) + \text{KOH}(\text{aq}) \longrightarrow$
- 4.25 Separate samples of a solution of an unknown salt are treated with dilute solutions of  $\text{HBr}$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{NaOH}$ . A precipitate forms in all three cases. Which of the following cations could the solution contain:  $\text{K}^+$ ,  $\text{Pb}^{2+}$ ,  $\text{Ba}^{2+}$ ?
- 4.26 Separate samples of a solution of an unknown ionic compound are treated with dilute  $\text{AgNO}_3$ ,  $\text{Pb}(\text{NO}_3)_2$ , and  $\text{BaCl}_2$ . Precipitates form in all three cases. Which of the following could be the anion of the unknown salt:  $\text{Br}^-$ ,  $\text{CO}_3^{2-}$ ,  $\text{NO}_3^-$ ?
- 4.27 You know that an unlabeled bottle contains a solution of one of the following:  $\text{AgNO}_3$ ,  $\text{CaCl}_2$ , or  $\text{Al}_2(\text{SO}_4)_3$ . A friend suggests that you test a portion of the solution with  $\text{Ba}(\text{NO}_3)_2$  and then with  $\text{NaCl}$  solutions. Explain how these two tests together would be sufficient to determine which salt is present in the solution.
- 4.28 Three solutions are mixed together to form a single solution. One contains 0.2 mol  $\text{Pb}(\text{CH}_3\text{COO})_2$ , the second contains 0.1 mol  $\text{Na}_2\text{S}$ , and the third contains 0.1 mol  $\text{CaCl}_2$ . (a) Write the net ionic equations for the precipitation reaction or reactions that occur. (b) What are the spectator ions in the solution?

## Acid–Base Reactions

- 4.29 Which of the following solutions has the largest concentration of solvated protons: (a) 0.2 M  $\text{LiOH}$ , (b) 0.2 M  $\text{HCl}$ , (c) 1.0 M methyl alcohol ( $\text{CH}_3\text{OH}$ )? Explain.
- 4.30 Which of the following solutions is the most basic? (a) 0.6 M  $\text{NH}_3$ , (b) 0.150 M  $\text{KOH}$ , (c) 0.100 M  $\text{Ba}(\text{OH})_2$ . Explain.
- 4.31 What is the difference between (a) a monoprotic acid and a diprotic acid, (b) a weak acid and a strong acid, (c) an acid and a base?
- 4.32 Explain the following observations: (a)  $\text{NH}_3$  contains no  $\text{OH}^-$  ions, and yet its aqueous solutions are basic; (b)  $\text{HF}$  is called a weak acid, and yet it is very reactive; (c) although sulfuric acid is a strong electrolyte, an aqueous solution of  $\text{H}_2\text{SO}_4$  contains more  $\text{HSO}_4^-$  ions than  $\text{SO}_4^{2-}$  ions.
- 4.33  $\text{HCl}$ ,  $\text{HBr}$ , and  $\text{HI}$  are strong acids, yet  $\text{HF}$  is a weak acid. What does this mean in terms of the extent to which these substances are ionized in solution?
- 4.34 What is the relationship between the solubility rules in Table 4.1 and the list of strong bases in Table 4.2? Another way of asking this question is, why is  $\text{Cd}(\text{OH})_2$ , for example, not listed as a strong base in Table 4.2?
- 4.35 Label each of the following substances as an acid, base, salt, or none of the above. Indicate whether the substance exists in aqueous solution entirely in molecular form, entirely as ions, or as a mixture of molecules and ions. (a)  $\text{HF}$ ; (b) acetonitrile,  $\text{CH}_3\text{CN}$ ; (c)  $\text{NaClO}_4$ ; (d)  $\text{Ba}(\text{OH})_2$ .
- 4.36 An aqueous solution of an unknown solute is tested with litmus paper and found to be acidic. The solution is weakly conducting compared with a solution of  $\text{NaCl}$  of the same concentration. Which of the following substances could the unknown be:  $\text{KOH}$ ,  $\text{NH}_3$ ,  $\text{HNO}_3$ ,  $\text{KClO}_2$ ,  $\text{H}_3\text{PO}_3$ ,  $\text{CH}_3\text{COCH}_3$  (acetone)?
- 4.37 Classify each of the following substances as a nonelectrolyte, weak electrolyte, or strong electrolyte in water: (a)  $\text{H}_2\text{SO}_3$ , (b)  $\text{C}_2\text{H}_5\text{OH}$  (ethanol), (c)  $\text{NH}_3$ , (d)  $\text{KClO}_3$ , (e)  $\text{Cu}(\text{NO}_3)_2$ .
- 4.38 Classify each of the following aqueous solutions as a nonelectrolyte, weak electrolyte, or strong electrolyte: (a)  $\text{HClO}_4$ , (b)  $\text{HNO}_3$ , (c)  $\text{NH}_4\text{Cl}$ , (d)  $\text{CH}_3\text{COCH}_3$  (acetone), (e)  $\text{CoSO}_4$ , (f)  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  (sucrose).
- 4.39 Complete and balance the following molecular equations, and then write the net ionic equation for each:  
 (a)  $\text{HBr}(\text{aq}) + \text{Ca}(\text{OH})_2(\text{aq}) \longrightarrow$   
 (b)  $\text{Cu}(\text{OH})_2(\text{s}) + \text{HClO}_4(\text{aq}) \longrightarrow$   
 (c)  $\text{Al}(\text{OH})_3(\text{s}) + \text{HNO}_3(\text{aq}) \longrightarrow$
- 4.40 Write the balanced molecular and net ionic equations for each of the following neutralization reactions:  
 (a) Aqueous acetic acid is neutralized by aqueous potassium hydroxide.  
 (b) Solid chromium(III) hydroxide reacts with nitric acid.  
 (c) Aqueous hypochlorous acid and aqueous calcium hydroxide react.

**4.41** Write balanced molecular and net ionic equations for the following reactions, and identify the gas formed in each: (a) solid cadmium sulfide reacts with an aqueous solution of sulfuric acid; (b) solid magnesium carbonate reacts with an aqueous solution of perchloric acid.

**4.42** Because the oxide ion is basic, metal oxides react readily with acids. (a) Write the net ionic equation for the following reaction:

(b) Based on the equation in part (a), write the net ionic equation for the reaction that occurs between NiO(s) and an aqueous solution of nitric acid.

**4.43** Write a balanced molecular equation and a net ionic equation for the reaction that occurs when (a) solid  $\text{CaCO}_3$  reacts with an aqueous solution of nitric acid; (b) solid iron(II) sulfide reacts with an aqueous solution of hydrobromic acid.

**4.44** As  $\text{K}_2\text{O}$  dissolves in water, the oxide ion reacts with water molecules to form hydroxide ions. Write the molecular and net ionic equations for this reaction. Based on the definitions of acid and base, what ion is the base in this reaction? What is the acid? What is the spectator ion in the reaction?

## Oxidation-Reduction Reactions

**4.45** Define oxidation and reduction in terms of (a) electron transfer and (b) oxidation numbers.

**4.46** Can oxidation occur without accompanying reduction? Explain.

**4.47** Which circled region of the periodic table shown here contains the most readily oxidized elements? Which contains the least readily oxidized?

The diagram shows a periodic table with four regions circled:
 

- Region A:** The first column (Group 1), alkali metals.
- Region B:** The d-block, transition metals.
- Region C:** The p-block elements from Boron to Tellurium, metalloids.
- Region D:** The seventh column (Group 17), halogens.

 Below the main table is a separate grid of 10 empty boxes.

**4.48** From the elements listed in Table 4.5, select an element that lies in region A of the periodic table shown above and an element that lies in region C. Write a balanced oxidation-reduction equation that shows the oxidation of one metal and reduction of an ion of the other. You will need to decide which element is oxidized and which is reduced.

**4.49** Determine the oxidation number for the indicated element in each of the following substances: (a) S in  $\text{SO}_2$ , (b) C in  $\text{COCl}_2$ , (c) Mn in  $\text{MnO}_4^-$ , (d) Br in  $\text{HBrO}$ , (e) As in  $\text{As}_4$ , (f) O in  $\text{K}_2\text{O}_2$ .

**4.50** Determine the oxidation number for the indicated element in each of the following compounds: (a) Ti in  $\text{TiO}_2$ , (b) Sn in  $\text{SnCl}_3^-$ , (c) C in  $\text{C}_2\text{O}_4^{2-}$ , (d) N in  $\text{N}_2\text{H}_4$ , (e) N in  $\text{HNO}_2$ , (f) Cr in  $\text{Cr}_2\text{O}_7^{2-}$ .

**4.51** Which element is oxidized and which is reduced in the following reactions?

**4.52** Which of the following are redox reactions? For those that are, indicate which element is oxidized and which is reduced. For those that are not, indicate whether they are precipitation or acid-base reactions.

**4.53** Write balanced molecular and net ionic equations for the reactions of (a) manganese with dilute sulfuric acid; (b) chromium with hydrobromic acid; (c) tin with hydrochloric acid; (d) aluminum with formic acid,  $\text{HCOOH}$ .

**4.54** Write balanced molecular and net ionic equations for the reactions of (a) hydrochloric acid with nickel; (b) dilute sulfuric acid with iron; (c) hydrobromic acid with magnesium; (d) acetic acid,  $\text{CH}_3\text{COOH}$ , with zinc.

**4.55** Using the activity series (Table 4.5), write balanced chemical equations for the following reactions. If no reaction occurs, simply write NR. (a) Iron metal is added to a solution of copper(II) nitrate; (b) zinc metal is added to a solution of magnesium sulfate; (c) hydrobromic acid is added to tin metal; (d) hydrogen gas is bubbled through an aqueous solution of nickel(II) chloride; (e) aluminum metal is added to a solution of cobalt(II) sulfate.

**4.56** Based on the activity series (Table 4.5), what is the outcome (if any) of each of the following reactions?

**4.57** The metal cadmium tends to form  $\text{Cd}^{2+}$  ions. The following observations are made: (i) When a strip of zinc metal is placed in  $\text{CdCl}_2(aq)$ , cadmium metal is deposited on

the strip. (ii) When a strip of cadmium metal is placed in  $\text{Ni}(\text{NO}_3)_2(\text{aq})$ , nickel metal is deposited on the strip. (a) Write net ionic equations to explain each of the observations made above. (b) What can you conclude about the position of cadmium in the activity series? (c) What experiments would you need to perform to locate more precisely the position of cadmium in the activity series?

## Solution Composition; Molarity

- 4.59 (a) Is the concentration of a solution an intensive or an extensive property? (b) What is the difference between 0.50 mol HCl and 0.50 M HCl?
- 4.60 (a) Suppose you prepare 500 mL of a 0.10 M solution of some salt and then spill some of it. What happens to the concentration of the solution left in the container? (b) Suppose you prepare 500 mL of a 0.10 M aqueous solution of some salt and let it sit out, uncovered, for a long time, and some water evaporates. What happens to the concentration of the solution left in the container? (c) A certain volume of a 0.50 M solution contains 4.5 g of a salt. What mass of the salt is present in the same volume of a 2.50 M solution?
- 4.61 (a) Calculate the molarity of a solution that contains 0.0250 mol  $\text{NH}_4\text{Cl}$  in exactly 500 mL of solution. (b) How many moles of  $\text{HNO}_3$  are present in 50.0 mL of a 2.50 M solution of nitric acid? (c) How many milliliters of 1.50 M KOH solution are needed to provide 0.275 mol of KOH?
- 4.62 (a) Calculate the molarity of a solution made by dissolving 0.750 grams of  $\text{Na}_2\text{SO}_4$  in enough water to form exactly 850 mL of solution. (b) How many moles of  $\text{KMnO}_4$  are present in 250 mL of a 0.0475 M solution? (c) How many milliliters of 11.6 M HCl solution are needed to obtain 0.250 mol of HCl?
- 4.63 The average adult human male has a total blood volume of 5.0 L. If the concentration of sodium ion in this average individual is 0.135 M, what is the mass of sodium ion circulating in the blood?
- 4.64 A person suffering from hyponatremia has a sodium ion concentration in the blood of 0.118 M and a total blood volume of 4.6 L. What mass of sodium chloride would need to be added to the blood to bring the sodium ion concentration up to 0.138 M, assuming no change in blood volume?
- 4.65 The concentration of alcohol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) in blood, called the "blood alcohol concentration" or BAC, is given in units of grams of alcohol per 100 mL of blood. The legal definition of intoxication, in many states of the United States, is that the BAC is 0.08 or higher. What is the concentration of alcohol, in terms of molarity, in blood if the BAC is 0.08?
- 4.66 The average adult male has a total blood volume of 5.0 L. After drinking a few beers, he has a BAC of 0.10 (see Exercise 4.65). What mass of alcohol is circulating in his blood?
- 4.58 (a) Use the following reactions to prepare an activity series for the halogens:  

$$\text{Br}_2(\text{aq}) + 2 \text{NaI}(\text{aq}) \longrightarrow 2 \text{NaBr}(\text{aq}) + \text{I}_2(\text{aq})$$

$$\text{Cl}_2(\text{aq}) + 2 \text{NaBr}(\text{aq}) \longrightarrow 2 \text{NaCl}(\text{aq}) + \text{Br}_2(\text{aq})$$
 (b) Relate the positions of the halogens in the periodic table with their locations in this activity series. (c) Predict whether a reaction occurs when the following reagents are mixed:  $\text{Cl}_2(\text{aq})$  and  $\text{KI}(\text{aq})$ ;  $\text{Br}_2(\text{aq})$  and  $\text{LiCl}(\text{aq})$ .
- 4.67 Calculate (a) the number of grams of solute in 0.250 L of 0.175 M KBr, (b) the molar concentration of a solution containing 14.75 g of  $\text{Ca}(\text{NO}_3)_2$  in 1.375 L, (c) the volume of 1.50 M  $\text{Na}_3\text{PO}_4$  in milliliters that contains 2.50 g of solute.
- 4.68 (a) How many grams of solute are present in 50.0 mL of 0.488 M  $\text{K}_2\text{Cr}_2\text{O}_7$ ? (b) If 4.00 g of  $(\text{NH}_4)_2\text{SO}_4$  is dissolved in enough water to form 400 mL of solution, what is the molarity of the solution? (c) How many milliliters of 0.0250 M  $\text{CuSO}_4$  contain 1.75 g of solute?
- 4.69 (a) Which will have the highest concentration of potassium ion: 0.20 M KCl, 0.15 M  $\text{K}_2\text{CrO}_4$ , or 0.080 M  $\text{K}_3\text{PO}_4$ ? (b) Which will contain the greater number of moles of potassium ion: 30.0 mL of 0.15 M  $\text{K}_2\text{CrO}_4$  or 25.0 mL of 0.080 M  $\text{K}_3\text{PO}_4$ ?
- 4.70 In each of the following pairs, indicate which has the higher concentration of  $\text{Cl}^-$  ion: (a) 0.10 M  $\text{CaCl}_2$  or 0.15 M KCl solution, (b) 100 mL of 0.10 M KCl solution or 400 mL of 0.080 M LiCl solution, (c) 0.050 M HCl solution or 0.020 M  $\text{CdCl}_2$  solution.
- 4.71 Indicate the concentration of each ion or molecule present in the following solutions: (a) 0.25 M  $\text{NaNO}_3$ , (b)  $1.3 \times 10^{-2}$  M  $\text{MgSO}_4$ , (c) 0.0150 M  $\text{C}_6\text{H}_{12}\text{O}_6$ , (d) a mixture of 45.0 mL of 0.272 M NaCl and 65.0 mL of 0.0247 M  $(\text{NH}_4)_2\text{CO}_3$ . Assume that the volumes are additive.
- 4.72 Indicate the concentration of each ion present in the solution formed by mixing (a) 42.0 mL of 0.170 M NaOH and 37.6 mL of 0.400 M NaOH, (b) 44.0 mL of 0.100 M and  $\text{Na}_2\text{SO}_4$  and 25.0 mL of 0.150 M KCl, (c) 3.60 g KCl in 75.0 mL of 0.250 M  $\text{CaCl}_2$  solution. Assume that the volumes are additive.
- 4.73 (a) You have a stock solution of 14.8 M  $\text{NH}_3$ . How many milliliters of this solution should you dilute to make 1000.0 mL of 0.250 M  $\text{NH}_3$ ? (b) If you take a 10.0-mL portion of the stock solution and dilute it to a total volume of 0.500 L, what will be the concentration of the final solution?
- 4.74 (a) How many milliliters of a stock solution of 10.0 M  $\text{HNO}_3$  would you have to use to prepare 0.450 L of 0.500 M  $\text{HNO}_3$ ? (b) If you dilute 25.0 mL of the stock solution to a final volume of 0.500 L, what will be the concentration of the diluted solution?
- 4.75 (a) Starting with solid sucrose,  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ , describe how you would prepare 250 mL of a 0.250 M sucrose solution. (b) Describe how you would prepare 350.0 mL of 0.100 M  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  starting with 3.00 L of 1.50 M  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ .

- 4.76 (a) How would you prepare 175.0 mL of 0.150 M  $\text{AgNO}_3$  solution starting with pure solute? (b) An experiment calls for you to use 100 mL of 0.50 M  $\text{HNO}_3$  solution. All you have available is a bottle of 3.6 M  $\text{HNO}_3$ . How would you prepare the desired solution?
- [4.77] Pure acetic acid, known as glacial acetic acid, is a liquid with a density of 1.049 g/mL at 25 °C. Calculate the molarity of a solution of acetic acid made by dissolving 20.00 mL of glacial acetic acid at 25 °C in enough water to make 250.0 mL of solution.
- [4.78] Glycerol,  $\text{C}_3\text{H}_8\text{O}_3$ , is a substance used extensively in the manufacture of cosmetics, foodstuffs, antifreeze, and plastics. Glycerol is a water-soluble liquid with a density of 1.2656 g/L at 15 °C. Calculate the molarity of a solution of glycerol made by dissolving 50.000 mL glycerol at 15 °C in enough water to make 250.00 mL of solution.

## Solution Stoichiometry; Titrations

- 4.79 What mass of KCl is needed to precipitate the silver ions from 15.0 mL of 0.200 M  $\text{AgNO}_3$  solution?
- 4.80 What mass of NaOH is needed to precipitate the  $\text{Cd}^{2+}$  ions from 35.0 mL of 0.500 M  $\text{Cd}(\text{NO}_3)_2$  solution?
- 4.81 (a) What volume of 0.115 M  $\text{HClO}_4$  solution is needed to neutralize 50.00 mL of 0.0875 M NaOH? (b) What volume of 0.128 M HCl is needed to neutralize 2.87 g of  $\text{Mg}(\text{OH})_2$ ? (c) If 25.8 mL of  $\text{AgNO}_3$  is needed to precipitate all the  $\text{Cl}^-$  ions in a 785-mg sample of KCl (forming AgCl), what is the molarity of the  $\text{AgNO}_3$  solution? (d) If 45.3 mL of 0.108 M HCl solution is needed to neutralize a solution of KOH, how many grams of KOH must be present in the solution?
- 4.82 (a) How many milliliters of 0.120 M HCl are needed to completely neutralize 50.0 mL of 0.101 M  $\text{Ba}(\text{OH})_2$  solution? (b) How many milliliters of 0.125 M  $\text{H}_2\text{SO}_4$  are needed to neutralize 0.200 g of NaOH? (c) If 55.8 mL of  $\text{BaCl}_2$  solution is needed to precipitate all the sulfate ion in a 752-mg sample of  $\text{Na}_2\text{SO}_4$ , what is the molarity of the solution? (d) If 42.7 mL of 0.208 M HCl solution is needed to neutralize a solution of  $\text{Ca}(\text{OH})_2$ , how many grams of  $\text{Ca}(\text{OH})_2$  must be in the solution?
- 4.83 Some sulfuric acid is spilled on a lab bench. You can neutralize the acid by sprinkling sodium bicarbonate on it and then mopping up the resultant solution. The sodium bicarbonate reacts with sulfuric acid as follows:
- $$2 \text{NaHCO}_3(\text{s}) + \text{H}_2\text{SO}_4(\text{aq}) \longrightarrow \text{Na}_2\text{SO}_4(\text{aq}) + 2 \text{H}_2\text{O}(\text{l}) + 2 \text{CO}_2(\text{g})$$
- Sodium bicarbonate is added until the fizzing due to the formation of  $\text{CO}_2(\text{g})$  stops. If 27 mL of 6.0 M  $\text{H}_2\text{SO}_4$  was spilled, what is the minimum mass of  $\text{NaHCO}_3$  that must be added to the spill to neutralize the acid?
- 4.84 The distinctive odor of vinegar is due to acetic acid,  $\text{CH}_3\text{COOH}$ , which reacts with sodium hydroxide in the following fashion:
- $$\text{CH}_3\text{COOH}(\text{aq}) + \text{NaOH}(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{NaC}_2\text{H}_3\text{O}_2(\text{aq})$$
- If 3.45 mL of vinegar needs 42.5 mL of 0.115 M NaOH to reach the equivalence point in a titration, how many grams of acetic acid are in a 1.00-qt sample of this vinegar?
- 4.85 A sample of solid  $\text{Ca}(\text{OH})_2$  is stirred in water at 30 °C until the solution contains as much dissolved  $\text{Ca}(\text{OH})_2$  as it can hold. A 100-mL sample of this solution is withdrawn and titrated with  $5.00 \times 10^{-2}$  M HBr. It requires 48.8 mL of the acid solution for neutralization. What is the molarity of the  $\text{Ca}(\text{OH})_2$  solution? What is the solubility of  $\text{Ca}(\text{OH})_2$  in water, at 30 °C, in grams of  $\text{Ca}(\text{OH})_2$  per 100 mL of solution?
- 4.86 In a laboratory, 6.82 g of  $\text{Sr}(\text{NO}_3)_2$  is dissolved in enough water to form 0.500 L of solution. A 0.100-L sample is withdrawn from this stock solution and titrated with a 0.0245 M solution of  $\text{Na}_2\text{CrO}_4$ . What volume of  $\text{Na}_2\text{CrO}_4$  solution is needed to precipitate all the  $\text{Sr}^{2+}(\text{aq})$  as  $\text{SrCrO}_4$ ?
- 4.87 A solution of 100.0 mL of 0.200 M KOH is mixed with a solution of 200.0 mL of 0.150 M  $\text{NiSO}_4$ . (a) Write the balanced chemical equation for the reaction that occurs. (b) What precipitate forms? (c) What is the limiting reactant? (d) How many grams of this precipitate form? (e) What is the concentration of each ion that remains in solution?
- 4.88 A solution is made by mixing 12.0 g of NaOH and 75.0 mL of 0.200 M  $\text{HNO}_3$ . (a) Write a balanced equation for the reaction that occurs between the solutes. (b) Calculate the concentration of each ion remaining in solution. (c) Is the resultant solution acidic or basic?
- [4.89] A 0.5895-g sample of impure magnesium hydroxide is dissolved in 100.0 mL of 0.2050 M HCl solution. The excess acid then needs 19.85 mL of 0.1020 M NaOH for neutralization. Calculate the percent by mass of magnesium hydroxide in the sample, assuming that it is the only substance reacting with the HCl solution.
- [4.90] A 1.248-g sample of limestone rock is pulverized and then treated with 30.00 mL of 1.035 M HCl solution. The excess acid then requires 11.56 mL of 1.010 M NaOH for neutralization. Calculate the percent by mass of calcium carbonate in the rock, assuming that it is the only substance reacting with the HCl solution.

## ADDITIONAL EXERCISES

- 4.91 Explain why a titration experiment is a good way to measure the unknown concentration of a compound in solution.
- 4.92 The accompanying photo shows the reaction between a solution of  $\text{Cd}(\text{NO}_3)_2$  and one of  $\text{Na}_2\text{S}$ . What is the identity of the precipitate? What ions remain in solution? Write the net ionic equation for the reaction.

- 4.93 Suppose you have a solution that might contain any or all of the following cations:  $\text{Ni}^{2+}$ ,  $\text{Ag}^+$ ,  $\text{Sr}^{2+}$ , and  $\text{Mn}^{2+}$ . Addition of  $\text{HCl}$  solution causes a precipitate to form. After filtering off the precipitate,  $\text{H}_2\text{SO}_4$  solution is added to the resultant solution and another precipitate forms. This is filtered off, and a solution of  $\text{NaOH}$  is added to the resulting solution. No precipitate is observed. Which ions are present in each of the precipitates? Which of the four ions listed above must be absent from the original solution?
- 4.94 You choose to investigate some of the solubility guidelines for two ions not listed in Table 4.1, the chromate ion ( $\text{CrO}_4^{2-}$ ) and the oxalate ion ( $\text{C}_2\text{O}_4^{2-}$ ). You are given 0.01 M solutions (A, B, C, D) of four water-soluble salts:

Solution	Solute	Color of Solution
A	$\text{Na}_2\text{CrO}_4$	Yellow
B	$(\text{NH}_4)_2\text{C}_2\text{O}_4$	Colorless
C	$\text{AgNO}_3$	Colorless
D	$\text{CaCl}_2$	Colorless

When these solutions are mixed, the following observations are made:

Expt Number	Solutions	
	Mixed	Result
1	A + B	No precipitate, yellow solution
2	A + C	Red precipitate forms
3	A + D	No precipitate, yellow solution
4	B + C	White precipitate forms
5	B + D	White precipitate forms
6	C + D	White precipitate forms

- (a) Write a net ionic equation for the reaction that occurs in each of the experiments. (b) Identify the precipitate formed, if any, in each of the experiments. (c) Based on these limited observations, which ion tends to form the more soluble salts, chromate or oxalate?
- 4.95 Antacids are often used to relieve pain and promote healing in the treatment of mild ulcers. Write balanced net ionic equations for the reactions between the  $\text{HCl}(\text{aq})$  in the stomach and each of the following substances used in various antacids: (a)  $\text{Al}(\text{OH})_3(\text{s})$ , (b)  $\text{Mg}(\text{OH})_2(\text{s})$ , (c)  $\text{MgCO}_3(\text{s})$ , (d)  $\text{NaAl}(\text{CO}_3)(\text{OH})_2(\text{s})$ , (e)  $\text{CaCO}_3(\text{s})$ .
- [4.96] Salts of the sulfite ion,  $\text{SO}_3^{2-}$ , react with acids in a way similar to that of carbonates. (a) Predict the chemical formula, and name the weak acid that forms when the sulfite ion reacts with acids. (b) The acid formed in part (a) decomposes to form water and a gas. Predict the molecular formula, and name the gas formed. (c) Use a source book such as the *CRC Handbook of Chemistry and Physics* to confirm that the substance in part (b) is a gas under normal room-temperature conditions. (d) Write balanced net ionic equations of the reaction of  $\text{HCl}(\text{aq})$  with (i)  $\text{Na}_2\text{SO}_3(\text{aq})$ , (ii)  $\text{Ag}_2\text{SO}_3(\text{s})$ , (iii)  $\text{KHSO}_3(\text{s})$ , and (iv)  $\text{ZnSO}_3(\text{aq})$ .
- [4.97] The commercial production of nitric acid involves the following chemical reactions:
- $$4 \text{NH}_3(\text{g}) + 5 \text{O}_2(\text{g}) \longrightarrow 4 \text{NO}(\text{g}) + 6 \text{H}_2\text{O}(\text{g})$$
- $$2 \text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{NO}_2(\text{g})$$
- $$3 \text{NO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{HNO}_3(\text{aq}) + \text{NO}(\text{g})$$
- (a) Which of these reactions are redox reactions? (b) In each redox reaction identify the element undergoing oxidation and the element undergoing reduction.
- 4.98 Use Table 4.5 to predict which of the following ions can be reduced to their metal forms by reacting with zinc: (a)  $\text{Na}^+(\text{aq})$ , (b)  $\text{Pb}^{2+}(\text{aq})$ , (c)  $\text{Mg}^{2+}(\text{aq})$ , (d)  $\text{Fe}^{2+}(\text{aq})$ , (e)  $\text{Cu}^{2+}(\text{aq})$ , (f)  $\text{Al}^{3+}(\text{aq})$ . Write the balanced net ionic equation for each reaction that occurs.
- [4.99] Lanthanum metal forms cations with a charge of 3+. Consider the following observations about the chemistry of lanthanum: When lanthanum metal is exposed to air, a white solid (compound A) is formed that contains lanthanum and one other element. When lanthanum metal is added to water, gas bubbles are observed and a different white solid (compound B) is formed. Both A and B dissolve in hydrochloric acid to give a clear solution. When either of these solutions is evaporated, a soluble white solid (compound C) remains. If compound C is dissolved in water and sulfuric acid is added, a white precipitate (compound D) forms. (a) Propose identities for the substances A, B, C, and D. (b) Write net ionic equations for all the reactions described. (c) Based on the preceding observations, what can be said about the position of lanthanum in the activity series (Table 4.5)?
- 4.100 A 35.0-mL sample of 1.00 M KBr and a 60.0-mL sample of 0.600 M KBr are mixed. The solution is then heated to evaporate water until the total volume is 50.0 mL. What is the molarity of the KBr in the final solution?

- 4.101** Using modern analytical techniques, it is possible to detect sodium ions in concentrations as low as 50 pg/mL. What is this detection limit expressed in (a) molarity of  $\text{Na}^+$ , (b)  $\text{Na}^+$  ions per cubic centimeter?
- 4.102** Hard water contains  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ , and  $\text{Fe}^{2+}$ , which interfere with the action of soap and leave an insoluble coating on the insides of containers and pipes when heated. Water softeners replace these ions with  $\text{Na}^+$ . If 1500 L of hard water contains 0.020 M  $\text{Ca}^{2+}$  and 0.0040 M  $\text{Mg}^{2+}$ , how many moles of  $\text{Na}^+$  are needed to replace these ions?
- 4.103** Tartaric acid,  $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ , has two acidic hydrogens. The acid is often present in wines and precipitates from solution as the wine ages. A solution containing an unknown concentration of the acid is titrated with NaOH. It requires 24.65 mL of 0.2500 M NaOH solution to titrate both acidic protons in 50.00 mL of the tartaric acid solution. Write a balanced net ionic equation for the neutralization reaction, and calculate the molarity of the tartaric acid solution.
- 4.104** The concentration of hydrogen peroxide in a solution is determined by titrating a 10.0-mL sample of the solution with permanganate ion.
- $$2 \text{MnO}_4^-(aq) + 5 \text{H}_2\text{O}_2(aq) + 6 \text{H}^+(aq) \longrightarrow 2 \text{Mn}^{2+}(aq) + 5 \text{O}_2(g) + 8 \text{H}_2\text{O}(l)$$
- If it takes 14.8 mL of 0.134 M  $\text{MnO}_4^-$  solution to reach the equivalence point, what is the molarity of the hydrogen peroxide solution?
- [4.105]** A solid sample of  $\text{Zn}(\text{OH})_2$  is added to 0.350 L of 0.500 M aqueous HBr. The solution that remains is still acidic. It is then titrated with 0.500 M NaOH solution, and it takes 88.5 mL of the NaOH solution to reach the equivalence point. What mass of  $\text{Zn}(\text{OH})_2$  was added to the HBr solution?

## INTEGRATIVE EXERCISES

- 4.106** (a) By titration, 15.0 mL of 0.1008 M sodium hydroxide is needed to neutralize a 0.2053-g sample of an organic acid. What is the molar mass of the acid if it is monoprotic? (b) An elemental analysis of the acid indicates that it is composed of 5.89% H, 70.6% C, and 23.5% O by mass. What is its molecular formula?
- 4.107** A 3.455-g sample of a mixture was analyzed for barium ion by adding a small excess of sulfuric acid to an aqueous solution of the sample. The resultant reaction produced a precipitate of barium sulfate, which was collected by filtration, washed, dried, and weighed. If 0.2815 g of barium sulfate was obtained, what was the mass percentage of barium in the sample?
- [4.108]** A tanker truck carrying  $5.0 \times 10^3$  kg of concentrated sulfuric acid solution tips over and spills its load. If the sulfuric acid is 95.0%  $\text{H}_2\text{SO}_4$  by mass and has a density of 1.84 g/mL, how many kilograms of sodium carbonate must be added to neutralize the acid?
- 4.109** A sample of 5.53 g of  $\text{Mg}(\text{OH})_2$  is added to 25.0 mL of 0.200 M  $\text{HNO}_3$ . (a) Write the chemical equation for the reaction that occurs. (b) Which is the limiting reactant in the reaction? (c) How many moles of  $\text{Mg}(\text{OH})_2$ ,  $\text{HNO}_3$ , and  $\text{Mg}(\text{NO}_3)_2$  are present after the reaction is complete?
- 4.110** A sample of 1.50 g of lead(II) nitrate is mixed with 125 mL of 0.100 M sodium sulfate solution. (a) Write the chemical equation for the reaction that occurs. (b) Which is the limiting reactant in the reaction? (c) What are the concentrations of all ions that remain in solution after the reaction is complete?
- 4.111** A mixture contains 76.5% NaCl, 6.5%  $\text{MgCl}_2$ , and 17.0%  $\text{Na}_2\text{SO}_4$  by mass. What is the molarity of  $\text{Cl}^-$  ions in a solution formed by dissolving 7.50 g of the mixture in enough water to form 500.0 mL of solution?
- [4.112]** The average concentration of bromide ion in seawater is 65 mg of bromide ion per kg of seawater. What is the molarity of the bromide ion if the density of the seawater is 1.025 g/mL?
- [4.113]** The mass percentage of chloride ion in a 25.00-mL sample of seawater was determined by titrating the sample with silver nitrate, precipitating silver chloride. It took 42.58 mL of 0.2997 M silver nitrate solution to reach the equivalence point in the titration. What is the mass percentage of chloride ion in the seawater if its density is 1.025 g/mL?
- 4.114** The arsenic in a 1.22-g sample of a pesticide was converted to  $\text{AsO}_4^{3-}$  by suitable chemical treatment. It was then titrated using  $\text{Ag}^+$  to form  $\text{Ag}_3\text{AsO}_4$  as a precipitate. (a) What is the oxidation state of As in  $\text{AsO}_4^{3-}$ ? (b) Name  $\text{Ag}_3\text{AsO}_4$  by analogy to the corresponding compound containing phosphorus in place of arsenic. (c) If it took 25.0 mL of 0.102 M  $\text{Ag}^+$  to reach the equivalence point in this titration, what is the mass percentage of arsenic in the pesticide?
- [4.115]** The newest U.S. standard for arsenate in drinking water, mandated by the Safe Drinking Water Act, required that by January 2006, public water supplies must contain no greater than 10 parts per billion (ppb) arsenic. If this arsenic is present as arsenate,  $\text{AsO}_4^{3-}$ , what mass of sodium arsenate would be present in a 1.00-L sample of drinking water that just meets the standard?
- [4.116]** The safe drinking water standard for arsenic (which is usually found as arsenate, see 4.115) is 50 parts per billion (ppb) in most developing countries. (a) How many grams of sodium arsenate are in 55 gallons of water, if the concentration of arsenate is 50 ppb? (b) In 1993,

naturally occurring arsenic was discovered as a major contaminant in the drinking water across the country of Bangladesh. Approximately 12 million people in Bangladesh still drink water from wells that have higher concentrations of arsenic than the standard. Recently, a chemistry professor from George Mason University was awarded a \$1 million Grainger Challenge Prize for Sustainability for his development of a simple, inexpensive system for filtering naturally occurring arsenic from drinking water. The system uses buckets of sand, cast iron, activated carbon, and wood chips for trapping arsenic-containing minerals. Assuming the efficiency of such a bucket system is 90% (meaning, 90% of the arsenic that comes in is retained in the bucket and 10% passes out of the bucket), how many times should water that is 500 ppb in arsenic be passed through to meet the 50 ppb standard?

- [4.117] Federal regulations set an upper limit of 50 parts per million (ppm) of  $\text{NH}_3$  in the air in a work environment [that is, 50 molecules of  $\text{NH}_3(\text{g})$  for every million molecules in the air]. Air from a manufacturing operation was drawn through a solution containing  $1.00 \times 10^2$  mL of 0.0105 M HCl. The  $\text{NH}_3$  reacts with HCl as follows:

After drawing air through the acid solution for 10.0 min at a rate of 10.0 L/min, the acid was titrated. The remaining acid needed 13.1 mL of 0.0588 M NaOH to reach the equivalence point. (a) How many grams of  $\text{NH}_3$  were drawn into the acid solution? (b) How many ppm of  $\text{NH}_3$  were in the air? (Air has a density of 1.20 g/L and an average molar mass of 29.0 g/mol under the conditions of the experiment.) (c) Is this manufacturer in compliance with regulations?

CHAPTER  
5

# THERMOCHEMISTRY

**WILDFLOWERS.** Plants use solar energy to carry out photosynthesis of carbohydrates, which provide the energy needed for plant growth. Among the molecules produced by plants are  $O_2$  and ethylene,  $C_2H_4$ .

## WHAT'S AHEAD

---

### 5.1 The Nature of Energy

We begin by considering the nature of *energy* and the forms it takes, notably *kinetic energy* and *potential energy*. We will also discuss the units used in measuring energy and the fact that energy can be used to accomplish *work* or to transfer *heat*. To study energy changes, we focus on a particular part of the universe, which we call the *system*. Everything else is called the *surroundings*.

### 5.2 The First Law of Thermodynamics

We will then explore the *first law of thermodynamics*: Energy cannot be created or destroyed, but it can be transformed from one form to another or transferred between systems and surroundings. The energy possessed by a system is called its *internal energy*. Internal energy,  $E$ , is a *state function*, a quantity whose value depends only on the state, or condition, of a system now, not on how the system came to be in that state.

### 5.3 Enthalpy

Next, we will encounter a state function called *enthalpy*,  $H$ , that relates to energy. This function is useful because the change in enthalpy,  $\Delta H$ , measures the quantity of heat energy gained or lost by a system in a process occurring under a constant pressure.

### 5.4 Enthalpies of Reaction

We will see that the enthalpy change associated with a chemical reaction ( $\Delta H_{\text{rxn}}$ ) is given by the enthalpies of the products minus the enthalpies of the reactants. This quantity is directly proportional to the amount of reactant consumed in the process.

### 5.5 Calorimetry

We will next examine *calorimetry*, which is an experimental technique that we use to measure heat changes in chemical processes.

### 5.6 Hess's Law

We will observe that the enthalpy change for a reaction can be calculated using appropriate enthalpy changes for other reactions. To do so, we apply *Hess's law*, which uses the fact that enthalpy, like energy, is a state function.

### 5.7 Enthalpies of Formation

Then we will discuss how to establish standard values for enthalpy changes in chemical reactions and how to use them to calculate enthalpy changes for reactions ( $\Delta H_{\text{rxn}}$ ).

### 5.8 Foods and Fuels

Finally, we will examine foods and fuels as sources of energy and discuss some related health and social issues.

**MODERN SOCIETY DEPENDS ON ENERGY** for its existence.

Energy is used to drive our machinery and appliances, to power our transportation vehicles, and to keep us warm in the winter and cool in the summer. It is not just modern society, however, that depends on energy. Energy is

necessary for all life. Plants, such as those in the chapter-opening photograph, use solar energy to carry out photosynthesis, allowing the plants to grow. The plants, in turn, provide food, from which we humans derive the energy we need to move, to maintain body temperature, and to carry out bodily functions. What exactly is energy, though, and what principles are involved in its many transactions and transformations, such as those from the sun to plants to animals?

In this chapter we begin to explore energy and its changes. We are motivated partly by the fact that energy changes invariably accompany chemical reactions. Indeed, sometimes we use a chemical reaction specifically to obtain energy, as when we burn fuels. Thus, energy is very much a chemical topic. Nearly all of the energy on which we depend is derived from chemical reactions, whether those reactions are associated with the combustion of fuels, the discharge of a battery, or the metabolism of our foods. If we are to properly

understand chemistry, we must also understand the energy changes that accompany chemical reactions.

The study of energy and its transformations is known as **thermodynamics** (Greek: *thérme*-, “heat”; *dy’namis*, “power”). In this chapter we will examine an aspect of thermodynamics that involves the relationships between chemical reactions and energy changes involving heat. This portion of thermodynamics is called **thermochemistry**. We will discuss additional aspects of thermodynamics in Chapter 19.

(a)

(b)

▲ **Figure 5.1 Work and heat.** Energy can be used to achieve two basic types of tasks: (a) Work is energy used to cause an object with mass to move. (b) Heat is energy used to cause the temperature of an object to increase.

## 5.1 THE NATURE OF ENERGY

Although the idea of energy is a familiar one, it is a bit challenging to deal with the concept in a precise way. **Energy** is commonly defined as *the capacity to do work or to transfer heat*. This definition requires us to understand the concepts of work and heat. We can think of **work** as *the energy used to cause an object with mass to move against a force* and **heat** as *the energy used to cause the temperature of an object to increase* (Figure 5.1 ◀). We will consider each of these concepts more closely to give them fuller meaning. Let’s begin by examining the ways in which matter can possess energy and how that energy can be transferred from one piece of matter to another.

### Kinetic Energy and Potential Energy

Objects, whether they are tennis balls or molecules, can possess **kinetic energy**, the energy of *motion*. The magnitude of the kinetic energy,  $E_k$ , of an object depends on its mass,  $m$ , and speed,  $v$ :

$$E_k = \frac{1}{2}mv^2 \quad [5.1]$$

Equation 5.1 shows that the kinetic energy increases as the speed of an object increases. For example, a car moving at 55 miles per hour (mph) has greater kinetic energy than it does at 40 mph. For a given speed the kinetic energy increases with increasing mass. Thus, a large sport-utility vehicle traveling at 55 mph has greater kinetic energy than a small sedan traveling at the same speed because the SUV has greater mass than the sedan. Atoms and molecules have mass and are in motion. They therefore possess kinetic energy.

All other kinds of energy—the energy stored in chemical bonds, the energy of attraction of north and south poles of magnets, for example—are potential energy. An object can possess **potential energy** by virtue of its *position* relative to other objects. Potential energy arises when a force operates on an object. A **force** is any kind of push or pull exerted on an object. The most familiar force is the pull of gravity. Think of a cyclist poised at the top of a hill, as illustrated in Figure 5.2 ▼. Gravity acts upon her and her bicycle, exerting a force directed toward the center of Earth. At the top of the hill the cyclist and her bicycle possess a certain potential energy by virtue of their elevation. The potential energy,  $E_p$ ,

(a)

(b)

► **Figure 5.2 Potential energy and kinetic energy.** (a) A bicycle at the top of a hill has a high potential energy relative to the bottom of the hill. (b) As the bicycle proceeds down the hill, the potential energy is converted into kinetic energy.

is given by the equation  $E_p = mgh$ , where  $m$  is the mass of the object in question (in this case the cyclist and her bicycle),  $h$  is the height of the object relative to some reference height, and  $g$  is the gravitational constant,  $9.8 \text{ m/s}^2$ . Once in motion, without any further effort on her part, the cyclist gains speed as the bicycle rolls down the hill. Her potential energy decreases as she moves downward, but the energy does not simply disappear. It is converted to other forms of energy, principally kinetic energy, the energy of motion. This example illustrates that forms of energy are interconvertible.

Gravity is an important force for large objects, such as the cyclist and Earth. Chemistry, however, deals mostly with extremely small objects—atoms and molecules. Gravitational forces play a negligible role in the ways these submicroscopic objects interact with one another. Forces that arise from electrical charges are more important when dealing with atoms and molecules.

One of the most important forms of potential energy in chemistry is *electrostatic potential energy*, which arises from the interactions between charged particles. The electrostatic potential energy,  $E_{el}$ , is proportional to the electrical charges on the two interacting objects,  $Q_1$  and  $Q_2$ , and is inversely proportional to the distance separating them:

$$E_{el} = \frac{\kappa Q_1 Q_2}{d} \quad [5.2]$$

Here  $\kappa$  is simply a constant of proportionality,  $8.99 \times 10^9 \text{ J}\cdot\text{m}/\text{C}^2$ . (C is the coulomb, a unit of electrical charge  $\rightleftharpoons$  (Section 2.2), and J is the joule, a unit of energy that we will soon discuss.) When dealing with molecular-level objects, the electrical charges  $Q_1$  and  $Q_2$  are typically on the order of magnitude of the charge of the electron ( $1.60 \times 10^{-19} \text{ C}$ ). When  $Q_1$  and  $Q_2$  have the same sign (for example, both are positive), the two charges repel one another, pushing them apart;  $E_{el}$  is positive. When they have opposite signs, they attract one another, pulling them toward each other;  $E_{el}$  is negative. The lower the energy of a system, the more stable it is. Thus, the more strongly opposite charges interact, the more stable the system.

One of our goals in chemistry is to relate the energy changes that we see in our macroscopic world to the kinetic or potential energy of substances at the atomic or molecular level. Many substances—fuels, for example—release energy when they react. The *chemical energy* of these substances is due to the potential energy stored in the arrangements of their atoms. Likewise, we will see that the energy a substance possesses because of its temperature (its *thermal energy*) is associated with the kinetic energy of the molecules in the substance.

### GIVE IT SOME THOUGHT

What are the terms for the energy an object possesses (a) because of its motion, (b) because of its position? What terms are used to describe changes of energy associated with (c) temperature changes, (d) moving an object against a force?

### Units of Energy

The SI unit for energy is the **joule** (pronounced “jool”), J, in honor of James Joule (1818–1889), a British scientist who investigated work and heat:  $1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2$ . A mass of 2 kg moving at a speed of 1 m/s possesses a kinetic energy of 1 J:

$$E_k = \frac{1}{2} mv^2 = \frac{1}{2}(2 \text{ kg})(1 \text{ m/s})^2 = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2 = 1 \text{ J}$$

A joule is not a large amount of energy, and we will often use *kilojoules* (kJ) in discussing the energies associated with chemical reactions.

Traditionally, energy changes accompanying chemical reactions have been expressed in calories, a non-SI unit still widely used in chemistry, biology, and biochemistry. A **calorie** (cal) was originally defined as the amount of energy

required to raise the temperature of 1 g of water from 14.5 °C to 15.5 °C. A calorie is now defined in terms of the joule:

$$1 \text{ cal} = 4.184 \text{ J (exactly)}$$

A related energy unit used in nutrition is the nutritional *Calorie* (note that this unit is capitalized):  $1 \text{ Cal} = 1000 \text{ cal} = 1 \text{ kcal}$ .

▲ **Figure 5.3 A closed system and its surroundings.** Hydrogen and oxygen gases are confined in a cylinder with a movable piston. If we are interested only in the properties of these gases, the gases are the system and the cylinder and piston are part of the surroundings. Because the system can exchange energy (in the form of heat and work) but not matter with its surroundings, it is a closed system.

## System and Surroundings

When we analyze energy changes, we need to focus our attention on a limited and well-defined part of the universe to keep track of the energy changes that occur. The portion we single out for study is called the **system**; everything else is called the **surroundings**. When we study the energy change that accompanies a chemical reaction in the laboratory, the reactants and products constitute the system. The container and everything beyond it are considered the surroundings.

Systems may be open, closed, or isolated. An *open* system is one in which matter and energy can be exchanged with the surroundings. A boiling pot of water on a stove, without its lid, is an open system: heat comes into the system from the stove, and water is released to the surroundings as steam.

The systems we can most readily study in thermochemistry are called *closed systems*. A closed system can exchange energy but not matter with its surroundings. For example, consider a mixture of hydrogen gas,  $\text{H}_2$ , and oxygen gas,  $\text{O}_2$ , in a cylinder, as illustrated in Figure 5.3 ◀. The system in this case is just the hydrogen and oxygen; the cylinder, piston, and everything beyond them (including us) are the surroundings. If the hydrogen and oxygen react to form water, energy is liberated:

Although the chemical form of the hydrogen and oxygen atoms in the system is changed by this reaction, the system has not lost or gained mass; it undergoes no exchange of matter with its surroundings. However, it can exchange energy with its surroundings in the form of *work* and *heat*.

An *isolated* system is one in which neither energy nor matter can be exchanged with the surroundings. An insulated thermos containing hot coffee approximates an isolated system. We know, however, that the coffee eventually cools, so it is not perfectly isolated.

## GIVE IT SOME THOUGHT

Is a human being an isolated, closed, or open system? Explain your choice.

## Transferring Energy: Work and Heat

Figure 5.1 illustrates the two ways that we experience energy changes in our everyday lives—in the form of work or heat. In Figure 5.1(a) energy is transferred from the tennis racquet to the ball, changing the direction and speed of the ball's movement. In Figure 5.1(b) energy is transferred in the form of heat. Indeed, energy is transferred between systems and surroundings in two general ways, as *work* or *heat*.

Energy used to cause an object to move against a force is called *work*. Thus, we can define work,  $w$ , as the energy transferred when a force moves an object. The magnitude of this work equals the product of the force,  $F$ , and the distance,  $d$ , that the object is moved:

$$w = F \times d \quad [5.3]$$

We perform work, for example, when we lift an object against the force of gravity or when we bring two like charges closer together. If we define the object as the system, then we—as part of the surroundings—are performing work on that system, transferring energy to it.

The other way in which energy is transferred is as heat. *Heat* is the energy transferred from a hotter object to a colder one. Or stating this idea in a slightly more abstract but nevertheless useful way, heat is the energy transferred between a system and its surroundings because of their difference in temperature. A combustion reaction, such as the burning of natural gas illustrated in Figure 5.1(b), releases the chemical energy stored in the molecules of the fuel.  (Section 3.2) If we define the substances involved in the reaction as the system and everything else as the surroundings, we find that the released energy causes the temperature of the system to increase. Energy in the form of heat is then transferred from the hotter system to the cooler surroundings.

### ■ SAMPLE EXERCISE 5.1 | Describing and Calculating Energy Changes

A bowler lifts a 5.4-kg (12-lb) bowling ball from ground level to a height of 1.6 m (5.2 feet) and then drops the ball back to the ground. (a) What happens to the potential energy of the bowling ball as it is raised from the ground? (b) What quantity of work, in J, is used to raise the ball? (c) After the ball is dropped, it gains kinetic energy. If we assume that all of the work done in part (b) has been converted to kinetic energy by the time the ball strikes the ground, what is the speed of the ball at the instant just before it hits the ground? (Note: The force due to gravity is  $F = m \times g$ , where  $m$  is the mass of the object and  $g$  is the gravitational constant;  $g = 9.8 \text{ m/s}^2$ .)

#### SOLUTION

**Analyze:** We need to relate the potential energy of the bowling ball to its position relative to the ground. We then need to establish the relationship between work and the change in potential energy of the ball. Finally, we need to connect the change in potential energy when the ball is dropped with the kinetic energy attained by the ball.

**Plan:** We can calculate the work done in lifting the ball by using Equation 5.3:  $w = F \times d$ . The kinetic energy of the ball at the moment of impact equals its initial potential energy. We can use the kinetic energy and Equation 5.1 to calculate the speed,  $v$ , at impact.

#### Solve:

(a) Because the bowling ball is raised to a greater height above the ground, its potential energy increases.

(b) The ball has a mass of 5.4 kg, and it is lifted a distance of 1.6 m. To calculate the work performed to raise the ball, we use both Equation 5.3 and  $F = m \times g$  for the force that is due to gravity:

$$w = F \times d = m \times g \times d = (5.4 \text{ kg})(9.8 \text{ m/s}^2)(1.6 \text{ m}) = 85 \text{ kg}\cdot\text{m}^2/\text{s}^2 = 85 \text{ J}$$

Thus, the bowler has done 85 J of work to lift the ball to a height of 1.6 m.

(c) When the ball is dropped, its potential energy is converted to kinetic energy. At the instant just before the ball hits the ground, we assume that the kinetic energy is equal to the work done in part (b), 85 J:

$$E_k = \frac{1}{2}mv^2 = 85 \text{ J} = 85 \text{ kg}\cdot\text{m}^2/\text{s}^2$$

We can now solve this equation for  $v$ :

$$v^2 = \left(\frac{2E_k}{m}\right) = \left(\frac{2(85 \text{ kg}\cdot\text{m}^2/\text{s}^2)}{5.4 \text{ kg}}\right) = 31.5 \text{ m}^2/\text{s}^2$$

$$v = \sqrt{31.5 \text{ m}^2/\text{s}^2} = 5.6 \text{ m/s}$$

**Check:** Work must be done in part (b) to increase the potential energy of the ball, which is in accord with our experience. The units are appropriate in both parts (b) and (c). The work is in units of J and the speed in units of m/s. In part (c) we have carried an additional digit in the intermediate calculation involving the square root, but we report the final value to only two significant figures, as appropriate.

**Comment:** A speed of 1 m/s is roughly 2 mph, so the bowling ball has a speed greater than 10 mph upon impact.

### ■ PRACTICE EXERCISE

What is the kinetic energy, in J, of (a) an Ar atom moving with a speed of 650 m/s, (b) a mole of Ar atoms moving with a speed of 650 m/s (Hint: 1 amu =  $1.66 \times 10^{-27}$  kg)

**Answers:** (a)  $1.4 \times 10^{-20}$  J, (b)  $8.4 \times 10^3$  J

## 5.2 THE FIRST LAW OF THERMODYNAMICS

We have seen that the potential energy of a system can be converted into kinetic energy, and vice versa. We have also seen that energy can be transferred back and forth between a system and its surroundings in the forms of work and heat. In general, energy can be converted from one form to another, and it can be transferred from one place to another. All of these transactions proceed in accord with one of the most important observations in science—that energy can be neither created nor destroyed. A simple statement known as the **first law of thermodynamics** summarizes this simple truth: *Energy is conserved*. Any energy that is lost by the system must be gained by the surroundings, and vice versa. To apply the first law of thermodynamics quantitatively, we must first define the energy of a system more precisely.

### Internal Energy

The **internal energy** of a system is the sum of *all* the kinetic and potential energies of all its components. For the system in Figure 5.3, for example, the internal energy includes the motions of the H<sub>2</sub> and O<sub>2</sub> molecules through space, their rotations, and their internal vibrations. It also includes the energies of the nuclei of each atom and of the component electrons. We represent the internal energy with the symbol  $E$ . (Some texts, particularly more advanced ones, use the symbol  $U$ .) We generally do not know the actual numerical value of  $E$ . What we can hope to know, however, is  $\Delta E$  (read “delta E”),\* the change in  $E$  that accompanies a change in the system.

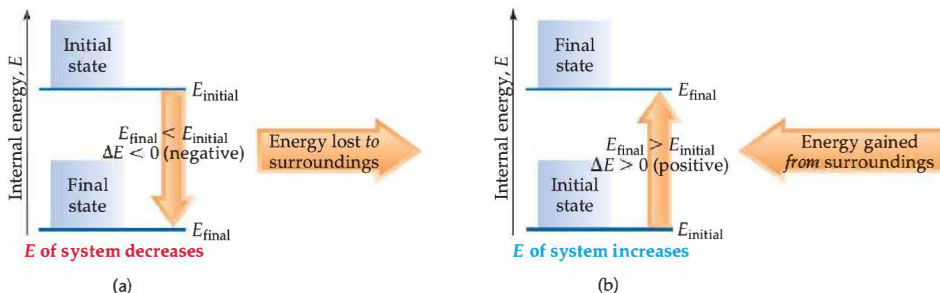

Imagine that we start with a system with an initial internal energy,  $E_{\text{initial}}$ . The system then undergoes a change, which might involve work being done or heat being transferred. After the change, the final internal energy of the system is  $E_{\text{final}}$ . We define the *change in internal energy*,  $\Delta E$ , as the difference between  $E_{\text{final}}$  and  $E_{\text{initial}}$ :

$$\Delta E = E_{\text{final}} - E_{\text{initial}} \quad [5.4]$$

To apply the first law of thermodynamics, we need only the value of  $\Delta E$ . We do not really need to know the actual values of  $E_{\text{final}}$  or  $E_{\text{initial}}$  for the system.

Thermodynamic quantities such as  $\Delta E$  have three parts: (1) a number and (2) a unit, that together give the magnitude of the change, and (3) a sign that gives the direction. A *positive* value of  $\Delta E$  results when  $E_{\text{final}} > E_{\text{initial}}$ , indicating the system has gained energy from its surroundings. A *negative* value of  $\Delta E$  is obtained when  $E_{\text{final}} < E_{\text{initial}}$ , indicating the system has lost energy to its surroundings. Notice that we are taking the point of view of the system rather than that of the surroundings in discussing the energy changes. We need to remember, however, that any change in the energy of the system is accompanied by an opposite change in the energy of the surroundings. These features of energy changes are summarized in Figure 5.4  $\blacktriangledown$ .

**▼ Figure 5.4 Changes in internal energy.** (a) When a system loses energy, that energy is released to the surroundings. The loss of energy is represented by an arrow that points downward between the initial and final states of the system. In this case, the energy change of the system,  $\Delta E = E_{\text{final}} - E_{\text{initial}}$ , is negative. (b) When a system gains energy, that energy is gained from the surroundings. In this case, the gain of energy is represented by an arrow that points upward between the initial and final states of the system, and the energy change of the system is positive. Notice in both (a) and (b) that the vertical arrow originates at the initial state and has its head at the final state.

\*The symbol  $\Delta$  is commonly used to denote change. For example, a change in height,  $h$ , can be represented by  $\Delta h$ .

In a chemical reaction, the initial state of the system refers to the reactants, and the final state refers to the products. When hydrogen and oxygen form water at a given temperature, the system loses energy to the surroundings. Because energy is lost from the system, the internal energy of the products (final state) is less than that of the reactants (initial state), and  $\Delta E$  for the process is negative. Thus, the *energy diagram* in Figure 5.5 shows that the internal energy of the mixture of  $\text{H}_2$  and  $\text{O}_2$  is greater than that of  $\text{H}_2\text{O}$ .

### GIVE IT SOME THOUGHT

The internal energy for  $\text{Mg}(s)$  and  $\text{Cl}_2(g)$  is greater than that of  $\text{MgCl}_2(s)$ . Sketch an energy diagram that represents the reaction  $\text{MgCl}_2(s) \rightarrow \text{Mg}(s) + \text{Cl}_2(g)$ .

### Relating $\Delta E$ to Heat and Work

As we noted in Section 5.1, a system may exchange energy with its surroundings as heat or as work. The internal energy of a system changes in magnitude as heat is added to or removed from the system or as work is done on it or by it. If we think of internal energy as the system's bank account of energy, we see that deposits or withdrawals can be made either in terms of heat or in terms of work. Deposits increase the energy of the system (positive  $\Delta E$ ), whereas withdrawals decrease the energy of the system (negative  $\Delta E$ ).

We can use these ideas to write a very useful algebraic expression of the first law of thermodynamics. When a system undergoes any chemical or physical change, the magnitude and sign of the accompanying change in internal energy,  $\Delta E$ , is given by the heat added to or liberated from the system,  $q$ , plus the work done on or by the system,  $w$ :

$$\Delta E = q + w \quad [5.5]$$

When heat is added to a system or work is done on a system, its internal energy increases. Therefore, when heat is transferred to the system from the surroundings,  $q$  has a positive value. Adding heat to the system is like making a deposit to the energy account—the total amount of energy goes up. Likewise, when work is done on the system by the surroundings,  $w$  has a positive value (Figure 5.6). Work also is a deposit, increasing the internal energy of the system. Conversely, both the heat lost by the system to the surroundings and the work done by the system on the surroundings have negative values; that is, they lower the internal energy of the system. They are energy withdrawals and as a result, lower the total amount of energy in the energy account. The sign conventions for  $q$ ,  $w$ , and  $\Delta E$  are summarized in Table 5.1. Notice that any energy entering the system as either heat or work carries a positive sign.

▲ **Figure 5.5** Energy diagram for the interconversion of  $\text{H}_2(g)$ ,  $\text{O}_2(g)$ , and  $\text{H}_2\text{O}(l)$ . A system composed of  $\text{H}_2(g)$  and  $\text{O}_2(g)$  has a greater internal energy than one composed of  $\text{H}_2\text{O}(l)$ . The system loses energy ( $\Delta E < 0$ ) when  $\text{H}_2$  and  $\text{O}_2$  are converted to  $\text{H}_2\text{O}$ . It gains energy ( $\Delta E > 0$ ) when  $\text{H}_2\text{O}$  is decomposed into  $\text{H}_2$  and  $\text{O}_2$ .

▲ **Figure 5.6** Sign conventions for heat and work. Heat,  $q$ , gained by a system and work,  $w$ , done on a system are both positive quantities. Both increase the internal energy,  $E$ , of the system, causing  $\Delta E$  to be a positive quantity.

**TABLE 5.1** Sign Conventions for  $q$ ,  $w$ , and  $\Delta E$

For $q$	+ means system <i>gains</i> heat	– means system <i>loses</i> heat
For $w$	+ means work done <i>on</i> system	– means work done <i>by</i> system
For $\Delta E$	+ means <i>net gain</i> of energy by system	– means <i>net loss</i> of energy by system

### SAMPLE EXERCISE 5.2 Relating Heat and Work to Changes of Internal Energy

Two gases,  $\text{A}(g)$  and  $\text{B}(g)$ , are confined in a cylinder-and-piston arrangement like that in Figure 5.3. Substances **A** and **B** react to form a solid product:  $\text{A}(g) + \text{B}(g) \rightarrow \text{C}(s)$ . As the reaction occurs, the system loses 1150 J of heat to the surroundings. The piston moves downward as the gases react to form a solid. As the volume of the gas decreases under the constant pressure of the atmosphere, the surroundings do 480 J of work on the system. What is the change in the internal energy of the system?

(a)

(b)

▲ **Figure 5.7** Examples of endothermic and exothermic reactions.

(a) When ammonium thiocyanate and barium hydroxide octahydrate are mixed at room temperature, an endothermic reaction occurs:

As a result, the temperature of the system drops from about 20 °C to -9 °C.

(b) The reaction of powdered aluminum with  $\text{Fe}_2\text{O}_3$  (the thermite reaction) is highly exothermic. The reaction proceeds vigorously to form  $\text{Al}_2\text{O}_3$  and molten iron:

$$2 \text{Al}(s) + \text{Fe}_2\text{O}_3(s) \longrightarrow \text{Al}_2\text{O}_3(s) + 2 \text{Fe}(l)$$

### SOLUTION

**Analyze:** The question asks us to determine  $\Delta E$ , given information about  $q$  and  $w$ .

**Plan:** We first determine the signs of  $q$  and  $w$  (Table 5.1) and then use Equation 5.5,  $\Delta E = q + w$ , to calculate  $\Delta E$ .

**Solve:** Heat is transferred from the system to the surroundings, and work is done on the system by the surroundings, so  $q$  is negative and  $w$  is positive:  $q = -1150 \text{ J}$  and  $w = 480 \text{ kJ}$ . Thus,

$$\Delta E = q + w = (-1150 \text{ J}) + (480 \text{ J}) = -670 \text{ J}$$

The negative value of  $\Delta E$  tells us that a net quantity of 670 J of energy has been transferred from the system to the surroundings.

**Comment:** You can think of this change as a decrease of 670 J in the net value of the system's energy bank account (hence the negative sign); 1150 J is withdrawn in the form of heat, while 480 J is deposited in the form of work. Notice that as the volume of the gases decreases, work is being done on the system by the surroundings, resulting in a deposit of energy.

### PRACTICE EXERCISE

Calculate the change in the internal energy of the system for a process in which the system absorbs 140 J of heat from the surroundings and does 85 J of work on the surroundings.

**Answer:** +55 J

## Endothermic and Exothermic Processes

When a process occurs in which the system absorbs heat, the process is called **endothermic**. (*Endo-* is a prefix meaning "into.") During an endothermic process, such as the melting of ice, heat flows *into* the system from its surroundings. If we, as part of the surroundings, touch a container in which ice is melting, it feels cold to us because heat has passed from our hands to the container.

A process in which the system loses heat is called **exothermic**. (*Exo-* is a prefix meaning "out of.") During an exothermic process, such as the combustion of gasoline, heat *exits* or flows *out* of the system and into the surroundings. Figure 5.7 ◀ shows two examples of chemical reactions: one endothermic and the other highly exothermic. In the endothermic process shown in Figure 5.7(a), the temperature in the beaker decreases. In this example the system consists of the chemical reactants and products. The solvent in which they are dissolved is part of the surroundings. Heat flows from the solvent, as part of the surroundings, into the system as reactants are converted to products. Thus, the temperature of the solution drops.

### GIVE IT SOME THOUGHT

Using Figure 5.5 as a reference, indicate whether the reaction  $2 \text{H}_2\text{O}(l) \longrightarrow 2 \text{H}_2(g) + \text{O}_2(g)$  is exothermic or endothermic. What feature(s) of the figure indicate whether the reaction is exothermic or endothermic?

## State Functions

Although we usually have no way of knowing the precise value of the internal energy of a system,  $E$ , it does have a fixed value for a given set of conditions. The conditions that influence internal energy include the temperature and pressure. Furthermore, the total internal energy of a system is proportional to the total quantity of matter in the system because energy is an extensive property. ◀ (Section 1.3)

Suppose we define our system as 50 g of water at 25 °C, as in Figure 5.8 ▶. The system could have arrived at this state by cooling 50 g of water from 100 °C or by melting 50 g of ice and subsequently warming the water to 25 °C.

◀ **Figure 5.8 Internal energy,  $E$ , a state function.**  $E$  depends only on the present state of the system and not on the path by which it arrived at that state. The internal energy of 50 g of water at 25 °C is the same whether the water is cooled from a higher temperature to 25 °C or warmed from a lower temperature to 25 °C.

The internal energy of the water at 25 °C is the same in either case. Internal energy is an example of a **state function**, a property of a system that is determined by specifying the system's condition, or state (in terms of temperature, pressure, and so forth). *The value of a state function depends only on the present state of the system, not on the path the system took to reach that state.* Because  $E$  is a state function,  $\Delta E$  depends only on the initial and final states of the system, not on how the change occurs.

An analogy may help to explain the difference between quantities that are state functions and those that are not. Suppose you are traveling between Chicago and Denver. Chicago is 596 ft above sea level; Denver is 5280 ft above sea level. No matter what route you take, the altitude change will be 4684 ft. The distance you travel, however, will depend on your route. Altitude is analogous to a state function because the change in altitude is independent of the path taken. Distance traveled is not a state function.

Some thermodynamic quantities, such as  $E$ , are state functions. Other quantities, such as  $q$  and  $w$ , are not. Although  $\Delta E = q + w$  does not depend on how the change occurs, the specific amounts of heat and work produced depend on the way in which the change is carried out, analogous to the choice of travel route between Chicago and Denver. Nevertheless, if changing the path by which a system goes from an initial state to a final state increases the value of  $q$ , that path change will also decrease the value of  $w$  by exactly the same amount. The result is that the value for  $\Delta E$  for the two paths will be the same.

We can illustrate this principle with the example of a flashlight battery as our system. In Figure 5.9▶, we consider two possible ways of discharging the battery at constant temperature. If a coil of wire shorts out the battery, no work is accomplished because nothing is moved against a force. All the energy is lost from the battery in the form of heat. (The wire coil will get warmer and release heat to the surrounding air.) On the other hand, if the battery is used to make a small motor turn, the discharge of the battery produces work. Some heat will be released as well, although not as much as when the battery is shorted out. The magnitudes of  $q$  and  $w$  are different for these two cases. If the initial and final states of the battery are identical in both cases, however, then  $\Delta E = q + w$  must be the same in both cases because  $\Delta E$  is a state function. Thus,  $\Delta E$  depends only on the initial and final states of the system, regardless of how the transfers of energy occur in terms of heat and work.

▲ **Figure 5.9 Internal energy is a state function, but heat and work are not.** The amounts of heat and work transferred between the system and the surroundings depend on the way in which the system goes from one state to another. (a) A battery shorted out by a wire loses energy to the surroundings only as heat; no work is performed by the system. (b) A battery discharged through a motor loses energy as work (to make the fan turn) and also loses energy as heat. Now, however, the amount of heat lost is much less than in (a). The value of  $\Delta E$  is the same for both processes even though the values of  $q$  and  $w$  in (a) are different from the values of  $q$  and  $w$  in (b).

### GIVE IT SOME THOUGHT

In what ways is the balance in your checkbook a state function?

## 5.3 ENTHALPY

The chemical and physical changes that occur around us, such as photosynthesis in the leaves of a plant, the evaporation of water from a lake, or a reaction in an open beaker in a laboratory, occur at essentially constant atmospheric pressure. The changes can result in the release or absorption of heat or can be accompanied by work that is done by or on the system. The heat flow is the easiest change to measure, so we will begin to focus on that aspect of reactions. Nevertheless, we still need to account for any work that accompanies the process.

Most commonly, the only kind of work produced by chemical or physical changes open to the atmosphere is the mechanical work associated with a change in the volume of the system. Consider, for example, the reaction of zinc metal with hydrochloric acid solution:

If we carry out this reaction in the laboratory hood in an open beaker, we can see the evolution of hydrogen gas, but it may not be so obvious that work is being done. Still, the hydrogen gas that is being produced must expand against the existing atmosphere, which requires the system to do work. We can see this better by conducting the reaction in a closed vessel at constant pressure, as illustrated in Figure 5.10. In this apparatus the piston moves up or down to maintain a constant pressure in the reaction vessel. If we assume for simplicity that the piston has no mass, the pressure in the apparatus is the same as the atmospheric pressure outside the apparatus. As the reaction proceeds,  $\text{H}_2$  gas forms, and the piston rises. The gas within the flask is thus doing work on the surroundings by lifting the piston against the force of atmospheric pressure that presses down on it.

The work involved in the expansion or compression of gases is called **pressure-volume work** (or  $P$ - $V$  work). When the pressure is constant, as in our example, the sign and magnitude of the pressure-volume work is given by

$$w = -P \Delta V \quad [5.7]$$

where  $P$  is pressure and  $\Delta V$  is the change in volume of the system ( $\Delta V = V_{\text{final}} - V_{\text{initial}}$ ). The negative sign in Equation 5.7 is necessary to conform to the sign conventions given in Table 5.1. Thus, when the volume expands,  $\Delta V$  is a positive quantity and  $w$  is a negative quantity. That is, energy leaves the system as work, indicating that work is done *by* the system *on* the surroundings. On the other hand, when a gas is compressed,  $\Delta V$  is a negative quantity

► **Figure 5.10 A system that does work on its surroundings.** (a) An apparatus for studying the reaction of zinc metal with hydrochloric acid at constant pressure. The piston is free to move up and down in its cylinder to maintain a constant pressure equal to atmospheric pressure inside the apparatus. Notice the pellets of zinc in the L-shaped arm on the left. When this arm is rotated and the pellets will fall into the main container and the reaction will begin. (b) When zinc is added to the acid solution, hydrogen gas is evolved. The hydrogen gas does work on the surroundings, raising the piston against atmospheric pressure to maintain constant pressure inside the reaction vessel.

(the volume decreases), which makes  $w$  a positive quantity. That is, energy enters the system as work, indicating that work is done on the system by the surroundings. The “A Closer Look” box discusses pressure-volume work in more detail, but all you really need to keep in mind for now is Equation 5.7, which applies to processes occurring at constant pressure. We will take up the properties of gases in more detail in Chapter 10.

### GIVE IT SOME THOUGHT

If a system does not change its volume during the course of a process, does it do pressure-volume work?

A thermodynamic function called **enthalpy** (from the Greek word *enthalpein*, meaning “to warm”) accounts for heat flow in processes occurring at constant pressure when no forms of work are performed other than  $P$ - $V$  work. Enthalpy, which we denote by the symbol  $H$ , equals the internal energy plus the product of the pressure and volume of the system:

$$H = E + PV \quad [5.8]$$

Enthalpy is a state function because internal energy, pressure, and volume are all state functions.

When a change occurs at constant pressure, the change in enthalpy,  $\Delta H$ , is given by the following relationship:

$$\begin{aligned} \Delta H &= \Delta(E + PV) \\ &= \Delta E + P \Delta V \end{aligned} \quad [5.9]$$

That is, the change in enthalpy equals the change in internal energy plus the product of the constant pressure times the change in volume.

We can gain further insight into enthalpy change by recalling that  $\Delta E = q + w$  (Equation 5.5) and that the work involved in the expansion or compression of gases is  $w = -P \Delta V$ . If we substitute  $-w$  for  $P \Delta V$  and  $q + w$  for  $\Delta E$  into Equation 5.9, we have

$$\Delta H = \Delta E + P \Delta V = (q_p + w) - w = q_p \quad [5.10]$$

where the subscript  $P$  on the heat,  $q$ , emphasizes changes at constant pressure. Thus, *the change in enthalpy equals the heat gained or lost at constant pressure*. Because  $q_p$  is something we can either measure or readily calculate and because so many physical and chemical changes of interest to us occur at constant pressure, enthalpy is a more useful function than internal energy. For most reactions the difference in  $\Delta H$  and  $\Delta E$  is small because  $P \Delta V$  is small.

When  $\Delta H$  is positive (that is, when  $q_p$  is positive), the system has gained heat from the surroundings (Table 5.1), which is an endothermic process. When  $\Delta H$  is negative, the system has released heat to the surroundings, which is an exothermic process. These cases are diagrammed in Figure 5.11 ►.

Because  $H$  is a state function,  $\Delta H$  (which equals  $q_p$ ) depends only on the initial and final states of the system, not on how the change occurs. At first glance this statement might seem to contradict our earlier discussion in Section 5.2, in which we said that  $q$  is *not* a state function. There is no contradiction, however, because the relationship between  $\Delta H$  and heat ( $q_p$ ) has the special limitations that only  $P$ - $V$  work is involved and the pressure is constant.

▲ **Figure 5.11 Endothermic and exothermic processes.** (a) If the system absorbs heat (endothermic process),  $\Delta H$  will be positive ( $\Delta H > 0$ ). (b) If the system loses heat (exothermic process),  $\Delta H$  will be negative ( $\Delta H < 0$ ).

### GIVE IT SOME THOUGHT

What is the advantage of using enthalpy rather than internal energy to describe energy changes in reactions?

## A Closer Look

ENERGY, ENTHALPY, AND  $P$ - $V$  WORK

In chemistry we are interested mainly in two types of work: electrical work and mechanical work done by expanding gases. We will focus here only on the latter, called pressure-volume, or  $P$ - $V$ , work. Expanding gases in the cylinder of an automobile engine do  $P$ - $V$  work on the piston; this work eventually turns the wheels. Expanding gases from an open reaction vessel do  $P$ - $V$  work on the atmosphere. This work accomplishes nothing in a practical sense, but we must keep track of all work, useful or not, when monitoring the energy changes of a system.

Consider a gas confined to a cylinder with a movable piston of cross-sectional area  $A$  (Figure 5.12). A downward force,  $F$ , acts on the piston. The pressure,  $P$ , on the gas is the force per area:  $P = F/A$ . We will assume that the piston is weightless and that the only pressure acting on it is the atmospheric pressure that is due to the weight of Earth's atmosphere, which we will assume to be constant.

Suppose the gas in the cylinder expands and the piston moves a distance,  $\Delta h$ . From Equation 5.3, the magnitude of the

work done by the system equals the distance moved times the force acting on the piston:

$$\text{Magnitude of work} = \text{force} \times \text{distance} = F \times \Delta h \quad [5.11]$$

We can rearrange the definition of pressure,  $P = F/A$ , to  $F = P \times A$ . In addition, the volume change,  $\Delta V$ , resulting from the movement of the piston, is the product of the cross-sectional area of the piston and the distance it moves:  $\Delta V = A \times \Delta h$ . Substituting into Equation 5.11,

$$\begin{aligned} \text{Magnitude of work} &= F \times \Delta h = P \times A \times \Delta h \\ &= P \times \Delta V \end{aligned}$$

Because the system (the confined gas) is doing work on the surroundings, the work is a negative quantity:

$$w = -P \Delta V \quad [5.12]$$

Now, if  $P$ - $V$  work is the only work that can be done, we can substitute Equation 5.12 into Equation 5.5 to give

$$\Delta E = q + w = q - P \Delta V \quad [5.13]$$

When a reaction is carried out in a constant-volume container ( $\Delta V = 0$ ), the heat transferred equals the change in internal energy:

$$\Delta E = q_V \quad (\text{constant volume}) \quad [5.14]$$

The subscript  $V$  indicates that the volume is constant.

Most reactions are run under constant-pressure conditions. In this case Equation 5.13 becomes

$$\begin{aligned} \Delta E &= q_P - P \Delta V \text{ or} \\ q_P &= \Delta E + P \Delta V \quad (\text{constant pressure}) \quad [5.15] \end{aligned}$$

But we see from Equation 5.9 that the right-hand side of Equation 5.15 is just the enthalpy change under constant-pressure conditions. Thus,  $\Delta H = q_P$ , as we saw earlier in Equation 5.10.

In summary, the change in internal energy is equal to the heat gained or lost at constant volume; the change in enthalpy is equal to the heat gained or lost at constant pressure. The difference between  $\Delta E$  and  $\Delta H$  is the amount of  $P$ - $V$  work done by the system when the process occurs at constant pressure,  $-P \Delta V$ . The volume change accompanying many reactions is close to zero, which makes  $P \Delta V$ , and therefore the difference between  $\Delta E$  and  $\Delta H$ , small. It is generally satisfactory to use  $\Delta H$  as the measure of energy changes during most chemical processes.

**Related Exercises:** 5.33, 5.34, 5.35, 5.36

**▲ Figure 5.12 Pressure-volume work.** A piston moving upward, expanding the volume of the system against an external pressure,  $P$ , does work on the surroundings. The amount of work done by the system on the surroundings is  $w = -P \Delta V$ .

### SAMPLE EXERCISE 5.3 | Determining the Sign of $\Delta H$

Indicate the sign of the enthalpy change,  $\Delta H$ , in each of the following processes carried out under atmospheric pressure, and indicate whether the process is endothermic or exothermic: (a) An ice cube melts; (b) 1 g of butane ( $C_4H_{10}$ ) is combusted in sufficient oxygen to give complete combustion to  $CO_2$  and  $H_2O$ .

#### SOLUTION

**Analyze:** Our goal is to determine whether  $\Delta H$  is positive or negative for each process. Because each process appears to occur at constant pressure, the enthalpy change of each one equals the amount of heat absorbed or released,  $\Delta H = q_P$ .

**Plan:** We must predict whether heat is absorbed or released by the system in each process. Processes in which heat is absorbed are endothermic and have a positive sign for  $\Delta H$ ; those in which heat is released are exothermic and have a negative sign for  $\Delta H$ .

**Solve:** In (a) the water that makes up the ice cube is the system. The ice cube absorbs heat from the surroundings as it melts, so  $\Delta H$  is positive and the process is endothermic. In (b) the system is the 1 g of butane and the oxygen required to combust it. The combustion of butane in oxygen gives off heat, so  $\Delta H$  is negative and the process is exothermic.

### PRACTICE EXERCISE

Suppose we confine 1 g of butane and sufficient oxygen to completely combust it in a cylinder like that in Figure 5.12. The cylinder is perfectly insulating, so no heat can escape to the surroundings. A spark initiates combustion of the butane, which forms carbon dioxide and water vapor. If we used this apparatus to measure the enthalpy change in the reaction, would the piston rise, fall, or stay the same?

**Answer:** The piston must move to maintain a constant pressure in the cylinder. The products contain more molecules of gas than the reactants, as shown by the balanced equation

As a result, the piston would rise to make room for the additional molecules of gas. Heat is given off, so the piston would also rise an additional amount to accommodate the expansion of the gases because of the temperature increase.

## 5.4 ENTHALPIES OF REACTION

Because  $\Delta H = H_{\text{final}} - H_{\text{initial}}$ , the enthalpy change for a chemical reaction is given by the enthalpy of the products minus the enthalpy of the reactants:

$$\Delta H = H_{\text{products}} - H_{\text{reactants}} \quad [5.16]$$

The enthalpy change that accompanies a reaction is called the **enthalpy of reaction**, or merely the *heat of reaction*, and is sometimes written  $\Delta H_{\text{rxn}}$ , where “rxn” is a commonly used abbreviation for “reaction.”

The combustion of hydrogen is shown in Figure 5.13 ▼. When the reaction is controlled so that 2 mol  $\text{H}_2(\text{g})$  burn to form 2 mol  $\text{H}_2\text{O}(\text{g})$  at a constant pressure, the system releases 483.6 kJ of heat. We can summarize this information as

▲ **Figure 5.13 Exothermic reaction of hydrogen with oxygen.** (a) A candle is held near a balloon filled with hydrogen gas and oxygen gas. (b) The  $\text{H}_2(\text{g})$  ignites, reacting with  $\text{O}_2(\text{g})$  to form  $\text{H}_2\text{O}(\text{g})$ . The resultant explosion produces a ball of flame. The system gives off heat to its surroundings. (c) The enthalpy diagram for this reaction, showing its exothermic character.

$\Delta H$  is negative, so this reaction is exothermic. Notice that  $\Delta H$  is reported at the end of the balanced equation, without explicitly mentioning the amounts of chemicals involved. In such cases the coefficients in the balanced equation represent the number of moles of reactants and products producing the associated enthalpy change. Balanced chemical equations that show the associated enthalpy change in this way are called *thermochemical equations*.

### GIVE IT SOME THOUGHT

What information is summarized by the coefficients in a *thermochemical equation*?

**▲ Figure 5.14 The burning of the hydrogen-filled airship Hindenburg.** This photograph was taken only 22 seconds after the first explosion occurred. This tragedy, which occurred in Lakehurst, New Jersey, on May 6, 1937, led to the discontinuation of hydrogen as a buoyant gas in such craft. Modern-day blimps are filled with helium, which is not as buoyant as hydrogen but is not flammable.

The enthalpy change accompanying a reaction may also be represented in an *enthalpy diagram* such as that shown in Figure 5.13(c). Because the combustion of  $\text{H}_2(\text{g})$  is exothermic, the enthalpy of the products in the reaction is lower than the enthalpy of the reactants. The enthalpy of the system is lower after the reaction because energy has been lost in the form of heat released to the surroundings.

The reaction of hydrogen with oxygen is highly exothermic ( $\Delta H$  is negative and has a large magnitude), and it occurs rapidly once it starts. It can occur with explosive violence, too, as demonstrated by the disastrous explosions of the German airship *Hindenburg* in 1937 (Figure 5.14 ◀) and the space shuttle *Challenger* in 1986.

The following guidelines are helpful when using thermochemical equations and enthalpy diagrams:

1. *Enthalpy is an extensive property.* The magnitude of  $\Delta H$ , therefore, is directly proportional to the amount of reactant consumed in the process. For the combustion of methane to form carbon dioxide and liquid water, for example, 890 kJ of heat is produced when 1 mol of  $\text{CH}_4$  is burned in a constant-pressure system:

Because the combustion of 1 mol of  $\text{CH}_4$  with 2 mol of  $\text{O}_2$  releases 890 kJ of heat, the combustion of 2 mol of  $\text{CH}_4$  with 4 mol of  $\text{O}_2$  releases twice as much heat, 1780 kJ.

2. *The enthalpy change for a reaction is equal in magnitude, but opposite in sign, to  $\Delta H$  for the reverse reaction.* For example, if we could reverse Equation 5.18 so that  $\text{CH}_4(\text{g})$  and  $\text{O}_2(\text{g})$  formed from  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ ,  $\Delta H$  for the process would be +890 kJ:

When we reverse a reaction, we reverse the roles of the products and the reactants. As a result, the reactants in a reaction become the products of the reverse reaction, and so forth. From Equation 5.16, we can see that reversing the products and reactants leads to the same magnitude, but a change in sign for  $\Delta H_{\text{rxn}}$ . This relationship is diagrammed for Equations 5.18 and 5.19 in Figure 5.15 ◀.

3. *The enthalpy change for a reaction depends on the state of the reactants and products.* If the product in the combustion of methane (Equation 5.18) were gaseous  $\text{H}_2\text{O}$  instead of liquid  $\text{H}_2\text{O}$ ,  $\Delta H_{\text{rxn}}$  would be  $-802 \text{ kJ}$  instead of

**▲ Figure 5.15  $\Delta H$  for a reverse reaction.** Reversing a reaction changes the sign but not the magnitude of the enthalpy change:  $\Delta H_2 = -\Delta H_1$ .

−890 kJ. Less heat would be available for transfer to the surroundings because the enthalpy of  $\text{H}_2\text{O}(\text{g})$  is greater than that of  $\text{H}_2\text{O}(\text{l})$ . One way to see this is to imagine that the product is initially liquid water. The liquid water must be converted to water vapor, and the conversion of 2 mol  $\text{H}_2\text{O}(\text{l})$  to 2 mol  $\text{H}_2\text{O}(\text{g})$  is an endothermic process that absorbs 88 kJ:

Thus, it is important to specify the states of the reactants and products in thermochemical equations. In addition, we will generally assume that the reactants and products are both at the same temperature, 25 °C, unless otherwise indicated.

#### **SAMPLE EXERCISE 5.4** | Relating $\Delta H$ to Quantities of Reactants and Products

How much heat is released when 4.50 g of methane gas is burned in a constant-pressure system? (Use the information given in Equation 5.18.)

#### **SOLUTION**

**Analyze:** Our goal is to use a thermochemical equation to calculate the heat produced when a specific amount of methane gas is combusted. According to Equation 5.18, 890 kJ is released by the system when 1 mol  $\text{CH}_4$  is burned at constant pressure ( $\Delta H = -890 \text{ kJ}$ ).

**Plan:** Equation 5.18 provides us with a stoichiometric conversion factor: 1 mol  $\text{CH}_4 \Rightarrow -890 \text{ kJ}$ . Thus, we can convert moles of  $\text{CH}_4$  to kJ of energy. First, however, we must convert grams of  $\text{CH}_4$  to moles of  $\text{CH}_4$ . Thus, the conversion sequence is grams  $\text{CH}_4$  (given)  $\rightarrow$  moles  $\text{CH}_4 \rightarrow$  kJ (unknown to be found).

**Solve:** By adding the atomic weights of C and 4 H, we have 1 mol  $\text{CH}_4 = 16.0 \text{ g CH}_4$ . We can use the appropriate conversion factors to convert grams of  $\text{CH}_4$  to moles of  $\text{CH}_4$  to kilojoules:

$$\text{Heat} = (4.50 \text{ g CH}_4) \left( \frac{1 \text{ mol CH}_4}{16.0 \text{ g CH}_4} \right) \left( \frac{-890 \text{ kJ}}{1 \text{ mol CH}_4} \right) = -250 \text{ kJ}$$

The negative sign indicates that the system released 250 kJ into the surroundings.

#### **PRACTICE EXERCISE**

Hydrogen peroxide can decompose to water and oxygen by the following reaction:

Calculate the value of  $q$  when 5.00 g of  $\text{H}_2\text{O}_2(\text{l})$  decomposes at constant pressure.

*Answer:* −14.4 kJ

In many situations it is valuable to know the enthalpy change associated with a given chemical process. As we will see in the following sections,  $\Delta H$  can be determined directly by experiment or calculated from the known enthalpy changes of other reactions by invoking the first law of thermodynamics.

## 5.5 CALORIMETRY

The value of  $\Delta H$  can be determined experimentally by measuring the heat flow accompanying a reaction at constant pressure. Typically, we can determine the magnitude of the heat flow by measuring the magnitude of the temperature change the heat flow produces. The measurement of heat flow is **calorimetry**; a device used to measure heat flow is a **calorimeter**.

### Heat Capacity and Specific Heat

The more heat an object gains, the hotter it gets. All substances change temperature when they are heated, but the magnitude of the temperature change produced by a given quantity of heat varies from substance to substance.

## Strategies in Chemistry

## USING ENTHALPY AS A GUIDE

If you hold a brick in the air and let it go, it will fall as the force of gravity pulls it toward Earth. A process that is thermodynamically favored to happen, such as a falling brick, is called a *spontaneous* process. A spontaneous process can be either fast or slow. Speed is not the issue in thermodynamics.

Many chemical processes are thermodynamically favored, or spontaneous, too. By “spontaneous,” we do not mean that the reaction will form products without any intervention. That can be the case, but often some energy must be imparted to get the process started. The enthalpy change in a reaction gives one indication as to whether the reaction is likely to be spontaneous. The combustion of  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$ , for example, is a highly exothermic process:

Hydrogen gas and oxygen gas can exist together in a volume indefinitely without noticeable reaction occurring, as in Figure 5.13(a). Once initiated, however, energy is rapidly transferred from the system (the reactants) to the surroundings. As the reaction proceeds, large amounts of heat are released, which greatly increases the temperature of the reactants and the products. The system then loses enthalpy by transferring the heat to the surroundings. (Recall that the first law of thermodynamics indicates that the total energy of the system plus the surroundings will not change; energy is conserved.)

Enthalpy change is not the only consideration in the spontaneity of reactions, however, nor is it a foolproof guide. For example, the melting of ice is an endothermic process:

Even though this process is endothermic, it is spontaneous at temperatures above the freezing point of water ( $0^\circ\text{C}$ ). The reverse process, the freezing of water to ice, is spontaneous at temperatures below  $0^\circ\text{C}$ . Thus, we know that ice at room temperature will melt and that water put into a freezer at  $-20^\circ\text{C}$  will turn into ice. Both of these processes are spontaneous under different conditions even though they are the reverse of one another. In Chapter 19 we will address the spontaneity of processes more fully. We will see why a process can be spontaneous at one temperature, but not at another, as is the case for the conversion of water to ice.

Despite these complicating factors, however, you should pay attention to the enthalpy changes in reactions. As a general observation, when the enthalpy change is large, it is the dominant factor in determining spontaneity. Thus, reactions for which  $\Delta H$  is *large* and *negative* tend to be spontaneous. Reactions for which  $\Delta H$  is *large* and *positive* tend to be spontaneous only in the reverse direction. The enthalpy of a reaction can be estimated in a number of ways. From these estimates, the likelihood of the reaction being thermodynamically favorable can be predicted.

*Related Exercises:* 5.45, 5.46

▲ **Figure 5.16 Specific heat of water.**

Specific heat indicates the amount of heat that must be added to one gram of a substance to raise its temperature by  $1 \text{ K}$  (or  $1^\circ\text{C}$ ). Specific heats can vary slightly with temperature, so for precise measurements the temperature is specified. The specific heat of  $\text{H}_2\text{O}(\text{l})$  at  $14.5^\circ\text{C}$  is  $4.184 \text{ J/g}\cdot\text{K}$ ; the addition of  $4.184 \text{ J}$  of heat to  $1 \text{ g}$  of liquid water at this temperature raises the temperature to  $15.5^\circ\text{C}$ . This amount of energy defines the calorie:  $1 \text{ cal} = 4.184 \text{ J}$ .

The temperature change experienced by an object when it absorbs a certain amount of heat is determined by its **heat capacity**,  $C$ . The heat capacity of an object is the amount of heat required to raise its temperature by  $1 \text{ K}$  (or  $1^\circ\text{C}$ ). The greater the heat capacity, the greater the heat required to produce a given increase in temperature.

For pure substances the heat capacity is usually given for a specified amount of the substance. The heat capacity of one mole of a substance is called its **molar heat capacity**,  $C_m$ . The heat capacity of one gram of a substance is called its **specific heat capacity**, or merely its **specific heat** (Figure 5.16 ◀). The specific heat,  $C_s$ , of a substance can be determined experimentally by measuring the temperature change,  $\Delta T$ , that a known mass,  $m$ , of the substance undergoes when it gains or loses a specific quantity of heat,  $q$ :

$$\text{Specific heat} = \frac{\text{(quantity of heat transferred)}}{\text{(grams of substance)} \times \text{(temperature change)}}$$

$$C_s = \frac{q}{m \times \Delta T} \quad [5.21]$$

For example,  $209 \text{ J}$  is required to increase the temperature of  $50.0 \text{ g}$  of water by  $1.00 \text{ K}$ . Thus, the specific heat of water is

$$C_s = \frac{209 \text{ J}}{(50.0 \text{ g})(1.00 \text{ K})} = 4.18 \frac{\text{J}}{\text{g}\cdot\text{K}}$$

A temperature change in kelvins is equal in magnitude to the temperature change in degrees Celsius:  $\Delta T$  in  $\text{K} = \Delta T$  in  $^\circ\text{C}$ . ◀◀ (Section 1.4) When the

TABLE 5.2 ■ Specific Heats of Some Substances at 298 K

Elements		Compounds	
Substance	Specific Heat (J/g·K)	Substance	Specific Heat (J/g·K)
N <sub>2</sub> (g)	1.04	H <sub>2</sub> O(l)	4.18
Al(s)	0.90	CH <sub>4</sub> (g)	2.20
Fe(s)	0.45	CO <sub>2</sub> (g)	0.84
Hg(l)	0.14	CaCO <sub>3</sub> (s)	0.82

sample gains heat (positive  $q$ ), the temperature of the sample increases (positive  $\Delta T$ ). Rearranging Equation 5.21, we get

$$q = C_s \times m \times \Delta T \quad [5.22]$$

Thus, we can calculate the quantity of heat that a substance has gained or lost by using its specific heat together with its measured mass and temperature change.

The specific heats of several substances are listed in Table 5.2 ▲. Notice that the specific heat of liquid water is higher than those of the other substances listed. For example, it is about five times as great as that of aluminum metal. The high specific heat of water affects Earth's climate because it makes the temperatures of the oceans relatively resistant to change. It also is very important in maintaining a constant temperature in our bodies, as we will discuss in the "Chemistry and Life" box later in this chapter.

### GIVE IT SOME THOUGHT

Which substance in Table 5.2 will undergo the greatest temperature change when the same mass of each substance absorbs the same quantity of heat?

### SAMPLE EXERCISE 5.5 | Relating Heat, Temperature Change, and Heat Capacity

(a) How much heat is needed to warm 250 g of water (about 1 cup) from 22 °C (about room temperature) to near its boiling point, 98 °C? The specific heat of water is 4.18 J/g·K. (b) What is the molar heat capacity of water?

#### SOLUTION

**Analyze:** In part (a) we must find the quantity of heat ( $q$ ) needed to warm the water, given the mass of water ( $m$ ), its temperature change ( $\Delta T$ ), and its specific heat ( $C_s$ ). In part (b) we must calculate the molar heat capacity (heat capacity per mole,  $C_m$ ) of water from its specific heat (heat capacity per gram).

**Plan:** (a) Given  $C_s$ ,  $m$ , and  $\Delta T$ , we can calculate the quantity of heat,  $q$ , using Equation 5.22. (b) We can use the molar mass of water and dimensional analysis to convert from heat capacity per gram to heat capacity per mole.

#### Solve:

(a) The water undergoes a temperature change of

$$\Delta T = 98\text{ °C} - 22\text{ °C} = 76\text{ °C} = 76\text{ K}$$

Using Equation 5.22, we have

$$\begin{aligned} q &= C_s \times m \times \Delta T \\ &= (4.18\text{ J/g}\cdot\text{K})(250\text{ g})(76\text{ K}) = 7.9 \times 10^4\text{ J} \end{aligned}$$

(b) The molar heat capacity is the heat capacity of one mole of substance. Using the atomic weights of hydrogen and oxygen, we have

$$1\text{ mol H}_2\text{O} = 18.0\text{ g H}_2\text{O}$$

From the specific heat given in part (a), we have

$$C_m = \left(4.18\frac{\text{J}}{\text{g}\cdot\text{K}}\right)\left(\frac{18.0\text{ g}}{1\text{ mol}}\right) = 75.2\text{ J/mol}\cdot\text{K}$$

### PRACTICE EXERCISE

(a) Large beds of rocks are used in some solar-heated homes to store heat. Assume that the specific heat of the rocks is 0.82 J/g·K. Calculate the quantity of heat absorbed by 50.0 kg of rocks if their temperature increases by 12.0 °C. (b) What temperature change would these rocks undergo if they emitted 450 kJ of heat?

**Answers:** (a)  $4.9 \times 10^5\text{ J}$ , (b) 11 K decrease = 11 °C decrease

▲ **Figure 5.17 Coffee-cup calorimeter.** This simple apparatus is used to measure heat-accompanying reactions at constant pressure.

## Constant-Pressure Calorimetry

The techniques and equipment employed in calorimetry depend on the nature of the process being studied. For many reactions, such as those occurring in solution, it is easy to control pressure so that  $\Delta H$  is measured directly. (Recall that  $\Delta H = q_p$ ) Although the calorimeters used for highly accurate work are precision instruments, a very simple “coffee-cup” calorimeter, as shown in Figure 5.17 ◀, is often used in general chemistry labs to illustrate the principles of calorimetry. Because the calorimeter is not sealed, the reaction occurs under the essentially constant pressure of the atmosphere.

In this case there is no physical boundary between the system and the surroundings. The reactants and products of the reaction are the system, and the water in which they dissolve as well as the calorimeter are part of the surroundings. If we assume that the calorimeter perfectly prevents the gain or loss of heat from the solution, the heat gained by the solution must be produced from the chemical reaction under study. In other words, the heat produced by the reaction,  $q_{\text{rxn}}$ , is entirely absorbed by the solution; it does not escape the calorimeter. (We also assume that the calorimeter itself does not absorb heat. In the case of the coffee-cup calorimeter, this is a reasonable approximation because the calorimeter has a very low thermal conductivity and heat capacity.) For an exothermic reaction, heat is “lost” by the reaction and “gained” by the solution, so the temperature of the solution rises. The opposite occurs for an endothermic reaction. The heat gained by the solution,  $q_{\text{soln}}$ , is therefore equal in magnitude to  $q_{\text{rxn}}$  but opposite in sign:  $q_{\text{soln}} = -q_{\text{rxn}}$ . The value of  $q_{\text{soln}}$  is readily calculated from the mass of the solution, its specific heat, and the temperature change:

$$q_{\text{soln}} = (\text{specific heat of solution}) \times (\text{grams of solution}) \times \Delta T = -q_{\text{rxn}} \quad [5.23]$$

For dilute aqueous solutions the specific heat of the solution will be approximately the same as that of water, 4.18 J/g·K.

Equation 5.23 makes it possible to calculate  $q_{\text{rxn}}$  from the temperature change of the solution in which the reaction occurs. A temperature increase ( $\Delta T > 0$ ) means the reaction is exothermic ( $q_{\text{rxn}} < 0$ ).

### GIVE IT SOME THOUGHT

(a) How are the energy changes of a system and its surroundings related? (b) How is the heat gained or lost by a system related to the heat gained or lost by its surroundings?

### SAMPLE EXERCISE 5.6 | Measuring $\Delta H$ Using a Coffee-Cup Calorimeter

When a student mixes 50 mL of 1.0 M HCl and 50 mL of 1.0 M NaOH in a coffee-cup calorimeter, the temperature of the resultant solution increases from 21.0 °C to 27.5 °C. Calculate the enthalpy change for the reaction in kJ/mol HCl, assuming that the calorimeter loses only a negligible quantity of heat, that the total volume of the solution is 100 mL, that its density is 1.0 g/mL, and that its specific heat is 4.18 J/g·K.

#### SOLUTION

**Analyze:** Mixing solutions of HCl and NaOH results in an acid–base reaction:

We need to calculate the heat produced per mole of HCl, given the temperature increase of the solution, the number of moles of HCl and NaOH involved, and the density and specific heat of the solution.

**Plan:** The total heat produced can be calculated using Equation 5.23. The number of moles of HCl consumed in the reaction must be calculated from the volume and molarity of this substance, and this amount then used to determine the heat produced per mol HCl.

**Solve:**

Because the total volume of the solution is 100 mL, its mass is

$$(100 \text{ mL})(1.0 \text{ g/mL}) = 100 \text{ g}$$

The temperature change is

$$\Delta T = 27.5^\circ\text{C} - 21.0^\circ\text{C} = 6.5^\circ\text{C} = 6.5 \text{ K}$$

Using Equation 5.23, we have

$$\begin{aligned} q_{\text{rxn}} &= -C_s \times m \times \Delta T \\ &= -(4.18 \text{ J/g}\cdot\text{K})(100 \text{ g})(6.5 \text{ K}) = -2.7 \times 10^3 \text{ J} = -2.7 \text{ kJ} \end{aligned}$$

Because the process occurs at constant pressure,

$$\Delta H = q_p = -2.7 \text{ kJ}$$

To express the enthalpy change on a molar basis, we use the fact that the number of moles of HCl is given by the product of the respective solution volumes (50 mL = 0.050 L) and concentrations (1.0 M = 1.0 mol/L):

$$(0.050 \text{ L})(1.0 \text{ mol/L}) = 0.050 \text{ mol}$$

Thus, the enthalpy change per mole of HCl is

$$\Delta H = -2.7 \text{ kJ}/0.050 \text{ mol} = -54 \text{ kJ/mol}$$

**Check:**  $\Delta H$  is negative (exothermic), which is expected for the reaction of an acid with a base and evidenced by the fact that the reaction causes the temperature of the solution to increase. The molar magnitude of the heat produced seems reasonable.

**PRACTICE EXERCISE**

When 50.0 mL of 0.100 M  $\text{AgNO}_3$  and 50.0 mL of 0.100 M HCl are mixed in a constant-pressure calorimeter, the temperature of the mixture increases from 22.30  $^\circ\text{C}$  to 23.11  $^\circ\text{C}$ . The temperature increase is caused by the following reaction:

Calculate  $\Delta H$  for this reaction in kJ/mol  $\text{AgNO}_3$ , assuming that the combined solution has a mass of 100.0 g and a specific heat of 4.18 J/g  $^\circ\text{C}$ .

**Answer:**  $-68,000 \text{ J/mol} = -68 \text{ kJ/mol}$

**Bomb Calorimetry (Constant-Volume Calorimetry)**

One of the most important types of reactions studied using calorimetry is combustion, in which a compound (usually an organic compound) reacts completely with excess oxygen.  $\infty$  (Section 3.2) Combustion reactions are most conveniently studied using a **bomb calorimeter**, a device shown schematically in Figure 5.18  $\blacktriangleright$ . The substance to be studied is placed in a small cup within a sealed vessel called a *bomb*. The bomb, which is designed to withstand high pressures, has an inlet valve for adding oxygen and electrical contacts to initiate the combustion. After the sample has been placed in the bomb, the bomb is sealed and pressurized with oxygen. It is then placed in the calorimeter, which is essentially an insulated container, and covered with an accurately measured quantity of water. When all the components within the calorimeter have come to the same temperature, the combustion reaction is initiated by passing an electrical current through a fine wire that is in contact with the sample. When the wire becomes sufficiently hot, the sample ignites.

Heat is released when combustion occurs. This heat is absorbed by the calorimeter contents, causing a rise in the temperature of the water. The temperature of the water is very carefully measured before reaction and then after reaction when the contents of the calorimeter have again arrived at a common temperature.

To calculate the heat of combustion from the measured temperature increase in the bomb calorimeter, we must know the total heat capacity of the calorimeter,  $C_{\text{cal}}$ . This quantity is determined by combusting a sample that releases a known quantity of heat and measuring the resulting temperature change. For example, the combustion of exactly 1 g of benzoic acid,  $\text{C}_6\text{H}_5\text{COOH}$ , in a bomb calorimeter produces 26.38 kJ of heat. Suppose 1.000 g of benzoic acid is combusted in a calorimeter, and it increases the temperature by 4.857  $^\circ\text{C}$ . The heat capacity of the calorimeter is then given by  $C_{\text{cal}} = 26.38 \text{ kJ}/4.857^\circ\text{C} = 5.431 \text{ kJ}/^\circ\text{C}$ . Once we know the value of  $C_{\text{cal}}$ , we can measure temperature changes produced by other reactions, and from these we can calculate the heat evolved in the reaction,  $q_{\text{rxn}}$ :

$$q_{\text{rxn}} = -C_{\text{cal}} \times \Delta T \quad [5.24]$$

**▲ Figure 5.18 Bomb calorimeter.** This device is used to measure heat accompanying combustion reactions at constant volume.

**SAMPLE EXERCISE 5.7** | Measuring  $q_{\text{rxn}}$  Using a Bomb Calorimeter

Methylhydrazine ( $\text{CH}_6\text{N}_2$ ) is used as a liquid rocket fuel. The combustion of methylhydrazine with oxygen produces  $\text{N}_2(\text{g})$ ,  $\text{CO}_2(\text{g})$ , and  $\text{H}_2\text{O}(\text{l})$ :

When 4.00 g of methylhydrazine is combusted in a bomb calorimeter, the temperature of the calorimeter increases from 25.00 °C to 39.50 °C. In a separate experiment the heat capacity of the calorimeter is measured to be 7.794 kJ/°C. Calculate the heat of reaction for the combustion of a mole of  $\text{CH}_6\text{N}_2$ .

**SOLUTION**

**Analyze:** We are given a temperature change and the total heat capacity of the calorimeter. We are also given the amount of reactant combusted. Our goal is to calculate the enthalpy change per mole for combustion of the reactant.

**Plan:** We will first calculate the heat evolved for the combustion of the 4.00-g sample. We will then convert this heat to a molar quantity.

**Solve:**

For combustion of the 4.00-g sample of methylhydrazine, the temperature change of the calorimeter is

$$\Delta T = (39.50 \text{ °C} - 25.00 \text{ °C}) = 14.50 \text{ °C}$$

We can use  $\Delta T$  and the value for  $C_{\text{cal}}$  to calculate the heat of reaction (Equation 5.24):

$$q_{\text{rxn}} = -C_{\text{cal}} \times \Delta T = -(7.794 \text{ kJ/°C})(14.50 \text{ °C}) = -113.0 \text{ kJ}$$

We can readily convert this value to the heat of reaction for a mole of  $\text{CH}_6\text{N}_2$ :

$$\left( \frac{-113.0 \text{ kJ}}{4.00 \text{ g CH}_6\text{N}_2} \right) \times \left( \frac{46.1 \text{ g CH}_6\text{N}_2}{1 \text{ mol CH}_6\text{N}_2} \right) = -1.30 \times 10^3 \text{ kJ/mol CH}_6\text{N}_2$$

**Check:** The units cancel properly, and the sign of the answer is negative as it should be for an exothermic reaction.

**PRACTICE EXERCISE**

A 0.5865-g sample of lactic acid ( $\text{HC}_3\text{H}_5\text{O}_3$ ) is burned in a calorimeter whose heat capacity is 4.812 kJ/°C. The temperature increases from 23.10 °C to 24.95 °C. Calculate the heat of combustion of lactic acid (a) per gram and (b) per mole.

**Answers:** (a)  $-15.2 \text{ kJ/g}$ , (b)  $-1370 \text{ kJ/mol}$

Because the reactions in a bomb calorimeter are carried out under constant-volume conditions, the heat transferred corresponds to the change in internal energy,  $\Delta E$ , rather than the change in enthalpy,  $\Delta H$  (Equation 5.14). For most reactions, however, the difference between  $\Delta E$  and  $\Delta H$  is very small. For the reaction discussed in Sample Exercise 5.7, for example, the difference between  $\Delta E$  and  $\Delta H$  is only about 1 kJ/mol—a difference of less than 0.1%. It is possible to correct the measured heat changes to obtain  $\Delta H$  values, and these form the basis of the tables of enthalpy change that we will see in the following sections. However, we need not concern ourselves with how these small corrections are made.

## 5.6 HESS'S LAW

Many enthalpies of reaction have been measured and tabulated. In this section and the next we will see that it is often possible to calculate the  $\Delta H$  for a reaction from the tabulated  $\Delta H$  values of other reactions. Thus, it is not necessary to make calorimetric measurements for all reactions.

Because enthalpy is a state function, the enthalpy change,  $\Delta H$ , associated with any chemical process depends only on the amount of matter that undergoes change and on the nature of the initial state of the reactants and the final state of the products. This means that whether a particular reaction is carried out in one step or in a series of steps, the sum of the enthalpy changes associated with the individual steps must be the same as the enthalpy change associated with the one-step process. As an example, the combustion of methane gas,  $\text{CH}_4(\text{g})$ , to

For most of us, the question “Are you running a fever?” was one of our first introductions to medical diagnosis. Indeed, a deviation in body temperature of only a few degrees indicates that something is amiss. In the laboratory you may have tried to maintain a solution at a constant temperature, only to find how difficult it can be. Yet our bodies manage to maintain a near-constant temperature in spite of widely varying weather, levels of physical activity, and periods of high metabolic activity (such as after a meal). How does the human body manage this task, and how does it relate to some of the topics we have discussed in this chapter?

Maintaining a near-constant temperature is one of the primary physiological functions of the human body. Normal body temperature generally ranges from 35.8 °C to 37.2 °C (96.5 °F–99 °F). This very narrow temperature range is essential to proper muscle function and to the control of the rates of the biochemical reactions in the body. You will learn more about the effects of temperature on reaction rates in Chapter 14.

A portion of the human brain stem called the *hypothalamus* regulates the temperature. The hypothalamus acts as a thermostat for body temperature. When body temperature rises above the high end of the normal range, the hypothalamus triggers mechanisms to lower the temperature. It likewise triggers mechanisms to increase the temperature if body temperature drops too low.

To understand qualitatively how the body’s heating and cooling mechanisms operate, we can view the body as a thermodynamic system. The body increases its internal energy content by ingesting foods from the surroundings.  (Section 5.8) The foods, such as glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>), are metabolized—a process that is essentially controlled oxidation to CO<sub>2</sub> and H<sub>2</sub>O:

Roughly 40% of the energy produced is ultimately used to do work in the form of muscle contractions and nerve cell activities. The remainder of the energy is released as heat, part of which is used to maintain body temperature. When the body produces too much heat, as in times of heavy physical exertion, it dissipates the excess to the surroundings.

Heat is transferred from the body to its surroundings primarily by *radiation*, *convection*, and *evaporation*. Radiation is the direct loss of heat from the body to cooler surroundings, much as a hot stovetop radiates heat to its surroundings. Convection is heat loss by virtue of heating air that is in contact with the body. The heated air rises and is replaced with cooler air, and the process continues. Warm clothing, which usually consists of insulating layers of material with “dead air” in between, decreases convective heat loss in cold weather. Evaporative cooling occurs when perspiration is generated at the skin surface by the sweat glands. Heat is removed from the body as the perspiration evaporates into the surroundings. Perspiration is predominantly water, so the process involved is the endothermic conversion of liquid water into water vapor:

The speed with which evaporative cooling occurs decreases as the atmospheric humidity increases, which is why people seem to be more sweaty and uncomfortable on hot and humid days.

When the hypothalamus senses that the body temperature has risen too high, it increases heat loss from the body in two principal ways. First, it increases the flow of blood near the surface of the skin, which allows for increased radiational and convective cooling. The reddish “flushed” appearance of a hot individual is the result of this increased subsurface blood flow. Second, the hypothalamus stimulates the secretion of perspiration from the sweat glands, which increases evaporative cooling. During periods of extreme activity, the amount of liquid secreted as perspiration can be as high as 2 to 4 liters per hour. As a result, water must be replenished to the body during these periods (Figure 5.19▼). If the body loses too much fluid through perspiration, it will no longer be able to cool itself and blood volume decreases, which can lead to *heat exhaustion* or the more serious and potentially fatal *heat stroke*, during which the body temperature can rise to as high as 41 °C to 45 °C (106 °F–113 °F). On the other hand, replenishing water without replenishing the electrolytes that are lost during perspiration can also lead to serious problems as pointed out in the “Chemistry in Life” box in Section 4.5.

When body temperature drops too low, the hypothalamus decreases the blood flow to the surface of the skin, thereby decreasing heat loss. It also triggers small involuntary contractions of the muscles; the biochemical reactions that generate the energy to do this work also generate more heat for the body. When these contractions get large enough—as when the body feels a chill—a *shiver* results. If the body is unable to maintain a temperature above 35 °C (95 °F), the very dangerous condition called *hypothermia* can result.

▲ **Figure 5.19 Marathon runner drinking water.** Runners must constantly replenish the water in their bodies that is lost through perspiration.

form  $\text{CO}_2(\text{g})$  and liquid water can be thought of as occurring in two steps: (1) the combustion of  $\text{CH}_4(\text{g})$  to form  $\text{CO}_2(\text{g})$  and gaseous water,  $\text{H}_2\text{O}(\text{g})$  and (2) the condensation of gaseous water to form liquid water,  $\text{H}_2\text{O}(\text{l})$ . The enthalpy change for the overall process is simply the sum of the enthalpy changes for these two steps:

**▲ Figure 5.20** An enthalpy diagram comparing a one-step and a two-step process for a reaction. The enthalpy change of the direct reaction on the left equals the sum of the two steps on the right. That is,  $\Delta H$  for the overall reaction equals the sum of the  $\Delta H$  values for the two steps shown.

The net equation is

To obtain the net equation, the sum of the reactants of the two equations is placed on one side of the arrow and the sum of the products on the other side. Because  $2 \text{H}_2\text{O}(\text{g})$  occurs on both sides, it can be canceled like an algebraic quantity that appears on both sides of an equal sign. Figure 5.20 ◀ compares the two-step reaction with the direct one.

**Hess's law** states that *if a reaction is carried out in a series of steps,  $\Delta H$  for the overall reaction will equal the sum of the enthalpy changes for the individual steps.* The overall enthalpy change for the process is independent of the number of steps or the particular nature of the path by which the reaction is carried out. This principle is a consequence of the fact that enthalpy is a state function, and  $\Delta H$  is therefore independent of the path between the initial and final states. We can therefore calculate  $\Delta H$  for any process, as long as we find a route for which  $\Delta H$  is known for each step. This means that a relatively small number of experimental measurements can be used to calculate  $\Delta H$  for a vast number of different reactions.

Hess's law provides a useful means of calculating energy changes that are difficult to measure directly. For instance, it is impossible to measure directly the enthalpy for the combustion of carbon to form carbon monoxide. Combustion of 1 mol of carbon with 0.5 mol of  $\text{O}_2$  produces both  $\text{CO}$  and  $\text{CO}_2$ , leaving some carbon unreacted. However, solid carbon and carbon monoxide can both be completely burned in  $\text{O}_2$  to produce  $\text{CO}_2$ . We can use the enthalpy changes of these reactions to calculate the heat of combustion of  $\text{C}$  to  $\text{CO}$ , as shown in Sample Exercise 5.8.

### GIVE IT SOME THOUGHT

What effect do the following changes have on  $\Delta H$  for a reaction: (a) reversing a reaction, (b) multiplying coefficients by 2?

#### SAMPLE EXERCISE 5.8 | Using Hess's Law to Calculate $\Delta H$

The enthalpy of reaction for the combustion of  $\text{C}$  to  $\text{CO}_2$  is  $-393.5 \text{ kJ/mol C}$ , and the enthalpy for the combustion of  $\text{CO}$  to  $\text{CO}_2$  is  $-283.0 \text{ kJ/mol CO}$ :

Using these data, calculate the enthalpy for the combustion of  $\text{C}$  to  $\text{CO}$ :

#### SOLUTION

**Analyze:** We are given two thermochemical equations, and our goal is to combine them in such a way as to obtain the third equation and its enthalpy change.

**Plan:** We will use Hess's law. In doing so, we first note the numbers of moles of substances among the reactants and products in the target equation, (3). We then manipulate equations (1) and (2) to give the same number of moles of these substances, so that when the resulting equations are added, we obtain the target equation. At the same time, we keep track of the enthalpy changes, which we add.

**Solve:** To use equations (1) and (2), we arrange them so that C(s) is on the reactant side and CO(g) is on the product side of the arrow, as in the target reaction, equation (3). Because equation (1) has C(s) as a reactant, we can use that equation just as it is. We need to turn equation (2) around, however, so that CO(g) is a product. Remember that when reactions are turned around, the sign of  $\Delta H$  is reversed. We arrange the two equations so that they can be added to give the desired equation:

When we add the two equations,  $\text{CO}_2\text{(g)}$  appears on both sides of the arrow and therefore cancels out. Likewise,  $\frac{1}{2}\text{O}_2\text{(g)}$  is eliminated from each side.

**Comment:** It is sometimes useful to add subscripts to the enthalpy changes, as we have done here, to keep track of the associations between the chemical reactions and their  $\Delta H$  values.

### ■ PRACTICE EXERCISE

Carbon occurs in two forms, graphite and diamond. The enthalpy of the combustion of graphite is  $-393.5 \text{ kJ/mol}$  and that of diamond is  $-395.4 \text{ kJ/mol}$ :

Calculate  $\Delta H$  for the conversion of graphite to diamond:

**Answer:**  $\Delta H_3 = +1.9 \text{ kJ}$

### ■ SAMPLE EXERCISE 5.9 Using Three Equations with Hess's Law to Calculate $\Delta H$

Calculate  $\Delta H$  for the reaction

given the following chemical equations and their respective enthalpy changes:

### SOLUTION

**Analyze:** We are given a chemical equation and asked to calculate its  $\Delta H$  using three chemical equations and their associated enthalpy changes.

**Plan:** We will use Hess's law, summing the three equations or their reverses and multiplying each by an appropriate coefficient so that they add to give the net equation for the reaction of interest. At the same time, we keep track of the  $\Delta H$  values, reversing their signs if the reactions are reversed and multiplying them by whatever coefficient is employed in the equation.

**Solve:** Because the target equation has  $\text{C}_2\text{H}_2$  as a product, we turn the first equation around; the sign of  $\Delta H$  is therefore changed. The desired equation has  $2 \text{C(s)}$  as a reactant, so we multiply the second equation and its  $\Delta H$  by 2. Because the target equation has  $\text{H}_2$  as a reactant, we keep the third equation as it is. We then add the three equations and their enthalpy changes in accordance with Hess's law:

When the equations are added, there are  $2 \text{CO}_2$ ,  $\frac{5}{2}\text{O}_2$ , and  $\text{H}_2\text{O}$  on both sides of the arrow. These are canceled in writing the net equation.

**Check:** The procedure must be correct because we obtained the correct net equation. In cases like this you should go back over the numerical manipulations of the  $\Delta H$  values to ensure that you did not make an inadvertent error with signs.

### PRACTICE EXERCISE

Calculate  $\Delta H$  for the reaction

given the following information:

**Answer:**  $-304.1 \text{ kJ}$

**▲ Figure 5.21** An enthalpy diagram illustrating Hess's law. Because  $H$  is a state function, the enthalpy change for the combustion of 1 mol  $\text{CH}_4$  is independent of whether the reaction takes place in one or more steps:

$$\Delta H_1 = \Delta H_2 + \Delta H_3.$$

The key point of these examples is that  $H$  is a state function, so for a particular set of reactants and products,  $\Delta H$  is the same whether the reaction takes place in one step or in a series of steps. For example, consider the reaction of methane ( $\text{CH}_4$ ) and oxygen ( $\text{O}_2$ ) to form  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . We can envision the reaction forming  $\text{CO}_2$  directly or with the initial formation of  $\text{CO}$ , which is then combusted to  $\text{CO}_2$ . These two paths are compared in Figure 5.21. Because  $H$  is a state function, both paths *must* produce the same value of  $\Delta H$ . In the enthalpy diagram, that means  $\Delta H_1 = \Delta H_2 + \Delta H_3$ .

## 5.7 ENTHALPIES OF FORMATION

By using the methods we have just discussed, we can calculate the enthalpy changes for a great many reactions from tabulated  $\Delta H$  values. Many experimental data are tabulated according to the type of process. For example, extensive tables exist of *enthalpies of vaporization* ( $\Delta H$  for converting liquids to gases), *enthalpies of fusion* ( $\Delta H$  for melting solids), *enthalpies of combustion* ( $\Delta H$  for combusting a substance in oxygen), and so forth. A particularly important process used for tabulating thermochemical data is the formation of a compound from its constituent elements. The enthalpy change associated with this process is called the **enthalpy of formation** (or *heat of formation*) and is labeled  $\Delta H_f$ , where the subscript  $f$  indicates that the substance has been *formed* from its component elements.

The magnitude of any enthalpy change depends on the conditions of temperature, pressure, and state (gas, liquid, or solid crystalline form) of the reactants and products. To compare the enthalpies of different reactions, we must define a set of conditions, called a *standard state*, at which most enthalpies are tabulated. The standard state of a substance is its pure form at atmospheric pressure (1 atm; [Section 10.2](#)) and the temperature of interest, which we usually choose to be 298 K (25 °C).\* The **standard enthalpy change** of a reaction is defined as the enthalpy change when all reactants and products are in their standard states. We denote a standard enthalpy change as  $\Delta H^\circ$ , where the superscript  $^\circ$  indicates standard-state conditions.

\*The definition of the standard state for gases has been changed to 1 bar (1 atm = 1.013 bar), a slightly lower pressure than the value of 1 atm that is used for the data in this text. For most purposes, this change makes very little difference in the standard changes.

The **standard enthalpy of formation** of a compound,  $\Delta H_f^\circ$ , is the change in enthalpy for the reaction that forms one mole of the compound from its elements, with all substances in their standard states:

We usually report  $\Delta H_f^\circ$  values at 298 K. If an element exists in more than one form under standard conditions, the most stable form of the element is usually used for the formation reaction. For example, the standard enthalpy of formation for ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , is the enthalpy change for the following reaction:

The elemental source of oxygen is  $\text{O}_2$ , not O or  $\text{O}_3$ , because  $\text{O}_2$  is the stable form of oxygen at 298 K and standard atmospheric pressure. Similarly, the elemental source of carbon is graphite and not diamond, because graphite is more stable (lower energy) at 298 K and standard atmospheric pressure (see Practice Exercise 5.8). Likewise, the most stable form of hydrogen under standard conditions is  $\text{H}_2(\text{g})$ , so this is used as the source of hydrogen in Equation 5.25.

The stoichiometry of formation reactions always indicates that one mole of the desired substance is produced, as in Equation 5.25. As a result, enthalpies of formation are reported in kJ/mol of the substance being formed. Several standard enthalpies of formation are given in Table 5.3. A more complete table is provided in Appendix C.

By definition, the *standard enthalpy of formation of the most stable form of any element is zero* because there is no formation reaction needed when the element is already in its standard state. Thus, the values of  $\Delta H_f^\circ$  for C(graphite),  $\text{H}_2(\text{g})$ ,  $\text{O}_2(\text{g})$ , and the standard states of other elements are zero by definition.

### GIVE IT SOME THOUGHT

In Table 5.3, the standard enthalpy of formation of  $\text{C}_2\text{H}_2(\text{g})$  is listed as 226.7 kJ/mol. Write the thermochemical equation associated with  $\Delta H_f^\circ$  for this substance.

**TABLE 5.3** ■ Standard Enthalpies of Formation,  $\Delta H_f^\circ$ , at 298 K

Substance	Formula	$\Delta H_f^\circ$ (kJ/mol)	Substance	Formula	$\Delta H_f^\circ$ (kJ/mol)
Acetylene	$\text{C}_2\text{H}_2(\text{g})$	226.7	Hydrogen chloride	$\text{HCl}(\text{g})$	-92.30
Ammonia	$\text{NH}_3(\text{g})$	-46.19	Hydrogen fluoride	$\text{HF}(\text{g})$	-268.60
Benzene	$\text{C}_6\text{H}_6(\text{l})$	49.0	Hydrogen iodide	$\text{HI}(\text{g})$	25.9
Calcium carbonate	$\text{CaCO}_3(\text{s})$	-1207.1	Methane	$\text{CH}_4(\text{g})$	-74.80
Calcium oxide	$\text{CaO}(\text{s})$	-635.5	Methanol	$\text{CH}_3\text{OH}(\text{l})$	-238.6
Carbon dioxide	$\text{CO}_2(\text{g})$	-393.5	Propane	$\text{C}_3\text{H}_8(\text{g})$	-103.85
Carbon monoxide	$\text{CO}(\text{g})$	-110.5	Silver chloride	$\text{AgCl}(\text{s})$	-127.0
Diamond	$\text{C}(\text{s})$	1.88	Sodium bicarbonate	$\text{NaHCO}_3(\text{s})$	-947.7
Ethane	$\text{C}_2\text{H}_6(\text{g})$	-84.68	Sodium carbonate	$\text{Na}_2\text{CO}_3(\text{s})$	-1130.9
Ethanol	$\text{C}_2\text{H}_5\text{OH}(\text{l})$	-277.7	Sodium chloride	$\text{NaCl}(\text{s})$	-410.9
Ethylene	$\text{C}_2\text{H}_4(\text{g})$	52.30	Sucrose	$\text{C}_{12}\text{H}_{22}\text{O}_{11}(\text{s})$	-2221
Glucose	$\text{C}_6\text{H}_{12}\text{O}_6(\text{s})$	-1273	Water	$\text{H}_2\text{O}(\text{l})$	-285.8
Hydrogen bromide	$\text{HBr}(\text{g})$	-36.23	Water vapor	$\text{H}_2\text{O}(\text{g})$	-241.8

### SAMPLE EXERCISE 5.10 Identifying Equations Associated with Enthalpies of Formation

For which of the following reactions at 25 °C would the enthalpy change represent a standard enthalpy of formation? For each that does not, what changes are needed to make it an equation whose  $\Delta H$  is an enthalpy of formation?

- (a)  $2 \text{Na}(s) + \frac{1}{2} \text{O}_2(g) \longrightarrow \text{Na}_2\text{O}(s)$   
 (b)  $2 \text{K}(l) + \text{Cl}_2(g) \longrightarrow 2 \text{KCl}(s)$   
 (c)  $\text{C}_6\text{H}_{12}\text{O}_6(s) \longrightarrow 6 \text{C}(\text{diamond}) + 6 \text{H}_2(g) + 3 \text{O}_2(g)$

#### SOLUTION

**Analyze:** The standard enthalpy of formation is represented by a reaction in which each reactant is an element in its standard state and the product is one mole of the compound.

**Plan:** We need to examine each equation to determine, first, whether the reaction is one in which one mole of substance is formed from the elements. Next, we need to determine whether the reactant elements are in their standard states.

**Solve:** In (a) 1 mol  $\text{Na}_2\text{O}$  is formed from the elements sodium and oxygen in their proper states, solid Na and  $\text{O}_2$  gas, respectively. Therefore, the enthalpy change for reaction (a) corresponds to a standard enthalpy of formation.

In (b) potassium is given as a liquid. It must be changed to the solid form, its standard state at room temperature. Furthermore, two moles of product are formed, so the enthalpy change for the reaction as written is twice the standard enthalpy of formation of  $\text{KCl}(s)$ . The equation for the formation reaction of 1 mol of  $\text{KCl}(s)$  is

Reaction (c) does not form a substance from its elements. Instead, a substance decomposes to its elements, so this reaction must be reversed. Next, the element carbon is given as diamond, whereas graphite is the standard state of carbon at room temperature and 1 atm pressure. The equation that correctly represents the enthalpy of formation of glucose from its elements is

#### PRACTICE EXERCISE

Write the equation corresponding to the standard enthalpy of formation of liquid carbon tetrachloride ( $\text{CCl}_4$ ).

*Answer:*  $\text{C}(\text{graphite}) + 2 \text{Cl}_2(g) \longrightarrow \text{CCl}_4(l)$

## Using Enthalpies of Formation to Calculate Enthalpies of Reaction

Tabulations of  $\Delta H_f^\circ$ , such as those in Table 5.3 and Appendix C, have many important uses. As we will see in this section, we can use Hess's law to calculate the standard enthalpy change for any reaction for which we know the  $\Delta H_f^\circ$  values for all reactants and products. For example, consider the combustion of propane gas,  $\text{C}_3\text{H}_8(g)$ , with oxygen to form  $\text{CO}_2(g)$  and  $\text{H}_2\text{O}(l)$  under standard conditions:

We can write this equation as the sum of three formation reactions:

From Hess's law we can write the standard enthalpy change for the overall reaction, Equation 5.29, as the sum of the enthalpy changes for the processes in

Equations 5.26 through 5.28. We can then use values from Table 5.3 to compute a numerical value for  $\Delta H^\circ$  for the overall reaction:

$$\begin{aligned}\Delta H_{\text{rxn}}^\circ &= \Delta H_1 + \Delta H_2 + \Delta H_3 \\ &= -\Delta H_f^\circ[\text{C}_3\text{H}_8(\text{g})] + 3\Delta H_f^\circ[\text{CO}_2(\text{g})] + 4\Delta H_f^\circ[\text{H}_2\text{O}(\text{l})] \\ &= -(-103.85 \text{ kJ}) + 3(-393.5 \text{ kJ}) + 4(-285.8 \text{ kJ}) = -2219.9 \text{ kJ}\end{aligned}\quad [5.30]$$

Several aspects of this calculation depend on the guidelines we discussed in Section 5.4.

- Equation 5.26 is the reverse of the formation reaction for  $\text{C}_3\text{H}_8(\text{g})$ , so the enthalpy change for this reaction is  $-\Delta H_f^\circ[\text{C}_3\text{H}_8(\text{g})]$ .
- Equation 5.27 is the formation reaction for 3 mol of  $\text{CO}_2(\text{g})$ . Because enthalpy is an extensive property, the enthalpy change for this step is  $3\Delta H_f^\circ[\text{CO}_2(\text{g})]$ . Similarly, the enthalpy change for Equation 5.28 is  $4\Delta H_f^\circ[\text{H}_2\text{O}(\text{l})]$ . The reaction specifies that  $\text{H}_2\text{O}(\text{l})$ , was produced, so be careful to use the value of  $\Delta H_f^\circ$  for  $\text{H}_2\text{O}(\text{l})$ , not  $\text{H}_2\text{O}(\text{g})$ .
- We assume that the stoichiometric coefficients in the balanced equation represent moles. For Equation 5.29, therefore, the value  $\Delta H_{\text{rxn}}^\circ = -2220 \text{ kJ}$  represents the enthalpy change for the reaction of 1 mol  $\text{C}_3\text{H}_8$  and 5 mol  $\text{O}_2$  to form 3 mol  $\text{CO}_2$  and 4 mol  $\text{H}_2\text{O}$ . The product of the number of moles and the enthalpy change in kJ/mol has the units kJ: (number of moles)  $\times$  ( $\Delta H_f^\circ$  in kJ/mol) = kJ. We therefore report  $\Delta H_{\text{rxn}}^\circ$  in kJ.

Figure 5.22  $\blacktriangledown$  presents an enthalpy diagram for Equation 5.29, showing how it can be broken into steps involving formation reactions.

We can break down any reaction into formation reactions as we have done here. When we do, we obtain the general result that the standard enthalpy change of a reaction is the sum of the standard enthalpies of formation of the products minus the standard enthalpies of formation of the reactants:

$$\Delta H_{\text{rxn}}^\circ = \Sigma n\Delta H_f^\circ(\text{products}) - \Sigma m\Delta H_f^\circ(\text{reactants}) \quad [5.31]$$

The symbol  $\Sigma$  (sigma) means “the sum of,” and  $n$  and  $m$  are the stoichiometric coefficients of the chemical equation. The first term in Equation 5.31 represents the formation reactions of the products, which are written in the “forward” direction, that is, elements reacting to form products. This term is analogous to Equations 5.27 and 5.28 in the previous example. The second term represents the reverse of the formation reactions of the reactants, as in Equation 5.26, which is why the  $\Delta H_f^\circ$  values have a minus sign in front of them.

$\blacktriangleleft$  **Figure 5.22 An enthalpy diagram relating the enthalpy change for a reaction to enthalpies of formation.** For the combustion of propane gas,  $\text{C}_3\text{H}_8(\text{g})$ , the reaction is  $\text{C}_3\text{H}_8(\text{g}) + 5 \text{O}_2(\text{g}) \rightarrow 3 \text{CO}_2(\text{g}) + 4 \text{H}_2\text{O}(\text{l})$ . We can imagine this reaction as occurring in three steps. First,  $\text{C}_3\text{H}_8(\text{g})$  is decomposed to its elements, so  $\Delta H_1 = \Delta H_f^\circ[\text{C}_3\text{H}_8(\text{g})]$ . Second, 3 mol  $\text{CO}_2(\text{g})$  are formed, so  $\Delta H_2 = 3\Delta H_f^\circ[\text{CO}_2(\text{g})]$ . Finally, 4 mol  $\text{H}_2\text{O}(\text{l})$  are formed, so  $\Delta H_3 = 4\Delta H_f^\circ[\text{H}_2\text{O}(\text{l})]$ . Hess’s law tells us that  $\Delta H_{\text{rxn}}^\circ = \Delta H_1 + \Delta H_2 + \Delta H_3$ . This same result is given by Equation 5.31 because  $\Delta H_f^\circ[\text{O}_2(\text{g})] = 0$ .

**SAMPLE EXERCISE 5.11** | Calculating an Enthalpy of Reaction from Enthalpies of Formation

(a) Calculate the standard enthalpy change for the combustion of 1 mol of benzene,  $C_6H_6(l)$ , to form  $CO_2(g)$  and  $H_2O(l)$ . (b) Compare the quantity of heat produced by combustion of 1.00 g propane to that produced by 1.00 g benzene.

**SOLUTION**

**Analyze:** (a) We are given a reaction [combustion of  $C_6H_6(l)$  to form  $CO_2(g)$  and  $H_2O(l)$ ] and asked to calculate its standard enthalpy change,  $\Delta H^\circ$ . (b) We then need to compare the quantity of heat produced by combustion of 1.00 g  $C_6H_6$  with that produced by 1.00 g  $C_3H_8$ , whose combustion was treated above in the text. (See Equations 5.29 and 5.30.)

**Plan:** (a) We need to write the balanced equation for the combustion of  $C_6H_6$ . We then look up  $\Delta H_f^\circ$  values in Appendix C or in Table 5.3 and apply Equation 5.31 to calculate the enthalpy change for the reaction. (b) We use the molar mass of  $C_6H_6$  to change the enthalpy change per mole to that per gram. We similarly use the molar mass of  $C_3H_8$  and the enthalpy change per mole calculated in the text above to calculate the enthalpy change per gram of that substance.

**Solve:**

(a) We know that a combustion reaction involves  $O_2(g)$  as a reactant. Thus, the balanced equation for the combustion reaction of 1 mol  $C_6H_6(l)$  is

We can calculate  $\Delta H^\circ$  for this reaction by using Equation 5.31 and data in Table 5.3. Remember to multiply the  $\Delta H_f^\circ$  value for each substance in the reaction by that substance's stoichiometric coefficient. Recall also that  $\Delta H_f^\circ = 0$  for any element in its most stable form under standard conditions, so  $\Delta H_f^\circ(O_2(g)) = 0$

$$\begin{aligned} \Delta H_{\text{rxn}}^\circ &= [6\Delta H_f^\circ(CO_2) + 3\Delta H_f^\circ(H_2O)] - [\Delta H_f^\circ(C_6H_6) + \frac{15}{2}\Delta H_f^\circ(O_2)] \\ &= [6(-393.5 \text{ kJ}) + 3(-285.8 \text{ kJ})] - [(49.0 \text{ kJ}) + \frac{15}{2}(0 \text{ kJ})] \\ &= (-2361 - 857.4 - 49.0) \text{ kJ} \\ &= -3267 \text{ kJ} \end{aligned}$$

(b) From the example worked in the text,  $\Delta H^\circ = -2220 \text{ kJ}$  for the combustion of 1 mol of propane. In part (a) of this exercise we determined that  $\Delta H^\circ = -3267 \text{ kJ}$  for the combustion of 1 mol benzene. To determine the heat of combustion per gram of each substance, we use the molar masses to convert moles to grams:

$$\begin{aligned} C_3H_8(g): & \quad (-2220 \text{ kJ/mol})(1 \text{ mol}/44.1 \text{ g}) = -50.3 \text{ kJ/g} \\ C_6H_6(l): & \quad (-3267 \text{ kJ/mol})(1 \text{ mol}/78.1 \text{ g}) = -41.8 \text{ kJ/g} \end{aligned}$$

**Comment:** Both propane and benzene are hydrocarbons. As a rule, the energy obtained from the combustion of a gram of hydrocarbon is between 40 and 50 kJ.

**PRACTICE EXERCISE**

Using the standard enthalpies of formation listed in Table 5.3, calculate the enthalpy change for the combustion of 1 mol of ethanol:

**Answer:**  $-1367 \text{ kJ}$

**SAMPLE EXERCISE 5.12** | Calculating an Enthalpy of Formation Using an Enthalpy of Reaction

The standard enthalpy change for the reaction

is 178.1 kJ. From the values for the standard enthalpies of formation of  $CaO(s)$  and  $CO_2(g)$  given in Table 5.3, calculate the standard enthalpy of formation of  $CaCO_3(s)$ .

**SOLUTION**

**Analyze:** We need to obtain  $\Delta H_f^\circ(CaCO_3)$ .

**Plan:** We begin by writing the expression for the standard enthalpy change for the reaction:

$$\Delta H_{\text{rxn}}^\circ = [\Delta H_f^\circ(CaO) + \Delta H_f^\circ(CO_2)] - \Delta H_f^\circ(CaCO_3)$$

**Solve:** Inserting the given  $\Delta H_{\text{rxn}}^\circ$  and the known  $\Delta H_f^\circ$  values from Table 5.3 or Appendix C, we have

$$178.1 \text{ kJ} = -635.5 \text{ kJ} - 393.5 \text{ kJ} - \Delta H_f^\circ(CaCO_3)$$

Solving for  $\Delta H_f^\circ(CaCO_3)$  gives

$$\Delta H_f^\circ(CaCO_3) = -1207.1 \text{ kJ/mol}$$

**Check:** We expect the enthalpy of formation of a stable solid such as calcium carbonate to be negative, as obtained.

**PRACTICE EXERCISE**

Given the following standard enthalpy change, use the standard enthalpies of formation in Table 5.3 to calculate the standard enthalpy of formation of CuO(s):

**Answer:**  $-156.1 \text{ kJ/mol}$

## 5.8 FOODS AND FUELS

Most chemical reactions used for the production of heat are combustion reactions. The energy released when one gram of a material is combusted is often called its **fuel value**. Although fuel values represent the heat *released* in a combustion reaction, fuel values are reported as positive numbers. The fuel value of any food or fuel can be measured by calorimetry.

### Foods

Most of the energy our bodies need comes from carbohydrates and fats. The forms of carbohydrate known as starch are decomposed in the intestines into glucose,  $\text{C}_6\text{H}_{12}\text{O}_6$ . Glucose is soluble in blood, and in the human body it is known as blood sugar. It is transported by the blood to cells, where it reacts with  $\text{O}_2$  in a series of steps, eventually producing  $\text{CO}_2\text{(g)}$ ,  $\text{H}_2\text{O(l)}$ , and energy:

The breakdown of carbohydrates is rapid, so their energy is quickly supplied to the body. However, the body stores only a very small amount of carbohydrates. The average fuel value of carbohydrates is  $17 \text{ kJ/g}$  ( $4 \text{ kcal/g}$ ).

Like carbohydrates, fats produce  $\text{CO}_2$  and  $\text{H}_2\text{O}$  when metabolized and when subjected to combustion in a bomb calorimeter. The reaction of tristearin,  $\text{C}_{57}\text{H}_{110}\text{O}_6$ , a typical fat, is as follows:

The body uses the chemical energy from foods to maintain body temperature (see the “Chemistry and Life” box in Section 5.6), to contract muscles, and to construct and repair tissues. Any excess energy is stored as fats. Fats are well suited to serve as the body’s energy reserve for at least two reasons: (1) They are insoluble in water, which facilitates storage in the body; and (2) they produce more energy per gram than either proteins or carbohydrates, which makes them efficient energy sources on a mass basis. The average fuel value of fats is  $38 \text{ kJ/g}$  ( $9 \text{ kcal/g}$ ).

The metabolism of proteins in the body produces less energy than combustion in a calorimeter because the products are different. Proteins contain nitrogen, which is released in the bomb calorimeter as  $\text{N}_2$ . In the body this nitrogen ends up mainly as urea,  $(\text{NH}_2)_2\text{CO}$ . Proteins are used by the body mainly as building materials for organ walls, skin, hair, muscle, and so forth. On average, the metabolism of proteins produces  $17 \text{ kJ/g}$  ( $4 \text{ kcal/g}$ ), the same as for carbohydrates.

The fuel values for a variety of common foods are shown in Table 5.4 ▼. Labels on packaged foods show the amounts of carbohydrate, fat, and protein contained in an average serving, as well as the amount of energy supplied by a serving (Figure 5.23 ►). The amount of energy our bodies require varies considerably depending on such factors as weight, age, and muscular activity. About  $100 \text{ kJ}$  per kilogram of body weight per day is required to keep the body functioning at a minimal level. An average  $70\text{-kg}$  ( $154\text{-lb}$ ) person expends about  $800 \text{ kJ/hr}$  when doing light work, such as slow walking or light gardening. Strenuous activity, such as running, often requires  $2000 \text{ kJ/hr}$  or more. When the energy value, or caloric content, of our food exceeds the energy we expend, our body stores the surplus as fat.

▲ **Figure 5.23 Labels of processed foods showing nutritional information.** Such labels give information about the quantities of different nutrients and the energy value (caloric value) in an average serving.

TABLE 5.4 ■ Compositions and Fuel Values of Some Common Foods

	Approximate Composition (% by mass)			Fuel Value	
	Carbohydrate	Fat	Protein	kJ/g	kcal/g (Cal/g)
Carbohydrate	100	–	–	17	4
Fat	–	100	–	38	9
Protein	–	–	100	17	4
Apples	13	0.5	0.4	2.5	0.59
Beer*	1.2	–	0.3	1.8	0.42
Bread	52	3	9	12	2.8
Cheese	4	37	28	20	4.7
Eggs	0.7	10	13	6.0	1.4
Fudge	81	11	2	18	4.4
Green beans	7.0	–	1.9	1.5	0.38
Hamburger	–	30	22	15	3.6
Milk (whole)	5.0	4.0	3.3	3.0	0.74
Peanuts	22	39	26	23	5.5

\*Beers typically contain 3.5% ethanol, which has fuel value.

### GIVE IT SOME THOUGHT

Which releases the greatest amount of energy per gram upon metabolism, carbohydrates, proteins, or fats?

#### SAMPLE EXERCISE 5.13 | Comparing Fuel Values

A plant such as celery contains carbohydrates in the form of starch and cellulose. These two kinds of carbohydrates have essentially the same fuel values when combusted in a bomb calorimeter. When we consume celery, however, our bodies receive fuel value from the starch only. What can we conclude about the difference between starch and cellulose as foods?

#### SOLUTION

If cellulose does not provide fuel value, we must conclude that it is not converted in the body into  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , as starch is. A slight, but critical, difference in the structures of starch and cellulose explains why only starch is broken down into glucose in the body. Cellulose passes through without undergoing significant chemical change. It serves as fiber, or roughage, in the diet, but provides no caloric value.

#### PRACTICE EXERCISE

The nutritional label on a bottle of canola oil indicates that 10 g of the oil has an energy value of 86 kcal. A similar label on a bottle of pancake syrup indicates that 60 mL (about 60 g) has an energy value of 200 kcal. Account for the difference.

*Answer:* The oil has a fuel value of 8.6 kcal/g, whereas the syrup has a fuel value of about 3.3 kcal/g. The higher fuel value for the canola oil arises because the oil is essentially pure fat, whereas the syrup is a solution of sugars (carbohydrates) in water. The oil has a higher fuel value per gram; in addition, the syrup is diluted by water.

#### SAMPLE EXERCISE 5.14 | Estimating the Fuel Value of a Food from Its Composition

(a) A 28-g (1-oz) serving of a popular breakfast cereal served with 120 mL of skim milk provides 8 g protein, 26 g carbohydrates, and 2 g fat. Using the average fuel values of these kinds of substances, estimate the energy value (caloric content) of this serving.  
 (b) A person of average weight uses about 100 Cal/mi when running or jogging. How many servings of this cereal provide the energy value requirements for running 3 mi?

#### SOLUTION

(a) **Analyze:** The energy value of the serving will be the sum of the energy values of the protein, carbohydrates, and fat.

**Plan:** We are given the masses of the protein, carbohydrates, and fat contained in the combined . We can use the data in Table 5.4 to convert these masses to their energy values, which we can sum to get the total energy value.

$$\text{Solve: } (8 \text{ g protein})\left(\frac{17 \text{ kJ}}{1 \text{ g protein}}\right) + (26 \text{ g carbohydrate})\left(\frac{17 \text{ kJ}}{1 \text{ g carbohydrate}}\right) + (2 \text{ g fat})\left(\frac{38 \text{ kJ}}{1 \text{ g fat}}\right) = 650 \text{ kJ (to two significant figures)}$$

This corresponds to 160 kcal:

$$(650 \text{ kJ})\left(\frac{1 \text{ kcal}}{4.18 \text{ kJ}}\right) = 160 \text{ kcal}$$

Recall that the dietary Calorie is equivalent to 1 kcal. Thus, the serving provides 160 Cal.

**(b) Analyze:** Here we are faced with the reverse problem, calculating the quantity of food that provides a specific energy value.

**Plan:** The problem statement provides a conversion factor between Calories and miles. The answer to part (a) provides us with a conversion factor between servings and Calories.

**Solve:** We can use these factors in a straightforward dimensional analysis to determine the number of servings needed, rounded to the nearest whole number:

$$\text{Servings} = (3 \text{ mi})\left(\frac{100 \text{ Cal}}{1 \text{ mi}}\right)\left(\frac{1 \text{ serving}}{160 \text{ Cal}}\right) = 2 \text{ servings}$$

### ■ PRACTICE EXERCISE

(a) Dry red beans contain 62% carbohydrate, 22% protein, and 1.5% fat. Estimate the fuel value of these beans. (b) During a very light activity, such as reading or watching television, the average adult uses about 7 kJ/min. How many minutes of such activity can be sustained by the energy provided by a serving of chicken noodle soup containing 13 g protein, 15 g carbohydrate, and 5 g fat?

**Answers:** (a) 15 kJ/g, (b) 95 min

## Fuels

The elemental compositions and fuel values of several common fuels are compared in Table 5.5. During the complete combustion of fuels, carbon is converted to  $\text{CO}_2$  and hydrogen is converted to  $\text{H}_2\text{O}$ , both of which have large negative enthalpies of formation. Consequently, the greater the percentage of carbon and hydrogen in a fuel, the higher its fuel value. Compare, for example, the compositions and fuel values of bituminous coal and wood. The coal has a higher fuel value because of its greater carbon content.

In 2005 the United States consumed  $1.05 \times 10^{17}$  kJ of energy. This value corresponds to an average daily energy consumption per person of  $9.6 \times 10^5$  kJ which is roughly 100 times greater than the per capita food-energy needs.

**TABLE 5.5** ■ Fuel Values and Compositions of Some Common Fuels

	Approximate Elemental Composition (mass %)			Fuel Value (kJ/g)
	C	H	O	
Wood (pine)	50	6	44	18
Anthracite coal (Pennsylvania)	82	1	2	31
Bituminous coal (Pennsylvania)	77	5	7	32
Charcoal	100	0	0	34
Crude oil (Texas)	85	12	0	45
Gasoline	85	15	0	48
Natural gas	70	23	0	49
Hydrogen	0	100	0	142

▲ **Figure 5.24 Sources of energy consumed in the United States.** In 2005 the United States consumed a total of  $1.05 \times 10^{17}$  kJ of energy.

Although the population of the United States is only about 4.5% of the world's population, the U.S. accounts for nearly one-fourth of the world's total energy consumption. Figure 5.24 illustrates the sources of this energy.

Coal, petroleum, and natural gas, which are the world's major sources of energy, are known as **fossil fuels**. All have formed over millions of years from the decomposition of plants and animals and are being depleted far more rapidly than they are being formed. **Natural gas** consists of gaseous hydrocarbons, compounds of hydrogen and carbon. It contains primarily methane ( $\text{CH}_4$ ), with small amounts of ethane ( $\text{C}_2\text{H}_6$ ), propane ( $\text{C}_3\text{H}_8$ ), and butane ( $\text{C}_4\text{H}_{10}$ ). We determined the fuel value of propane in Sample Exercise 5.11. **Petroleum** is a liquid composed of hundreds of compounds, most of which are hydrocarbons, with the remainder being chiefly organic compounds containing sulfur, nitrogen, or oxygen. **Coal**, which is solid, contains hydrocarbons of high molecular weight as well as compounds containing sulfur, oxygen, or nitrogen. Coal is the most abundant fossil fuel; it constitutes 80% of the fossil fuel reserves of the United States and 90% of those of the world. However, the use of coal presents a number of problems. Coal is a complex mixture of substances, and it contains components that cause air pollution. When coal is combusted, the sulfur it contains is converted mainly to sulfur dioxide,  $\text{SO}_2$ , a very troublesome air pollutant. Because coal is a solid, recovery from its underground deposits is expensive and often dangerous. Furthermore, coal deposits are not always close to locations of high-energy use, so there are often substantial shipping costs.

One promising way to utilize coal reserves is to use them to produce a mixture of gaseous hydrocarbons called *syngas* (for "synthesis gas"). In this process, called *coal gasification*, the coal typically is pulverized and treated with superheated steam. Sulfur-containing compounds, water, and carbon dioxide can be removed from the products, leading to a gaseous mixture of  $\text{CH}_4$ ,  $\text{H}_2$ , and  $\text{CO}$ , all of which have high fuel values:

## Chemistry Put to Work

### THE HYBRID CAR

The hybrid cars now entering the automobile marketplace nicely illustrate the convertibility of energy from one form to another. Hybrid cars run on either gasoline or electricity. The so-called "full hybrids" are cars capable of running at low speeds on a battery-powered electrical engine alone (Figure 5.25). The "mild hybrid" cars are best described as electrically assisted gasoline engines.

Full hybrid cars are more efficient than the mild hybrid designs but are more costly to produce and require more technological advances than the mild hybrid versions. The mild hybrids are likely to be more widely produced and sold within the next several years. Let's consider how they operate and some of the interesting thermodynamic considerations they incorporate.

Figure 5.26 shows a schematic diagram of the power system for a mild hybrid car. In addition to the 12-volt battery that is standard on conventional autos, the hybrid car typically carries a 48-volt battery pack. The electrical energy from this battery pack is not employed to move the car directly; an electrical engine capable of doing that, as in the full hybrids, requires from 150 to 300 volts. (The popular Toyota Prius has a battery pack consisting of 228 cells of 1.2 V each, thereby generating a nominal voltage of 270 V.)

▲ **Figure 5.25 A hybrid car.** The Lexus GS450h is the first rear-drive full hybrid luxury car, evidence of the widespread movement of hybrid cars into the marketplace.

In the mild hybrid cars the added electrical source is employed to run various auxiliary devices that would otherwise be run off the gasoline engine, such as water pump, power steering, and air systems. To save on energy, when the hybrid

Because it is gaseous, syngas can be easily transported in pipelines. Additionally, because much of the sulfur in coal is removed during the gasification process, combustion of syngas causes less air pollution than burning coal. For these reasons, the economical conversion of coal and petroleum into “cleaner” fuels such as syngas and hydrogen is a very active area of current research in chemistry and engineering.

### Other Energy Sources

*Nuclear energy* is energy that is released in either the splitting or the fusion (combining) of the nuclei of atoms. Nuclear power is currently used to produce about 22% of the electric power in the United States and comprises about 8% of the total U.S. energy production (Figure 5.24). Nuclear energy is, in principle, free of the polluting emissions that are a major problem in the generation of energy from fossil fuels. However, nuclear power plants produce radioactive waste products, and their use has therefore been fraught with controversy. We will discuss issues related to the production of nuclear energy in Chapter 21.

Fossil fuel and nuclear energy are *nonrenewable* sources of energy; they are limited resources that we are consuming at a much greater rate than they are being regenerated. Eventually these fuels will be expended, although estimates vary greatly as to when this will occur. Because nonrenewable sources of energy will eventually be used up, a great deal of research is being conducted into sources of *renewable energy*, energy sources that are essentially inexhaustible. Renewable energy sources include *solar energy* from the Sun, *wind energy* harnessed by windmills, *geothermal energy* from the heat stored in the mass of Earth, *hydroelectric energy* from flowing rivers, and *biomass energy* from crops, such as trees and corn, and from biological waste matter. Currently, renewable sources provide about 6.0% of the U.S. annual energy consumption, with hydroelectric and biomass sources as the major contributors.

Providing our future energy needs will most certainly depend on developing the technology to harness solar energy with greater efficiency. Solar energy is the world’s largest energy source. On a clear day about 1 kJ of solar energy

car comes to a stop, the engine shuts off. It restarts automatically when the driver presses the accelerator. This feature saves fuel that would otherwise be used to keep the engine idling at traffic lights and other stopping situations.

▲ **Figure 5.26 Schematic diagram of a mild hybrid car.** The 48-volt battery pack provides energy for operating several auxiliary functions. It is recharged from the engine and through the braking system.

The idea is that the added electrical system will improve overall fuel efficiency of the car. The added battery, moreover, is not supposed to need recharging from an external power source. Where, then, can the improved fuel efficiency come from? Clearly, if the battery pack is to continue to operate auxiliary devices such as the water pump, it must be recharged. We can think of it this way: The source of the voltage that the battery develops is a chemical reaction. Recharging the battery thus represents a conversion of mechanical energy into chemical potential energy. The recharging occurs in part through the agency of an alternator, which runs off the engine and provides a recharging voltage. In the mild hybrid car, the braking system serves as an additional source of mechanical energy for recharging. When the brakes are applied in a conventional car, the car’s kinetic energy is converted through the brake pads in the wheels into heat, so no useful work is done. In the hybrid car, some of the car’s kinetic energy is used to recharge the battery when the brakes are applied. Thus, kinetic energy that would otherwise be dissipated as heat is partially converted into useful work. Overall, the mild hybrid cars are expected to yield 10–20% improvements in fuel economy as compared with similar conventional cars.

reaches each square meter of Earth's surface every second. The average solar energy that falls on only 0.1% of U.S. land area is equivalent to all the energy that this nation currently uses. Harnessing this energy is difficult because it is dilute (it is distributed over a wide area) and it varies with time of day and weather conditions. The effective use of solar energy will depend on the development of some means of storing the collected energy for use at a later time. Any practical means for doing this will almost certainly involve use of an endothermic chemical process that can be later reversed to release heat. One such reaction is the following:

This reaction proceeds in the forward direction at high temperatures, which can be obtained in a solar furnace. The CO and H<sub>2</sub> formed in the reaction could then be stored and allowed to react later, with the heat released being put to useful work.

A survey taken about 25 years ago at Walt Disney's EPCOT Center revealed that nearly 30% of the visitors expected that solar energy would be the principal source of energy in the United States in the year 2000. The future of solar energy has proven to be a lot like the Sun itself: big and bright but farther away than it seems. Nevertheless, important progress has been made in recent years. Perhaps the most direct way to make use of the Sun's energy is to convert it directly into electricity by use of photovoltaic devices, sometimes called *solar cells*. The efficiencies of solar energy conversion by use of such devices have increased dramatically during the past few years because of intensive research efforts. Photovoltaics are vital to the generation of power for the space station. More significant for our Earth-bound concerns, the unit costs of solar panels have been steadily declining, even as their efficiencies have improved dramatically.

In 2006 construction was started in southern Portugal on what the builders claim will be the world's biggest solar energy power station. The first module of the station is planned to cover about 150 acres and is capable of generating 11 MW (megawatts) of electrical power—enough for 8000 homes. When fully constructed, the plant is projected to cover 620 acres and supply over 100 MW of power. Several other large solar plants with capacities over 100 MW have also been announced in Australia, Israel, and China.

### SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

Trinitroglycerin, C<sub>3</sub>H<sub>5</sub>N<sub>3</sub>O<sub>9</sub> (usually referred to simply as nitroglycerin), has been widely used as an explosive. Alfred Nobel used it to make dynamite in 1866. Rather surprisingly, it also is used as a medication, to relieve angina (chest pains resulting from partially blocked arteries to the heart) by dilating the blood vessels. The enthalpy of decomposition at 1 atm pressure of trinitroglycerin to form nitrogen gas, carbon dioxide gas, liquid water, and oxygen gas at 25 °C is -1541.4 kJ/mol. (a) Write a balanced chemical equation for the decomposition of trinitroglycerin. (b) Calculate the standard heat of formation of trinitroglycerin. (c) A standard dose of trinitroglycerin for relief of angina is 0.60 mg. If the sample is eventually oxidized in the body (not explosively, though!) to nitrogen gas, carbon dioxide gas, and liquid water, what number of calories is released? (d) One common form of trinitroglycerin melts at about 3 °C. From this information and the formula for the substance, would you expect it to be a molecular or ionic compound? Explain. (e) Describe the various conversions of forms of energy when trinitroglycerin is used as an explosive to break rockfaces in highway construction.

### SOLUTION

(a) The general form of the equation we must balance is

We go about balancing in the usual way. To obtain an even number of nitrogen atoms on the left, we multiply the formula for C<sub>3</sub>H<sub>5</sub>N<sub>3</sub>O<sub>9</sub> by 2. This then gives us 3 mol of N<sub>2</sub>, 6 mol of CO<sub>2</sub> and 5 mol of H<sub>2</sub>O. Everything is balanced except for oxygen. We have an odd number of oxygen atoms on the right. We can balance the oxygen by adding  $\frac{1}{2}$  mol of O<sub>2</sub> on the right:

We multiply through by 2 to convert all coefficients to whole numbers:

(At the temperature of the explosion, water is a gas. The rapid expansion of the gaseous products creates the force of an explosion.)

(b) The heat of formation is the enthalpy change in the balanced chemical equation:

We can obtain the value of  $\Delta H_f^\circ$  by using the equation for the heat of decomposition of trinitrolycerin:

The enthalpy change in this reaction is  $4(-1541.4 \text{ kJ}) = -6165.6 \text{ kJ}$ . [We need to multiply by 4 because there are 4 mol of  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)$  in the balanced equation.] This enthalpy change is given by the sum of the heats of formation of the products minus the heats of formation of the reactants, each multiplied by its coefficient in the balanced equation:

$$-6165.6 \text{ kJ} = \{6\Delta H_f^\circ[\text{N}_2(g)] + 12\Delta H_f^\circ[\text{CO}_2(g)] + 10\Delta H_f^\circ[\text{H}_2\text{O}(l)] + \Delta H_f^\circ[\text{O}_2(g)]\} - 4\Delta H_f^\circ[\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)]$$

The  $\Delta H_f^\circ$  values for  $\text{N}_2(g)$  and  $\text{O}_2(g)$  are zero, by definition. We look up the values for  $\text{H}_2\text{O}(l)$  and  $\text{CO}_2(g)$  from Table 5.3 and find that

$$-6165.6 \text{ kJ} = 12(-393.5 \text{ kJ}) + 10(-285.8 \text{ kJ}) - 4\Delta H_f^\circ[\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)]$$

$$\Delta H_f^\circ[\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)] = -353.6 \text{ kJ/mol}$$

(c) We know that on oxidation 1 mol of  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)$  yields 1541.4 kJ. We need to calculate the number of moles of  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)$  in 0.60 mg:

$$0.60 \times 10^{-3} \text{ g C}_3\text{H}_5\text{N}_3\text{O}_9 \left( \frac{1 \text{ mol C}_3\text{H}_5\text{N}_3\text{O}_9}{227 \text{ g C}_3\text{H}_5\text{N}_3\text{O}_9} \right) \left( \frac{1541.4 \text{ kJ}}{1 \text{ mol C}_3\text{H}_5\text{N}_3\text{O}_9} \right) = 4.1 \times 10^{-3} \text{ kJ}$$

$$= 4.1 \text{ J}$$

(d) Because trinitrolycerin melts below room temperature, we expect that it is a molecular compound. With few exceptions, ionic substances are generally hard, crystalline materials that melt at high temperatures.  $\rightleftharpoons$  (Sections 2.5 and 2.6) Also, the molecular formula suggests that it is likely to be a molecular substance. All the elements of which it is composed are nonmetals.

(e) The energy stored in trinitrolycerin is chemical potential energy. When the substance reacts explosively, it forms substances such as carbon dioxide, water, and nitrogen gas, which are of lower potential energy. In the course of the chemical transformation, energy is released in the form of heat; the gaseous reaction products are very hot. This very high heat energy is transferred to the surroundings; the gases expand against the surroundings, which may be solid materials. Work is done in moving the solid materials and imparting kinetic energy to them. For example, a chunk of rock might be impelled upward. It has been given kinetic energy by transfer of energy from the hot, expanding gases. As the rock rises, its kinetic energy is transformed into potential energy. Eventually, it again acquires kinetic energy as it falls to Earth. When it strikes Earth, its kinetic energy is converted largely to thermal energy, though some work may be done on the surroundings as well.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 5.1** Thermodynamics is the study of energy and its transformations. In this chapter we have focused on **thermochemistry**, the transformations of energy—especially heat—during chemical reactions. An object can possess energy in two forms: (1) **kinetic energy** is the energy due to the motion of the object; and (2) **potential energy** is the energy that an object possesses by virtue of its position relative to other objects. An electron in motion near a proton, for example, has kinetic energy because of its motion and potential energy because of its electrostatic attraction to the proton. The SI unit of ener-

gy is the **joule** (J):  $1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2$ . Another common energy unit is the **calorie** (cal), which was originally defined as the quantity of energy necessary to increase the temperature of 1 g of water by  $1^\circ\text{C}$ :  $1 \text{ cal} = 4.184 \text{ J}$ . When we study thermodynamic properties, we define a specific amount of matter as the **system**. Everything outside the system is the **surroundings**. When we study a chemical reaction, the system is generally the reactants and products. A closed system can exchange energy, but not matter, with the surroundings. Energy can be transferred between the system and the surroundings as work or

heat. **Work** is the energy expended to move an object against a **force**. **Heat** is the energy that is transferred from a hotter object to a colder one. **Energy** is the capacity to do work or to transfer heat.

**Section 5.2** The **internal energy** of a system is the sum of all the kinetic and potential energies of its component parts. The internal energy of a system can change because of energy transferred between the system and the surroundings. According to the **first law of thermodynamics**, the change in the internal energy of a system,  $\Delta E$ , is the sum of the heat,  $q$ , transferred into or out of the system and the work,  $w$ , done on or by the system:  $\Delta E = q + w$ . Both  $q$  and  $w$  have a sign that indicates the direction of energy transfer. When heat is transferred from the surroundings to the system,  $q > 0$ . Likewise, when the surroundings do work on the system,  $w > 0$ . In an **endothermic** process the system absorbs heat from the surroundings; in an **exothermic** process the system releases heat to the surroundings. The internal energy,  $E$ , is a **state function**. The value of any state function depends only on the state or condition of the system and not on the details of how it came to be in that state. The heat,  $q$ , and the work,  $w$ , are not state functions; their values depend on the particular way in which a system changes its state.

**Sections 5.3 and 5.4** When a gas is produced or consumed in a chemical reaction occurring at constant pressure, the system may perform **pressure-volume (P-V) work** against the prevailing pressure. For this reason, we define a new state function called **enthalpy**,  $H$ , which is related to energy:  $H = E + PV$ . In systems where only pressure-volume work that is due to gases is involved, the change in the enthalpy of a system,  $\Delta H$ , equals the heat gained or lost by the system at constant pressure,  $\Delta H = q_p$ . For an endothermic process,  $\Delta H > 0$ ; for an exothermic process,  $\Delta H < 0$ . Every substance has a characteristic enthalpy. In a chemical process, the **enthalpy of reaction** is the enthalpy of the products minus the enthalpy of the reactants:  $\Delta H_{\text{rxn}} = H(\text{products}) - H(\text{reactants})$ . Enthalpies of reaction follow some simple rules: (1) The enthalpy of reaction is proportional to the amount of reactant that reacts. (2) Reversing a reaction changes the sign of  $\Delta H$ . (3) The enthalpy of reaction depends on the physical states of the reactants and products.

**Section 5.5** The amount of heat transferred between the system and the surroundings is measured experimentally by **calorimetry**. A **calorimeter** measures the temperature change accompanying a process. The temperature change of a calorimeter depends on its **heat capacity**, the amount of heat required to raise its temperature by 1 K. The heat capacity for one mole of a pure substance is called its **molar heat capacity**; for one gram of the substance, we use the term

**specific heat**. Water has a very high specific heat, 4.18 J/g·K. The amount of heat,  $q$ , absorbed by a substance is the product of its specific heat ( $C_s$ ), its mass, and its temperature change:  $q = C_s \times m \times \Delta T$ . If a calorimetry experiment is carried out under a constant pressure, the heat transferred provides a direct measure of the enthalpy change of the reaction. Constant-volume calorimetry is carried out in a vessel of fixed volume called a **bomb calorimeter**. Bomb calorimeters are used to measure the heat evolved in combustion reactions. The heat transferred under constant-volume conditions is equal to  $\Delta E$ . However, corrections can be applied to  $\Delta E$  values to yield enthalpies of combustion.

**Section 5.6** Because enthalpy is a state function,  $\Delta H$  depends only on the initial and final states of the system. Thus, the enthalpy change of a process is the same whether the process is carried out in one step or in a series of steps. **Hess's law** states that if a reaction is carried out in a series of steps,  $\Delta H$  for the reaction will be equal to the sum of the enthalpy changes for the steps. We can therefore calculate  $\Delta H$  for any process, as long as we can write the process as a series of steps for which  $\Delta H$  is known.

**Section 5.7** The **enthalpy of formation**,  $\Delta H_f^\circ$ , of a substance is the enthalpy change for the reaction in which the substance is formed from its constituent elements. The **standard enthalpy change** of a reaction,  $\Delta H^\circ$ , is the enthalpy change when all reactants and products are at 1 atm pressure and a specific temperature, usually 298 K (25 °C). Combining these ideas, the **standard enthalpy of formation**,  $\Delta H_f^\circ$ , of a substance is the change in enthalpy for the reaction that forms one mole of the substance from its elements in their most stable form with all reactants and products at 1 atm pressure and usually 298 K. For any element in its most stable state at 298 K and 1 atm pressure,  $\Delta H_f^\circ = 0$ . The standard enthalpy change for any reaction can be readily calculated from the standard enthalpies of formation of the reactants and products in the reaction:

$$\Delta H_{\text{rxn}}^\circ = \sum n \Delta H_f^\circ(\text{products}) - \sum m \Delta H_f^\circ(\text{reactants})$$

**Section 5.8** The **fuel value** of a substance is the heat released when one gram of the substance is combusted. Different types of foods have different fuel values and differing abilities to be stored in the body. The most common fuels are hydrocarbons that are found as **fossil fuels**, such as **natural gas**, **petroleum**, and **coal**. Coal is the most abundant fossil fuel, but the sulfur present in most coals causes air pollution. Coal gasification is one possible way to use existing resources as sources of cleaner energy in the future. Sources of **renewable energy** include solar energy, wind energy, biomass, and hydroelectric energy. Nuclear power does not utilize fossil fuels but does create serious waste-disposal problems.

## KEY SKILLS

- Interconvert energy units.
- Express the relationships among the quantities  $q$ ,  $w$ ,  $\Delta E$ , and  $\Delta H$ . Understand their sign conventions, including how the signs of  $q$  and  $\Delta H$  relate to whether a process is exothermic or endothermic.

- State the first law of thermodynamics.
- Understand the concept of a state function and be able to give examples.
- Use thermochemical equations to relate the amount of heat energy transferred in reactions at constant pressure ( $\Delta H$ ) to the amount of substance involved in the reaction.
- Calculate the heat transferred in a process from temperature measurements together with heat capacities or specific heats (calorimetry).
- Use Hess's law to determine enthalpy changes for reactions.
- Use standard enthalpies of formation to calculate  $\Delta H^\circ$  for reactions.

## KEY EQUATIONS

$$\bullet E_k = \frac{1}{2} mv^2 \quad [5.1]$$

$$\bullet \Delta E = E_{\text{final}} - E_{\text{initial}} \quad [5.4]$$

$$\bullet \Delta E = q + w \quad [5.5]$$

$$\bullet w = -P \Delta V \quad [5.7]$$

$$\bullet \Delta H = \Delta E + P \Delta V = q_p \quad [5.10]$$

$$\bullet q = C_s \times m \times \Delta T \quad [5.22]$$

$$\bullet \Delta H_{\text{rxn}}^\circ = \sum n \Delta H_f^\circ(\text{products}) - \sum m \Delta H_f^\circ(\text{reactants}) \quad [5.31]$$

Kinetic energy

The change in internal energy

Relates the change in internal energy to heat and work (the first law of thermodynamics)

The work done by an expanding gas at constant pressure

Enthalpy change at constant pressure

Heat gained or lost based on specific heat, mass, and temperature change.

Standard enthalpy change of a reaction

## VISUALIZING CONCEPTS

- 5.1 Imagine a book that is falling from a shelf. At a particular moment during its fall, the book has a kinetic energy of 13 J and a potential energy with respect to the floor of 72 J. How does the book's kinetic energy and its potential energy change as it continues to fall? What is its total kinetic energy at the instant just before it strikes the floor? [Section 5.1]

- 5.2 Consider the accompanying energy diagram. (a) Does this diagram represent an increase or decrease in the internal energy of the system? (b) What sign is given to  $\Delta E$  for this process? (c) If there is no work associated with the process, is it exothermic or endothermic? [Section 5.2]

- 5.3 The contents of the closed box in each of the following illustrations represent a system, and the arrows show the changes to the system during some process. The

lengths of the arrows represent the relative magnitudes of  $q$  and  $w$  (a) Which of these processes is endothermic? (b) For which of these processes, if any, is  $\Delta E < 0$ ? (c) For which process, if any, is there a net gain in internal energy? [Section 5.2]

- 5.4 Imagine that you are climbing a mountain. (a) Is the distance you travel to the top a state function? Why or why not? (b) Is the change in elevation between your base camp and the peak a state function? Why or why not? [Section 5.2]

- 5.5 In the cylinder diagrammed below, a chemical process occurs at constant temperature and pressure. (a) Is the sign of  $w$  indicated by this change positive or negative? (b) If the process is endothermic, does the internal energy of the system within the cylinder increase or decrease during the change and is  $\Delta E$  positive or negative? [Sections 5.2 and 5.3]

- 5.6 Imagine a container placed in a tub of water, as depicted in the accompanying diagram. (a) If the contents of the container are the system and heat is able to flow through the container walls, what qualitative changes will occur in the temperatures of the system and in its surroundings? What is the sign of  $q$  associated with each change? From the system's perspective, is the process exothermic or endothermic? (b) If neither the volume nor the pressure of the system changes during the process, how is the change in internal energy related to the change in enthalpy? [Sections 5.2 and 5.3]

- 5.7 Which will release more heat as it cools from 50 °C to 25 °C, 1 kg of water or 1 kg of aluminum? How do you know? [Section 5.5]
- 5.8 A gas-phase reaction was run in an apparatus designed to maintain a constant pressure. (a) Write a balanced

chemical equation for the reaction depicted, and predict whether  $w$  is positive, negative, or zero. (b) Using data from Appendix C, determine  $\Delta H$  for the formation of one mole of the product. Why is this enthalpy change called the enthalpy of formation of the involved product? [Sections 5.3 and 5.7]

- 5.9 Consider the two diagrams below. (a) Based on (i), write an equation showing how  $\Delta H_A$  is related to  $\Delta H_B$  and  $\Delta H_C$ . How do both diagram (i) and your equation relate to the fact that enthalpy is a state function? (b) Based on (ii), write an equation relating  $\Delta H_Z$  to the other enthalpy changes in the diagram. (c) How do these diagrams relate to Hess's law? [Section 5.6]

- 5.10 Does  $\Delta H_{rxn}$  for the reaction represented by the following equation equal the standard enthalpy of formation for  $\text{CH}_3\text{OH}(l)$ ? Why or why not? [Section 5.7]

## EXERCISES

### The Nature of Energy

- 5.11 In what two ways can an object possess energy? How do these two ways differ from one another?
- 5.12 Suppose you toss a tennis ball upward. (a) Does the kinetic energy of the ball increase or decrease as it moves higher? (b) What happens to the potential energy of the ball as it moves higher? (c) If the same amount of energy were imparted to a ball the same size as a tennis ball, but of twice the mass, how high would it go in comparison to the tennis ball? Explain your answers.
- 5.13 (a) Calculate the kinetic energy in joules of a 45-g golf ball moving at 61 m/s. (b) Convert this energy to calories. (c) What happens to this energy when the ball lands in a sand trap?
- 5.14 (a) What is the kinetic energy in joules of an 850-lb motorcycle moving at 66 mph? (b) By what factor will the kinetic energy change if the speed of the motorcycle is decreased to 33 mph? (c) Where does the kinetic energy of the motorcycle go when the rider brakes to a stop?
- 5.15 The use of the British thermal unit (Btu) is common in much engineering work. A Btu is the amount of heat required to raise the temperature of 1 lb of water by 1 °F. Calculate the number of joules in a Btu.

- 5.16 A watt is a measure of power (the rate of energy change) equal to 1 J/s. (a) Calculate the number of joules in a kilowatt-hour. (b) An adult person radiates heat to the surroundings at about the same rate as a 100-watt electric incandescent lightbulb. What is the total amount of energy in kcal radiated to the surroundings by an adult in 24 hours?

- 5.17 (a) What is meant by the term *system* in thermodynamics? (b) What is a *closed system*?

- 5.18 In a thermodynamic study a scientist focuses on the properties of a solution in an apparatus as illustrated. A solution is continuously flowing into the apparatus at the top and out at the bottom, such that the amount of solution in the apparatus is constant with time. (a) Is the solution in the apparatus a closed system, open system, or isolated system? Explain your choice. (b) If it is not a closed system, what could be done to make it a closed system?

- 5.19 (a) What is work? (b) How do we determine the amount of work done, given the force associated with the work?
- 5.20 (a) What is heat? (b) Under what conditions is heat transferred from one object to another?
- 5.21 Identify the force present, and explain whether work is being performed in the following cases: (a) You lift a

pencil off the top of a desk. (b) A spring is compressed to half its normal length.

- 5.22 Identify the force present, and explain whether work is done when (a) a positively charged particle moves in a circle at a fixed distance from a negatively charged particle; (b) an iron nail is pulled off a magnet.

## The First Law of Thermodynamics

- 5.23 (a) State the first law of thermodynamics. (b) What is meant by the *internal energy* of a system? (c) By what means can the internal energy of a closed system increase?
- 5.24 (a) Write an equation that expresses the first law of thermodynamics in terms of heat and work. (b) Under what conditions will the quantities  $q$  and  $w$  be negative numbers?
- 5.25 Calculate  $\Delta E$ , and determine whether the process is endothermic or exothermic for the following cases: (a) A system absorbs 105 kJ of heat from its surroundings while doing 29 kJ of work on the surroundings; (b)  $q = 1.50$  kJ and  $w = -657$  J; (c) the system releases 57.5 kJ of heat while doing 22.5 kJ of work on the surroundings.
- 5.26 For the following processes, calculate the change in internal energy of the system and determine whether the process is endothermic or exothermic: (a) A balloon is heated by adding 850 J of heat. It expands, doing 382 J of work on the atmosphere. (b) A 50-g sample of water is cooled from 30 °C to 15 °C, thereby losing approximately 3140 J of heat. (c) A chemical reaction releases 6.47 kJ of heat and does no work on the surroundings.

- 5.27 A gas is confined to a cylinder fitted with a piston and an electrical heater, as shown in the accompanying illustration. Suppose that current is supplied to the heater so that 100 J of energy is added. Consider two different situations. In case (1) the piston is allowed to move as the energy is added. In case (2) the piston is fixed so that it cannot move. (a) In which case does the gas have the higher temperature after addition of the electrical energy? Explain.

(b) What can you say about the values of  $q$  and  $w$  in each of these cases? (c) What can you say about the relative values of  $\Delta E$  for the system (the gas in the cylinder) in the two cases?

- 5.28 Consider a system consisting of two oppositely charged spheres hanging by strings and separated by a distance  $r_1$ , as shown in the accompanying illustration. Suppose they are separated to a larger distance  $r_2$ , by moving them apart along a track. (a) What change, if any, has occurred in the potential energy of the system? (b) What effect, if any, does this process have on the value of  $\Delta E$ ? (c) What can you say about  $q$  and  $w$  for this process?

- 5.29 (a) What is meant by the term *state function*? (b) Give an example of a quantity that is a state function and one that is not. (c) Is work a state function? Why or why not?
- 5.30 Indicate which of the following is independent of the path by which a change occurs: (a) the change in potential energy when a book is transferred from table to shelf, (b) the heat evolved when a cube of sugar is oxidized to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ , (c) the work accomplished in burning a gallon of gasoline.

## Enthalpy

- 5.31 (a) Why is the change in enthalpy usually easier to measure than the change in internal energy? (b) For a given process at constant pressure,  $\Delta H$  is negative. Is the process endothermic or exothermic?
- 5.32 (a) Under what condition will the enthalpy change of a process equal the amount of heat transferred into or out of the system? (b) During a constant-pressure process the system absorbs heat from the surroundings. Does the enthalpy of the system increase or decrease during the process?
- 5.33 You are given  $\Delta H$  for a process that occurs at constant pressure. What additional information do you need to determine  $\Delta E$  for the process?

- 5.34 Suppose that the gas-phase reaction  $2 \text{NO}(\text{g}) + \text{O}_2(\text{g}) \rightarrow 2 \text{NO}_2(\text{g})$  were carried out in a constant-volume container at constant temperature. Would the measured heat change represent  $\Delta H$  or  $\Delta E$ ? If there is a difference, which quantity is larger for this reaction? Explain.

- 5.35 A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.3. When the gas undergoes a particular chemical reaction, it releases 79 kJ of heat to its surroundings and does 18 kJ of  $P$ - $V$  work on its surroundings. What are the values of  $\Delta H$  and  $\Delta E$  for this process?
- 5.36 A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.3. When 378 J

of heat is added to the gas, it expands and does 56 J of work on the surroundings. What are the values of  $\Delta H$  and  $\Delta E$  for this process?

- 5.37** The complete combustion of acetic acid,  $\text{CH}_3\text{COOH}(l)$ , to form  $\text{H}_2\text{O}(l)$  and  $\text{CO}_2(g)$  at constant pressure releases 871.7 kJ of heat per mole of  $\text{CH}_3\text{COOH}$ . (a) Write a balanced thermochemical equation for this reaction. (b) Draw an enthalpy diagram for the reaction.
- 5.38** The decomposition of zinc carbonate,  $\text{ZnCO}_3(s)$ , into zinc oxide,  $\text{ZnO}(s)$ , and  $\text{CO}_2(g)$  at constant pressure requires the addition of 71.5 kJ of heat per mole of  $\text{ZnCO}_3$ . (a) Write a balanced thermochemical equation for the reaction. (b) Draw an enthalpy diagram for the reaction.
- 5.39** Consider the following reaction, which occurs at room temperature and pressure:

Which has the higher enthalpy under these conditions,  $2 \text{Cl}(g)$  or  $\text{Cl}_2(g)$ ?

- 5.40** Without referring to tables, predict which of the following has the higher enthalpy in each case: (a) 1 mol  $\text{CO}_2(s)$  or 1 mol  $\text{CO}_2(g)$  at the same temperature, (b) 2 mol of hydrogen atoms or 1 mol of  $\text{H}_2$ , (c) 1 mol  $\text{H}_2(g)$  and 0.5 mol  $\text{O}_2(g)$  at 25 °C or 1 mol  $\text{H}_2\text{O}(g)$  at 25 °C, (d) 1 mol  $\text{N}_2(g)$  at 100 °C or 1 mol  $\text{N}_2(g)$  at 300 °C.

- 5.41** Consider the following reaction:

(a) Is this reaction exothermic or endothermic? (b) Calculate the amount of heat transferred when 2.4 g of  $\text{Mg}(s)$  reacts at constant pressure. (c) How many grams of  $\text{MgO}$  are produced during an enthalpy change of  $-96.0 \text{ kJ}$ ? (d) How many kilojoules of heat are absorbed when 7.50 g of  $\text{MgO}(s)$  is decomposed into  $\text{Mg}(s)$  and  $\text{O}_2(g)$  at constant pressure?

- 5.42** Consider the following reaction:

(a) Is heat absorbed or released in the course of this reaction? (b) Calculate the amount of heat transferred when 45.0 g of  $\text{CH}_3\text{OH}(g)$  is decomposed by this reaction at constant pressure. (c) For a given sample of  $\text{CH}_3\text{OH}$ , the enthalpy change on reaction is 25.8 kJ. How many grams of hydrogen gas are produced? What is the value of  $\Delta H$  for the reverse of the previous reaction? (d) How

many kilojoules of heat are released when 50.9 g of  $\text{CO}(g)$  reacts completely with  $\text{H}_2(g)$  to form  $\text{CH}_3\text{OH}(g)$  at constant pressure?

- 5.43** When solutions containing silver ions and chloride ions are mixed, silver chloride precipitates:

(a) Calculate  $\Delta H$  for production of 0.200 mol of  $\text{AgCl}$  by this reaction. (b) Calculate  $\Delta H$  for the production of 250 g of  $\text{AgCl}$ . (c) Calculate  $\Delta H$  when 0.150 mmol of  $\text{AgCl}$  dissolves in water.

- 5.44** At one time, a common means of forming small quantities of oxygen gas in the laboratory was to heat  $\text{KClO}_3$ :

For this reaction, calculate  $\Delta H$  for the formation of (a) 0.632 mol of  $\text{O}_2$  and (b) 8.57 g of  $\text{KCl}$ . (c) The decomposition of  $\text{KClO}_3$  proceeds spontaneously when it is heated. Do you think that the reverse reaction, the formation of  $\text{KClO}_3$  from  $\text{KCl}$  and  $\text{O}_2$ , is likely to be feasible under ordinary conditions? Explain your answer.

- 5.45** Consider the combustion of liquid methanol,  $\text{CH}_3\text{OH}(l)$ :

(a) What is the enthalpy change for the reverse reaction? (b) Balance the forward reaction with whole-number coefficients. What is  $\Delta H$  for the reaction represented by this equation? (c) Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction? (d) If the reaction were written to produce  $\text{H}_2\text{O}(g)$  instead of  $\text{H}_2\text{O}(l)$ , would you expect the magnitude of  $\Delta H$  to increase, decrease, or stay the same? Explain.

- 5.46** Consider the decomposition of liquid benzene,  $\text{C}_6\text{H}_6(l)$ , to gaseous acetylene,  $\text{C}_2\text{H}_2(g)$ :

(a) What is the enthalpy change for the reverse reaction? (b) What is  $\Delta H$  for the formation of 1 mol of acetylene? (c) Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction? (d) If  $\text{C}_6\text{H}_6(g)$  were consumed instead of  $\text{C}_6\text{H}_6(l)$ , would you expect the magnitude of  $\Delta H$  to increase, decrease, or stay the same? Explain.

## Calorimetry

- 5.47** (a) What are the units of molar heat capacity? (b) What are the units of specific heat? (c) If you know the specific heat of copper, what additional information do you need to calculate the heat capacity of a particular piece of copper pipe?

- 5.48** Two solid objects, A and B, are placed in boiling water and allowed to come to temperature there. Each is then lifted out and placed in separate beakers containing 1000 g water at 10.0 °C. Object A increases the water temperature by 3.50 °C; B increases the water temperature by 2.60 °C. (a) Which object has the larger heat capacity? (b) What can you say about the specific heats of A and B?

- 5.49** (a) What is the specific heat of liquid water? (b) What is the molar heat capacity of liquid water? (c) What is the heat capacity of 185 g of liquid water? (d) How many kJ of heat are needed to raise the temperature of 10.00 kg of liquid water from 24.6 °C to 46.2 °C?

- 5.50** (a) Which substance in Table 5.2 requires the smallest amount of energy to increase the temperature of 50.0 g of that substance by 10 K? (b) Calculate the energy needed for this temperature change.

- 5.51** The specific heat of iron metal is 0.450 J/g·K. How many J of heat are necessary to raise the temperature of a 1.05-kg block of iron from 25.0 °C to 88.5 °C?

5.52 The specific heat of ethylene glycol is 2.42 J/g·K. How many J of heat are needed to raise the temperature of 62.0 g of ethylene glycol from 13.1 °C to 40.5 °C?

5.53 When a 9.55-g sample of solid sodium hydroxide dissolves in 100.0 g of water in a coffee-cup calorimeter (Figure 5.17), the temperature rises from 23.6 °C to 47.4 °C. Calculate  $\Delta H$  (in kJ/mol NaOH) for the solution process

Assume that the specific heat of the solution is the same as that of pure water.

5.54 (a) When a 3.88-g sample of solid ammonium nitrate dissolves in 60.0 g of water in a coffee-cup calorimeter (Figure 5.17), the temperature drops from 23.0 °C to 18.4 °C. Calculate  $\Delta H$  (in kJ/mol  $\text{NH}_4\text{NO}_3$ ) for the solution process

Assume that the specific heat of the solution is the same as that of pure water. (b) Is this process endothermic or exothermic?

5.55 A 2.200-g sample of quinone ( $\text{C}_6\text{H}_4\text{O}_2$ ) is burned in a bomb calorimeter whose total heat capacity is 7.854 kJ/°C. The temperature of the calorimeter increases from 23.44 °C to 30.57 °C. What is the heat of combustion per gram of quinone? Per mole of quinone?

5.56 A 1.800-g sample of phenol ( $\text{C}_6\text{H}_5\text{OH}$ ) was burned in a bomb calorimeter whose total heat capacity is 11.66 kJ/°C. The temperature of the calorimeter plus contents increased from 21.36 °C to 26.37 °C. (a) Write a balanced chemical equation for the bomb calorimeter reaction. (b) What is the heat of combustion per gram of phenol? Per mole of phenol?

5.57 Under constant-volume conditions the heat of combustion of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) is 15.57 kJ/g. A 2.500-g sample of glucose is burned in a bomb calorimeter. The temperature of the calorimeter increased from 20.55 °C to 23.25 °C. (a) What is the total heat capacity of the calorimeter? (b) If the size of the glucose sample had been exactly twice as large, what would the temperature change of the calorimeter have been?

5.58 Under constant-volume conditions the heat of combustion of benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) is 26.38 kJ/g. A 1.640-g sample of benzoic acid is burned in a bomb calorimeter. The temperature of the calorimeter increases from 22.25 °C to 27.20 °C. (a) What is the total heat capacity of the calorimeter? (b) A 1.320-g sample of a new organic substance is combusted in the same calorimeter. The temperature of the calorimeter increases from 22.14 °C to 26.82 °C. What is the heat of combustion per gram of the new substance? (c) Suppose that in changing samples, a portion of the water in the calorimeter were lost. In what way, if any, would this change the heat capacity of the calorimeter?

## Hess's Law

5.59 What is the connection between Hess's law and the fact that  $H$  is a state function?

5.60 Consider the following hypothetical reactions:

(a) Use Hess's law to calculate the enthalpy change for the reaction  $A \longrightarrow C$ . (b) Construct an enthalpy diagram for substances A, B, and C, and show how Hess's law applies.

5.61 Calculate the enthalpy change for the reaction

given the following enthalpies of reaction:

5.62 From the enthalpies of reaction

calculate the heat of the reaction

5.63 From the enthalpies of reaction

calculate  $\Delta H$  for the reaction of ethylene with  $\text{F}_2$ :

5.64 Given the data

use Hess's law to calculate  $\Delta H$  for the reaction

## Enthalpies of Formation

5.65 (a) What is meant by the term *standard conditions*, with reference to enthalpy changes? (b) What is meant by the term *enthalpy of formation*? (c) What is meant by the term *standard enthalpy of formation*?

5.66 (a) Why are tables of standard enthalpies of formation so useful? (b) What is the value of the standard enthalpy of formation of an element in its most stable form? (c) Write the chemical equation for the reaction whose enthalpy change is the standard enthalpy of formation of glucose,  $\text{C}_6\text{H}_{12}\text{O}_6(s)$ ,  $\Delta H_f^\circ[\text{C}_6\text{H}_{12}\text{O}_6]$ .

**5.67** For each of the following compounds, write a balanced thermochemical equation depicting the formation of one mole of the compound from its elements in their standard states and use Appendix C to obtain the value of  $\Delta H_f^\circ$ : (a)  $\text{NH}_3(g)$ , (b)  $\text{SO}_2(g)$ , (c)  $\text{RbClO}_3(s)$ , (d)  $\text{NH}_4\text{NO}_3(s)$ .

**5.68** Write balanced equations that describe the formation of the following compounds from elements in their standard states, and use Appendix C to obtain the values of their standard enthalpies of formation: (a)  $\text{HBr}(g)$ , (b)  $\text{AgNO}_3(s)$ , (c)  $\text{Fe}_2\text{O}_3(s)$ , (d)  $\text{CH}_3\text{COOH}(l)$ .

**5.69** The following is known as the thermite reaction [Figure 5.7(b)]:

This highly exothermic reaction is used for welding massive units, such as propellers for large ships. Using standard enthalpies of formation in Appendix C, calculate  $\Delta H^\circ$  for this reaction.

**5.70** Many cigarette lighters contain liquid butane,  $\text{C}_4\text{H}_{10}(l)$ . Using standard enthalpies of formation, calculate the quantity of heat produced when 5.00 g of butane is completely combusted in air under standard conditions.

**5.71** Using values from Appendix C, calculate the standard enthalpy change for each of the following reactions:

- (a)  $2 \text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{SO}_3(g)$   
 (b)  $\text{Mg}(\text{OH})_2(s) \longrightarrow \text{MgO}(s) + \text{H}_2\text{O}(l)$   
 (c)  $\text{N}_2\text{O}_4(g) + 4 \text{H}_2(g) \longrightarrow \text{N}_2(g) + 4 \text{H}_2\text{O}(g)$   
 (d)  $\text{SiCl}_4(l) + 2 \text{H}_2\text{O}(l) \longrightarrow \text{SiO}_2(s) + 4 \text{HCl}(g)$

**5.72** Using values from Appendix C, calculate the value of  $\Delta H^\circ$  for each of the following reactions:

- (a)  $4 \text{HBr}(g) + \text{O}_2(g) \longrightarrow 2 \text{H}_2\text{O}(l) + 2 \text{Br}_2(l)$   
 (b)  $2 \text{Na}(\text{OH})(s) + \text{SO}_3(g) \longrightarrow \text{Na}_2\text{SO}_4(s) + \text{H}_2\text{O}(g)$   
 (c)  $\text{CH}_4(g) + 4 \text{Cl}_2(g) \longrightarrow \text{CCl}_4(l) + 4 \text{HCl}(g)$   
 (d)  $\text{Fe}_2\text{O}_3(s) + 6 \text{HCl}(g) \longrightarrow 2 \text{FeCl}_3(s) + 3 \text{H}_2\text{O}(g)$

**5.73** Complete combustion of 1 mol of acetone ( $\text{C}_3\text{H}_6\text{O}$ ) liberates 1790 kJ:

Using this information together with data from Appendix C, calculate the enthalpy of formation of acetone.

**5.74** Calcium carbide ( $\text{CaC}_2$ ) reacts with water to form acetylene ( $\text{C}_2\text{H}_2$ ) and  $\text{Ca}(\text{OH})_2$ . From the following enthalpy of reaction data and data in Appendix C, calculate  $\Delta H_f^\circ$  for  $\text{CaC}_2(s)$ :

**5.75** Gasoline is composed primarily of hydrocarbons, including many with eight carbon atoms, called *octanes*. One of the cleanest-burning octanes is a compound called 2,3,4-trimethylpentane, which has the following structural formula:

The complete combustion of one mole of this compound to  $\text{CO}_2(g)$  and  $\text{H}_2\text{O}(g)$  leads to  $\Delta H^\circ = -50649 \text{ kJ/mol}$ .

(a) Write a balanced equation for the combustion of 1 mol of  $\text{C}_8\text{H}_{18}(l)$ . (b) Write a balanced equation for the formation of  $\text{C}_8\text{H}_{18}(l)$  from its elements. (c) By using the information in this problem and data in Table 5.3, calculate  $\Delta H_f^\circ$  for 2,3,4-trimethylpentane.

**5.76** Naphthalene ( $\text{C}_{10}\text{H}_8$ ) is a solid aromatic compound often sold as mothballs. The complete combustion of this substance to yield  $\text{CO}_2(g)$  and  $\text{H}_2\text{O}(l)$  at 25 °C yields 5154 kJ/mol. (a) Write balanced equations for the formation of naphthalene from the elements and for its combustion. (b) Calculate the standard enthalpy of formation of naphthalene.

**5.77** Ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) is currently blended with gasoline as an automobile fuel. (a) Write a balanced equation for the combustion of liquid ethanol in air. (b) Calculate the standard enthalpy change for the reaction, assuming  $\text{H}_2\text{O}(g)$  as a product. (c) Calculate the heat produced per liter of ethanol by combustion of ethanol under constant pressure. Ethanol has a density of 0.789 g/mL. (d) Calculate the mass of  $\text{CO}_2$  produced per kJ of heat emitted.

**5.78** Methanol ( $\text{CH}_3\text{OH}$ ) is used as a fuel in race cars. (a) Write a balanced equation for the combustion of liquid methanol in air. (b) Calculate the standard enthalpy change for the reaction, assuming  $\text{H}_2\text{O}(g)$  as a product. (c) Calculate the heat produced by combustion per liter of methanol. Methanol has a density of 0.791 g/mL. (d) Calculate the mass of  $\text{CO}_2$  produced per kJ of heat emitted.

## Foods and Fuels

**5.79** (a) What is meant by the term *fuel value*? (b) Which is a greater source of energy as food, 5 g of fat or 9 g of carbohydrate?

**5.80** (a) Why are fats well suited for energy storage in the human body? (b) A particular chip snack food is composed of 12% protein, 14% fat, and the rest carbohydrate. What percentage of the calorie content of this food is fat? (c) How many grams of protein provide the same fuel value as 25 g of fat?

**5.81** A serving of condensed cream of mushroom soup contains 7 g fat, 9 g carbohydrate, and 1 g protein. Estimate the number of Calories in a serving.

**5.82** A pound of plain M&M<sup>®</sup> candies contains 96 g fat, 320 g carbohydrate, and 21 g protein. What is the fuel value in kJ in a 42-g (about 1.5 oz) serving? How many Calories does it provide?

**5.83** The heat of combustion of fructose,  $\text{C}_6\text{H}_{12}\text{O}_6$ , is  $-2812 \text{ kJ/mol}$ . If a fresh golden delicious apple weighing 4.23 oz (120 g) contains 16.0 g of fructose, what caloric content does the fructose contribute to the apple?

**5.84** The heat of combustion of ethanol,  $\text{C}_2\text{H}_5\text{OH}(l)$ , is  $-1367 \text{ kJ/mol}$ . A batch of Sauvignon Blanc wine contains 10.6% ethanol by mass. Assuming the density of

the wine to be 1.0 g/mL, what caloric content does the alcohol (ethanol) in a 6-oz glass of wine (177 mL) have?

- 5.85 The standard enthalpies of formation of gaseous propyne ( $C_3H_4$ ), propylene ( $C_3H_6$ ), and propane ( $C_3H_8$ ) are +185.4, +20.4, and  $-103.8$  kJ/mol, respectively. (a) Calculate the heat evolved per mole on combustion of each substance to yield  $CO_2(g)$  and  $H_2O(g)$ . (b) Calculate the heat evolved on combustion of 1 kg of each substance.

## ADDITIONAL EXERCISES

- 5.87 At 20 °C (approximately room temperature) the average velocity of  $N_2$  molecules in air is 1050 mph. (a) What is the average speed in m/s? (b) What is the kinetic energy (in J) of an  $N_2$  molecule moving at this speed? (c) What is the total kinetic energy of 1 mol of  $N_2$  molecules moving at this speed?
- 5.88 Suppose an Olympic diver who weighs 52.0 kg executes a straight dive from a 10-m platform. At the apex of the dive, the diver is 10.8 m above the surface of the water. (a) What is the potential energy of the diver at the apex of the dive, relative to the surface of the water? (b) Assuming that all the potential energy of the diver is converted into kinetic energy at the surface of the water, at what speed in m/s will the diver enter the water? (c) Does the diver do work on entering the water? Explain.
- 5.89 When a mole of dry ice,  $CO_2(s)$ , is converted to  $CO_2(g)$  at atmospheric pressure and  $-78$  °C, the heat absorbed by the system exceeds the increase in internal energy of the  $CO_2$ . Why is this so? What happens to the remaining energy?
- 5.90 The air bags that provide protection in autos in the event of an accident expand because of a rapid chemical reaction. From the viewpoint of the chemical reactants as the system, what do you expect for the signs of  $q$  and  $w$  in this process?
- [5.91] An aluminum can of a soft drink is placed in a freezer. Later, you find that the can is split open and its contents frozen. Work was done on the can in splitting it open. Where did the energy for this work come from?
- [5.92] A sample of gas is contained in a cylinder-and-piston arrangement. It undergoes the change in state shown in the drawing. (a) Assume first that the cylinder and piston are perfect thermal insulators that do not allow heat to be transferred. What is the value of  $q$  for the state

(c) Which is the most efficient fuel in terms of heat evolved per unit mass?

- 5.86 It is interesting to compare the “fuel value” of a hydrocarbon in a world where fluorine rather than oxygen is the combustion agent. The enthalpy of formation of  $CF_4(g)$  is  $-679.9$  kJ/mol. Which of the following two reactions is the more exothermic?

change? What is the sign of  $w$  for the state change? What can be said about  $\Delta E$  for the state change? (b) Now assume that the cylinder and piston are made up of a thermal conductor such as a metal. During the state change, the cylinder gets warmer to the touch. What is the sign of  $q$  for the state change in this case? Describe the difference in the state of the system at the end of the process in the two cases. What can you say about the relative values of  $\Delta E$ ?

- [5.93] Limestone stalactites and stalagmites are formed in caves by the following reaction:

If 1 mol of  $CaCO_3$  forms at 298 K under 1 atm pressure, the reaction performs 2.47 kJ of  $P-V$  work, pushing back the atmosphere as the gaseous  $CO_2$  forms. At the same time, 38.95 kJ of heat is absorbed from the environment. What are the values of  $\Delta H$  and of  $\Delta E$  for this reaction?

- [5.94] Consider the systems shown in Figure 5.9. In one case the battery becomes completely discharged by running the current through a heater, and in the other by running a fan. Both processes occur at constant pressure. In both cases the change in state of the system is the same: The battery goes from being fully charged to being fully discharged. Yet in one case the heat evolved is large, and in the other it is small. Is the enthalpy change the same in the two cases? If not, how can enthalpy be considered a state function? If it is, what can you say about the relationship between enthalpy change and  $q$  in this case, as compared with others that we have considered?
- 5.95 The enthalpy change for melting ice at 0 °C and constant atmospheric pressure is 6.01 kJ/mol. Calculate the quantity of energy required to melt a moderately large iceberg with a mass of 1.25 million metric tons. (A metric ton is 1000 kg.)
- 5.96 Comparing the energy associated with the rainstorm and that of a conventional explosive gives some idea of the immense amount of energy associated with a storm. (a) The heat of vaporization of water is 44.0 kJ/mol. Calculate the quantity of energy released when enough water vapor condenses to form 0.50 inches of rain over an area of one square mile. (b) The energy released when one ton of dynamite explodes is  $4.2 \times 10^6$  kJ. Calculate the number of tons of dynamite needed to provide the energy of the storm in part (a).
- 5.97 A house is designed to have passive solar energy features. Brickwork incorporated into the interior of the house acts as a heat absorber. Each brick weighs

approximately 1.8 kg. The specific heat of the brick is 0.85 J/g·K. How many bricks must be incorporated into the interior of the house to provide the same total heat capacity as  $1.7 \times 10^3$  gal of water?

**[5.98]** A coffee-cup calorimeter of the type shown in Figure 5.17 contains 150.0 g of water at 25.1 °C. A 121.0-g block of copper metal is heated to 100.4 °C by putting it in a beaker of boiling water. The specific heat of Cu(s) is 0.385 J/g·K. The Cu is added to the calorimeter, and after a time the contents of the cup reach a constant temperature of 30.1 °C. **(a)** Determine the amount of heat, in J, lost by the copper block. **(b)** Determine the amount of heat gained by the water. The specific heat of water is 4.18 J/g·K. **(c)** The difference between your answers for **(a)** and **(b)** is due to heat loss through the Styrofoam® cups and the heat necessary to raise the temperature of the inner wall of the apparatus. The heat capacity of the calorimeter is the amount of heat necessary to raise the temperature of the apparatus (the cups and the stopper) by 1 K. Calculate the heat capacity of the calorimeter in J/K. **(d)** What would be the final temperature of the system if all the heat lost by the copper block were absorbed by the water in the calorimeter?

**[5.99]** **(a)** When a 0.235-g sample of benzoic acid is combusted in a bomb calorimeter, the temperature rises 1.642 °C. When a 0.265-g sample of caffeine,  $C_8H_{10}O_2N_4$ , is burned, the temperature rises 1.525 °C. Using the value 26.38 kJ/g for the heat of combustion of benzoic acid, calculate the heat of combustion per mole of caffeine at constant volume. **(b)** Assuming that there is an uncertainty of 0.002 °C in each temperature reading and that the masses of samples are measured to 0.001 g, what is the estimated uncertainty in the value calculated for the heat of combustion per mole of caffeine?

**5.100** How many grams of methane [ $CH_4(g)$ ] must be combusted to heat 1.00 kg of water from 25.0 °C to 90.0 °C, assuming  $H_2O(l)$  as a product and 100% efficiency in heat transfer?

**5.101** Meals-ready-to-eat (MREs) are military meals that can be heated on a flameless heater. The heat is produced by the following reaction:  $Mg(s) + 2 H_2O(l) \rightarrow Mg(OH)_2(s) + H_2(g)$ . **(a)** Calculate the standard enthalpy change for this reaction. **(b)** Calculate the number of grams of Mg needed for this reaction to release enough energy to increase the temperature of 25 mL of water from 15 °C to 85 °C.

**5.102** Burning methane in oxygen can produce three different carbon-containing products: soot (very fine particles of graphite), CO(g), and CO<sub>2</sub>(g). **(a)** Write three balanced equations for the reaction of methane gas with oxygen to produce these three products. In each case assume that  $H_2O(l)$  is the only other product. **(b)** Determine the standard enthalpies for the reactions in part (a). **(c)** Why, when the oxygen supply is adequate, is CO<sub>2</sub>(g) the predominant carbon-containing product of the combustion of methane?

**5.103** **(a)** Calculate the standard enthalpy of formation of gaseous diborane ( $B_2H_6$ ) using the following thermochemical information:

**(b)** Pentaborane ( $B_5H_9$ ) is another boron hydride. What experiment or experiments would you need to perform to yield the data necessary to calculate the heat of formation of  $B_5H_9(l)$ ? Explain by writing out and summing any applicable chemical reactions.

**5.104** From the following data for three prospective fuels, calculate which could provide the most energy per unit volume:

Fuel	Density at 20 °C (g/cm <sup>3</sup> )	Molar Enthalpy of Combustion (kJ/mol)
Nitroethane, $C_2H_5NO_2(l)$	1.052	-1368
Ethanol, $C_2H_5OH(l)$	0.789	-1367
Methylhydrazine, $CH_6N_2(l)$	0.874	-1305

**5.105** The hydrocarbons acetylene ( $C_2H_2$ ) and benzene ( $C_6H_6$ ) have the same empirical formula. Benzene is an "aromatic" hydrocarbon, one that is unusually stable because of its structure. **(a)** By using the data in Appendix C, determine the standard enthalpy change for the reaction  $3 C_2H_2(g) \rightarrow C_6H_6(l)$ . **(b)** Which has greater enthalpy, 3 mol of acetylene gas or 1 mol of liquid benzene? **(c)** Determine the fuel value in kJ/g for acetylene and benzene.

**[5.106]** Ammonia ( $NH_3$ ) boils at -33 °C; at this temperature it has a density of 0.81 g/cm<sup>3</sup>. The enthalpy of formation of  $NH_3(g)$  is -46.2 kJ/mol, and the enthalpy of vaporization of  $NH_3(l)$  is 23.2 kJ/mol. Calculate the enthalpy change when 1 L of liquid  $NH_3$  is burned in air to give  $N_2(g)$  and  $H_2O(g)$ . How does this compare with  $\Delta H$  for the complete combustion of 1 L of liquid methanol,  $CH_3OH(l)$ ? For  $CH_3OH(l)$ , the density at 25 °C is 0.792 g/cm<sup>3</sup>, and  $\Delta H_f^\circ$  equals -239 kJ/mol.

**[5.107]** Three common hydrocarbons that contain four carbons are listed here, along with their standard enthalpies of formation:

Hydrocarbon	Formula	$\Delta H_f^\circ$ (kJ/mol)
1,3-Butadiene	$C_4H_6(g)$	111.9
1-Butene	$C_4H_8(g)$	1.2
n-Butane	$C_4H_{10}(g)$	-124.7

**(a)** For each of these substances, calculate the molar enthalpy of combustion to CO<sub>2</sub>(g) and H<sub>2</sub>O(l). **(b)** Calculate the fuel value in kJ/g for each of these compounds. **(c)** For each hydrocarbon, determine the percentage of hydrogen by mass. **(d)** By comparing your answers for parts (b) and (c), propose a relationship between hydrogen content and fuel value in hydrocarbons.

**5.108** The two common sugars, glucose ( $C_6H_{12}O_6$ ) and sucrose ( $C_{12}H_{22}O_{11}$ ), are both carbohydrates. Their standard enthalpies of formation are given in Table 5.3. Using these data, **(a)** calculate the molar enthalpy of combustion to CO<sub>2</sub>(g) and H<sub>2</sub>O(l) for the two sugars; **(b)** calculate the enthalpy of combustion per gram of each sugar; **(c)** determine how your answers to part (b) compare to the average fuel value of carbohydrates discussed in Section 5.8.

- 5.109** A 200-lb man decides to add to his exercise routine by walking up three flights of stairs (45 ft) 20 times per day. He figures that the work required to increase his potential energy in this way will permit him to eat an extra order of French fries, at 245 Cal, without adding to his weight. Is he correct in this assumption?
- 5.110** The sun supplies about 1.0 kilowatt of energy for each square meter of surface area ( $1.0 \text{ kW/m}^2$ , where a watt = 1 J/s). Plants produce the equivalent of about 0.20 g of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) per hour per square meter. Assuming that the sucrose is produced as follows, calculate the percentage of sunlight used to produce sucrose.

- [5.111]** It is estimated that the net amount of carbon dioxide fixed by photosynthesis on the landmass of Earth is  $5.5 \times 10^{16} \text{ g/yr}$  of  $\text{CO}_2$ . Assume that all this carbon is converted into glucose. (a) Calculate the energy stored by photosynthesis on land per year in kJ. (b) Calculate the average rate of conversion of solar energy into plant energy in MW ( $1 \text{ W} = 1 \text{ J/s}$ ). A large nuclear power plant produces about  $10^3 \text{ MW}$ . The energy of how many such nuclear power plants is equivalent to the solar energy conversion?

## INTEGRATIVE EXERCISES

- 5.112** Consider the combustion of a single molecule of  $\text{CH}_4(\text{g})$  forming  $\text{H}_2\text{O}(\text{l})$  as a product. (a) How much energy, in J, is produced during this reaction? (b) A typical X-ray photon has an energy of 8 keV. How does the energy of combustion compare to the energy of the X-ray photon?
- 5.113** Consider the dissolving of NaCl in water, illustrated in Figure 4.3. Assume the system consists of 0.1 mol NaCl and 1 L of water. Considering that the NaCl readily dissolves in the water and that the ions are strongly stabilized by the water molecules, as shown in the figure, is it safe to conclude that the dissolution of NaCl in water results in a lower enthalpy for the system? Explain your response. What experimental evidence would you examine to test this question?
- 5.114** Consider the following unbalanced oxidation-reduction reactions in aqueous solution:

(a) Balance each of the reactions. (b) By using data in Appendix C, calculate  $\Delta H^\circ$  for each of the reactions. (c) Based on the values you obtain for  $\Delta H^\circ$ , which of the reactions would you expect to be thermodynamically favored? (That is, which would you expect to be spontaneous?) (d) Use the activity series to predict which of these reactions should occur.  $\infty$  (Section 4.4) Are these results in accord with your conclusion in part (c) of this problem?

- [5.115]** Consider the following acid-neutralization reactions involving the strong base  $\text{NaOH}(\text{aq})$ :

(a) By using data in Appendix C, calculate  $\Delta H^\circ$  for each of the reactions. (b) As we saw in Section 4.3, nitric acid and hydrochloric acid are strong acids. Write net ionic equations for the neutralization of these acids. (c) Compare the values of  $\Delta H^\circ$  for the first two reactions. What can you conclude? (d) In the third equation  $\text{NH}_4^+(\text{aq})$  is acting as an acid. Based on the value of  $\Delta H^\circ$  for this reaction, do you think it is a strong or a weak acid? Explain.

- 5.116** Consider two solutions, the first being 50.0 mL of 1.00 M  $\text{CuSO}_4$  and the second 50.0 mL of 2.00 M KOH. When

the two solutions are mixed in a constant-pressure calorimeter, a precipitate forms and the temperature of the mixture rises from  $21.5^\circ \text{C}$  to  $27.7^\circ \text{C}$ . (a) Before mixing, how many grams of Cu are present in the solution of  $\text{CuSO}_4$ ? (b) Predict the identity of the precipitate in the reaction. (c) Write complete and net ionic equations for the reaction that occurs when the two solutions are mixed. (d) From the calorimetric data, calculate  $\Delta H$  for the reaction that occurs on mixing. Assume that the calorimeter absorbs only a negligible quantity of heat, that the total volume of the solution is 100.0 mL, and that the specific heat and density of the solution after mixing are the same as that of pure water.

- 5.117** The precipitation reaction between  $\text{AgNO}_3(\text{aq})$  and  $\text{NaCl}(\text{aq})$  proceeds as follows:

(a) By using Appendix C, calculate  $\Delta H^\circ$  for the net ionic equation of this reaction. (b) What would you expect for the value of  $\Delta H^\circ$  of the overall molecular equation compared to that for the net ionic equation? Explain. (c) Use the results from (a) and (b) along with data in Appendix C to determine the value of  $\Delta H_f^\circ$  for  $\text{AgNO}_3(\text{aq})$ .

- [5.118]** A sample of a hydrocarbon is combusted completely in  $\text{O}_2(\text{g})$  to produce 21.83 g  $\text{CO}_2(\text{g})$ , 4.47 g  $\text{H}_2\text{O}(\text{g})$ , and 311 kJ of heat. (a) What is the mass of the hydrocarbon sample that was combusted? (b) What is the empirical formula of the hydrocarbon? (c) Calculate the value of  $\Delta H_f^\circ$  per empirical-formula unit of the hydrocarbon. (d) Do you think that the hydrocarbon is one of those listed in Appendix C? Explain your answer.

- 5.119** The methane molecule,  $\text{CH}_4$ , has the geometry shown in Figure 2.21. Imagine a hypothetical process in which the methane molecule is "expanded," by simultaneously extending all four C—H bonds to infinity. We then have the process

(a) Compare this process with the reverse of the reaction that represents the standard enthalpy of formation. (b) Calculate the enthalpy change in each case. Which is the more endothermic process? What accounts for the difference in  $\Delta H^\circ$  values? (c) Suppose that 345 g  $\text{CH}_4(\text{g})$  is reacted with 1.22 g  $\text{F}_2(\text{g})$ , forming  $\text{CF}_4(\text{g})$  and  $\text{HF}(\text{g})$  as sole products. What is the limiting reagent in this reaction? If the reaction occurs at constant pressure, what amount of heat is evolved?

ELECTRONIC STRUCTURE  
OF ATOMS

THE GLASS TUBES OF NEON LIGHTS contain various gases that can be excited by electricity. Light is produced when electrically excited atoms return to their lowest-energy states.

## WHAT'S AHEAD

---

### 6.1 The Wave Nature of Light

We will learn that light (radiant energy, or *electromagnetic radiation*) has wavelike properties and so is characterized by *wavelength*, *frequency*, and *speed*.

### 6.2 Quantized Energy and Photons

We will recognize that many different types of experiments indicate that electromagnetic radiation also has particle-like properties and can be described in terms of *photons*, “particles” of light.

### 6.3 Line Spectra and the Bohr Model

We will explore the fact that atoms give off characteristic colors of light (*line spectra*), when appropriately stimulated. Line spectra provide clues about how electrons are arranged in atoms. Experiments show that electrons exist only at certain energy levels around a nucleus and that energy is involved in moving an electron from one level to another. The Bohr model of the atom pictures the atom as a miniature solar system, with the nucleus of an atom as the “Sun” about which electrons, like planets, orbit.

### 6.4 The Wave Behavior of Matter

We recognize that matter also has wavelike properties that are manifested at the atomic scale. Because of the fundamental particle-wave duality of matter, it is impossible to determine simultaneously the exact position and the exact motion of an electron in an atom (*Heisenberg's Uncertainty Principle*).

### 6.5 Quantum Mechanics and Atomic Orbitals

We will discover that classical mechanics treats matter as particles, while quantum mechanics

treats matter as waves. We will see that we can describe how an electron exists in atoms by thinking about the electron as a standing wave surrounding the nucleus. The *wave functions* that mathematically describe the electron's position and energy in an atom are called *atomic orbitals*. The orbitals can be described in a shorthand notation using *quantum numbers*.

### 6.6 Representations of Orbitals

We will see how to draw pictures of orbitals and interpret graphs of electron density.

### 6.7 Many-Electron Atoms

We will recognize that the energy levels for one electron in an atom are altered when multiple electrons are in an atom. The electron itself has a quantum-mechanical property called *spin*. The *Pauli exclusion principle* states that no two electrons in an atom can have the same four quantum numbers (three for the orbital and one for the spin). Therefore, an orbital can hold a maximum of two electrons.

### 6.8 Electron Configurations

We will realize that knowing the energies of orbitals as well as some fundamental characteristics of electrons described by *Hund's rule* allows us to determine how electrons are distributed among various orbitals in an atom (*electron configurations*).

### 6.9 Electron Configurations and the Periodic Table

We will observe that the electron configuration of an atom is related to the location of the element in the periodic table.

## WHAT HAPPENS WHEN someone switches on a neon light?

The electrons in the neon atoms, which are excited to a higher energy by electricity, emit light when they drop back down to a lower energy. The pleasing glow that results is explained by one of the most revolutionary

discoveries of the twentieth century, namely, the *quantum theory*. This theory explains much of the behavior of electrons in atoms. We will see that the behavior of electrons in an atom is quite unlike anything we see in our macroscopic world.

In this chapter we will explore the quantum theory and its importance in chemistry. We will begin by looking more closely at the nature of light and how our description of light was changed by the quantum theory. We will explore some of the tools used in *quantum mechanics*, the “new” physics that had to be developed to describe atoms correctly. We will then use the quantum

▲ **Figure 6.1 Water waves.** The movement of the boat through the water forms waves. The regular variation of the peaks and troughs enables us to sense the motion, or *propagation*, of the waves.

▲ **Figure 6.2 Characteristics of water waves.** (a) The distance between corresponding points on each wave is called the *wavelength*. In this drawing, the two corresponding points are two peaks, but they could be any other two corresponding points, such as two adjacent troughs. (b) The number of times per second that the cork bobs up and down is called the *frequency* of the wave.

theory to describe the arrangements of electrons in atoms—what we call the **electronic structure** of atoms. The electronic structure of an atom refers to the number of electrons in an atom as well as the distribution of the electrons around the nucleus and their energies. We will see that the quantum description of the electronic structure of atoms helps us to understand the elegant arrangement of the elements in the periodic table—why, for example, helium and neon are both unreactive gases, whereas sodium and potassium are both soft, reactive metals. In the chapters that follow, we will see how the concepts of quantum theory are used to explain trends in the periodic table and the formation of bonds between atoms.

## 6.1 THE WAVE NATURE OF LIGHT

Much of our present understanding of the electronic structure of atoms has come from analysis of the light either emitted or absorbed by substances. To understand electronic structure, therefore, we must first learn more about light. The light that we can see with our eyes, *visible light*, is an example of **electromagnetic radiation**. Because electromagnetic radiation carries energy through space, it is also known as *radiant energy*. There are many types of electromagnetic radiation in addition to visible light. These different forms—such as the radio waves that carry music to our radios, the infrared radiation (heat) from a glowing fireplace, and the X-rays used by a dentist—may seem very different from one another, but they all share certain fundamental characteristics.

All types of electromagnetic radiation move through a vacuum at a speed of  $3.00 \times 10^8$  m/s, the *speed of light*. All have wavelike characteristics similar to those of waves that move through water. Water waves are the result of energy imparted to the water, perhaps by the dropping of a stone or the movement of a boat on the water surface (Figure 6.1 ◀). This energy is expressed as the up-and-down movements of the water.

A cross section of a water wave (Figure 6.2 ◀) shows that it is periodic, which means that the pattern of peaks and troughs repeats itself at regular intervals. The distance between two adjacent peaks (or between two adjacent troughs) is called the **wavelength**. The number of complete wavelengths, or *cycles*, that pass a given point each second is the **frequency** of the wave. We can measure the frequency of a water wave by counting the number of times per second that a cork bobbing on the water moves through a complete cycle of upward and downward motion.

Just as with water waves, we can assign a frequency and wavelength to electromagnetic waves, as illustrated in Figure 6.3 ▼. These and all other wave

▼ **Figure 6.3 Characteristics of electromagnetic waves.** Radiant energy has wave characteristics; it consists of electromagnetic waves. Notice that the shorter the wavelength,  $\lambda$ , the higher the frequency,  $\nu$ . The wavelength in (b) is half as long as that in (a), and the frequency of the wave in (b) is therefore twice as great as the frequency in (a). The *amplitude* of the wave relates to the intensity of the radiation, which is the maximum extent of the oscillation of the wave. In these diagrams amplitude is measured as the vertical distance from the midline of the wave to its peak. The waves in (a) and (b) have the same amplitude. The wave in (c) has the same frequency as that in (b), but its amplitude is lower.

characteristics of electromagnetic radiation are due to the periodic oscillations in the intensities of the electric and magnetic fields associated with the radiation.

The speed of water waves can vary depending on how they are created—for example, the waves produced by a speedboat travel faster than those produced by a rowboat. In contrast, all electromagnetic radiation moves at the same speed, namely the speed of light. As a result, the wavelength and frequency of electromagnetic radiation are always related in a straightforward way. If the wavelength is long, there will be fewer cycles of the wave passing a point per second, and the frequency will be low. Conversely, for a wave to have a high frequency, the wave must have a short wavelength—that is, the distance between the peaks of the waves is small. This inverse relationship between the frequency and the wavelength of electromagnetic radiation can be expressed by the equation

$$c = \lambda \nu \quad [6.1]$$

where  $c$  is the speed of light,  $\lambda$  (lambda) is the wavelength, and  $\nu$  (nu) is the frequency.

Why do different forms of electromagnetic radiation have different properties? Their differences are due to their different wavelengths, which are expressed in units of length. Figure 6.4▲ shows the various types of electromagnetic radiation arranged in order of increasing wavelength, a display called the *electromagnetic spectrum*. Notice that the wavelengths span an enormous range. The wavelengths of gamma rays are similar to the diameters of atomic nuclei, whereas the wavelengths of radio waves can be longer than a football field. Notice also that visible light, which corresponds to wavelengths of about 400 to 700 nm ( $4 \times 10^{-7}$  m to  $7 \times 10^{-7}$  m), is an extremely small portion of the electromagnetic spectrum. We can see visible light because of the chemical reactions it triggers in our eyes. The unit of length normally chosen to express wavelength depends on the type of radiation, as shown in Table 6.1▼.

Frequency is expressed in cycles per second, a unit also called a *hertz* (Hz). Because it is understood that cycles are involved, the units of frequency are normally given simply as “per second,” which is denoted by  $s^{-1}$  or /s. For example, a frequency of 820 kilohertz (kHz), a typical frequency for an AM radio station, could be written as 820 kHz, 820,000 Hz,  $820,000 s^{-1}$ , or 820,000/s.

▲ **Figure 6.4 The electromagnetic spectrum.** Wavelengths in the spectrum range from very short gamma rays to very long radio waves. Notice that the color of visible light can be expressed quantitatively by wavelength.

**TABLE 6.1** ■ Common Wavelength Units for Electromagnetic Radiation

Unit	Symbol	Length (m)	Type of Radiation
Angstrom	Å	$10^{-10}$	X-ray
Nanometer	nm	$10^{-9}$	Ultraviolet, visible
Micrometer	$\mu\text{m}$	$10^{-6}$	Infrared
Millimeter	mm	$10^{-3}$	Microwave
Centimeter	cm	$10^{-2}$	Microwave
Meter	m	1	TV, radio
Kilometer	km	1000	Radio

## A Closer Look THE SPEED OF LIGHT

How do we know that light has a speed and does not move infinitely fast?

During the late 1600s, the Danish astronomer Ole Rømer (1644–1710) measured the orbits of several of Jupiter's moons. These moons move much faster than our own—they have orbits of 1–7 days and are eclipsed by Jupiter's shadow at every revolution. Over many months, Rømer measured discrepancies of up to 10 minutes in the times of these orbits. He reasoned that one possible explanation was that Jupiter was farther from Earth at different times of the year. Thus, the light from the Sun, which reflected off Jupiter and ultimately to his telescope, had farther to travel at different times of the year. Rømer's data led to an estimate of  $3.5 \times 10^8$  m/s for the speed of light. In 1704, Isaac Newton (1643–1727) used estimates of the distance from the Sun to Earth and the time it takes for the light to travel that distance to calculate the speed of light as  $2.4 - 2.7 \times 10^8$  m/s.

In 1927, A. A. Michelson (1852–1931) performed a famous experiment to determine the speed of light. Michelson set up a rotating mirror system at the top of Mount Wilson in southern California (Figure 6.5 ▶). The mirror system bounced light from the top of Mount Wilson to the top of Mount San Antonio, 22 miles away, where another mirror system bounced the light back to Mount Wilson. If the speed of light was instantaneous, or an exact multiple of the turn speed of the rotating mirror, the reflected spot of light would appear exactly super-

imposed on the original spot. Michelson was able to change the speed of the rotating mirror and measure small displacements in the position of the reflected spot. The value for the speed of light (in air) based on this experiment is  $2.9980 \pm 0.0002 \times 10^8$  m/s. The main source of error is the distance between the mirrors at the tops of the two mountains, which was measured within a fifth of an inch in 22 miles.

▲ Figure 6.5 View of Mount San Antonio from the top of Mount Wilson. The mountains are 22 miles apart.

### SAMPLE EXERCISE 6.1 | Concepts of Wavelength and Frequency

Two electromagnetic waves are represented in the margin. (a) Which wave has the higher frequency? (b) If one wave represents visible light and the other represents infrared radiation, which wave is which?

#### SOLUTION

(a) The lower wave has a longer wavelength (greater distance between peaks). The longer the wavelength, the lower the frequency ( $\nu = c/\lambda$ ). Thus, the lower wave has the lower frequency, and the upper wave has the higher frequency.

(b) The electromagnetic spectrum (Figure 6.4) indicates that infrared radiation has a longer wavelength than visible light. Thus, the lower wave would be the infrared radiation.

#### PRACTICE EXERCISE

If one of the waves in the margin represents blue light and the other red light, which is which?

**Answer:** The expanded visible-light portion of Figure 6.4 tells you that red light has a longer wavelength than blue light. The lower wave has the longer wavelength (lower frequency) and would be the red light.

### SAMPLE EXERCISE 6.2 | Calculating Frequency from Wavelength

The yellow light given off by a sodium vapor lamp used for public lighting has a wavelength of 589 nm. What is the frequency of this radiation?

#### SOLUTION

**Analyze:** We are given the wavelength,  $\lambda$ , of the radiation and asked to calculate its frequency,  $\nu$ .

**Plan:** The relationship between the wavelength (which is given) and the frequency (which is the unknown) is given by Equation 6.1. We can solve this equation for  $\nu$  and

then use the values of  $\lambda$  and  $c$  to obtain a numerical answer. (The speed of light,  $c$ , is a fundamental constant whose value is  $3.00 \times 10^8$  m/s.)

**Solve:** Solving Equation 6.1 for frequency gives  $\nu = c/\lambda$ . When we insert the values for  $c$  and  $\lambda$ , we note that the units of length in these two quantities are different. We can convert the wavelength from nanometers to meters, so the units cancel:

$$\nu = \frac{c}{\lambda} = \left( \frac{3.00 \times 10^8 \text{ m/s}}{589 \text{ nm}} \right) \left( \frac{1 \text{ nm}}{10^{-9} \text{ m}} \right) = 5.09 \times 10^{14} \text{ s}^{-1}$$

**Check:** The high frequency is reasonable because of the short wavelength. The units are proper because frequency has units of “per second,” or  $\text{s}^{-1}$ .

### ■ PRACTICE EXERCISE

(a) A laser used in eye surgery to fuse detached retinas produces radiation with a wavelength of 640.0 nm. Calculate the frequency of this radiation. (b) An FM radio station broadcasts electromagnetic radiation at a frequency of 103.4 MHz (megahertz;  $\text{MHz} = 10^6 \text{ s}^{-1}$ ). Calculate the wavelength of this radiation. The speed of light is  $2.998 \times 10^8$  m/s to four significant digits.

**Answers:** (a)  $4.688 \times 10^{14} \text{ s}^{-1}$ , (b) 2.901 m

### ▲ GIVE IT SOME THOUGHT

Our bodies are penetrated by X-rays but not by visible light. Is this because X-rays travel faster than visible light?

## 6.2 QUANTIZED ENERGY AND PHOTONS

Although the wave model of light explains many aspects of its behavior, this model cannot explain several phenomena. Three of these are particularly pertinent to our understanding of how electromagnetic radiation and atoms interact: (1) the emission of light from hot objects (referred to as *blackbody radiation* because the objects studied appear black before heating), (2) the emission of electrons from metal surfaces on which light shines (the *photoelectric effect*), and (3) the emission of light from electronically excited gas atoms (*emission spectra*). We examine the first two phenomena here and the third in Section 6.3.

### Hot Objects and the Quantization of Energy

When solids are heated, they emit radiation, as seen in the red glow of an electric stove burner and the bright white light of a tungsten lightbulb. The wavelength distribution of the radiation depends on temperature; a red-hot object is cooler than a white-hot one (Figure 6.6 ▶). During the late 1800s, a number of physicists were studying this phenomenon, trying to understand the relationship between the temperature and the intensity and wavelengths of the emitted radiation. The prevailing laws of physics could not account for the observations.

In 1900 a German physicist named Max Planck (1858–1947) solved the problem by assuming that energy can be either released or absorbed by atoms only in discrete “chunks” of some minimum size. Planck gave the name **quantum** (meaning “fixed amount”) to the smallest quantity of energy that can be emitted or absorbed as electromagnetic radiation. He proposed that the energy,  $E$ , of a single quantum equals a constant times the frequency of the radiation:

$$E = h\nu \quad [6.2]$$

The constant  $h$  is called **Planck’s constant** and has a value of  $6.626 \times 10^{-34}$  joule-second (J-s). According to Planck’s theory, matter is allowed to emit and absorb energy only in whole-number multiples of  $h\nu$ , such as  $h\nu$ ,  $2h\nu$ ,  $3h\nu$ , and so forth. If the quantity of energy emitted by an atom is  $3h\nu$ , for example, we say that three quanta of energy have been emitted (quanta

▲ **Figure 6.6 Color as a function of temperature.** The color and intensity of the light emitted by a hot object depend on the temperature of the object. The temperature is highest at the center of this pour of molten steel. As a result, the light emitted from the center is most intense and of shortest wavelength.

▲ **Figure 6.7** A model for quantized energy. The potential energy of a person walking up a ramp (a) increases in a uniform, continuous manner, whereas that of a person walking up steps (b) increases in a stepwise, quantized manner.

being the plural of quantum). Because the energy can be released only in specific amounts, we say that the allowed energies are *quantized*—their values are restricted to certain quantities. Planck’s revolutionary proposal that energy is quantized was proved correct, and he was awarded the 1918 Nobel Prize in Physics for his work on the quantum theory.

If the notion of quantized energies seems strange, it might be helpful to draw an analogy by comparing a ramp and a staircase (Figure 6.7 ◀). As you walk up a ramp, your potential energy increases in a uniform, continuous manner. When you climb a staircase, you can step only *on* individual stairs, not *between* them, so that your potential energy is restricted to certain values and is therefore quantized.

If Planck’s quantum theory is correct, why aren’t its effects more obvious in our daily lives? Why do energy changes seem continuous rather than quantized, or “jagged”? Notice that Planck’s constant is an extremely small number. Thus, a quantum of energy,  $h\nu$ , is an extremely small amount. Planck’s rules regarding the gain or loss of energy are always the same, whether we are concerned with objects on the size scale of our ordinary experience or with microscopic objects. With everyday macroscopic objects, however, the gain or loss of a single quantum of energy goes completely unnoticed. In contrast, when dealing with matter at the atomic level, the impact of quantized energies is far more significant.

### GIVE IT SOME THOUGHT

The temperature of stars is gauged by their colors. For example, red stars have a lower temperature than blue-white stars. How is this temperature scale consistent with Planck’s assumption?

▼ **Figure 6.8** The photoelectric effect. When photons of sufficiently high energy strike a metal surface, electrons are emitted from the metal, as in (a). The photoelectric effect is the basis of the photocell shown in (b). The emitted electrons are drawn toward the positive terminal. As a result, current flows in the circuit. Photocells are used in photographic light meters as well as in numerous other electronic devices.

### The Photoelectric Effect and Photons

A few years after Planck presented his theory, scientists began to see its applicability to a great many experimental observations. They recognized that Planck’s theory had within it the seeds of a revolution in the way we view the physical world. In 1905, Albert Einstein (1879–1955) used Planck’s quantum theory to explain the **photoelectric effect**, which is illustrated in Figure 6.8 ◀. Experiments had shown that light shining on a clean metal surface causes the surface to emit electrons. Each metal has a minimum frequency of light below which no electrons are emitted. For example, light with a frequency of  $4.60 \times 10^{14} \text{ s}^{-1}$  or greater will cause cesium metal to emit electrons, but light of lower frequency has no effect.

To explain the photoelectric effect, Einstein assumed that the radiant energy striking the metal surface does not behave like a wave but rather as if it were a stream of tiny energy packets. Each energy packet, called a **photon**, behaves like a tiny particle. Extending Planck’s quantum theory,

Einstein deduced that each photon must have an energy equal to Planck's constant times the frequency of the light:

$$\text{Energy of photon} = E = h\nu \quad [6.3]$$

Thus, radiant energy itself is quantized.

Under the right conditions, a photon can strike a metal surface and be absorbed. When this happens, the photon can transfer its energy to an electron in the metal. A certain amount of energy—called the *work function*—is required for an electron to overcome the attractive forces that hold it in the metal. If the photons of the radiation impinging on the metal have less energy than the work function, electrons do not acquire sufficient energy to escape from the metal surface, even if the light beam is intense. If the photons of radiation have sufficient energy, electrons are emitted from the metal. If the photons have more than the minimum energy required to free electrons, the excess energy appears as the kinetic energy of the emitted electrons. Einstein won the Nobel Prize in Physics in 1921 for his explanation of the photoelectric effect.

To better understand what a photon is, imagine that you have a light source that produces radiation with a single wavelength. Further suppose that you could switch the light on and off faster and faster to provide ever-smaller bursts of energy. Einstein's photon theory tells us that you would eventually come to the smallest energy burst, given by  $E = h\nu$ . This smallest burst of energy consists of a single photon of light.

### SAMPLE EXERCISE 6.3 | Energy of a Photon

Calculate the energy of one photon of yellow light with a wavelength of 589 nm.

#### SOLUTION

**Analyze:** Our task is to calculate the energy,  $E$ , of a photon, given  $\lambda = 589$  nm.

**Plan:** We can use Equation 6.1 to convert the wavelength to frequency:

$$\nu = c/\lambda$$

We can then use Equation 6.3 to calculate energy:

$$E = h\nu$$

**Solve:** The frequency,  $\nu$ , is calculated from the given wavelength, as shown in Sample Exercise 6.2:

$$\nu = c/\lambda = 5.09 \times 10^{14} \text{ s}^{-1}$$

The value of Planck's constant,  $h$ , is given both in the text and in the table of physical constants on the inside front cover of the text, and so we can easily calculate  $E$ :

$$E = (6.626 \times 10^{-34} \text{ J}\cdot\text{s})(5.09 \times 10^{14} \text{ s}^{-1}) = 3.37 \times 10^{-19} \text{ J}$$

**Comment:** If one photon of radiant energy supplies  $3.37 \times 10^{-19}$  J, then one mole of these photons will supply

$$(6.02 \times 10^{23} \text{ photons/mol})(3.37 \times 10^{-19} \text{ J/photon}) = 2.03 \times 10^5 \text{ J/mol}$$

This is the magnitude of enthalpies of reactions (Section 5.4), so radiation can break chemical bonds, producing what are called *photochemical reactions*.

### PRACTICE EXERCISE

(a) A laser emits light with a frequency of  $4.69 \times 10^{14} \text{ s}^{-1}$ . What is the energy of one photon of the radiation from this laser? (b) If the laser emits a pulse of energy containing  $5.0 \times 10^{17}$  photons of this radiation, what is the total energy of that pulse? (c) If the laser emits  $1.3 \times 10^{-2}$  J of energy during a pulse, how many photons are emitted during the pulse?

**Answers:** (a)  $3.11 \times 10^{-19}$  J, (b) 0.16 J, (c)  $4.2 \times 10^{16}$  photons

The idea that the energy of light depends on its frequency helps us understand the diverse effects that different kinds of electromagnetic radiation have on matter. For example, the high frequency (short wavelength) of X-rays

▲ **Figure 6.9 Quantum giants.**

Niels Bohr (right) with Albert Einstein. Bohr (1885–1962) made major contributions to the quantum theory. From 1911 to 1913 Bohr studied in England, working first with J. J. Thomson at Cambridge University and then with Ernest Rutherford at the University of Manchester. He published his quantum theory of the atom in 1914 and was awarded the Nobel Prize in Physics in 1922.

▲ **Figure 6.10 Monochromatic radiation.** Lasers produce light of a single wavelength, which we call *monochromatic light*. Different lasers produce light of different wavelengths. The photo shows beams from a variety of lasers that produce visible light of different colors. Other lasers produce light that is not visible, including infrared and ultraviolet light.

► **Figure 6.11 Creating a spectrum.** A continuous visible spectrum is produced when a narrow beam of white light is passed through a prism. The white light could be sunlight or light from an incandescent lamp.

(Figure 6.4) causes X-ray photons to have energy high enough to cause tissue damage and even cancer. Thus, signs are normally posted around X-ray equipment warning us of high-energy radiation.

Although Einstein's theory of light as a stream of particles rather than a wave explains the photoelectric effect and a great many other observations, it also poses a dilemma. Is light a wave, or does it consist of particles? The only way to resolve this dilemma is to adopt what might seem to be a bizarre position: We must consider that light possesses both wavelike and particle-like characteristics and, depending on the situation, will behave more like a wave or more like particles. We will soon see that this dual nature of light is also characteristic of matter.

### GIVE IT SOME THOUGHT

What has more energy, a photon of infrared light or a photon of ultraviolet light?

## 6.3 LINE SPECTRA AND THE BOHR MODEL

The work of Planck and Einstein paved the way for understanding how electrons are arranged in atoms. In 1913, the Danish physicist Niels Bohr (Figure 6.9▲) offered a theoretical explanation of *line spectra*, another phenomenon that had puzzled scientists during the nineteenth century. We will examine this phenomenon and then consider how Bohr used the ideas of Planck and Einstein.

### Line Spectra

A particular source of radiant energy may emit a single wavelength, as in the light from a laser (Figure 6.10◀). Radiation composed of a single wavelength is said to be *monochromatic*. However, most common radiation sources, including lightbulbs and stars, produce radiation containing many different wavelengths. A **spectrum** is produced when radiation from such sources is separated into its different wavelength components. Figure 6.11▼ shows how a prism spreads light from a light source into its component wavelengths. The resulting

spectrum consists of a continuous range of colors—violet merges into blue, blue into green, and so forth, with no blank spots. This rainbow of colors, containing light of all wavelengths, is called a **continuous spectrum**. The most familiar example of a continuous spectrum is the rainbow produced when raindrops or mist acts as a prism for sunlight.

Not all radiation sources produce a continuous spectrum. When a high voltage is applied to tubes that contain different gases under reduced pressure, the gases emit different colors of light (Figure 6.12 ▶). The light emitted by neon gas is the familiar red-orange glow of many “neon” lights, whereas sodium vapor emits the yellow light characteristic of some modern streetlights. When light coming from such tubes is passed through a prism, only a few wavelengths are present in the resultant spectra, as shown in Figure 6.13 ▼. Each wavelength is represented by a colored line in one of these spectra. A spectrum containing radiation of only specific wavelengths is called a **line spectrum**.

When scientists first detected the line spectrum of hydrogen in the mid-1800s, they were fascinated by its simplicity. At that time, only the four lines in the visible portion of the spectrum were observed, as shown in Figure 6.13. These lines correspond to wavelengths of 410 nm (violet), 434 nm (blue), 486 nm (blue-green), and 656 nm (red). In 1885, a Swiss schoolteacher named Johann Balmer showed that the wavelengths of these four visible lines of hydrogen fit an intriguingly simple formula that related the wavelengths of the visible line spectrum to integers. Later, additional lines were found to occur in the ultraviolet and infrared regions of the hydrogen spectrum. Soon Balmer’s equation was extended to a more general one, called the *Rydberg equation*, which allowed the calculation of the wavelengths of all the spectral lines of hydrogen:

$$\frac{1}{\lambda} = (R_H) \left( \frac{1}{n_1^2} - \frac{1}{n_2^2} \right) \quad [6.4]$$

In this formula  $\lambda$  is the wavelength of a spectral line,  $R_H$  is the *Rydberg constant* ( $1.096776 \times 10^7 \text{ m}^{-1}$ ), and  $n_1$  and  $n_2$  are positive integers, with  $n_2$  being larger than  $n_1$ . How could the remarkable simplicity of this equation be explained? It took nearly 30 more years to answer this question.

◀ **Figure 6.13 Line spectra.** Spectra obtained from the electrical discharge from (a) Na, (b) H. Light of only a few specific wavelengths is produced, as shown by colored lines in the spectra.

## Bohr’s Model

Rutherford’s discovery of the nuclear nature of the atom [⇔ \(Section 2.2\)](#) suggests that the atom can be thought of as a “microscopic solar system” in which electrons orbit the nucleus. To explain the line spectrum of hydrogen, Bohr assumed that electrons move in circular orbits around the nucleus. According to classical physics, however, an electrically charged particle (such as an electron) that moves in a circular path should continuously lose energy by emitting electromagnetic radiation. As the electron loses energy, it should spiral into the positively charged nucleus. This spiraling obviously does not happen since

hydrogen atoms are stable. So how can we explain this apparent violation of the laws of physics? Bohr approached this problem in much the same way that Planck had approached the problem of the nature of the radiation emitted by hot objects: Bohr assumed that the prevailing laws of physics were inadequate to describe all aspects of atoms. Furthermore, Bohr adopted Planck's idea that energies are quantized.

Bohr based his model on three postulates:

1. Only orbits of certain radii, corresponding to certain definite energies, are permitted for the electron in a hydrogen atom.
2. An electron in a permitted orbit has a specific energy and is in an "allowed" energy state. An electron in an allowed energy state will not radiate energy and therefore will not spiral into the nucleus.
3. Energy is emitted or absorbed by the electron only as the electron changes from one allowed energy state to another. This energy is emitted or absorbed as a photon,  $E = h\nu$ .

### GIVE IT SOME THOUGHT

Before reading further about the details of Bohr's model, speculate as to how they explain the fact that hydrogen gas emits a line spectrum (Figure 6.13) rather than a continuous spectrum.

### The Energy States of the Hydrogen Atom

Starting with his three postulates and using classical equations for motion and for interacting electrical charges, Bohr calculated the energies corresponding to each allowed orbit for the electron in the hydrogen atom. Ultimately, the energies that Bohr calculated fit the formula

$$E = (-hcR_H)\left(\frac{1}{n^2}\right) = (-2.18 \times 10^{-18} \text{ J})\left(\frac{1}{n^2}\right) \quad [6.5]$$

In this equation,  $h$ ,  $c$ , and  $R_H$  are Planck's constant, the speed of light, and the Rydberg constant, respectively. The product of these three constants equals  $2.18 \times 10^{-18} \text{ J}$ . The integer  $n$ , which can have whole number values of 1, 2, 3, ... to infinity ( $\infty$ ), is called the *principal quantum number*. Each orbit corresponds to a different value of  $n$ , and the radius of the orbit gets larger as  $n$  increases. Thus, the first allowed orbit (the one closest to the nucleus) has  $n = 1$ , the next allowed orbit (the one second closest to the nucleus) has  $n = 2$ , and so forth. The electron in the hydrogen atom can be in any allowed orbit. Equation 6.5 tells us the energy that the electron will have, depending on which orbit it is in.

The energies of the electron of a hydrogen atom given by Equation 6.5 are negative for all values of  $n$ . The lower (more negative) the energy is, the more stable the atom will be. The energy is lowest (most negative) for  $n = 1$ . As  $n$  gets larger, the energy becomes successively less negative and therefore increases. We can liken the situation to a ladder in which the rungs are numbered from the bottom rung on up. The higher one climbs the ladder (the greater the value of  $n$ ), the higher the energy. The lowest energy state ( $n = 1$ , analogous to the bottom rung) is called the **ground state** of the atom. When the electron is in a higher energy (less negative) orbit— $n = 2$  or higher—the atom is said to be in an **excited state**. Figure 6.14 shows the energy of the electron in a hydrogen atom for several values of  $n$ .

What happens to the orbit radius and the energy as  $n$  becomes infinitely large? The radius increases as  $n^2$ , so we reach a point at which the electron is completely separated from the nucleus. When  $n = \infty$ , the energy is zero:

$$E = (-2.18 \times 10^{-18} \text{ J})\left(\frac{1}{\infty^2}\right) = 0$$

▲ **Figure 6.14** Energy levels in the hydrogen atom from the Bohr model.

The arrows refer to the transitions of the electron from one allowed energy state to another. The states shown are those for which  $n = 1$  through  $n = 6$  and the state for  $n = \infty$  for which the energy,  $E$ , equals zero.

Thus, the state in which the electron is removed from the nucleus is the reference, or zero-energy, state of the hydrogen atom. This zero-energy state is *higher* in energy than the states with negative energies.

In his third postulate, Bohr assumed that the electron could “jump” from one allowed energy state to another by either absorbing or emitting photons whose radiant energy corresponds exactly to the energy difference between the two states. Energy must be absorbed for an electron to move to a higher energy state (one with a higher value of  $n$ ). Conversely, radiant energy is emitted when the electron jumps to a lower energy state (one with a lower value of  $n$ ). Thus, if the electron jumps from an initial state that has energy  $E_i$  to a final state of energy  $E_f$ , the change in energy is

$$\Delta E = E_f - E_i = E_{\text{photon}} = h\nu \quad [6.6]$$

Bohr’s model of the hydrogen atom states, therefore, that only the specific frequencies of light that satisfy Equation 6.6 can be absorbed or emitted by the atom.

Substituting the energy expression in Equation 6.5 into Equation 6.6 and recalling that  $\nu = c/\lambda$ , we have

$$\Delta E = h\nu = \frac{hc}{\lambda} = (-2.18 \times 10^{-18} \text{ J}) \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right) \quad [6.7]$$

In this equation  $n_i$  and  $n_f$  are the principal quantum numbers of the initial and final states of the atom, respectively. If  $n_f$  is smaller than  $n_i$ , the electron moves closer to the nucleus and  $\Delta E$  is a negative number, indicating that the atom releases energy. For example, if the electron moves from  $n_i = 3$  to  $n_f = 1$ , we have

$$\Delta E = (-2.18 \times 10^{-18} \text{ J}) \left( \frac{1}{1^2} - \frac{1}{3^2} \right) = (-2.18 \times 10^{-18} \text{ J}) \left( \frac{8}{9} \right) = -1.94 \times 10^{-18} \text{ J}$$

Knowing the energy for the emitted photon, we can calculate either its frequency or its wavelength. For the wavelength, we have

$$\lambda = \frac{c}{\nu} = \frac{hc}{\Delta E} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{1.94 \times 10^{-18} \text{ J}} = 1.03 \times 10^{-7} \text{ m}$$

We have not included the negative sign of the energy in this calculation because wavelength and frequency are always reported as positive quantities. The direction of energy flow is indicated by saying that a photon of wavelength  $1.03 \times 10^{-7} \text{ m}$  has been *emitted*.

If we solve Equation 6.7 for  $1/\lambda$ , we find that this equation derived from Bohr’s theory corresponds to the Rydberg equation, Equation 6.4, which was obtained using experimental data:

$$\frac{1}{\lambda} = \frac{-hcR_H}{hc} \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right) = R_H \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right)$$

Thus, the existence of discrete spectral lines can be attributed to the quantized jumps of electrons between energy levels.

### GIVE IT SOME THOUGHT

As the electron in a hydrogen atom jumps from the  $n = 3$  orbit to the  $n = 7$  orbit, does it absorb energy or emit energy?

**SAMPLE EXERCISE 6.4** | Electronic Transitions in the Hydrogen Atom

Using Figure 6.14, predict which of the following electronic transitions produces the spectral line having the longest wavelength:  $n = 2$  to  $n = 1$ ,  $n = 3$  to  $n = 2$ , or  $n = 4$  to  $n = 3$ .

**SOLUTION**

The wavelength increases as frequency decreases ( $\lambda = c/\nu$ ). Hence the longest wavelength will be associated with the lowest frequency. According to Planck's equation,  $E = h\nu$ , the lowest frequency is associated with the lowest energy. In Figure 6.14 the shortest vertical line represents the smallest energy change. Thus, the  $n = 4$  to  $n = 3$  transition produces the longest wavelength (lowest frequency) line.

**PRACTICE EXERCISE**

Indicate whether each of the following electronic transitions emits energy or requires the absorption of energy: (a)  $n = 3$  to  $n = 1$ ; (b)  $n = 2$  to  $n = 4$ .

*Answers:* (a) emits energy, (b) requires absorption of energy

### Limitations of the Bohr Model

While the Bohr model explains the line spectrum of the hydrogen atom, it cannot explain the spectra of other atoms, except in a rather crude way. Bohr also avoided the problem of why the negatively charged electron would not just fall into the positively charged nucleus by simply assuming it would not happen. Therefore, there is a problem with describing an electron merely as a small particle circling about the nucleus. As we will see in Section 6.4, the electron exhibits wavelike properties, a fact that any acceptable model of electronic structure must accommodate. As it turns out, the Bohr model was only an important step along the way toward the development of a more comprehensive model. What is most significant about Bohr's model is that it introduces two important ideas that are also incorporated into our current model: (1) Electrons exist only in certain discrete energy levels, which are described by quantum numbers, and (2) energy is involved in moving an electron from one level to another. We will now start to develop the successor to the Bohr model, which requires that we take a closer look at the behavior of matter.

## 6.4 THE WAVE BEHAVIOR OF MATTER

In the years following the development of Bohr's model for the hydrogen atom, the dual nature of radiant energy became a familiar concept. Depending on the experimental circumstances, radiation appears to have either a wavelike or a particle-like (photon) character. Louis de Broglie (1892–1987), who was working on his Ph.D. thesis in physics at the Sorbonne in Paris, boldly extended this idea. If radiant energy could, under appropriate conditions, behave as though it were a stream of particles, could matter, under appropriate conditions, possibly show the properties of a wave? Suppose that the electron orbiting the nucleus of a hydrogen atom could be thought of as a wave, with a characteristic wavelength, rather than as a particle. De Broglie suggested that as the electron moves about the nucleus, it is associated with a particular wavelength. He went on to propose that the characteristic wavelength of the electron, or of any other particle, depends on its mass,  $m$ , and on its velocity,  $v$ , (where  $h$  is Planck's constant):

$$\lambda = \frac{h}{mv} \quad [6.8]$$

The quantity  $mv$  for any object is called its **momentum**. De Broglie used the term **matter waves** to describe the wave characteristics of material particles.

Because de Broglie's hypothesis is applicable to all matter, any object of mass  $m$  and velocity  $v$  would give rise to a characteristic matter wave. However, Equation 6.8 indicates that the wavelength associated with an object of ordinary size, such as a golf ball, is so tiny as to be completely out of the range of any possible observation. This is not so for an electron because its mass is so small, as we see in Sample Exercise 6.5.

### SAMPLE EXERCISE 6.5 | Matter Waves

What is the wavelength of an electron moving with a speed of  $5.97 \times 10^6$  m/s? The mass of the electron is  $9.11 \times 10^{-31}$  kg.

#### SOLUTION

**Analyze:** We are given the mass,  $m$ , and velocity,  $v$ , of the electron, and we must calculate its de Broglie wavelength,  $\lambda$ .

**Plan:** The wavelength of a moving particle is given by Equation 6.8, so  $\lambda$  is calculated by inserting the known quantities  $h$ ,  $m$ , and  $v$ . In doing so, however, we must pay attention to units.

**Solve:** Using the value of Planck's constant,  $h = 6.626 \times 10^{-34}$  J·s

and recalling that

$$1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2$$

we have the following:

$$\begin{aligned}\lambda &= \frac{h}{mv} \\ &= \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})}{(9.11 \times 10^{-31} \text{ kg})(5.97 \times 10^6 \text{ m/s})} \left( \frac{1 \text{ kg}\cdot\text{m}^2/\text{s}^2}{1 \text{ J}} \right) \\ &= 1.22 \times 10^{-10} \text{ m} = 0.122 \text{ nm} = 1.22 \text{ \AA}\end{aligned}$$

**Comment:** By comparing this value with the wavelengths of electromagnetic radiation shown in Figure 6.4, we see that the wavelength of this electron is about the same as that of X-rays.

### PRACTICE EXERCISE

Calculate the velocity of a neutron whose de Broglie wavelength is 500 pm. The mass of a neutron is given in the table inside the back cover of the text.

**Answer:**  $7.92 \times 10^2$  m/s

Within a few years after de Broglie published his theory, the wave properties of the electron were demonstrated experimentally. As electrons passed through a crystal, they were diffracted by the crystal, just as X-rays are diffracted. Thus, a stream of moving electrons exhibits the same kinds of wave behavior as electromagnetic radiation.

The technique of electron diffraction has been highly developed. In the electron microscope, for instance, the wave characteristics of electrons are used to obtain images at the atomic scale. This microscope is an important tool for studying surface phenomena at very high magnifications. Electron microscopes can magnify objects by 3,000,000 times (x), far more than can be done with visible light (1000x), because the wavelength of the electrons is so small compared to visible light. Figure 6.15 is a photograph of an electron microscope image.

**▲ Figure 6.15 Electrons as waves.** The dots you see in this transmission electron micrograph are columns of atoms. Their regular spacing at the atomic level proves that this material is crystalline. Because this crystal is only about 15 nm in diameter, it is a nanocrystal, which has unusual properties that we will discuss in Chapter 12.

### GIVE IT SOME THOUGHT

A baseball pitcher throws a fastball that moves at 95 miles per hour. Does that moving baseball generate matter waves? If so, can we observe them?

## The Uncertainty Principle

The discovery of the wave properties of matter raised some new and interesting questions about classical physics. Consider, for example, a ball rolling down a ramp. Using the equations of classical physics, we can calculate the ball's position, direction of motion, and speed at any time, with great accuracy.

▲ **Figure 6.16 Werner Heisenberg (1901–1976).** During his postdoctoral assistantship with Niels Bohr, Heisenberg formulated his famous uncertainty principle. At the age of 25, he became the chair in theoretical physics at the University of Leipzig. At 32 he was one of the youngest scientists to receive the Nobel Prize.

Can we do the same for an electron, which exhibits wave properties? A wave extends in space, and therefore its location is not precisely defined. We might therefore anticipate that it is impossible to determine exactly where an electron is located at a specific time.

The German physicist Werner Heisenberg (Figure 6.16 ◀) proposed that the dual nature of matter places a fundamental limitation on how precisely we can know both the location and the momentum of any object. The limitation becomes important only when we deal with matter at the subatomic level (that is, with masses as small as that of an electron). Heisenberg's principle is called the **uncertainty principle**. When applied to the electrons in an atom, this principle states that it is inherently impossible for us to know simultaneously both the exact momentum of the electron and its exact location in space.

Heisenberg mathematically related the uncertainty of the position ( $\Delta x$ ) and the uncertainty in momentum  $\Delta(mv)$  to a quantity involving Planck's constant:

$$\Delta x \cdot \Delta(mv) \geq \frac{h}{4\pi} \quad [6.9]$$

A brief calculation illustrates the dramatic implications of the uncertainty principle. The electron has a mass of  $9.11 \times 10^{-31}$  kg and moves at an average speed of about  $5 \times 10^6$  m/s in a hydrogen atom. Let's assume that we know the speed to an uncertainty of 1% (that is, an uncertainty of  $(0.01)(5 \times 10^6 \text{ m/s}) = 5 \times 10^4$  m/s) and that this is the only important source of uncertainty in the momentum, so that  $\Delta(mv) = m\Delta v$ . We can then use Equation 6.9 to calculate the uncertainty in the position of the electron:

$$\Delta x \geq \frac{h}{4\pi m\Delta v} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})}{4\pi(9.11 \times 10^{-31} \text{ kg})(5 \times 10^4 \text{ m/s})} = 1 \times 10^{-9} \text{ m}$$

Because the diameter of a hydrogen atom is only about  $1 \times 10^{-10}$  m, the uncertainty is an order of magnitude greater than the size of the atom. Thus, we have essentially no idea of where the electron is located within the atom. On the other hand, if we were to repeat the calculation with an object of ordinary mass such as a tennis ball, the uncertainty would be so small that it would be inconsequential. In that case,  $m$  is large and  $\Delta x$  is out of the realm of measurement and therefore of no practical consequence.

De Broglie's hypothesis and Heisenberg's uncertainty principle set the stage for a new and more broadly applicable theory of atomic structure. In this new approach, any attempt to define precisely the instantaneous location and momentum of the electron is abandoned. The wave nature of the electron is recognized, and its behavior is described in terms appropriate to waves. The result is a model that precisely describes the energy of the electron while describing its location not precisely, but in terms of probabilities.

### GIVE IT SOME THOUGHT

What is the principal reason that the uncertainty principle should be considered when discussing electrons and other subatomic particles, but is not so necessary when discussing our macroscopic world?

## 6.5 QUANTUM MECHANICS AND ATOMIC ORBITALS

In 1926 the Austrian physicist Erwin Schrödinger (1887–1961) proposed an equation, now known as Schrödinger's wave equation, that incorporates both the wavelike behavior and the particle-like behavior of the electron. His work opened a new way of dealing with subatomic particles, known as either *quantum mechanics* or *wave mechanics*. The application of Schrödinger's equation

## A Closer Look

## MEASUREMENT AND THE UNCERTAINTY PRINCIPLE

Whenever any measurement is made, some uncertainty exists. Our experience with objects of ordinary dimensions, such as balls or trains or laboratory equipment, indicates that using more precise instruments can decrease the uncertainty of a measurement. In fact, we might expect that the uncertainty in a measurement can be made indefinitely small. However, the uncertainty principle states that there is an actual limit to the accuracy of measurements. This limit is not a restriction on how well instruments can be made; rather, it is inherent in nature. This limit has no practical consequences when dealing with ordinary-sized objects, but its implications are enormous when dealing with subatomic particles, such as electrons.

To measure an object, we must disturb it, at least a little, with our measuring device. Imagine using a flashlight to locate a large rubber ball in a dark room. You see the ball when the light from the flashlight bounces off the ball and strikes your eyes. When a beam of photons strikes an object of this size, it does not alter its position or momentum to any practical extent. Imagine, however, that you wish to locate an electron by similarly bouncing light off it into some detector. Objects can be located to an accuracy no greater than the wavelength of the radiation used. Thus, if we want an accurate position measurement for an electron, we must use a

short wavelength. This means that photons of high energy must be employed. The more energy the photons have, the more momentum they impart to the electron when they strike it, which changes the electron's motion in an unpredictable way. The attempt to measure accurately the electron's position introduces considerable uncertainty in its momentum; the act of measuring the electron's position at one moment makes our knowledge of its future position inaccurate.

Suppose, then, that we use photons of longer wavelength. Because these photons have lower energy, the momentum of the electron is not so appreciably changed during measurement, but its position will be correspondingly less accurately known. This is the essence of the uncertainty principle: *There is an uncertainty in simultaneously knowing either the position or the momentum of the electron that cannot be reduced beyond a certain minimum level.* The more accurately one is known, the less accurately the other is known. Although we can never know the exact position and momentum of the electron, we can talk about the probability of its being at certain locations in space. In Section 6.5 we introduce a model of the atom that provides the probability of finding electrons of specific energies at certain positions in atoms.

*Related Exercises: 6.45 and 6.46*

requires advanced calculus, and we will not be concerned with the details of his approach. We will, however, qualitatively consider the results he obtained, because they give us a powerful new way to view electronic structure. Let's begin by examining the electronic structure of the simplest atom, hydrogen.

In the same way that a plucked guitar string vibrates as a standing wave, Schrödinger treated the electron as a standing circular wave around the nucleus. Just as the plucked guitar string produces a fundamental frequency and higher overtones (harmonics), there is a lowest-energy standing wave, and higher-energy ones, for an electron in an atom. Solving Schrödinger's equation leads to a series of mathematical functions called **wave functions** that describe the electron in an atom. These wave functions are usually represented by the symbol  $\psi$  (the lowercase Greek letter *psi*). Although the wave function itself has no direct physical meaning, the square of the wave function,  $\psi^2$ , provides information about an electron's location when the electron is in an allowed energy state.

For the hydrogen atom, the allowed energies are the same as those predicted by the Bohr model. However, the Bohr model assumes that the electron is in a circular orbit of some particular radius about the nucleus. In the quantum mechanical model, the electron's location cannot be described so simply. According to the uncertainty principle, if we know the momentum of the electron with high accuracy, our simultaneous knowledge of its location is very uncertain. Thus, we cannot hope to specify the exact location of an individual electron around the nucleus. Rather, we must be content with a kind of statistical knowledge. In the quantum mechanical model, we therefore speak of the *probability* that the electron will be in a certain region of space at a given instant. As it turns out, the square of the wave function,  $\psi^2$ , at a given point in space represents the probability that the electron will be found at that location. For this reason,  $\psi^2$  is called either the **probability density** or the **electron density**.

One way of representing the probability of finding the electron in various regions of an atom is shown in Figure 6.17. In this figure the density of the dots represents the probability of finding the electron. The regions with a high

▲ **Figure 6.17 Electron-density distribution.** This rendering represents the probability of where in the space surrounding the nucleus the electron is to be found in a hydrogen atom in its ground state.

density of dots correspond to relatively large values for  $\psi^2$  and are therefore regions where there is a high probability of finding the electron. In Section 6.6 we will say more about the ways in which we can represent electron density.

### GIVE IT SOME THOUGHT

Is there a difference between stating, “The electron is located at a particular point in space” and “There is a high probability that the electron is located at a particular point in space”?

## Orbitals and Quantum Numbers

The solution to Schrödinger’s equation for the hydrogen atom yields a set of wave functions and corresponding energies. These wave functions are called **orbitals**. Each orbital describes a specific distribution of electron density in space, as given by the orbital’s probability density. Each orbital, therefore, has a characteristic energy and shape. For example, the lowest-energy orbital in the hydrogen atom has an energy of  $-2.18 \times 10^{-18}$  J and the shape illustrated in Figure 6.17. Note that an *orbital* (quantum mechanical model) is not the same as an *orbit* (Bohr model). The quantum mechanical model does not refer to orbits, because the motion of the electron in an atom cannot be precisely measured or tracked (Heisenberg uncertainty principle).

The Bohr model introduced a single quantum number,  $n$ , to describe an orbit. The quantum mechanical model uses three quantum numbers,  $n$ ,  $l$ , and  $m_l$ , which result naturally from the mathematics used, to describe an orbital. Let’s consider what information we obtain from each of these quantum numbers and how they are interrelated.

1. The *principal quantum number*,  $n$ , can have positive integral values of 1, 2, 3, and so forth. As  $n$  increases, the orbital becomes larger, and the electron spends more time farther from the nucleus. An increase in  $n$  also means that the electron has a higher energy and is therefore less tightly bound to the nucleus. For the hydrogen atom,  $E_n = -(2.18 \times 10^{-18} \text{ J})(1/n^2)$ , as in the Bohr model.
2. The second quantum number—the *angular momentum quantum number*,  $l$ —can have integral values from 0 to  $(n - 1)$  for each value of  $n$ . This quantum number defines the shape of the orbital. (We will consider these shapes in Section 6.6.) The value of  $l$  for a particular orbital is generally designated by the letters  $s$ ,  $p$ ,  $d$ , and  $f$ ,\* corresponding to  $l$  values of 0, 1, 2, and 3, respectively, as summarized here:

Value of $l$	0	1	2	3
Letter used	$s$	$p$	$d$	$f$

3. The *magnetic quantum number*,  $m_l$ , can have integral values between  $-l$  and  $l$ , including zero. This quantum number describes the orientation of the orbital in space, as we will discuss in Section 6.6.

Notice that because the value of  $n$  can be any positive integer, an infinite number of orbitals for the hydrogen atom is possible. The electron in a hydrogen atom is described by only one of these orbitals at any given time—we say that the electron *occupies* a certain orbital. The remaining orbitals are *unoccupied* for that particular state of the hydrogen atom. We will see that we are mainly interested in the orbitals of the hydrogen atom with small values of  $n$ .

\*The letters  $s$ ,  $p$ ,  $d$ , and  $f$  come from the words sharp, principal, diffuse, and fundamental, which were used to describe certain features of spectra before quantum mechanics was developed.

TABLE 6.2 Relationship among Values of  $n$ ,  $l$ , and  $m_l$  through  $n = 4$ 

$n$	Possible Values of $l$	Subshell Designation	Possible Values of $m_l$	Number of Orbitals in Subshell	Total Number of Orbitals in Shell

## GIVE IT SOME THOUGHT

What is the difference between an *orbit* (Bohr model) and an *orbital* (quantum mechanical model)?

The collection of orbitals with the same value of  $n$  is called an **electron shell**. All the orbitals that have  $n = 3$ , for example, are said to be in the third shell. Further, the set of orbitals that have the same  $n$  and  $l$  values is called a **subshell**. Each subshell is designated by a number (the value of  $n$ ) and a letter ( $s$ ,  $p$ ,  $d$ , or  $f$ , corresponding to the value of  $l$ ). For example, the orbitals that have  $n = 3$  and  $l = 2$  are called  $3d$  orbitals and are in the  $3d$  subshell.

Table 6.2 summarizes the possible values of the quantum numbers  $l$  and  $m_l$  for values of  $n$  through  $n = 4$ . The restrictions on the possible values of the quantum numbers give rise to the following very important observations:

1. The shell with principal quantum number  $n$  will consist of exactly  $n$  subshells. Each subshell corresponds to a different allowed value of  $l$  from 0 to  $(n - 1)$ . Thus, the first shell ( $n = 1$ ) consists of only one subshell, the  $1s$  ( $l = 0$ ); the second shell ( $n = 2$ ) consists of two subshells, the  $2s$  ( $l = 0$ ) and  $2p$  ( $l = 1$ ); the third shell consists of three subshells,  $3s$ ,  $3p$ , and  $3d$ , and so forth.
2. Each subshell consists of a specific number of orbitals. Each orbital corresponds to a different allowed value of  $m_l$ . For a given value of  $l$ , there are  $(2l + 1)$  allowed values of  $m_l$ , ranging from  $-l$  to  $+l$ . Thus, each  $s$  ( $l = 0$ ) subshell consists of one orbital, each  $p$  ( $l = 1$ ) subshell consists of three orbitals, each  $d$  ( $l = 2$ ) subshell consists of five orbitals, and so forth.
3. The total number of orbitals in a shell is  $n^2$ , where  $n$  is the principal quantum number of the shell. The resulting number of orbitals for the shells—1, 4, 9, 16—is related to a pattern seen in the periodic table: We see that the number of elements in the rows of the periodic table—2, 8, 18, and 32—equals twice these numbers. We will discuss this relationship further in Section 6.9.

Figure 6.18 shows the relative energies of the hydrogen atom orbitals through  $n = 3$ . Each box represents an orbital; orbitals of the same subshell, such as the  $2p$ , are grouped together. When the electron occupies the lowest-energy orbital ( $1s$ ), the hydrogen atom is said to be in its *ground state*. When the

▲ **Figure 6.18** Orbital energy levels in the hydrogen atom. Each box represents an orbital. Note that all orbitals with the same value for the principal quantum number,  $n$ , have the same energy. This is true only in one-electron systems, such as the hydrogen atom.

electron occupies any other orbital, the atom is in an *excited state*. At ordinary temperatures, essentially all hydrogen atoms are in the ground state. The electron can be excited to a higher-energy orbital by absorption of a photon of appropriate energy.

### GIVE IT SOME THOUGHT

In Figure 6.18, why is the energy difference between the  $n = 1$  and  $n = 2$  levels so much greater than the energy difference between the  $n = 2$  and  $n = 3$  levels?

#### SAMPLE EXERCISE 6.6 | Subshells of the Hydrogen Atom

(a) Without referring to Table 6.2, predict the number of subshells in the fourth shell, that is, for  $n = 4$ . (b) Give the label for each of these subshells. (c) How many orbitals are in each of these subshells?

**Analyze and Plan:** We are given the value of the principal quantum number,  $n$ . We need to determine the allowed values of  $l$  and  $m_l$  for this given value of  $n$  and then count the number of orbitals in each subshell.

#### SOLUTION

There are four subshells in the fourth shell, corresponding to the four possible values of  $l$  (0, 1, 2, and 3).

These subshells are labeled  $4s$ ,  $4p$ ,  $4d$ , and  $4f$ . The number given in the designation of a subshell is the principal quantum number,  $n$ ; the letter designates the value of the angular momentum quantum number,  $l$ : for  $l = 0$ ,  $s$ ; for  $l = 1$ ,  $p$ ; for  $l = 2$ ,  $d$ ; for  $l = 3$ ,  $f$ .

There is one  $4s$  orbital (when  $l = 0$ , there is only one possible value of  $m_l$ : 0). There are three  $4p$  orbitals (when  $l = 1$ , there are three possible values of  $m_l$ : 1, 0, and  $-1$ ). There are five  $4d$  orbitals (when  $l = 2$ , there are five allowed values of  $m_l$ : 2, 1, 0,  $-1$ ,  $-2$ ). There are seven  $4f$  orbitals (when  $l = 3$ , there are seven permitted values of  $m_l$ : 3, 2, 1, 0,  $-1$ ,  $-2$ ,  $-3$ ).

#### PRACTICE EXERCISE

(a) What is the designation for the subshell with  $n = 5$  and  $l = 1$ ? (b) How many orbitals are in this subshell? (c) Indicate the values of  $m_l$  for each of these orbitals.

**Answers:** (a)  $5p$ ; (b) 3; (c) 1, 0,  $-1$

## 6.6 REPRESENTATIONS OF ORBITALS

In our discussion of orbitals so far, we have emphasized their energies. But the wave function also provides information about the electron's location in space when it occupies an orbital. Let's examine the ways that we can picture the orbitals. In doing so, we will examine some important aspects of the electron-density distributions of the orbitals. First, we will look at the three-dimensional shape of the orbital—is it spherical, for example, or does it have directionality? Second, we will examine how the probability density changes as we move on a straight line farther and farther from the nucleus. Finally, we will look at the typical three-dimensional sketches that chemists use in describing the orbitals.

### The $s$ Orbitals

One representation of the lowest-energy orbital of the hydrogen atom, the  $1s$ , is shown in Figure 6.17. This type of drawing, which shows the distribution of electron density around the nucleus, is one of the several ways we use to help us visualize orbitals. The first thing that we notice about the electron density for the  $1s$  orbital is that it is *spherically symmetric*—in other words, the electron density at a given distance from the nucleus is the same regardless of the direction in which we proceed from the nucleus. All of the other  $s$  orbitals ( $2s$ ,  $3s$ ,  $4s$ , and so forth) are spherically symmetric as well. Recall that the  $l$  quantum number

▲ **Figure 6.19 Radial probability functions for the 1s, 2s, and 3s orbitals.** These plots show the probability of finding the electron as a function of distance from the nucleus. As  $n$  increases, the most likely distance at which to find the electron moves farther from the nucleus, similar to the Bohr model. In the 2s and 3s orbitals the radial probability function drops to zero at certain distances from the nucleus but then rises again. The points at which the probability is zero are called *nodes*.

for the  $s$  orbitals is 0; therefore the  $m_l$  quantum number must be 0. Therefore, for each value of  $n$ , there is only one  $s$  orbital.

So what is different about the  $s$  orbitals having different  $n$  quantum numbers? For example, how does the electron-density distribution of the hydrogen atom change when the electron is excited from the 1s orbital to the 2s orbital? To address questions like this, we must look at the *radial probability density*, that is, the probability that we will find the electron at a specific distance from the nucleus. In Figure 6.19▲ we have plotted the radial probability density for the 1s orbital as a function of  $r$ , the distance from the nucleus. The resulting curve is the **radial probability function** for the 1s orbital. (Radial probability functions are described more fully in the “A Closer Look” box in this section.) We see that the probability of finding the electron rises rapidly as we move away from the nucleus, maximizing at a distance of  $0.529 \text{ \AA}$  from the nucleus, and then falls off rapidly. Thus, when the electron occupies the 1s orbital, it is *most likely* to be found  $0.529 \text{ \AA}$  from the nucleus\*. We still use the probabilistic description, consistent with the uncertainty principle. Notice also that the probability of finding the electron at a distance greater than  $3 \text{ \AA}$  from the nucleus is essentially zero.

Figure 6.19(b) shows the radial probability function for the 2s orbital of the hydrogen atom. We can see three significant differences between this plot and that for the 1s orbital: (1) There are two separate maxima in the radial probability function for the 2s orbital, namely a small peak at about  $r = 0.5 \text{ \AA}$  and a much larger peak at about  $r = 3 \text{ \AA}$ ; (2) Between these two peaks is a point at which the function goes to zero (at about  $r = 1 \text{ \AA}$ ). An intermediate point at which a probability function goes to zero is called a **node**. There is a zero probability of finding the electron at a distance corresponding to a node, even though the electron might be found at shorter or longer distances; (3) The radial probability function for the 2s orbital is significantly broader (more spread out) than that for the 1s orbital. Thus, for the 2s orbital, there is a larger range of distances from the

\*In the quantum mechanical model, the most probable distance at which to find the electron in the 1s orbital— $0.529 \text{ \AA}$ —is identical to the radius of the orbit predicted by Bohr for  $n = 1$ . The distance  $0.529 \text{ \AA}$  is often called the Bohr radius.

▲ **Figure 6.20 Contour representations of the 1s, 2s, and 3s orbitals.** The relative radii of the spheres correspond to a 90% probability of finding the electron within each sphere.

nucleus at which there is a high probability of finding the electron than for the 1s orbital. This trend continues for the 3s orbital, as shown in Figure 6.19(c). The radial probability function for the 3s orbital has three peaks of increasing size, with the largest peak maximizing even farther from the nucleus (at about  $r = 7 \text{ \AA}$ ) at which it has two nodes and is even more spread out.

The radial probability functions in Figure 6.19 tell us that as  $n$  increases, there is also an increase in the most likely distance from the nucleus to find the electron. In other words, the size of the orbital increases with increasing  $n$ , just as it did in the Bohr model.

One widely used method of representing orbitals is to display a boundary surface that encloses some substantial portion, say 90%, of the total electron density for the orbital. For the s orbitals, these contour representations are spheres. The contour representations of the 1s, 2s, and 3s orbitals are shown in Figure 6.20 ◀. All the orbitals have the same shape, but they differ in size. Although the details of how the electron density varies within the contour representation are lost in these representations, this is not a serious disadvantage. For more qualitative discussions, the most important features of orbitals are their relative sizes and their shapes, which are adequately displayed by contour representations.

### GIVE IT SOME THOUGHT

How many maxima would you expect to find in the radial probability function for the 4s orbital of the hydrogen atom? How many nodes would you expect in the 4s radial probability function?

## A Closer Look

### PROBABILITY DENSITY AND RADIAL PROBABILITY FUNCTIONS

The quantum mechanical description of the hydrogen atom requires that we talk about the position of the electron in the atom in a somewhat unfamiliar way. In classical physics, we can exactly pinpoint the position and velocity of an orbiting object, such as a planet orbiting a star. Under quantum mechanics, however, we must describe the position of the electron in the hydrogen atom in terms of probabilities rather than an exact location—an exact answer would violate the uncertainty principle, which becomes important when considering subatomic particles. The information we need about the probability of finding the electron is contained in the wave functions,  $\psi$ , that are obtained when Schrödinger's equation is solved. Remember that there are an infinite number of wave functions (orbitals) for the hydrogen atom, but the electron can occupy only one of them at any given time. Here we will discuss briefly how we can use the orbitals to obtain radial probability functions, such as those in Figure 6.19.

In Section 6.5 we stated that the square of the wave function,  $\psi^2$ , gives the probability that the electron is at any one given point in space. Recall that this quantity is called the *probability density* for the point. For a spherically symmetric s orbital, the value of  $\psi$  depends only on the distance from the nucleus,  $r$ . Let's consider a straight line outward from the nucleus, as shown in Figure 6.21 ►. The probability of finding the electron at distance  $r$  from the nucleus along that line is  $|\psi(r)|^2$ , where  $\psi(r)$  is the value of  $\psi$  at distance  $r$ . Figure 6.23 ► shows plots of  $|\psi(r)|^2$  as a function of  $r$  for the 1s, 2s, and 3s orbitals of the hydrogen atom.

You will notice that the plots in Figure 6.23 look distinctly different from the radial probability functions plotted in Figure 6.19. These two types of plots for the s orbitals are very closely related, but they provide somewhat different information. The probability density,  $|\psi(r)|^2$ , tells us the probability of finding the electron at a *specific point* in space that is at distance  $r$  from the nucleus. The radial probability function, which we will denote  $P(r)$ , tells us the probability of finding the electron at *any point* that is distance  $r$  from the nucleus. In other words, to get  $P(r)$  we need to “add up” the probabilities of finding the electron over all the points at distance  $r$  from the nucleus. The difference between these descriptions may seem rather subtle, but mathematics provides us with a precise way to connect them.

▲ **Figure 6.21 Probability at a point.** The probability density,  $\psi(r)^2$  gives the probability that the electron will be found at a *specific point* at distance  $r$  from the nucleus. The radial probability function,  $4\pi r^2 \psi(r)^2$ , gives the probability that the electron will be found at *any point* distance  $r$  from the nucleus—in other words, at any point on the sphere of radius  $r$ .

## The $p$ Orbitals

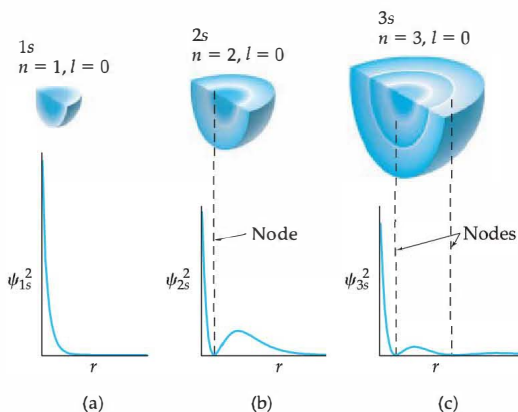

The distribution of electron density for a  $2p$  orbital is shown in Figure 6.22(a) ▼. As we can see from this figure, the electron density is not distributed in a spherically symmetric fashion as in an  $s$  orbital. Instead, the electron density is concentrated in two regions on either side of the nucleus, separated by a node at the nucleus. We say that this dumbbell-shaped orbital has two lobes. Recall that we are making no statement of how the electron is moving within the orbital. The only thing Figure 6.22(a) portrays is the averaged distribution of the electron density in a  $2p$  orbital.

▲ **Figure 6.22** The  $p$  orbitals.

(a) Electron-density distribution of a  $2p$  orbital. (b) Contour representations of the three  $p$  orbitals. Note that the subscript on the orbital label indicates the axis along which the orbital lies.

Beginning with the  $n = 2$  shell, each shell has three  $p$  orbitals. Recall that the  $l$  quantum number for  $p$  orbitals is 1. Therefore, the magnetic quantum number  $m_l$  can have three possible values:  $-1$ ,  $0$ , and  $+1$ . Thus, there are three  $2p$  orbitals, three  $3p$  orbitals, and so forth, corresponding to the three possible values of  $m_l$ . Each set of  $p$  orbitals has the dumbbell shapes shown in Figure 6.22(a) for the  $2p$  orbitals. For each value of  $n$ , the three  $p$  orbitals have the same size and shape but differ from one another in spatial orientation. We usually represent  $p$  orbitals by drawing the shape and orientation of their wave functions, as shown in Figure 6.22(b). It is convenient to label these as the  $p_x$ ,  $p_y$  and  $p_z$  orbitals. The letter subscript indicates the Cartesian axis along which the

◀ **Figure 6.23** Probability density distribution in  $1s$ ,  $2s$ , and  $3s$  orbitals. The lower part of the figure shows how the probability density,  $\psi(r)^2$ , varies as a function of distance  $r$  from the nucleus. The upper part of the figure shows a cutaway of the spherical electron density in each of the  $s$  orbitals.

to describe, however. The radial probability function at distance  $r$ ,  $P(r)$ , is simply the probability density at distance  $r$ ,  $[\psi(r)]^2$  multiplied by the surface area of the sphere, which is given by the formula  $4\pi r^2$ :

$$P(r) = 4\pi r^2 [\psi(r)]^2$$

Thus, the plots of  $P(r)$  in Figure 6.19 are equal to the plots of  $[\psi(r)]^2$  in Figure 6.23 multiplied by  $4\pi r^2$ . The fact that  $4\pi r^2$  increases rapidly as we move away from the nucleus makes the two sets of plots look very different. For example, the plot of  $[\psi(r)]^2$  for the  $3s$  orbital (Figure 6.23) shows that the function generally gets smaller the farther we go from the nucleus. But when we multiply by  $4\pi r^2$ , we see peaks that get larger and larger as we move away from the nucleus (Figure 6.19). We will see that the radial probability functions in Figure 6.19 provide us with the more useful information because they tell us the probability for finding the electron at *all* points distance  $r$  from the nucleus, not just one particular point.

**Related Exercises:** 6.48, 6.57, 6.58, and 6.91

As shown in Figure 6.21, the collection of points at distance  $r$  from the nucleus is simply a sphere of radius  $r$ . The probability density at every point on that sphere is  $[\psi(r)]^2$ . To add up all of the individual probability densities requires the use of calculus and is beyond the scope of this text (in the language of calculus “we integrate the probability density over the surface of the sphere”). The result we obtain is easy

▲ Figure 6.24 Contour representations of the five  $d$  orbitals.

orbital is oriented.\* Like  $s$  orbitals,  $p$  orbitals increase in size as we move from  $2p$  to  $3p$  to  $4p$ , and so forth.

### The $d$ and $f$ Orbitals

When  $n$  is 3 or greater, we encounter the  $d$  orbitals (for which  $l = 2$ ). There are five  $3d$  orbitals, five  $4d$  orbitals, and so forth because in each shell there are five possible values for the  $m_l$  quantum number:  $-2, -1, 0, 1,$  and  $2$ . The different  $d$  orbitals in a given shell have different shapes and orientations in space, as shown in Figure 6.24 ◀.

Four of the  $d$ -orbital contour representations have a “four-leaf clover” shape, and each lies primarily in a plane. The  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  lie in the  $xy$ ,  $xz$ , and  $yz$  planes, respectively, with the lobes oriented *between* the axes. The lobes of the  $d_{x^2-y^2}$  orbital also lie in the  $xy$  plane, but the lobes lie *along* the  $x$  and  $y$  axes. The  $d_{z^2}$  orbital looks very different from the other four: It has two lobes along the  $z$  axis and a “doughnut” in the  $xy$  plane. Even though the  $d_{z^2}$  orbital looks different from the other  $d$  orbitals, it has the same energy as the other four  $d$  orbitals. The representations in Figure 6.24 are commonly used for all  $d$  orbitals, regardless of principal quantum number.

When  $n$  is 4 or greater, there are seven equivalent  $f$  orbitals (for which  $l = 3$ ). The shapes of the  $f$  orbitals are even more complicated than those of the  $d$  orbitals and are not presented here. As you will see in the next section, however, you must be aware of  $f$  orbitals as we consider the electronic structure of atoms in the lower part of the periodic table.

In many instances later in the text you will find that knowing the number and shapes of atomic orbitals will help you understand chemistry at the molecular level. You will therefore find it useful to memorize the shapes of the orbitals shown in Figures 6.20, 6.23, and 6.24.

### GIVE IT SOME THOUGHT

Note in Figure 6.22(a) that the color is deep pink in the interior of each lobe but fades to pale pink at the edges. What does this change in color represent?

## 6.7 MANY-ELECTRON ATOMS

One of our goals in this chapter has been to determine the electronic structures of atoms. So far, we have seen that quantum mechanics leads to a very elegant description of the hydrogen atom. This atom, however, has only one electron. How must our description of the electronic structure of atoms change when we consider atoms with two or more electrons (a *many-electron* atom)? To describe these atoms, we must consider the nature of orbitals and their relative energies as well as how the electrons populate the available orbitals.

### Orbitals and Their Energies

The quantum mechanical model would not be very useful if we could not extend what we have learned about hydrogen to other atoms. Fortunately, we can describe the electronic structure of a many-electron atom in terms of orbitals

\*We cannot make a simple correspondence between the subscripts ( $x$ ,  $y$ , and  $z$ ) and the allowed  $m_l$  values ( $1, 0,$  and  $-1$ ). To explain why this is so is beyond the scope of an introductory text.

like those of the hydrogen atom. Thus, we can continue to designate orbitals as  $1s$ ,  $2p_x$ , and so forth. Further, these orbitals have the same general shapes as the corresponding hydrogen orbitals.

Although the shapes of the orbitals for many-electron atoms are the same as those for hydrogen, the presence of more than one electron greatly changes the energies of the orbitals. In hydrogen the energy of an orbital depends only on its principal quantum number,  $n$  (Figure 6.18); the  $3s$ ,  $3p$ , and  $3d$  subshells all have the same energy, for instance. In a many-electron atom, however, the electron–electron repulsions cause the different subshells to be at different energies, as shown in Figure 6.25. To understand why this is so, we must consider the forces between the electrons and how these forces are affected by the shapes of the orbitals. We will, however, forgo this analysis until Chapter 7.

The important idea is this: *In a many-electron atom, for a given value of  $n$ , the energy of an orbital increases with increasing value of  $l$ .* You can see this illustrated in Figure 6.25. Notice, for example, that the  $n = 3$  orbitals (red) increase in energy in the order  $3s < 3p < 3d$ . Figure 6.25 is a qualitative energy-level diagram; the exact energies of the orbitals and their spacings differ from one atom to another. Notice that all orbitals of a given subshell (such as the five  $3d$  orbitals) still have the same energy as one another, just as they do in the hydrogen atom. Orbitals with the same energy are said to be **degenerate**.

### GIVE IT SOME THOUGHT

For a many-electron atom, can we predict unambiguously whether the  $4s$  orbital is lower in energy or higher in energy than the  $3d$  orbitals?

## Electron Spin and the Pauli Exclusion Principle

We have now seen that we can use hydrogen-like orbitals to describe many-electron atoms. What, however, determines which orbitals the electrons reside in? That is, how do the electrons of a many-electron atom populate the available orbitals? To answer this question, we must consider an additional property of the electron.

When scientists studied the line spectra of many-electron atoms in great detail, they noticed a very puzzling feature: Lines that were originally thought to be single were actually closely spaced pairs. This meant, in essence, that there were twice as many energy levels as there were “supposed” to be. In 1925 the Dutch physicists George Uhlenbeck and Samuel Goudsmit proposed a solution to this dilemma. They postulated that electrons have an intrinsic property, called **electron spin**, that causes each electron to behave as if it were a tiny sphere spinning on its own axis.

By now it probably does not surprise you to learn that electron spin is quantized. This observation led to the assignment of a new quantum number for the electron, in addition to  $n$ ,  $l$ , and  $m_l$ , which we have already discussed. This new quantum number, the **spin magnetic quantum number**, is denoted  $m_s$  (the subscript  $s$  stands for *spin*). Two possible values are allowed for  $m_s$ ,  $+\frac{1}{2}$  or  $-\frac{1}{2}$ , which was first interpreted as indicating the two opposite directions in which the electron can spin. A spinning charge produces a magnetic field. The two opposite directions of spin therefore produce oppositely directed magnetic fields, as shown in Figure 6.26.\* These two opposite magnetic fields lead to the splitting of spectral lines into closely spaced pairs.

Electron spin is crucial for understanding the electronic structures of atoms. In 1925 the Austrian-born physicist Wolfgang Pauli (1900–1958) discovered the principle that governs the arrangements of electrons in many-electron atoms. The **Pauli exclusion principle** states that *no two electrons in an atom can have the same*

**▲ Figure 6.25 Orbital energy levels in many-electron atoms.** In a many-electron atom, the energies of the subshells in each shell follow the order  $ns < np < nd < nf$ . As in Figure 6.18, each box represents an orbital.

**▲ Figure 6.26 Electron spin.** The electron behaves as if it were spinning about an axis, thereby generating a magnetic field whose direction depends on the direction of spin. The two directions for the magnetic field correspond to the two possible values for the spin quantum number,  $m_s$ .

\*As we discussed earlier, the electron has both particle-like and wavelike properties. Thus, the picture of an electron as a spinning charged sphere is, strictly speaking, just a useful pictorial representation that helps us understand the two directions of magnetic field that an electron can possess.

## A Closer Look

## EXPERIMENTAL EVIDENCE FOR ELECTRON SPIN

Even before electron spin had been proposed, there was experimental evidence that electrons had an additional property that needed explanation. In 1921, Otto Stern and Walter Gerlach succeeded in separating a beam of neutral atoms into two groups by passing them through a nonhomogeneous magnetic field. Their experiment is diagrammed in Figure 6.27. Let's assume that they used a beam of hydrogen atoms (in actuality, they used silver atoms, which contain just one unpaired electron). We would normally expect that neutral atoms would not be affected by a magnetic field. However, the magnetic field arising from the electron's spin interacts with the magnet's field, deflecting the atom from its straight-line path. As shown in Figure 6.27, the magnetic field splits the beam in two, suggesting that there are two (and only two) equivalent values for the electron's own magnetic field. The Stern–Gerlach experiment could be readily interpreted once it was realized that there are exactly two values for the spin of the electron. These values will produce equal magnetic fields that are opposite in direction.

Related Exercise: 6.94

▲ **Figure 6.27 The Stern–Gerlach experiment.** Atoms in which the electron spin quantum number ( $m_s$ ) of the unpaired electron is  $+\frac{1}{2}$  are deflected in one direction, and those in which  $m_s$  is  $-\frac{1}{2}$  are deflected in the other.

set of four quantum numbers  $n$ ,  $l$ ,  $m_l$ , and  $m_s$ . For a given orbital ( $1s$ ,  $2p_z$ , and so forth), the values of  $n$ ,  $l$ , and  $m_l$  are fixed. Thus, if we want to put more than one electron in an orbital and satisfy the Pauli exclusion principle, our only choice is to assign different  $m_s$  values to the electrons. Because there are only two such values, we conclude that *an orbital can hold a maximum of two electrons and they must have opposite spins*. This restriction allows us to index the electrons in an atom, giving their quantum numbers and thereby defining the region in space where each electron is most likely to be found. It also provides the key to one of the great problems in chemistry—understanding the structure of the periodic table of the elements. We will discuss these issues in the next two sections.

## 6.8 ELECTRON CONFIGURATIONS

Armed with knowledge of the relative energies of orbitals and the Pauli exclusion principle, we are now in a position to consider the arrangements of electrons in atoms. The way in which the electrons are distributed among the various orbitals of an atom is called the **electron configuration** of the atom. The most stable electron configuration of an atom—the ground state—is that in which the electrons are in the lowest possible energy states. If there were no restrictions on the possible values for the quantum numbers of the electrons, all the electrons would crowd into the  $1s$  orbital because it is the lowest in energy (Figure 6.25). The Pauli exclusion principle tells us, however, that there can be at most two electrons in any single orbital. Thus, *the orbitals are filled in order of increasing energy, with no more than two electrons per orbital*. For example, consider the lithium atom, which has three electrons. (Recall that the number of electrons in a neutral atom equals its atomic number.) The  $1s$  orbital can accommodate two of the electrons. The third one goes into the next lowest energy orbital, the  $2s$ .

We can represent any electron configuration by writing the symbol for the occupied subshell and adding a superscript to indicate the number of electrons in that subshell. For example, for lithium we write  $1s^2 2s^1$  (read “ $1s$  two,  $2s$  one”). We can also show the arrangement of the electrons as

In this kind of representation, which we call an *orbital diagram*, each orbital is denoted by a box and each electron by a half arrow. A half arrow pointing up ( $\uparrow$ ) represents an electron with a positive spin magnetic quantum number ( $m_s = +\frac{1}{2}$ ) and a half arrow pointing down ( $\downarrow$ ) represents an electron with a negative spin magnetic quantum number ( $m_s = -\frac{1}{2}$ ). This pictorial representation of electron spin is quite convenient. In fact, chemists and physicists often refer to electrons as “spin-up” and “spin-down” rather than specifying the value for  $m_s$ .

Electrons having opposite spins are said to be *paired* when they are in the same orbital ( $\uparrow\downarrow$ ). An *unpaired electron* is one not accompanied by a partner of opposite spin. In the lithium atom the two electrons in the 1s orbital are paired and the electron in the 2s orbital is unpaired.

### Hund's Rule

Consider now how the electron configurations of the elements change as we move from element to element across the periodic table. Hydrogen has one electron, which occupies the 1s orbital in its ground state.

The choice of a spin-up electron here is arbitrary; we could equally well show the ground state with one spin-down electron in the 1s orbital. It is customary, however, to show unpaired electrons with their spins up.

The next element, helium, has two electrons. Because two electrons with opposite spins can occupy an orbital, both of helium's electrons are in the 1s orbital.

The two electrons present in helium complete the filling of the first shell. This arrangement represents a very stable configuration, as is evidenced by the chemical inertness of helium.

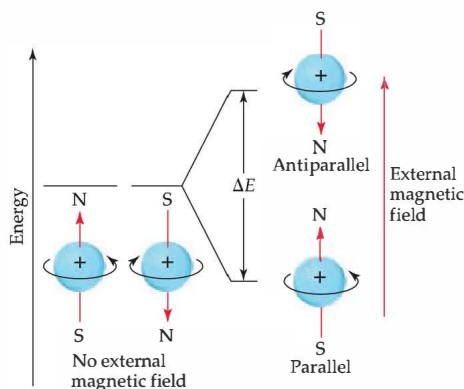

The electron configurations of lithium and several elements that follow it in the periodic table are shown in Table 6.3. For the third electron of lithium, the change in principal quantum number represents a large jump in energy and a corresponding jump in the average distance of the electron from the nucleus.

**TABLE 6.3** ■ Electron Configurations of Several Lighter Elements

Element	Total Electrons	Orbital Diagram							Electron Configuration
		1s	2s	2p			3s		
Li	3	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$1s^2 2s^1$
Be	4	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow\downarrow}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$1s^2 2s^2$
B	5	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$1s^2 2s^2 2p^1$
C	6	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow}$	$\boxed{\uparrow}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\phantom{\uparrow}}$	$1s^2 2s^2 2p^2$

Na	11	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow\downarrow}$	$\boxed{\uparrow\downarrow}$	$\boxed{\phantom{\uparrow}}$	$\boxed{\uparrow}$	$1s^2 2s^2 2p^6 3s^1$

A major challenge facing medical diagnosis is seeing inside the human body from the outside. Until recently, this was accomplished primarily by using X-rays to image human bones, muscles, and organs. However, there are several drawbacks to using X-rays for medical imaging. First, X-rays do not give well-resolved images of overlapping physiological structures. Moreover, because damaged or diseased tissue often yields the same image as healthy tissue, X-rays frequently fail to detect illness or injuries. Finally, X-rays are high-energy radiation that can cause physiological harm, even in low doses.

During the 1980s, a new technique called *magnetic resonance imaging* (MRI) moved to the forefront of medical imaging technology. The foundation of MRI is a phenomenon called nuclear magnetic resonance (NMR), which was discovered in the mid-1940s. Today NMR has become one of the most important spectroscopic methods used in chemistry. It is based on the observation that, like electrons, the nuclei of many elements possess an intrinsic spin. Like electron spin, nuclear spin is quantized. For example, the nucleus of  $^1\text{H}$  (a proton) has two possible magnetic nuclear spin quantum numbers,  $+\frac{1}{2}$  and  $-\frac{1}{2}$ . The hydrogen nucleus is the most common one studied by NMR.

▲ **Figure 6.28 Nuclear spin.** Like electron spin, nuclear spin generates a small magnetic field and has two allowed values. In the absence of an external magnetic field (left), the two spin states have the same energy. If an external magnetic field is applied (right), the parallel alignment of the nuclear magnetic field is lower in energy than the antiparallel alignment. The energy difference,  $\Delta E$ , is in the radio frequency portion of the electromagnetic spectrum.

A spinning hydrogen nucleus acts like a tiny magnet. In the absence of external effects, the two spin states have the same energy. However, when the nuclei are placed in an external magnetic field, they can align either parallel or opposed (antiparallel) to the field, depending on their spin. The parallel alignment is lower in energy than the antiparallel one by a certain amount,  $\Delta E$  (Figure 6.28). If the nuclei are irradiated with photons with energy equal to  $\Delta E$ , the spin of the nuclei can be “flipped,” that is, excited from the parallel to the antiparallel alignment. Detection of the flipping of nuclei between the two spin states leads to an NMR spectrum. The radiation used in an NMR experiment is in the radiofrequency range, typically 100 to 900 MHz, which is far less energetic per photon than X-rays.

Because hydrogen is a major constituent of aqueous body fluids and fatty tissue, the hydrogen nucleus is the most convenient one for study by MRI. In MRI a person’s body is placed in a strong magnetic field. By irradiating the body with pulses of radiofrequency radiation and using sophisticated detection techniques, tissue can be imaged at specific depths within the body, giving pictures with spectacular detail (Figure 6.29). The ability to sample at different depths allows medical technicians to construct a three-dimensional picture of the body.

MRI has none of the disadvantages of X-rays. Diseased tissue appears very different from healthy tissue, resolving overlapping structures at different depths in the body is much easier, and the radiofrequency radiation is not harmful to humans in the doses used. The technique has had such a profound influence on the modern practice of medicine that Paul Lauterbur, a chemist, and Peter Mansfield, a physicist, were awarded the 2003 Nobel Prize in Physiology or Medicine for their discoveries concerning MRI. The major drawback of this technique is expense: The current cost of a new MRI instrument for clinical applications is over \$1.5 million.

*Related Exercises: 6.94 and 6.95*

◀ **Figure 6.29 MRI image.** This image of a human head, obtained using MRI, shows the structures of a normal brain, airways, and facial tissues.

It represents the start of a new shell occupied with electrons. As you can see by examining the periodic table, lithium starts a new row of the table. It is the first member of the alkali metals (group 1A).

The element that follows lithium is beryllium; its electron configuration is  $1s^2 2s^2$  (Table 6.3). Boron, atomic number 5, has the electron configuration  $1s^2 2s^2 2p^1$ . The fifth electron must be placed in a  $2p$  orbital because the  $2s$  orbital is filled. Because all the three  $2p$  orbitals are of equal energy, it does not matter which  $2p$  orbital is occupied.

With the next element, carbon, we encounter a new situation. We know that the sixth electron must go into a  $2p$  orbital. However, does this new electron go into the  $2p$  orbital that already has one electron, or into one of the other two  $2p$  orbitals? This question is answered by **Hund's rule**, which states that *for degenerate orbitals, the lowest energy is attained when the number of electrons with the same spin is maximized*. This means that electrons will occupy orbitals singly to the maximum extent possible and that these single electrons in a given subshell will all have the same spin magnetic quantum number. Electrons arranged in this way are said to have *parallel spins*. For a carbon atom to achieve its lowest energy, therefore, the two  $2p$  electrons will have the same spin. For this to happen, the electrons must be in different  $2p$  orbitals, as shown in Table 6.3. Thus, a carbon atom in its ground state has two unpaired electrons. Similarly, for nitrogen in its ground state, Hund's rule requires that the three  $2p$  electrons singly occupy each of the three  $2p$  orbitals. This is the only way that all three electrons can have the same spin. For oxygen and fluorine, we place four and five electrons, respectively, in the  $2p$  orbitals. To achieve this, we pair up electrons in the  $2p$  orbitals, as we will see in Sample Exercise 6.7.

Hund's rule is based in part on the fact that electrons repel one another. By occupying different orbitals, the electrons remain as far as possible from one another, thus minimizing electron–electron repulsions.

### SAMPLE EXERCISE 6.7 | Orbital Diagrams and Electron Configurations

Draw the orbital diagram for the electron configuration of oxygen, atomic number 8. How many unpaired electrons does an oxygen atom possess?

#### SOLUTION

**Analyze and Plan:** Because oxygen has an atomic number of 8, each oxygen atom has 8 electrons. Figure 6.25 shows the ordering of orbitals. The electrons (represented as arrows) are placed in the orbitals (represented as boxes) beginning with the lowest-energy orbital, the  $1s$ . Each orbital can hold a maximum of two electrons (the Pauli exclusion principle). Because the  $2p$  orbitals are degenerate, we place one electron in each of these orbitals (spin-up) before pairing any electrons (Hund's rule).

**Solve:** Two electrons each go into the  $1s$  and  $2s$  orbitals with their spins paired. This leaves four electrons for the three degenerate  $2p$  orbitals. Following Hund's rule, we put one electron into each  $2p$  orbital until all three orbitals have one electron each. The fourth electron is then paired up with one of the three electrons already in a  $2p$  orbital, so that the representation is

The corresponding electron configuration is written  $1s^2 2s^2 2p^4$ . The atom has two unpaired electrons.

#### PRACTICE EXERCISE

(a) Write the electron configuration for phosphorus, element 15. (b) How many unpaired electrons does a phosphorus atom possess?

**Answers:** (a)  $1s^2 2s^2 2p^6 3s^2 3p^3$ , (b) three

## Condensed Electron Configurations

The filling of the  $2p$  subshell is complete at neon (Table 6.3), which has a stable configuration with eight electrons (an *octet*) in the outermost occupied shell. The next element, sodium, atomic number 11, marks the beginning of a new row of the periodic table. Sodium has a single  $3s$  electron beyond the stable configuration of neon. We can therefore abbreviate the electron configuration of sodium as

The symbol [Ne] represents the electron configuration of the ten electrons of neon,  $1s^2 2s^2 2p^6$ . Writing the electron configuration as [Ne] $3s^1$  helps focus attention on the outermost electrons of the atom, which are the ones largely responsible for the chemical behavior of an element.

We can generalize what we have just done for the electron configuration of sodium. In writing the *condensed electron configuration* of an element, the electron configuration of the nearest noble-gas element of lower atomic number is represented by its chemical symbol in brackets. For example, we can write the electron configuration of lithium as

We refer to the electrons represented by the symbol for a noble gas as the *noble-gas core* of the atom. More usually, these inner-shell electrons are referred to as the **core electrons**. The electrons given after the noble-gas core are called the *outer-shell electrons*. The outer-shell electrons include the electrons involved in chemical bonding, which are called the **valence electrons**. For lighter elements (those with atomic number of 30 or less), all of the outer-shell electrons are valence electrons. As we will discuss later, many of the heavier elements have completely filled subshells that are not involved in bonding and are therefore not considered valence electrons.

By comparing the condensed electron configuration of lithium with that of sodium, we can appreciate why these two elements are so similar chemically. They have the same type of electron configuration in the outermost occupied shell. Indeed, all the members of the alkali metal group (1A) have a single *s* valence electron beyond a noble-gas configuration.

### Transition Metals

The noble-gas element argon marks the end of the row started by sodium. The configuration for argon is  $1s^2 2s^2 2p^6 3s^2 3p^6$ . The element following argon in the periodic table is potassium (K), atomic number 19. In all its chemical properties, potassium is clearly a member of the alkali metal group. The experimental facts about the properties of potassium leave no doubt that the outermost electron of this element occupies an *s* orbital. But this means that the electron with the highest energy has *not* gone into a *3d* orbital, which we might have expected it to do. Here the ordering of energy levels is such that the *4s* orbital is lower in energy than the *3d* orbital (Figure 6.25). Hence, the condensed electron configuration of potassium is

Following the complete filling of the *4s* orbital (this occurs in the calcium atom), the next set of orbitals to be filled is the *3d* (You will find it helpful as we go along to refer often to the periodic table on the front inside cover.) Beginning with scandium and extending through zinc, electrons are added to the five *3d* orbitals until they are completely filled. Thus, the fourth row of the periodic table is ten elements wider than the two previous rows. These ten elements are known as either **transition elements** or **transition metals**. Note the position of these elements in the periodic table.

In deriving the electron configurations of the transition elements, the orbitals are filled in accordance with Hund's rule—electrons are added to the *3d* orbitals singly until all five orbitals have one electron each. Additional electrons are then placed in the *3d* orbitals with spin pairing until the shell is completely filled.

The condensed electron configurations and the corresponding orbital diagram representations of two transition elements are as follows:

Once all the 3*d* orbitals have been filled with two electrons each, the 4*p* orbitals begin to be occupied until the completed octet of outer electrons (4s<sup>2</sup>4*p*<sup>6</sup>) is reached with krypton (Kr), atomic number 36, another of the noble gases. Rubidium (Rb) marks the beginning of the fifth row. Refer again to the periodic table on the front inside cover. Notice that this row is in every respect like the preceding one, except that the value for *n* is greater by 1.

### GIVE IT SOME THOUGHT

Based on the structure of the periodic table, which becomes occupied first, the 6*s* orbital or the 5*d* orbitals?

## The Lanthanides and Actinides

The sixth row of the periodic table begins similarly to the preceding one: one electron in the 6*s* orbital of cesium (Cs) and two electrons in the 6*s* orbital of barium (Ba). Notice, however, that the periodic table then has a break, and the subsequent set of elements (elements 57–70) is placed below the main portion of the table. This place is where we begin to encounter a new set of orbitals, the 4*f*.

There are seven degenerate 4*f* orbitals, corresponding to the seven allowed values of *m<sub>l</sub>*, ranging from 3 to –3. Thus, it takes 14 electrons to fill the 4*f* orbitals completely. The 14 elements corresponding to the filling of the 4*f* orbitals are known as either the **lanthanide elements** or the **rare earth elements**. These elements are set below the other elements to avoid making the periodic table unduly wide. The properties of the lanthanide elements are all quite similar, and these elements occur together in nature. For many years it was virtually impossible to separate them from one another.

Because the energies of the 4*f* and 5*d* orbitals are very close to each other, the electron configurations of some of the lanthanides involve 5*d* electrons. For example, the elements lanthanum (La), cerium (Ce), and praseodymium (Pr) have the following electron configurations:

Because La has a single 5*d* electron, it is sometimes placed below yttrium (Y) as the first member of the third series of transition elements; Ce is then placed as the first member of the lanthanides. Based on their chemistry, however, La can be considered the first element in the lanthanide series. Arranged this way, there are fewer apparent exceptions to the regular filling of the 4*f* orbitals among the subsequent members of the series.

After the lanthanide series, the third transition element series is completed by the filling of the 5*d* orbitals, followed by the filling of the 6*p* orbitals. This brings us to radon (Rn), heaviest of the known noble-gas elements.

The final row of the periodic table begins by filling the 7s orbitals. The **actinide elements**, of which uranium (U, element 92) and plutonium (Pu, element 94) are the best known, are then built up by completing the 5f orbitals. The actinide elements are radioactive, and most of them are not found in nature.

## 6.9 ELECTRON CONFIGURATIONS AND THE PERIODIC TABLE

**TABLE 6.4** ■ Electron Configurations of the Group 2A and 3A Elements

Group 2A	
Be	[He] $2s^2$
Mg	[Ne] $3s^2$
Ca	[Ar] $4s^2$
Sr	[Kr] $5s^2$
Ba	[Xe] $6s^2$
Ra	[Rn] $7s^2$
Group 3A	
B	[He] $2s^2 2p^1$
Al	[Ne] $3s^2 3p^1$
Ga	[Ar] $3d^{10} 4s^2 4p^1$
In	[Kr] $4d^{10} 5s^2 5p^1$
Tl	[Xe] $4f^{14} 5d^{10} 6s^2 6p^1$

Our rather brief survey of electron configurations of the elements has taken us through the periodic table. We have seen that the electron configurations of the elements are related to their locations in the periodic table. The periodic table is structured so that elements with the same pattern of outer-shell (valence) electron configuration are arranged in columns. For example, the electron configurations for the elements in groups 2A and 3A are given in Table 6.4. We see that all the 2A elements have  $ns^2$  outer configurations, while all the 3A elements have  $ns^2 np^1$  configurations.

Earlier, in Table 6.2, we saw that the total number of orbitals in each shell is equal to  $n^2$ : 1, 4, 9, or 16. Because each orbital can hold two electrons, each shell can accommodate up to  $2n^2$  electrons: 2, 8, 18, or 32. The structure of the periodic table reflects this orbital structure. The first row has two elements, the second and third rows have eight elements, the fourth and fifth rows have 18 elements, and the sixth row has 32 elements (including the lanthanide metals). Some of the numbers repeat because we reach the end of a row of the periodic table before a shell completely fills. For example, the third row has eight elements, which corresponds to filling the 3s and 3p orbitals. The remaining orbitals of the third shell, the 3d orbitals, do not begin to fill until the fourth row of the periodic table (and after the 4s orbital is filled). Likewise, the 4d orbitals do not begin to fill until the fifth row of the table, and the 4f orbitals don't begin filling until the sixth row.

All these observations are evident in the structure of the periodic table. For this reason, we will emphasize that *the periodic table is your best guide to the order in which orbitals are filled*. You can easily write the electron configuration of an element based on its location in the periodic table. The pattern is summarized in Figure 6.30. Notice that the elements can be grouped by the *type* of orbital into which the electrons are placed. On the left are *two* columns of elements, depicted in blue. These elements, known as the alkali metals (group 1A) and alkaline earth metals (group 2A), are those in which the valence s orbitals are being filled. On the right is a pink block of six columns. These are the elements in which the valence p orbitals are being filled. The s block and the p block of the periodic table together are the **representative elements**, which are sometimes called the **main-group elements**.

**▲ Figure 6.30** **Regions of the periodic table.** This block diagram of the periodic table shows the order in which electrons are added to orbitals as we move through the table from beginning to end.

In the middle of Figure 6.30 is a gold block of *ten* columns containing the transition metals. These are the elements in which the valence d orbitals are being filled. Below the main portion of the table are two tan rows containing 14 columns. These elements are often referred to as the **f-block metals**, because they are the ones in which the valence f orbitals are being filled. Recall that the numbers 2, 6, 10, and 14 are precisely the number of electrons that can fill the s, p, d, and f subshells, respectively. Recall also that the 1s subshell is the first s subshell, the 2p is the first p subshell, the 3d is the first d subshell, and the 4f is the first f subshell.

**SAMPLE EXERCISE 6.8** | Electron Configurations for a Group

What is the characteristic valence electron configuration of the group 7A elements, the halogens?

**SOLUTION**

**Analyze and Plan:** We first locate the halogens in the periodic table, write the electron configurations for the first two elements, and then determine the general similarity between them.

**Solve:** The first member of the halogen group is fluorine, atomic number 9. The condensed electron configuration for fluorine is

Similarly, that for chlorine, the second halogen, is

From these two examples, we see that the characteristic valence electron configuration of a halogen is  $ns^2np^5$ , where  $n$  ranges from 2 in the case of fluorine to 6 in the case of astatine.

**PRACTICE EXERCISE**

Which family of elements is characterized by an  $ns^2np^2$  electron configuration in the outermost occupied shell?

*Answer:* group 4A

**SAMPLE EXERCISE 6.9** | Electron Configurations from the Periodic Table

(a) Write the electron configuration for bismuth, element number 83. (b) Write the condensed electron configuration for this element. (c) How many unpaired electrons does each atom of bismuth possess?

**SOLUTION**

(a) We write the electron configuration by moving across the periodic table one row at a time and writing the occupancies of the orbital corresponding to each row (refer to Figure 6.29).

First row	$1s^2$
Second row	$2s^22p^6$
Third row	$3s^23p^6$
Fourth row	$4s^23d^{10}4p^6$
Fifth row	$5s^24d^{10}5p^6$
Sixth row	$6s^24f^{14}5d^{10}6p^3$
Total:	$1s^22s^22p^63s^23p^63d^{10}4s^24p^64d^{10}4f^{14}5s^25p^65d^{10}6s^26p^3$

Note that 3 is the lowest possible value that  $n$  may have for a  $d$  orbital and that 4 is the lowest possible value of  $n$  for an  $f$  orbital.

The total of the superscripted numbers should equal the atomic number of bismuth, 83. The electrons may be listed, as shown above in the "Total" row, in the order of increasing principal quantum number. However, it is equally correct to list the orbitals in the order in which they are read from Figure 6.30:  $1s^22s^22p^63s^23p^64s^23d^{10}4p^65s^24d^{10}5p^66s^24f^{14}5d^{10}6p^3$ .

(b) We write the condensed electron configuration by locating bismuth on the periodic table and then moving *backward* to the nearest noble gas, which is Xe, element 54. Thus, the noble-gas core is [Xe]. The outer electrons are then read from the periodic table as before. Moving from Xe to Cs, element 55, we find ourselves in the sixth row. Moving across this row to Bi gives us the outer electrons. Thus, the abbreviated electron configuration is [Xe] $6s^24f^{14}5d^{10}6p^3$  or [Xe] $4f^{14}5d^{10}6s^26p^3$ .

(c) We can see from the abbreviated electron configuration that the only partially occupied subshell is the  $6p$ . The orbital diagram representation for this subshell is

In accordance with Hund's rule, the three  $6p$  electrons occupy the three  $6p$  orbitals singly, with their spins parallel. Thus, there are three unpaired electrons in each atom of bismuth.

**PRACTICE EXERCISE**

Use the periodic table to write the condensed electron configurations for (a) Co (atomic number 27), (b) Te (atomic number 52).

*Answers:* (a) [Ar] $4s^23d^7$  or [Ar] $3d^74s^2$ , (b) [Kr] $5s^24d^{10}5p^4$  or [Kr] $4d^{10}5s^25p^4$

## Anomalous Electron Configurations

If you inspect Figure 6.31 closely, you will see that the electron configurations of certain elements appear to violate the rules we have just discussed. For example, the electron configuration of chromium is  $[\text{Ar}]3d^54s^1$  rather than the  $[\text{Ar}]3d^44s^2$  configuration we might have expected. Similarly, the configuration of copper is  $[\text{Ar}]3d^{10}4s^1$  instead of  $[\text{Ar}]3d^94s^2$ . This anomalous behavior is largely a consequence of the closeness of the  $3d$  and  $4s$  orbital energies. It frequently occurs when there are enough electrons to lead to precisely half-filled sets of degenerate orbitals (as in chromium) or to completely fill a  $d$  subshell (as in copper). There are a few similar cases among the heavier transition metals (those with partially filled  $4d$  or  $5d$  orbitals) and among the  $f$ -block metals. Although these minor departures from the expected are interesting, they are not of great chemical significance.

### GIVE IT SOME THOUGHT

The elements Ni, Pd, and Pt are all in the same group. By examining the electron configurations for these elements in Figure 6.31, what can you conclude about the relative energies of the  $nd$  and  $(n + 1)s$  orbitals for this group?

### SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

Boron, atomic number 5, occurs naturally as two isotopes,  $^{10}\text{B}$  and  $^{11}\text{B}$ , with natural abundances of 19.9% and 80.1%, respectively. (a) In what ways do the two isotopes differ from each other? Does the electronic configuration of  $^{10}\text{B}$  differ from that of  $^{11}\text{B}$ ? (b) Draw the orbital diagram for an atom of  $^{11}\text{B}$ . Which electrons are the valence electrons? (c) Indicate three major ways in which the  $1s$  electrons in boron differ from its  $2s$  electrons. (d) Elemental boron reacts with fluorine to form  $\text{BF}_3$ , a gas. Write a balanced chemical equation for the reaction of solid boron with fluorine gas. (e)  $\Delta H_f^\circ$  for  $\text{BF}_3(\text{g})$  is  $-1135.6 \text{ kJ mol}^{-1}$ . Calculate the standard enthalpy change in the reaction of boron with fluorine. (f) When  $\text{BCl}_3$ , also a gas at room temperature, comes into contact with water, the two react to form hydrochloric acid and boric acid,  $\text{H}_3\text{BO}_3$ , a very weak acid in water. Write a balanced net ionic equation for this reaction.

### SOLUTION

- (a) The two isotopes of boron differ in the number of neutrons in the nucleus.  (Sections 2.3 and 2.4) Each of the isotopes contains five protons, but  $^{10}\text{B}$  contains five neutrons, whereas  $^{11}\text{B}$  contains six neutrons. The two isotopes of boron have identical electron configurations,  $1s^22s^22p^1$ , because each has five electrons.
- (b) The complete orbital diagram is

The valence electrons are the ones in the outermost occupied shell, the  $2s^2$  and  $2p^1$  electrons. The  $1s^2$  electrons constitute the core electrons, which we represent as  $[\text{He}]$  when we write the condensed electron configuration,  $[\text{He}]2s^22p^1$ .

- (c) The  $1s$  and  $2s$  orbitals are both spherical, but they differ in three important respects: First, the  $1s$  orbital is lower in energy than the  $2s$  orbital. Second, the average distance of the  $2s$  electrons from the nucleus is greater than that of the  $1s$  electrons, so the  $1s$  orbital is smaller than the  $2s$ . Third, the  $2s$  orbital has one node, whereas the  $1s$  orbital has no nodes (Figure 6.19).

- (d) The balanced chemical equation is

- (e)  $\Delta H^\circ = 2(-1135.6) - [0 + 0] = -2271.2 \text{ kJ}$ . The reaction is strongly exothermic.
- (f)  $\text{BCl}_3(\text{g}) + 3 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_3\text{BO}_3(\text{aq}) + 3 \text{H}^+(\text{aq}) + 3 \text{Cl}^-(\text{aq})$ . Note that because  $\text{H}_3\text{BO}_3$  is a very weak acid, its chemical formula is written in molecular form, as discussed in Section 4.3.

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Introduction and Section 6.1** The electronic structure of an atom describes the energies and arrangement of electrons around the atom. Much of what is known about the electronic structure of atoms was obtained by observing the interaction of light with matter. Visible light and other forms of **electromagnetic radiation** (also known as radiant energy) move through a vacuum at the speed of light,  $c = 3.00 \times 10^8$  m/s. Electromagnetic radiation has both electric and magnetic components that vary periodically in wavelike fashion. The wave characteristics of radiant energy allow it to be described in terms of **wavelength**,  $\lambda$  and **frequency**,  $\nu$ , which are interrelated:  $c = \lambda\nu$ .

**Section 6.2** Planck proposed that the minimum amount of radiant energy that an object can gain or lose is related to the frequency of the radiation:  $E = h\nu$ . This smallest quantity is called a **quantum** of energy. The constant  $h$  is called **Planck's constant**:  $h = 6.626 \times 10^{-34}$  J·s. In the quantum theory, energy is quantized, meaning that it can have only certain allowed values. Einstein used the quantum theory to explain the **photoelectric effect**, the emission of electrons from metal surfaces by light. He proposed that light behaves as if it consists of quantized energy packets called **photons**. Each photon carries energy,  $E = h\nu$ .

**Section 6.3** Dispersion of radiation into its component wavelengths produces a **spectrum**. If the spectrum contains all wavelengths, it is called a **continuous spectrum**; if it contains only certain specific wavelengths, the spectrum is called a **line spectrum**. The radiation emitted by excited hydrogen atoms forms a line spectrum; the frequencies observed in the spectrum follow a simple mathematical relationship that involves small integers.

Bohr proposed a model of the hydrogen atom that explains its line spectrum. In this model the energy of the electron in the hydrogen atom depends on the value of a number  $n$ , called the quantum number. The value of  $n$  must be a positive integer (1, 2, 3, ...), and each value of  $n$  corresponds to a different specific energy,  $E_n$ . The energy of the atom increases as  $n$  increases. The lowest energy is achieved for  $n = 1$ ; this is called the **ground state** of the hydrogen atom. Other values of  $n$  correspond to **excited states** of the atom. Light is emitted when the electron drops from a higher energy state to a lower energy state; light must be absorbed to excite the electron from a lower energy state to a higher one. The frequency of light emitted or absorbed must be such that  $h\nu$  equals the difference in energy between two allowed states of the atom.

**Section 6.4** De Broglie proposed that matter, such as electrons, should exhibit wavelike properties. This hypothesis of **matter waves** was proved experimentally

by observing the diffraction of electrons. An object has a characteristic wavelength that depends on its **momentum**,  $mv$ :  $\lambda = h/mv$ . Discovery of the wave properties of the electron led to Heisenberg's **uncertainty principle**, which states that there is an inherent limit to the accuracy with which the position and momentum of a particle can be measured simultaneously.

**Section 6.5** In the quantum mechanical model of the hydrogen atom, the behavior of the electron is described by mathematical functions called **wave functions**, denoted with the Greek letter  $\psi$ . Each allowed wave function has a precisely known energy, but the location of the electron cannot be determined exactly; rather, the probability of it being at a particular point in space is given by the **probability density**,  $\psi^2$ . The **electron density** distribution is a map of the probability of finding the electron at all points in space.

The allowed wave functions of the hydrogen atom are called **orbitals**. An orbital is described by a combination of an integer and a letter, corresponding to values of three quantum numbers for the orbital. The principal quantum number,  $n$ , is indicated by the integers 1, 2, 3, .... This quantum number relates most directly to the size and energy of the orbital. The angular momentum quantum number,  $l$ , is indicated by the letters  $s, p, d, f$ , and so on, corresponding to the values of 0, 1, 2, 3, .... The  $l$  quantum number defines the shape of the orbital. For a given value of  $n$ ,  $l$  can have integer values ranging from 0 to  $(n - 1)$ . The magnetic quantum number,  $m_l$ , relates to the orientation of the orbital in space. For a given value of  $l$ ,  $m_l$  can have integral values ranging from  $-l$  to  $l$ , including 0. Cartesian labels can be used to label the orientations of the orbitals. For example, the three  $3p$  orbitals are designated  $3p_x, 3p_y$ , and  $3p_z$ , with the subscripts indicating the axis along which the orbital is oriented.

An **electron shell** is the set of all orbitals with the same value of  $n$ , such as  $3s, 3p$ , and  $3d$ . In the hydrogen atom all the orbitals in an electron shell have the same energy. A **subshell** is the set of one or more orbitals with the same  $n$  and  $l$  values; for example,  $3s, 3p$ , and  $3d$  are each subshells of the  $n = 3$  shell. There is one orbital in an  $s$  subshell, three in a  $p$  subshell, five in a  $d$  subshell, and seven in a  $f$  subshell.

**Section 6.6** Contour representations are useful for visualizing the spatial characteristics (shapes) of the orbitals. Represented this way,  $s$  orbitals appear as spheres that increase in size as  $n$  increases. The **radial probability function** tells us the probability that the electron will be found at a certain distance from the nucleus. The wave function for each  $p$  orbital has two lobes on opposite sides of the nucleus. They are oriented along the  $x$ -,  $y$ -, and  $z$ -axes. Four of the  $d$  orbitals appear as shapes with four

lobes around the nucleus; the fifth one, the  $d_{z^2}$  orbital, is represented as two lobes along the z-axis and a “doughnut” in the  $xy$  plane. Regions in which the wave function is zero are called **nodes**. There is zero probability that the electron will be found at a node.

**Section 6.7** In many-electron atoms, different subshells of the same electron shell have different energies. For a given value of  $n$ , the energy of the subshells increases as the value of  $l$  increases:  $ns < np < nd < nf$ . Orbitals within the same subshell are **degenerate**, meaning they have the same energy.

Electrons have an intrinsic property called **electron spin**, which is quantized. The **spin magnetic quantum number**,  $m_s$ , can have two possible values,  $+\frac{1}{2}$  and  $-\frac{1}{2}$ , which can be envisioned as the two directions of an electron spinning about an axis. The **Pauli exclusion principle** states that no two electrons in an atom can have the same values for  $n$ ,  $l$ ,  $m_l$ , and  $m_s$ . This principle places a limit of two on the number of electrons that can occupy any one atomic orbital. These two electrons differ in their value of  $m_s$ .

**Sections 6.8 and 6.9** The **electron configuration** of an atom describes how the electrons are distributed among the orbitals of the atom. The ground-state electron configurations are generally obtained by placing the electrons in the atomic orbitals of lowest possible energy with the restriction that each orbital can hold no more than two electrons. When electrons occupy a subshell with more than one degenerate orbital, such as the  $2p$  subshell, **Hund’s rule** states that the lowest energy is attained by maximizing the number of electrons with the same electron spin.

For example, in the ground-state electron configuration of carbon, the two  $2p$  electrons have the same spin and must occupy two different  $2p$  orbitals.

Elements in any given group in the periodic table have the same type of electron arrangements in their outermost shells. For example, the electron configurations of the halogens fluorine and chlorine are  $[\text{He}]2s^22p^5$  and  $[\text{Ne}]3s^23p^5$ , respectively. The outer-shell electrons are those that lie outside the orbitals occupied in the next lowest noble-gas element. The outer-shell electrons that are involved in chemical bonding are the **valence electrons** of an atom; for the elements with atomic number 30 or less, all the outer-shell electrons are valence electrons. The electrons that are not valence electrons are called **core electrons**.

The periodic table is partitioned into different types of elements, based on their electron configurations. Those elements in which the outermost subshell is an  $s$  or  $p$  subshell are called the **representative** (or **main-group**) **elements**. The alkali metals (group 1A), halogens (group 7A), and noble gases (group 8A) are representative elements. Those elements in which a  $d$  subshell is being filled are called the **transition elements** (or **transition metals**). The elements in which the  $4f$  subshell is being filled are called the **lanthanide** (or **rare earth**) **elements**. The **actinide elements** are those in which the  $5f$  subshell is being filled. The lanthanide and actinide elements are collectively referred to as the **f-block metals**. These elements are shown as two rows of 14 elements below the main part of the periodic table. The structure of the periodic table, summarized in Figure 6.30, allows us to write the electron configuration of an element from its position in the periodic table.

## KEY SKILLS

- Be able to calculate the wavelength of electromagnetic radiation given its frequency or its frequency given its wavelength.
- Be able to order the common kinds of radiation in the electromagnetic spectrum according to their wavelengths or energy.
- Understand the concept of photons, and be able to calculate their energies given either their frequency or wavelength.
- Be able to explain how line spectra of the elements relate to the idea of quantized energy states of electrons in atoms.
- Be familiar with the wavelike properties of matter.
- Understand how the uncertainty principle limits how precisely we can specify the position and the momentum of subatomic particles such as electrons.
- Know how the quantum numbers relate to the number and type of orbitals, and recognize the different orbital shapes.
- Interpret radial probability function graphs for the orbitals.
- Be able to draw an energy-level diagram for the orbitals in a many-electron atom, and describe how electrons populate the orbitals in the ground-state of an atom, using the Pauli Exclusion Principle and Hund’s rule.
- Be able to use the periodic table to write abbreviated electron configurations and determine the number of unpaired electrons in an atom.

## KEY EQUATIONS

- $c = \lambda\nu$  [6.1] light as a wave:  $c =$  speed of light ( $3.00 \times 10^8$  m/s),  $\lambda =$  wavelength in meters,  $\nu =$  frequency in  $s^{-1}$
- $E = h\nu$  [6.2] light as a particle (photon):  $E =$  energy of photon in Joules,  $h =$  Planck's constant ( $6.626 \times 10^{-34}$  J-s),  $\nu =$  frequency in  $s^{-1}$  (same frequency as previous formula)
- $\lambda = h/mv$  [6.8] matter as a wave:  $\lambda =$  wavelength,  $h =$  Planck's constant,  $m =$  mass of object in kg,  $v =$  speed of object in m/s
- $\Delta x \cdot \Delta(mv) \geq \frac{h}{4\pi}$  [6.9] Heisenberg's uncertainty principle. The uncertainty in position ( $\Delta x$ ) and momentum ( $\Delta(mv)$ ) of an object cannot be zero; the smallest value of their product is  $h/4\pi$

## VISUALIZING CONCEPTS

- 6.1 Consider the water wave shown here. (a) How could you measure the speed of this wave? (b) How would you determine the wavelength of the wave? (c) Given the speed and wavelength of the wave, how could you determine the frequency of the wave? (d) Suggest an independent experiment to determine the frequency of the wave. [Section 6.1]

- 6.2 A popular kitchen appliance produces electromagnetic radiation with a frequency of 2450 MHz. With reference to Figure 6.4, answer the following: (a) Estimate the wavelength of this radiation. (b) Would the radiation produced by the appliance be visible to the human eye? (c) If the radiation is not visible, do photons of this radiation have more or less energy than photons of visible light? (d) Propose the identity of the kitchen appliance. [Section 6.1]
- 6.3 As shown in the accompanying photograph, an electric stove burner on its highest setting exhibits an orange glow. (a) When the burner setting is changed to low, the burner continues to produce heat but the orange glow disappears. How can this observation be explained with reference to one of the fundamental observations that led to the notion of quanta? (b) Suppose that the energy provided to the burner could be increased beyond the highest setting of the stove. What would we expect to observe with regard to visible light emitted by the burner? [Section 6.2]

- 6.4 The familiar phenomenon of a rainbow results from the diffraction of sunlight through raindrops. (a) Does the wavelength of light increase or decrease as we proceed outward from the innermost band of the rainbow? (b) Does the frequency of light increase or decrease as we proceed outward? (c) Suppose that instead of sunlight, the visible light from a hydrogen discharge tube (Figure 6.12) was used as the light source. What do you think the resulting "hydrogen discharge rainbow" would look like? [Section 6.3]

- 6.5 A certain quantum mechanical system has the energy levels shown in the diagram below. The energy levels are indexed by a single quantum number  $n$  that is an integer. (a) As drawn, which quantum numbers are involved in the transition that requires the most energy? (b) Which quantum numbers are involved in the transition that requires the least energy? (c) Based on the drawing, put the following in order of increasing wavelength of the light absorbed or emitted during the transition: (i)  $n = 1$  to  $n = 2$ ; (ii)  $n = 3$  to  $n = 2$ ; (iii)  $n = 2$  to  $n = 4$ ; (iv)  $n = 3$  to  $n = 1$ . [Section 6.3]

- 6.6 Consider a fictitious one-dimensional system with one electron. The wave function for the electron, drawn at the top of the next column, is  $\psi(x) = \sin x$  from  $x = 0$  to  $x = 2\pi$ . (a) Sketch the probability density,  $\psi^2(x)$ , from  $x = 0$  to  $x = 2\pi$  (b) At what value or values of  $x$  will there be the greatest probability of finding the electron? (c) What is the probability that the electron will be found at  $x = \pi$ ? What is such a point in a wave function called? [Section 6.5]

- 6.7 The contour representation of one of the orbitals for the  $n = 3$  shell of a hydrogen atom is shown below. (a) What is the quantum number  $l$  for this orbital? (b) How do we label this orbital? (c) How would you modify this sketch to show the analogous orbital for the  $n = 4$  shell? [Section 6.6]

- 6.8 The drawing below shows part of the orbital diagram for an element. (a) As drawn, the drawing is *incorrect*. Why? (b) How would you correct the drawing without changing the number of electrons? (c) To which group in the periodic table does the element belong? [Section 6.8]

## EXERCISES

### The Wave Nature of Light

- 6.9 What are the basic SI units for (a) the wavelength of light, (b) the frequency of light, (c) the speed of light?
- 6.10 (a) What is the relationship between the wavelength and the frequency of radiant energy? (b) Ozone in the upper atmosphere absorbs energy in the 210–230-nm range of the spectrum. In what region of the electromagnetic spectrum does this radiation occur?
- 6.11 Label each of the following statements as true or false. For those that are false, correct the statement. (a) Visible light is a form of electromagnetic radiation. (b) The frequency of radiation increases as the wavelength increases. (c) Ultraviolet light has longer wavelengths than visible light. (d) X-rays travel faster than microwaves. (e) Electromagnetic radiation and sound waves travel at the same speed.
- 6.12 Determine which of the following statements are false, and correct them. (a) Electromagnetic radiation is incapable of passing through water. (b) Electromagnetic radiation travels through a vacuum at a constant speed, regardless of wavelength. (c) Infrared light has higher

frequencies than visible light. (d) The glow from a fireplace, the energy within a microwave oven, and a foghorn blast are all forms of electromagnetic radiation.

- 6.13 Arrange the following kinds of electromagnetic radiation in order of increasing wavelength: infrared, green light, red light, radio waves, X-rays, ultraviolet light.
- 6.14 List the following types of electromagnetic radiation in order of increasing wavelength: (a) the gamma rays produced by a radioactive nuclide used in medical imaging; (b) radiation from an FM radio station at 93.1 MHz on the dial; (c) a radio signal from an AM radio station at 680 kHz on the dial; (d) the yellow light from sodium vapor streetlights; (e) the red light of a light-emitting diode, such as in a calculator display.
- 6.15 (a) What is the frequency of radiation that has a wavelength of  $10 \mu\text{m}$ , about the size of a bacterium? (b) What is the wavelength of radiation that has a frequency of  $5.50 \times 10^{14} \text{ s}^{-1}$ ? (c) Would the radiations in part (a) or part (b) be visible to the human eye? (d) What distance does electromagnetic radiation travel in  $50.0 \mu\text{s}$ ?

- 6.16 (a) What is the frequency of radiation whose wavelength is  $10.0 \text{ \AA}$ ? (b) What is the wavelength of radiation that has a frequency of  $7.6 \times 10^{10} \text{ s}^{-1}$ ? (c) Would the radiations in part (a) or part (b) be detected by an X-ray detector? (d) What distance does electromagnetic radiation travel in 25.5 fs?
- 6.17 An argon ion laser emits light at 532 nm. What is the frequency of this radiation? Using Figure 6.4, predict the color associated with this wavelength.
- 6.18 It is possible to convert radiant energy into electrical energy using photovoltaic cells. Assuming equal efficiency of conversion, would infrared or ultraviolet radiation yield more electrical energy on a per-photon basis?

## Quantized Energy and Photons

- 6.19 If human height were quantized in one-foot increments, what would happen to the height of a child as she grows up?
- 6.20 Einstein's 1905 paper on the photoelectric effect was the first important application of Planck's quantum hypothesis. Describe Planck's original hypothesis, and explain how Einstein made use of it in his theory of the photoelectric effect.
- 6.21 (a) A red laser pointer emits light with a wavelength of 650 nm. What is the frequency of this light? (b) What is the energy of 1 mole of these photons? (c) The laser pointer emits light because electrons in the material are excited (by a battery) from their ground state to an upper excited state. When the electrons return to the ground state they lose the excess energy in the form of 650 nm photons. What is the energy gap between the ground state and excited state in the laser material?
- 6.22 If you put 120 volts of electricity through a pickle, the pickle will smoke and start glowing an orange-yellow color. The light is emitted because the sodium ions in the pickle become excited; their return to the ground state results in light emission (see Figure 6.13b and Sample Exercise 6.3). (a) The wavelength of this emitted light is 589 nm. Calculate its frequency. (b) What is the energy of 0.10 mole of these photons? (c) Calculate the energy gap between the excited and ground states for the sodium ion. (d) If you soaked the pickle for a long time in a different salt solution, such as strontium chloride, would you still observe 589 nm light emission? Why or why not?
- 6.23 (a) Calculate and compare the energy of a photon of wavelength  $3.3 \text{ }\mu\text{m}$  with that of wavelength 0.154 nm. (b) Use Figure 6.4 to identify the region of the electromagnetic spectrum to which each belongs.
- 6.24 An AM radio station broadcasts at 1010 kHz, and its FM partner broadcasts at 98.3 MHz. Calculate and compare the energy of the photons emitted by these two radio stations.
- 6.25 One type of sunburn occurs on exposure to UV light of wavelength in the vicinity of 325 nm. (a) What is the energy of a photon of this wavelength? (b) What is the energy of a mole of these photons? (c) How many photons are in a 1.00 mJ burst of this radiation? (d) These UV photons can break chemical bonds in your skin to cause sunburn—a form of radiation damage. If the 325-nm radiation provides exactly the energy to break an average chemical bond in the skin, estimate the average energy of these bonds in kJ/mol.
- 6.26 The energy from radiation can be used to cause the rupture of chemical bonds. A minimum energy of 941 kJ/mol is required to break the nitrogen–nitrogen bond in  $\text{N}_2$ . What is the longest wavelength of radiation that possesses the necessary energy to break the bond? What type of electromagnetic radiation is this?
- 6.27 A diode laser emits at a wavelength of 987 nm. (a) In what portion of the electromagnetic spectrum is this radiation found? (b) All of its output energy is absorbed in a detector that measures a total energy of 0.52 J over a period of 32 s. How many photons per second are being emitted by the laser?
- 6.28 A stellar object is emitting radiation at 3.55 mm. (a) What type of electromagnetic spectrum is this radiation? (b) If the detector is capturing  $3.2 \times 10^8$  photons per second at this wavelength, what is the total energy of the photons detected in one hour?
- 6.29 Molybdenum metal must absorb radiation with a minimum frequency of  $1.09 \times 10^{15} \text{ s}^{-1}$  before it can eject an electron from its surface via the photoelectric effect. (a) What is the minimum energy needed to eject an electron? (b) What wavelength of radiation will provide a photon of this energy? (c) If molybdenum is irradiated with light of wavelength of 120 nm, what is the maximum possible kinetic energy of the emitted electrons?
- 6.30 Sodium metal requires a photon with a minimum energy of  $4.41 \times 10^{-19} \text{ J}$  to emit electrons. (a) What is the minimum frequency of light necessary to emit electrons from sodium via the photoelectric effect? (b) What is the wavelength of this light? (c) If sodium is irradiated with light of 439 nm, what is the maximum possible kinetic energy of the emitted electrons? (d) What is the maximum number of electrons that can be freed by a burst of light whose total energy is  $1.00 \text{ }\mu\text{J}$ ?

## Bohr's Model; Matter Waves

- 6.31 Explain how the existence of line spectra is consistent with Bohr's theory of quantized energies for the electron in the hydrogen atom.
- 6.32 (a) In terms of the Bohr theory of the hydrogen atom, what process is occurring when excited hydrogen atoms emit radiant energy of certain wavelengths and only those wavelengths? (b) Does a hydrogen atom "expand" or "contract" as it moves from its ground state to an excited state?

- 6.33** Is energy emitted or absorbed when the following electronic transitions occur in hydrogen: (a) from  $n = 4$  to  $n = 2$ , (b) from an orbit of radius  $2.12 \text{ \AA}$  to one of radius  $8.46 \text{ \AA}$ , (c) an electron adds to the  $\text{H}^+$  ion and ends up in the  $n = 3$  shell?
- 6.34** Indicate whether energy is emitted or absorbed when the following electronic transitions occur in hydrogen: (a) from  $n = 2$  to  $n = 6$ , (b) from an orbit of radius  $4.76 \text{ \AA}$  to one of  $0.529 \text{ \AA}$ , (c) from the  $n = 6$  to the  $n = 9$  state.
- 6.35** (a) Using Equation 6.5, calculate the energy of an electron in the hydrogen atom when  $n = 2$  and when  $n = 6$ . Calculate the wavelength of the radiation released when an electron moves from  $n = 6$  to  $n = 2$ . Is this line in the visible region of the electromagnetic spectrum? If so, what color is it? (b) Calculate the energies of an electron in the hydrogen atom for  $n = 1$  and for  $n = (\infty)$ . How much energy does it require to move the electron out of the atom completely (from  $n = 1$  to  $n = \infty$ ), according to Bohr? Put your answer in kJ/mol. (c) The energy for the process  $\text{H} + \text{energy} \rightarrow \text{H}^+ + \text{e}^-$  is called the ionization energy of hydrogen. The experimentally determined value for the ionization energy of hydrogen is  $1310 \text{ kJ/mol}$ . How does this compare to your calculation?
- 6.36** For each of the following electronic transitions in the hydrogen atom, calculate the energy, frequency, and wavelength of the associated radiation, and determine whether the radiation is emitted or absorbed during the transition: (a) from  $n = 4$  to  $n = 1$ , (b) from  $n = 5$  to  $n = 2$ , (c) from  $n = 3$  to  $n = 6$ . Does any of these transitions emit or absorb visible light?
- 6.37** The visible emission lines observed by Balmer all involved  $n_f = 2$ . (a) Explain why only the lines with  $n_f = 2$  were observed in the visible region of the electromagnetic spectrum. (b) Calculate the wavelengths of the first three lines in the Balmer series—those for which  $n_i = 3, 4,$  and  $5$ —and identify these lines in the emission spectrum shown in Figure 6.13.
- 6.38** The Lyman series of emission lines of the hydrogen atom are those for which  $n_f = 1$ . (a) Determine the region of the electromagnetic spectrum in which the lines of the Lyman series are observed. (b) Calculate the wavelengths of the first three lines in the Lyman series—those for which  $n_i = 2, 3,$  and  $4$ .
- 6.39** One of the emission lines of the hydrogen atom has a wavelength of  $93.8 \text{ nm}$ . (a) In what region of the electromagnetic spectrum is this emission found? (b) Determine the initial and final values of  $n$  associated with this emission.
- 6.40** The hydrogen atom can absorb light of wavelength  $2626 \text{ nm}$ . (a) In what region of the electromagnetic spectrum is this absorption found? (b) Determine the initial and final values of  $n$  associated with this absorption.
- 6.41** Use the de Broglie relationship to determine the wavelengths of the following objects: (a) an  $85\text{-kg}$  person skiing at  $50 \text{ km/hr}$ , (b) a  $10.0\text{-g}$  bullet fired at  $250 \text{ m/s}$ , (c) a lithium atom moving at  $2.5 \times 10^5 \text{ m/s}$ , (d) an ozone ( $\text{O}_3$ ) molecule in the upper atmosphere moving at  $550 \text{ m/s}$ .
- 6.42** Among the elementary subatomic particles of physics is the muon, which decays within a few nanoseconds after formation. The muon has a rest mass  $206.8$  times that of an electron. Calculate the de Broglie wavelength associated with a muon traveling at a velocity of  $8.85 \times 10^9 \text{ cm/s}$ .
- 6.43** Neutron diffraction is an important technique for determining the structures of molecules. Calculate the velocity of a neutron needed to achieve a wavelength of  $0.955 \text{ \AA}$ . (Refer to the inside cover for the mass of the neutron).
- 6.44** The electron microscope has been widely used to obtain highly magnified images of biological and other types of materials. When an electron is accelerated through a particular potential field, it attains a speed of  $9.38 \times 10^6 \text{ m/s}$ . What is the characteristic wavelength of this electron? Is the wavelength comparable to the size of atoms?
- 6.45** Using Heisenberg's uncertainty principle, calculate the uncertainty in the position of (a) a  $1.50\text{-mg}$  mosquito moving at a speed of  $1.40 \text{ m/s}$  if the speed is known to within  $\pm 0.01 \text{ m/s}$ ; (b) a proton moving at a speed of  $(5.00 \pm 0.01) \times 10^4 \text{ m/s}$ . (The mass of a proton is given in the table of fundamental constants in the inside cover of the text.)
- 6.46** Calculate the uncertainty in the position of (a) an electron moving at a speed of  $(3.00 \pm 0.01) \times 10^5 \text{ m/s}$ , (b) a neutron moving at this same speed. (The masses of an electron and a neutron are given in the table of fundamental constants in the inside cover of the text.) (c) What are the implications of these calculations to our model of the atom?

## Quantum Mechanics and Atomic Orbitals

- 6.47** (a) Why does the Bohr model of the hydrogen atom violate the uncertainty principle? (b) In what way is the description of the electron using a wave function consistent with de Broglie's hypothesis? (c) What is meant by the term *probability density*? Given the wave function, how do we find the probability density at a certain point in space?
- 6.48** (a) According to the Bohr model, an electron in the ground state of a hydrogen atom orbits the nucleus at a specific radius of  $0.53 \text{ \AA}$ . In the quantum mechanical description of the hydrogen atom, the most probable distance of the electron from the nucleus is  $0.53 \text{ \AA}$ . Why are these two statements different? (b) Why is the use of Schrödinger's wave equation to describe the location of a particle very different from the description obtained from classical physics? (c) In the quantum mechanical description of an electron, what is the physical significance of the square of the wave function,  $\psi^2$ ?

- 6.49 (a) For  $n = 4$ , what are the possible values of  $l$ ? (b) For  $l = 2$ , what are the possible values of  $m_l$ ? (c) If  $m_l$  is 2, what are the possible values for  $l$ ?
- 6.50 How many possible values for  $l$  and  $m_l$  are there when (a)  $n = 3$ ; (b)  $n = 5$ ?
- 6.51 Give the numerical values of  $n$  and  $l$  corresponding to each of the following orbital designations: (a)  $3p$ , (b)  $2s$ , (c)  $4f$ , (d)  $5d$ .
- 6.52 Give the values for  $n$ ,  $l$ , and  $m_l$  for (a) each orbital in the  $2p$  subshell, (b) each orbital in the  $5d$  subshell.
- 6.53 Which of the following represent impossible combinations of  $n$  and  $l$ : (a)  $1p$ , (b)  $4s$ , (c)  $5f$ , (d)  $2d$ ?
- 6.54 For the table below, write which orbital goes with the quantum numbers. Don't worry about  $x$ ,  $y$ ,  $z$  subscripts. If the quantum numbers are not allowed, write "not allowed."

$n$	$l$	$m_l$	Orbital
2	1	-1	$2p$ (example)
1	0	0	
3	-3	2	
3	2	-2	
2	0	-1	
0	0	0	
4	2	1	
5	3	0	

- 6.55 Sketch the shape and orientation of the following types of orbitals: (a)  $s$ , (b)  $p_z$ , (c)  $d_{xy}$ .
- 6.56 Sketch the shape and orientation of the following types of orbitals: (a)  $p_x$ , (b)  $d_{z^2}$ , (c)  $d_{x^2-y^2}$ .
- 6.57 (a) What are the similarities and differences between the  $1s$  and  $2s$  orbitals of the hydrogen atom? (b) In what sense does a  $2p$  orbital have directional character? Compare the "directional" characteristics of the  $p_x$  and  $d_{x^2-y^2}$  orbitals (that is, in what direction or region of space is the electron density concentrated?). (c) What can you say about the average distance from the nucleus of an electron in a  $2s$  orbital as compared with a  $3s$  orbital? (d) For the hydrogen atom, list the following orbitals in order of increasing energy (that is, most stable ones first):  $4f$ ,  $6s$ ,  $3d$ ,  $1s$ ,  $2p$ .
- 6.58 (a) With reference to Figure 6.19, what is the relationship between the number of nodes in an  $s$  orbital and the value of the principal quantum number? (b) Identify the number of nodes; that is, identify places where the electron density is zero, in the  $2p_x$  orbital; in the  $3s$  orbital. (c) What information is obtained from the radial probability functions in Figure 6.19? (d) For the hydrogen atom, list the following orbitals in order of increasing energy:  $3s$ ,  $2s$ ,  $2p$ ,  $5s$ ,  $4d$ .

## Many-Electron Atoms and Electron Configurations

- 6.59 For a given value of the principal quantum number,  $n$ , how do the energies of the  $s$ ,  $p$ ,  $d$ , and  $f$  subshells vary for (a) hydrogen, (b) a many-electron atom?
- 6.60 (a) The average distance from the nucleus of a  $3s$  electron in a chlorine atom is smaller than that for a  $3p$  electron. In light of this fact, which orbital is higher in energy? (b) Would you expect it to require more or less energy to remove a  $3s$  electron from the chlorine atom, as compared with a  $2p$  electron? Explain.
- 6.61 (a) What experimental evidence is there for the electron having a "spin"? (b) Draw an energy-level diagram that shows the relative energetic positions of a  $1s$  orbital and a  $2s$  orbital. Put two electrons in the  $1s$  orbital. (c) Draw an arrow showing the excitation of an electron from the  $1s$  to the  $2s$  orbital.
- 6.62 (a) State the Pauli exclusion principle in your own words. (b) The Pauli exclusion principle is, in an important sense, the key to understanding the periodic table. Explain why.
- 6.63 What is the maximum number of electrons that can occupy each of the following subshells: (a)  $3p$ , (b)  $5d$ , (c)  $2s$ , (d)  $4f$ ?
- 6.64 What is the maximum number of electrons in an atom that can have the following quantum numbers: (a)  $n = 2$ ,  $m_s = -\frac{1}{2}$ , (b)  $n = 5$ ,  $l = 3$ ; (c)  $n = 4$ ,  $l = 3$ ,  $m_l = -3$ ; (d)  $n = 4$ ,  $l = 1$ ,  $m_l = 1$ ?
- 6.65 (a) What are "valence electrons"? (b) What are "core electrons"? (c) What does each box in an orbital diagram represent? (d) What quantity is represented by the direction (up or down) of the half-arrows in an orbital diagram?
- 6.66 For each element, count the number of valence electrons, core electrons, and unpaired electrons in the ground state: (a) carbon, (b) phosphorus, (c) neon.
- 6.67 Write the condensed electron configurations for the following atoms, using the appropriate noble-gas core abbreviations: (a) Cs, (b) Ni, (c) Se, (d) Cd, (e) U, (f) Pb.
- 6.68 Write the condensed electron configurations for the following atoms, and indicate how many unpaired electrons each has: (a) Ga, (b) Ca, (c) V, (d) I, (e) Y, (f) Pt, (g) Lu.
- 6.69 Ions also have electron configurations (Section 7.4). Cations have fewer valence electrons, and anions have more valence electrons, respectively, than their parent atoms. For example, chloride,  $\text{Cl}^-$ , has an electron configuration of  $1s^2 2s^2 2p^6 3s^2 3p^6$ , for a total of 18 electrons, compared to 17 for neutral chlorine, the element. Na has an electron configuration of  $1s^2 2s^2 2p^6 3s^1$ , but  $\text{Na}^+$  has an electron configuration of  $1s^2 2s^2 2p^6$ . Write out the electron configurations for (a)  $\text{F}^-$ , (b)  $\Gamma$ , (c)  $\text{O}^{2-}$ , (d)  $\text{K}^+$ , (e)  $\text{Mg}^{2+}$ , (f)  $\text{Al}^{3+}$ .

- 6.70 In the transition metals (the  $d$ -block), the electron configuration of cations is different than what you might expect. Instead of the  $d$  electrons being lost first,  $s$  electrons are lost first. For example, the electron configuration of iron, Fe, is  $[\text{Ar}]4s^23d^6$ ; but the electron configuration of  $\text{Fe}^{2+}$  is  $[\text{Ar}]3d^6$ ; the  $4s$  electrons are eliminated to make the cation. Write out the electron configurations of (a)  $\text{Zn}^{2+}$  (b)  $\text{Pt}^{2+}$  (c)  $\text{Cr}^{3+}$  (d)  $\text{Ti}^{4+}$ .
- 6.71 Identify the specific element that corresponds to each of the following electron configurations: (a)  $1s^22s^2$ , (b)  $1s^22s^22p^4$ , (c)  $[\text{Ar}]4s^13d^5$ , (d)  $[\text{Kr}]5s^24d^{10}5p^4$ , (e)  $1s^1$ .

## ADDITIONAL EXERCISES

- 6.75 Consider the two waveshown here, which we will consider to represent two electromagnetic radiations:
- What is the wavelength of wave A? Of wave B?
  - What is the frequency of wave A? Of wave B?
  - Identify the regions of the electromagnetic spectrum to which waves A and B belong.

- 6.76 Certain elements emit light of a specific wavelength when they are burned. Historically, chemists used such emission wavelengths to determine whether specific elements were present in a sample. Some characteristic wavelengths for some of the elements are
- |    |          |    |          |
|----|----------|----|----------|
| Ag | 328.1 nm | Fe | 372.0 nm |
| Au | 267.6 nm | K  | 404.7 nm |
| Ba | 455.4 nm | Mg | 285.2 nm |
| Ca | 422.7 nm | Na | 589.6 nm |
| Cu | 324.8 nm | Ni | 341.5 nm |
- Determine which elements emit radiation in the visible part of the spectrum. (b) Which element emits photons of highest energy? Of lowest energy? (c) When burned, a sample of an unknown substance is found to emit light of frequency  $6.59 \times 10^{14} \text{ s}^{-1}$ . Which of these elements is probably in the sample?
- 6.77 In June 2004, the Cassini–Huygens spacecraft began orbiting Saturn and transmitting images to Earth. The closest distance between Saturn and Earth is 746 million miles. What is the minimum amount of time it takes for the transmitted signals to travel from the spacecraft to Earth?
- 6.78 The rays of the Sun that cause tanning and burning are in the ultraviolet portion of the electromagnetic spectrum. These rays are categorized by wavelength. So-called UV-A radiation has wavelengths in the range of 320–380 nm, whereas UV-B radiation has wavelengths in the range of 290–320 nm. (a) Calculate the frequency of light that has a wavelength of 320 nm. (b) Calculate

- 6.72 Identify the group of elements that corresponds to each of the following generalized electron configurations:
- [noble gas]  $ns^2np^5$
  - [noble gas]  $ns^2(n-1)d^2$
  - [noble gas]  $ns^2(n-1)d^{10}np^1$
  - [noble gas]  $ns^2(n-2)f^6$
- 6.73 What is wrong with the following electron configurations for atoms in their ground states? (a)  $1s^22s^23s^1$ , (b)  $[\text{Ne}]2s^22p^3$ , (c)  $[\text{Ne}]3s^23d^5$ .
- 6.74 The following electron configurations represent excited states. Identify the element, and write its ground-state condensed electron configuration. (a)  $1s^22s^23p^24p^1$ , (b)  $[\text{Ar}]3d^{10}4s^14p^45s^1$ , (c)  $[\text{Kr}]4d^65s^25p^1$ .

the energy of a mole of 320-nm photons. (c) Which are more energetic, photons of UV-A radiation or photons of UV-B radiation? (d) The UV-B radiation from the Sun is considered a greater cause of sunburn in humans than is UV-A radiation. Is this observation consistent with your answer to part (c)?

- 6.79 The watt is the derived SI unit of power, the measure of energy per unit time:  $1 \text{ W} = 1 \text{ J/s}$ . A semiconductor laser in a CD player has an output wavelength of 780 nm and a power level of 0.10 mW. How many photons strike the CD surface during the playing of a CD 69 minutes in length?
- 6.80 The color wheel (Figure 24.24) is a convenient way to relate what colors of light are absorbed by a sample and the visible appearance of the sample. If all visible colors are absorbed by a sample, the sample appears black. If no colors are absorbed by the sample, the sample appears white. If the sample absorbs red, then what we see is green; such *complementary colors* are across the wheel from each other. Carrots appear orange because they contain a compound called carotene. Based on the color wheel, what is the possible wavelength range for the light absorbed by carotene?
- 6.81 A photocell, such as the one illustrated in Figure 6.8(b), is a device used to measure the intensity of light. In a certain experiment, when light of wavelength 630 nm is directed onto the photocell, electrons are emitted at the rate of  $2.6 \times 10^{-12} \text{ Coulombs/sec}$ . Assume that each photon that impinges on the photocell emits one electron. How many photons per second are striking the photocell? How much energy per second is the photocell absorbing?
- 6.82 The light-sensitive substance in black-and-white photographic film is AgBr. Photons provide the energy necessary to transfer an electron from  $\text{Br}^-$  to  $\text{Ag}^+$  to produce elemental Ag and Br and thereby darken the film. (a) If a minimum energy of  $2.00 \times 10^5 \text{ J/mol}$  is needed for this process, what is the minimum energy needed from each photon? (b) Calculate the wavelength of the light necessary to provide photons of this energy. (c) Explain why this film can be handled in a darkroom under red light.
- 6.83 In an experiment to study the photoelectric effect, a scientist measures the kinetic energy of ejected electrons as a function of the frequency of radiation hitting a metal surface. She obtains the following plot: The point labeled “ $\nu_0$ ” corresponds to light with a wavelength of 680 nm.

(a) What is the value of  $\nu_0$  in  $s^{-1}$ ? (b) What is the value of the work function of the metal in units of kJ/mol of ejected electrons? (c) What happens when the metal is irradiated with light of frequency less than  $\nu_0$ ? (d) Note that when the frequency of the light is greater than  $\nu_0$ , the plot shows a straight line with a nonzero slope. Why is this the case? (e) Can you determine the slope of the line segment discussed in part (d)? Explain.

**6.84** The series of emission lines of the hydrogen atom for which  $n_f = 3$  is called the *Paschen series*. (a) Determine the region of the electromagnetic spectrum in which the lines of the Paschen series are observed. (b) Calculate the wavelengths of the first three lines in the Paschen series—those for which  $n_i = 4, 5, \text{ and } 6$ .

**6.85** When the spectrum of light from the Sun is examined in high resolution in an experiment similar to that illustrated in Figure 6.11, dark lines are evident. These are called Fraunhofer lines, after the scientist who studied them extensively in the early nineteenth century. Altogether, about 25,000 lines have been identified in the solar spectrum between 2950 Å and 10,000 Å. The Fraunhofer lines are attributed to absorption of certain wavelengths of the Sun's "white" light by gaseous elements in the Sun's atmosphere. (a) Describe the process that causes absorption of specific wavelengths of light from the solar spectrum. (b) If a scientist wanted to know which Fraunhofer lines belonged to a given element, say neon, what experiments could she conduct here on Earth to provide data?

**[6.86]** Bohr's model can be used for hydrogen-like ions—ions that have only one electron, such as  $\text{He}^+$  and  $\text{Li}^{2+}$ . (a) Why is the Bohr model applicable to  $\text{He}^+$  ions but not to neutral He atoms? (b) The ground-state energies of H,  $\text{He}^+$ , and  $\text{Li}^{2+}$  are tabulated as follows:

Atom or ion	H	$\text{He}^+$	$\text{Li}^{2+}$
Ground-state energy	$-2.18 \times 10^{-18} \text{ J}$	$-8.72 \times 10^{-18} \text{ J}$	$-1.96 \times 10^{-17} \text{ J}$

By examining these numbers, propose a relationship between the ground-state energy of hydrogen-like systems and the nuclear charge,  $Z$ . (c) Use the relationship you derive in part (b) to predict the ground-state energy of the  $\text{C}^{5+}$  ion.

**6.87** Under appropriate conditions, molybdenum emits X-rays that have a characteristic wavelength of 0.711 Å. These X-rays are used in diffraction experiments to determine the structures of molecules. (a) Why are X-rays,

and not visible light, suitable for the determination of structure at the atomic level? (b) How fast would an electron have to be moving to have the same wavelength as these X-rays?

**[6.88]** An electron is accelerated through an electric potential to a kinetic energy of 18.6 keV. What is its characteristic wavelength? [Hint: Recall that the kinetic energy of a moving object is  $E = \frac{1}{2}mv^2$ , where  $m$  is the mass of the object and  $v$  is the speed of the object.]

**6.89** In the television series *Star Trek*, the transporter beam is a device used to "beam down" people from the *Starship Enterprise* to another location, such as the surface of a planet. The writers of the show put a "Heisenberg compensator" into the transporter beam mechanism. Explain why such a compensator would be necessary to get around Heisenberg's uncertainty principle.

**6.90** Which of the quantum numbers governs (a) the shape of an orbital, (b) the energy of an orbital, (c) the spin properties of the electron, (d) the spatial orientation of the orbital?

**[6.91]** Consider the discussion of radial probability functions in the "A Closer Look" box in Section 6.6. (a) What is the difference between the probability density as a function of  $r$  and the radial probability function as a function of  $r$ ? (b) What is the significance of the term  $4\pi r^2$  in the radial probability functions for the  $s$  orbitals? (c) Based on Figures 6.19 and 6.22, make sketches of what you think the probability density as a function of  $r$  and the radial probability function would look like for the 4s orbital of the hydrogen atom.

**6.92** The "magic numbers" in the periodic table are the atomic numbers of elements with high stability (the noble gases): 2, 10, 18, 36, 54, and 86. In terms of allowed values of orbitals and spin quantum numbers, explain why these electron arrangements correspond to special stability.

**[6.93]** For non-spherically symmetric orbitals, the contour representations (as in Figures 6.23 and 6.24) suggest where nodal planes exist (that is, where the electron density is zero). For example, the  $p_x$  orbital has a node wherever  $x = 0$ . This equation is satisfied by all points on the  $yz$  plane, so this plane is called a nodal plane of the  $p_x$  orbital. (a) Determine the nodal plane of the  $p_z$  orbital. (b) What are the two nodal planes of the  $d_{xy}$  orbital? (c) What are the two nodal planes of the  $d_{x^2-y^2}$  orbital?

**[6.94]** As noted in Figure 6.26, the spin of an electron generates a magnetic field, with spin-up and spin-down electrons having opposite fields. In the absence of a magnetic field, a spin-up and a spin-down electron have the same energy. (a) Why do you think that the use of a magnet was important in the discovery of electron spin (see the "A Closer Look" box in Section 6.8)? (b) Imagine that the two spinning electrons in Figure 6.26 were placed between the poles of a horseshoe magnet, with the north pole of the magnet at the top of the figure. Based on what you know about magnets, would you expect the left or right electron in the figure to have the lower energy? (c) A phenomenon called *electron spin resonance* (ESR) is closely related to nuclear magnetic resonance. In ESR a compound with an unpaired electron is placed in a magnetic field, which causes the unpaired electron to have two different energy states analogous to Figure 6.28.

ESR uses microwave radiation to excite the unpaired electron from one state to the other. Based on your reading of the "Chemistry and Life" box in Section 6.8, does an ESR experiment require photons of greater or lesser energy than an NMR experiment?

- [6.95] The "Chemistry and Life" box in Section 6.8 described the techniques called NMR and MRI. (a) Instruments for obtaining MRI data are typically labeled with a frequency, such as 600 MHz. Why do you suppose this label is relevant to the experiment? (b) What is the value of  $\Delta E$  in Figure 6.28 that would correspond to the absorption of a photon of radiation with frequency 450 MHz? (c) In general, the stronger the magnetic field, the greater the

information obtained from an NMR or MRI experiment. Why do you suppose this is the case?

- 6.96 Suppose that the spin quantum number,  $m_s$ , could have three allowed values instead of two. How would this affect the number of elements in the first four rows of the periodic table?
- 6.97 Using only a periodic table as a guide, write the condensed electron configurations for the following atoms: (a) Se, (b) Rh, (c) Si, (d) Hg, (e) Hf.
- 6.98 Scientists have speculated that element 126 might have a moderate stability, allowing it to be synthesized and characterized. Predict what the condensed electron configuration of this element might be.

## INTEGRATIVE EXERCISES

- 6.99 Microwave ovens use microwave radiation to heat food. The energy of the microwaves is absorbed by water molecules in food, then transferred to other components of the food. (a) Suppose that the microwave radiation has a wavelength of 11.2 cm. How many photons are required to heat 200 mL of coffee from 23 °C to 60 °C? (b) Suppose the microwave's power is 900 W (1 Watt = 1 Joule/sec). How long would you have to heat the coffee in part (a)?
- 6.100 The stratospheric ozone ( $O_3$ ) layer helps to protect us from harmful ultraviolet radiation. It does so by absorbing ultraviolet light and falling apart into an  $O_2$  molecule and an oxygen atom, a process known as photodissociation.

Use the data in Appendix C to calculate the enthalpy change for this reaction. What is the maximum wavelength a photon can have if it is to possess sufficient energy to cause this dissociation? In what portion of the spectrum does this wavelength occur?

- 6.101 The discovery of hafnium, element number 72, provided a controversial episode in chemistry. G. Urbain, a French chemist, claimed in 1911 to have isolated an element number 72 from a sample of rare earth (elements 58–71) compounds. However, Niels Bohr believed that hafnium was more likely to be found along with zirconium than with the rare earths. D. Coster and G. von Hevesy, working in Bohr's laboratory in Copenhagen, showed in 1922 that element 72 was present in a sample of Norwegian zircon, an ore of zirconium. (The name hafnium comes from the Latin name for Copenhagen, *Hafnia*.) (a) How would you use electron configuration arguments to justify Bohr's prediction? (b) Zirconium, hafnium's neighbor in group 4B, can be produced as a metal by reduction of solid  $ZrCl_4$  with molten sodium metal. Write a balanced chemical equation for the reaction. Is this an oxidation-reduction reaction? If yes, what is reduced and what is oxidized? (c) Solid zirconium dioxide,  $ZrO_2$ , is reacted with chlorine gas in the presence of carbon. The products of the reaction are  $ZrCl_4$  and two gases,  $CO_2$  and CO in the ratio 1 : 2. Write a balanced chemical equation for the reaction. Starting with a 55.4-g sample of  $ZrO_2$ , calculate the mass of  $ZrCl_4$  formed, assuming that  $ZrO_2$  is the limiting reagent and assuming 100% yield. (d) Using their electron configurations, account for the fact that Zr and Hf form chlorides  $MCl_4$  and oxides  $MO_2$ .

- 6.102 (a) Account for formation of the following series of oxides in terms of the electron configurations of the elements and the discussion of ionic compounds in Section 2.7:  $K_2O$ ,  $CaO$ ,  $Sc_2O_3$ ,  $TiO_2$ ,  $V_2O_5$ ,  $CrO_3$ . (b) Name these oxides. (c) Consider the metal oxides whose enthalpies of formation (in  $\text{kJ mol}^{-1}$ ) are listed here.

Oxide	$K_2O(s)$	$CaO(s)$	$TiO_2(s)$	$V_2O_5(s)$
$\Delta H_f^\circ$	-363.2	-635.1	-938.7	-1550.6

Calculate the enthalpy changes in the following general reaction for each case:

(You will need to write the balanced equation for each case, then compute  $\Delta H^\circ$ .) (d) Based on the data given, estimate a value of  $\Delta H_f^\circ$  for  $Sc_2O_3(s)$ .

- 6.103 The first 25 years of the twentieth century were momentous for the rapid pace of change in scientists' understanding of the nature of matter. (a) How did Rutherford's experiments on the scattering of  $\alpha$  particles by a gold foil set the stage for Bohr's theory of the hydrogen atom? (b) In what ways is de Broglie's hypothesis, as it applies to electrons, consistent with J. J. Thomson's conclusion that the electron has mass? In what sense is it consistent with proposals that preceded Thomson's work, that the cathode rays are a wave phenomenon?
- [6.104] The two most common isotopes of uranium are  $^{235}\text{U}$  and  $^{238}\text{U}$ . (a) Compare the number of protons, the number of electrons, and the number of neutrons in atoms of these two isotopes. (b) Using the periodic table in the front inside cover, write the electron configuration for a U atom. (c) Compare your answer to part (b) to the electron configuration given in Figure 6.31. How can you explain any differences between these two electron configurations? (d)  $^{238}\text{U}$  undergoes radioactive decay to  $^{234}\text{Th}$ . How many protons, electrons, and neutrons are gained or lost by the  $^{238}\text{U}$  atom during this process? (e) Examine the electron configuration for Th in Figure 6.31. Are you surprised by what you find? Explain.
- 6.105 Imagine sunlight falling on three square areas. One is an inert black material. The second is a photovoltaic cell surface, which converts radiant energy into electricity. The third is an area on a green tree leaf. Draw diagrams that show the energy conversions in each case, using Figure 5.9 as a model. How are these three examples related to the idea of sustainable energy sources?

CHAPTER  
7

## PERIODIC PROPERTIES OF THE ELEMENTS

**OIL PAINTS CONTAIN PIGMENTS,** which are usually highly colored salts, suspended in an organic carrier composed of a variety of heavy hydrocarbon molecules. This painting, by the famous French Impressionist Claude Monet (1840–1926), is entitled *La rue Montorgueil, fête du 30 juin 1878*.

Photo credit: Claude Monet (1840–1926) "Rue Montorgueil in Paris, Festival of 30 June 1878," 1878. Herve Lewandowski/Reunion des Muses Nationaux/Art Resource, NY.

## WHAT'S AHEAD

---

### 7.1 Development of the Periodic Table

We begin our discussion with a brief history of the periodic table.

### 7.2 Effective Nuclear Charge

We next explore the many properties of atoms that depend both on the net attraction of the outer electrons to the nucleus and on the average distance of those electrons from the nucleus. The net positive charge of the nucleus experienced by the outer electrons is called the *effective nuclear charge*.

### 7.3 Sizes of Atoms and Ions

We explore the relative sizes (or radii) of atoms and ions, both of which follow trends that are related to their placement in the periodic table.

### 7.4 Ionization Energy

We next encounter the energy—called ionization energy—required to remove one or more electrons from an atom. The periodic trends in ionization energy depend upon variations in effective nuclear charge and atomic radii.

### 7.5 Electron Affinities

Next we will examine periodic trends in the energy released when an electron is added to an atom.

### 7.6 Metals, Nonmetals, and Metalloids

We recognize that the physical and chemical properties of metals and nonmetals are distinctly different and can be understood from the fundamental characteristics of atoms discussed earlier in the chapter, particularly ionization energy. Metalloids display properties that are intermediate between metals and nonmetals.

### 7.7 Group Trends for the Active Metals

We examine some periodic trends in the chemistry of the active metals (groups 1A and 2A).

### 7.8 Group Trends for Selected Nonmetals

We examine some periodic trends in the chemistry of hydrogen, as well as groups 6A, 7A, and 8A.

**THE BEAUTY OF AN IMPRESSIONIST OIL PAINTING**, such as the Monet masterpiece shown here, begins with chemistry. Colorful inorganic salts are suspended in various organic media that contain hydrocarbons and other molecular substances. Indeed, the great painters

had a gift for using compounds of elements that span nearly the entire periodic table.

Today the periodic table is still the most significant tool chemists have for organizing and remembering chemical facts. As we saw in Chapter 6, the periodic nature of the table arises from the repeating patterns in the electron configurations of the elements. Elements in the same column of the table contain the same number of electrons in their **valence orbitals**, the occupied orbitals that hold the electrons involved in bonding. For example, O ( $[\text{He}]2s^2 2p^4$ ) and S ( $[\text{Ne}]3s^2 3p^4$ ) are both members of group 6A. The similarity of the electron distribution in their valence *s* and *p* orbitals leads to similarities in the properties of these two elements.

When we compare O and S, however, it is apparent that they exhibit differences as well, not the least of which is that oxygen is a colorless gas at room

**▲ Figure 7.1 Oxygen and sulfur.** Because they are both group 6A elements, oxygen and sulfur have many chemical similarities. They also have many differences, however, including the forms they take at room temperature. Oxygen consists of  $O_2$  molecules that appear as a colorless gas (shown here enclosed in a glass container on the left). In contrast, sulfur consists of  $S_8$  molecules that form a yellow solid.

temperature, whereas sulfur is a yellow solid (Figure 7.1 ◀)! One of the major differences between atoms of these two elements is their electron configurations: the outermost electrons of O are in the second shell, whereas those of S are in the third shell. We will see that electron configurations can be used to explain differences as well as similarities in the properties of elements.

In this chapter we explore how some of the important properties of elements change as we move across a row or down a column of the periodic table. In many cases the trends within a row or column allow us to make predictions about the physical and chemical properties of the elements.

## 7.1 DEVELOPMENT OF THE PERIODIC TABLE

The discovery of the chemical elements has been an ongoing process since ancient times (Figure 7.2 ▼). Certain elements, such as gold, appear in nature in elemental form and were thus discovered thousands of years ago. In contrast, some elements, such as technetium, are radioactive and intrinsically unstable. We know about them only because of technology developed during the twentieth century.

The majority of the elements, although stable, readily form compounds. Consequently, they are not found in nature in their elemental form. For centuries, therefore, scientists were unaware of their existence. During the early nineteenth century, advances in chemistry made it easier to isolate elements from their compounds. As a result, the number of known elements more than doubled from 31 in 1800 to 63 by 1865.

As the number of known elements increased, scientists began to investigate the possibilities of classifying them in useful ways. In 1869, Dmitri Mendeleev in Russia and Lothar Meyer in Germany published nearly identical classification schemes. Both scientists noted that similar chemical and physical properties recur periodically when the elements are arranged in order of increasing atomic weight. Scientists at that time had no knowledge of atomic numbers. Atomic weights, however, generally increase with increasing atomic number, so both Mendeleev and Meyer fortuitously arranged the elements in proper sequence. The tables of elements advanced by Mendeleev and Meyer were the forerunners of the modern periodic table.

Although Mendeleev and Meyer came to essentially the same conclusion about the periodicity of elemental properties, Mendeleev is given credit for advancing his ideas more vigorously and stimulating much new work in chemistry.

**TABLE 7.1** ■ Comparison of the Properties of Eka-Silicon Predicted by Mendeleev with the Observed Properties of Germanium

Property	Mendeleev's Predictions for Eka-Silicon (made in 1871)	Observed Properties of Germanium (discovered in 1886)
Atomic weight	72	72.59
Density (g/cm <sup>3</sup> )	5.5	5.35
Specific heat (J/g·K)	0.305	0.309
Melting point (°C)	High	947
Color	Dark gray	Grayish white
Formula of oxide	XO <sub>2</sub>	GeO <sub>2</sub>
Density of oxide (g/cm <sup>3</sup> )	4.7	4.70
Formula of chloride	XCl <sub>4</sub>	GeCl <sub>4</sub>
Boiling point of chloride (°C)	A little under 100	84

His insistence that elements with similar characteristics be listed in the same family forced him to leave several blank spaces in his table. For example, both gallium (Ga) and germanium (Ge) were unknown at that time. Mendeleev boldly predicted their existence and properties, referring to them as *eka-aluminum* ("under" aluminum) and *eka-silicon* ("under" silicon), respectively, after the elements under which they appear in the periodic table. When these elements were discovered, their properties closely matched those predicted by Mendeleev, as shown in Table 7.1 ▲.

In 1913, two years after Rutherford proposed the nuclear model of the atom (Section 2.2), an English physicist named Henry Moseley (1887–1915) developed the concept of atomic numbers. Moseley determined the frequencies of X-rays emitted as different elements were bombarded with high-energy electrons. He found that each element produces X-rays of a unique frequency; furthermore, he found that the frequency generally increased as the atomic mass increased. He arranged the X-ray frequencies in order by assigning a unique whole number, called an *atomic number*, to each element. Moseley correctly identified the atomic number as the number of protons in the nucleus of the atom. (Section 2.3)

The concept of atomic number clarified some problems in the periodic table of Moseley's day, which was based on atomic weights. For example, the atomic weight of Ar (atomic number 18) is greater than that of K (atomic number 19), yet the chemical and physical properties of Ar are much more like that of Ne and Kr than they are like Na and Rb. However, when the elements are arranged in order of increasing atomic number, rather than increasing atomic weight, Ar and K appear in their correct places in the table. Moseley's studies also made it possible to identify "holes" in the periodic table, which led to the discovery of other previously unknown elements.

### GIVE IT SOME THOUGHT

Arranging the elements by atomic weight leads to a slightly different order than arranging them by atomic number. Why does this happen? Can you find an example, other than the case of Ar and K discussed above, where the order of the elements would be different if the elements were arranged in order of increasing atomic weight?

## 7.2 EFFECTIVE NUCLEAR CHARGE

Because electrons are negatively charged, they are attracted to nuclei, which are positively charged. Many of the properties of atoms depend on their electron configurations and on how strongly their outer electrons are attracted to the nucleus. Coulomb's law tells us that the strength of the interaction

between two electrical charges depends on the magnitudes of the charges and on the distance between them.  $\infty$  (Section 2.3) Thus, the force of attraction between an electron and the nucleus depends on the magnitude of the net nuclear charge acting on the electron and on the average distance between the nucleus and the electron. The force of attraction increases as the nuclear charge increases, and it decreases as the electron moves farther from the nucleus.

In a many-electron atom, each electron is simultaneously attracted to the nucleus and repelled by the other electrons. In general, there are so many electron–electron repulsions that we cannot analyze the situation exactly. We can, however, estimate the net attraction of each electron to the nucleus by considering how it interacts with the *average* environment created by the nucleus and the other electrons in the atom. This approach allows us to treat each electron individually as though it were moving in the net electric field created by the nucleus and the electron density of the other electrons. We can view this net electric field as if it results from a single positive charge located at the nucleus, called the **effective nuclear charge**,  $Z_{\text{eff}}$ .

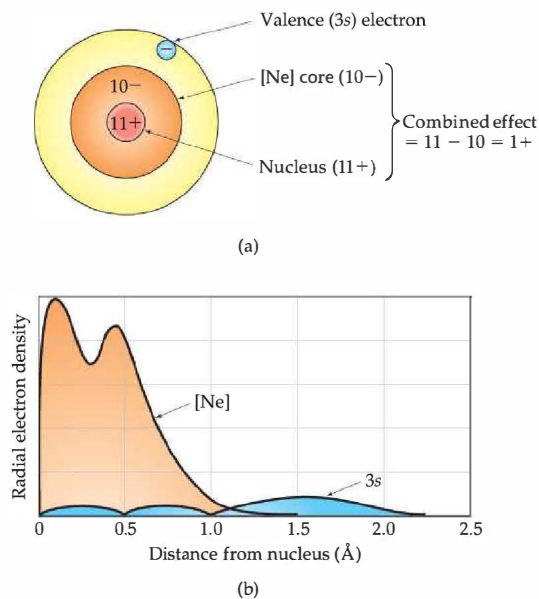

It is important to realize that the effective nuclear charge acting on an electron in an atom is smaller than the *actual* nuclear charge because the effective nuclear charge also accounts for the repulsion of the electron by the other electrons in the atom—in other words,  $Z_{\text{eff}} < Z$ . Let's consider how we can get a sense of the magnitude of  $Z_{\text{eff}}$  for an electron in an atom.

A valence electron in an atom is attracted to the nucleus of the atom and is repelled by the other electrons in the atom. In particular, the electron density that is due to the inner (core) electrons is particularly effective at partially canceling the attraction of the valence electron to the nucleus. We say that the inner electrons partially *shield* or *screen* the outer electrons from the attraction of the nucleus. We can therefore write a simple relationship between the effective nuclear charge,  $Z_{\text{eff}}$ , and the number of protons in the nucleus,  $Z$ :

$$Z_{\text{eff}} = Z - S \quad [7.1]$$

The factor  $S$  is a positive number called the *screening constant*. It represents the portion of the nuclear charge that is screened from the valence electron by the other electrons in the atom. Because the core electrons are most effective at screening a valence electron from the nucleus, *the value of  $S$  is usually close to the number of core electrons in an atom*. Electrons in the same valence shell do not screen one another very effectively, but they do affect the value of  $S$  slightly (see “A Closer Look” on Effective Nuclear Charge). Let's take a look at a Na atom to see what we would expect for the magnitude of  $Z_{\text{eff}}$ . Sodium (atomic number 11) has a condensed electron configuration of  $[\text{Ne}]3s^1$ . The nuclear charge of the atom is  $11+$ , and the Ne inner core consists of ten electrons ( $1s^2 2s^2 2p^6$ ). Very roughly then, we would expect the  $3s$  valence electron of the Na atom to experience an effective nuclear charge of about  $11 - 10 = 1+$ , as pictured in a simplified way in Figure 7.3(a)  $\blacktriangleleft$ . The situation is a bit more complicated because of the electron distributions of atomic orbitals.  $\infty$  (Section 6.6) Recall that a  $3s$  electron has a small probability of being found close to the nucleus and inside the core electrons, as shown in Figure 7.3(b). Thus, there is a probability that the  $3s$  electron will experience a greater attraction than our simple model suggests, which will increase the value of  $Z_{\text{eff}}$  somewhat. Indeed, the value of  $Z_{\text{eff}}$  obtained from detailed calculations indicate that the effective nuclear charge acting on the  $3s$  electron in Na is  $2.5+$ .

**▼ Figure 7.3 Effective nuclear charge.** (a) The effective nuclear charge experienced by the valence electron in sodium depends mostly on the  $11+$  charge of the nucleus and the  $10-$  charge of the neon core. If the neon core were totally effective in shielding the valence electron from the nucleus, then the valence electron would experience an effective nuclear charge of  $1+$ . (b) The  $3s$  electron has some probability of being inside the Ne core. Because of this “penetration,” the core is not completely effective in screening the  $3s$  electron from the nucleus. Thus, the effective nuclear charge experienced by the  $3s$  electron is somewhat greater than  $1+$ .

The notion of effective nuclear charge also explains an important effect we noted in Section 6.7, namely, that for a many-electron atom the energies of orbitals with the same  $n$  value increase with increasing  $l$  value. For example, consider a carbon atom, for which the electron configuration is  $1s^2 2s^2 2p^2$ . The energy of the  $2p$  orbital ( $l = 1$ ) is somewhat higher than that of the  $2s$  orbital ( $l = 0$ ) even though both of these orbitals are in the  $n = 2$  shell (Figure 6.25). The reason that these orbitals have different energy in a many-electron atom is due to the radial probability functions for the orbitals, shown in Figure 7.4. Notice that the  $2s$  probability function has a small peak fairly close to the nucleus, whereas the  $2p$  probability function does not. As a result, an electron in the  $2s$  orbital is less effectively screened by the core orbitals than is an electron in the  $2p$  orbital. In other words, the electron in the  $2s$  orbital experiences a higher effective nuclear charge than one in the  $2p$  orbital. The greater attraction between the  $2s$  electron and the nucleus leads to a lower energy for the  $2s$  orbital than for the  $2p$  orbital. The same reasoning explains the general trend in orbital energies ( $ns < np < nd$ ) in many-electron atoms.

Finally, let's examine the trends in  $Z_{\text{eff}}$  for valence electrons as we move from one element to another in the periodic table. The effective nuclear charge increases as we move across any row (period) of the table. Although the number of core electrons stays the same as we move across the row, the actual nuclear charge increases. The valence electrons added to counterbalance the increasing nuclear charge shield one another very ineffectively. Thus, the effective nuclear charge,  $Z_{\text{eff}}$ , increases steadily. For example, the  $1s^2$  core electrons of lithium ( $1s^2 2s^1$ ) shield the  $2s$  valence electron from the  $3+$  nucleus fairly efficiently. Consequently, the outer electron experiences an effective nuclear charge of roughly  $3 - 2 = 1+$ . For beryllium ( $1s^2 2s^2$ ) the effective nuclear charge experienced by each  $2s$  valence electron is larger; in this case, the inner  $1s$  electrons are shielding a  $4+$  nucleus, and each  $2s$  electron only partially shields the other from the nucleus. Consequently, the effective nuclear charge experienced by each  $2s$  electron is about  $4 - 2 = 2+$ .

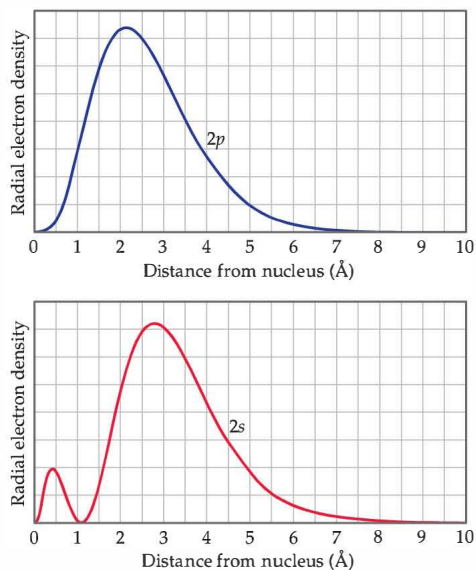

Going down a column, the effective nuclear charge experienced by valence electrons changes far less than it does across a row. For example, we would expect the effective nuclear charge for the outer electrons in lithium and sodium to be about the same, roughly  $3 - 2 = 1+$  for lithium and  $11 - 10 = 1+$  for sodium. In fact, however, the effective nuclear charge increases slightly as we go down a family because larger electron cores are less able to screen the outer electrons from the nuclear charge. In the case of the alkali metals, the value of  $Z_{\text{eff}}$  increases from  $1.3+$  for lithium, to  $2.5+$  for sodium, to  $3.5+$  for potassium. Nevertheless, the increase in effective nuclear charge that occurs moving down a column is smaller than the change that occurs when moving horizontally from one side of the periodic table to the other.

### GIVE IT SOME THOUGHT

Which would you expect to experience a greater effective nuclear charge, a  $2p$  electron of a Ne atom or a  $3s$  electron of a Na atom?

## 7.3 SIZES OF ATOMS AND IONS

Size is one of the important properties of an atom or an ion. We often think of atoms and ions as hard, spherical objects. According to the quantum mechanical model, however, atoms and ions do not have sharply defined boundaries at which the electron distribution becomes zero.  $\infty$  (Section 6.5) Nevertheless,

**▲ Figure 7.4 2s and 2p radial functions.** The radial probability function for the  $2s$  orbital of the hydrogen atom (red curve) shows a “bump” of probability close to the nucleus, whereas that for the  $2p$  orbital (blue curve) does not. As a result, an electron in the  $2s$  orbital for a many-electron atom “sees” more of the nuclear charge than does an electron in the  $2p$  orbital. Hence, the effective nuclear charge experienced by the  $2s$  electron is greater than that for the  $2p$  electron.

## A Closer Look

## EFFECTIVE NUCLEAR CHARGE

To get a better sense of how the effective nuclear charge varies as both the charge of the nucleus and the number of electrons increase, consider Figure 7.5. This figure shows the variation in  $Z_{\text{eff}}$  for elements in the second (Li – Ne) and third (Na – Ar) periods. The effective nuclear charge is plotted for electrons in the  $1s$  subshell (in red) and for the outermost valence electrons (in blue). These values are considered the most accurate estimate of  $Z_{\text{eff}}$ . Although the details of how they are calculated are beyond the scope of our discussion, the trends are instructive. The effective nuclear charge as felt by electrons in the  $1s$  subshell closely track the increasing charge of the nucleus,  $Z$ , (in black) because the other electrons do little to shield these innermost electrons from the charge of the nucleus.

Compare the values of  $Z_{\text{eff}}$  experienced by the inner core electron (in red) with those experienced by the outermost electrons (in blue). The values of  $Z_{\text{eff}}$  as felt by the outermost electrons are smaller because of screening by the inner electrons. In addition, the effective nuclear charge felt by the outermost electrons does not increase as steeply with increasing atomic number, because the valence electrons make a small, but non-negligible contribution to the screening constant,  $S$ . However, the most striking feature associated with the  $Z_{\text{eff}}$  for the outermost electrons is the sharp drop between the last element of the second period (Ne) and the first element of the third period (Na). This drop reflects the fact that the core electrons are much more effective than the valence electrons at screening the charge of the nucleus.

Effective nuclear charge is a tool that can be used to understand many physically measurable quantities, such as ionization energy, atomic radii, and electron affinity. Therefore, it is desirable to have a simple method for estimating  $Z_{\text{eff}}$  without resorting to sophisticated calculations or memorization. The charge of the nucleus,  $Z$ , is known exactly, so the challenge boils down to estimating accurately the value of the screening constant,  $S$ . The approach outlined in the text was to estimate  $S$  by assuming that the core electrons contribute a value of 1.00 to the screening constant, and the outer electrons contribute nothing to  $S$ . A more accurate approach is to use an empirical set of rules developed by John Slater. If we limit ourselves to elements that do not have electrons in  $d$  or  $f$  subshells (the rules become somewhat more complicated for such elements), Slater's rules are straightforward to apply. Electrons with larger values of  $n$ , the principal quantum number, than the electron of interest contribute 0 to the value of the screening constant,  $S$ . Electrons with the same value of  $n$ , as the electron of interest contribute 0.35 to the value of  $S$ . Electrons with a

▲ **Figure 7.5 Variations in effective nuclear charge.**

This figure shows the variation in effective nuclear charge,  $Z_{\text{eff}}$ , as felt by the innermost electrons, those in the  $1s$  subshell (red circles), which closely tracks the increase in nuclear charge,  $Z$  (black line). The  $Z_{\text{eff}}$  felt by the outermost valence electrons (blue squares) not only is significantly smaller than  $Z$ , it does not evolve linearly with increasing atomic number. It is also possible to estimate  $Z_{\text{eff}}$  using certain rules. The values shown as green triangles were obtained by assuming the core electrons are completely effective at screening and the valence electrons do not screen the nuclear charge at all. The values shown as grey diamonds were estimated using Slater's rules.

principal quantum number one less than the electron of interest contribute 0.85 to the value of  $S$ , while those with even smaller values of  $n$  contribute 1.00 to the value of  $S$ . Values of  $Z_{\text{eff}}$  as estimated using the simple method outlined in the text (in green), as well as those estimated with Slater's rules (in grey), are plotted in Figure 7.5. While neither of these methods exactly replicate the values of  $Z_{\text{eff}}$  obtained from more sophisticated calculations, we see that both methods effectively capture the periodic variation in  $Z_{\text{eff}}$ . While Slater's approach is more accurate, the method outlined in the text does a reasonably good job of estimating the effective nuclear charge, despite its simplicity. For our purposes, we can assume that the screening constant,  $S$ , in Equation 7.1 is roughly equal to the number of core electrons.

*Related Exercises:* 7.13, 7.14, 7.33, 7.34, 7.85, 7.87

we can define atomic size in several ways, based on the distances between atoms in various situations.

Imagine a collection of argon atoms in the gas phase. When two atoms collide with each other in the course of their motions, they ricochet apart—somewhat like billiard balls. This movement happens because the electron clouds of

the colliding atoms cannot penetrate each other to any significant extent. The closest distances separating the nuclei during such collisions determine the *apparent radii* of the argon atoms. We might call this radius the *nonbonding atomic radius* of an atom.

When two atoms are chemically bonded to each other, as in the  $\text{Cl}_2$  molecule, an attractive interaction exists between the two atoms leading to a chemical bond. We will discuss the nature of such bonding in Chapter 8. For now, the only thing we need to realize is that this attractive interaction brings the two atoms closer together than they would be in a nonbonding collision. We can define an atomic radius based on the distances separating the nuclei of atoms when they are chemically bonded to each other. This distance, called the **bonding atomic radius**, is shorter than the nonbonding atomic radius, as illustrated in Figure 7.6. Unless otherwise noted, we will refer to the bonding atomic radius when we speak of the size of an atom.

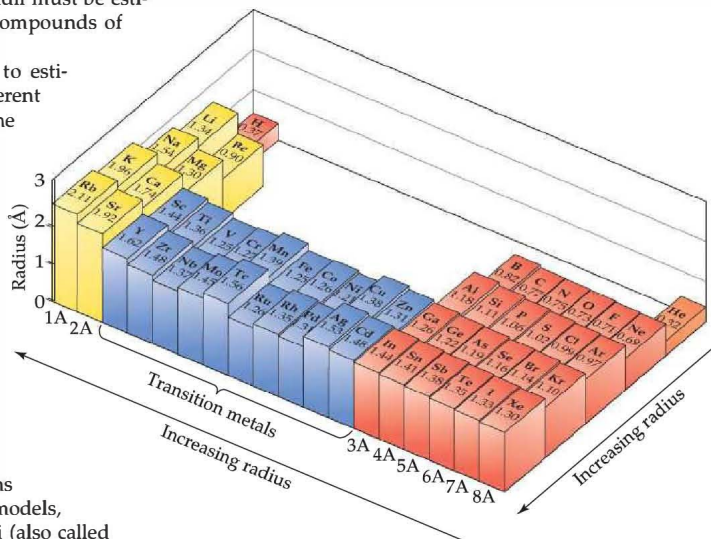

Scientists have developed a variety of experimental techniques for measuring the distances separating nuclei in molecules. From observations of these distances in many molecules, each element can be assigned a bonding atomic radius. For example, in the  $\text{I}_2$  molecule, the distance separating the iodine nuclei is observed to be  $2.66 \text{ \AA}$ .<sup>\*</sup> We can define the bonding atomic radius of iodine on this basis to be one-half of the bond distance, namely  $1.33 \text{ \AA}$ . Similarly, the distance separating two adjacent carbon nuclei in diamond, which is a three-dimensional solid network, is  $1.54 \text{ \AA}$ ; thus, the bonding atomic radius of carbon is assigned the value  $0.77 \text{ \AA}$ . The radii of other elements can be similarly defined (Figure 7.7). (For helium and neon, the bonding radii must be estimated because there are no known compounds of these elements.)

Knowing atomic radii allows us to estimate the bond lengths between different elements in molecules. For example, the  $\text{Cl}-\text{Cl}$  bond length in  $\text{Cl}_2$  is  $1.99 \text{ \AA}$ , so a radius of  $0.99 \text{ \AA}$  is assigned to Cl. In the compound  $\text{CCl}_4$  the measured length of the  $\text{C}-\text{Cl}$  bond is  $1.77 \text{ \AA}$ , very close to the sum ( $0.77 + 0.99 \text{ \AA}$ ) of the atomic radii of C and Cl.

If we consider the radius of an atom as one-half the distance between the nuclei of atoms that are held together by a bond, you may wonder why the spheres representing atoms seem to overlap in some drawings, such as those in Figures 1.1 and 2.20. These depictions of molecules are called *space-filling models*, and they use nonbonding atomic radii (also called *van der Waals radii*) to represent the sizes of different elements. Even in these representations the distance between the centers of two adjacent atoms in the molecule is determined from bonding atomic radii (also called *covalent radii*).

▲ **Figure 7.6 Distinction between nonbonding and bonding atomic radii.** The nonbonding atomic radius is the effective radius of an atom when it is not involved in bonding to another atom. Values of bonding atomic radii are obtained from measurements of interatomic distances in chemical compounds.

▲ **Figure 7.7 Trends in atomic radii.** Bonding atomic radii for the first 54 elements of the periodic table. The height of the bar for each element is proportional to its radius, giving a “relief map” view of the radii.

<sup>\*</sup>Remember: The angstrom ( $1 \text{ \AA} = 10^{-10} \text{ m}$ ) is a convenient metric unit for atomic measurements of length. The angstrom is not an SI unit. The most commonly used SI unit for such measurements is the picometer ( $1 \text{ pm} = 10^{-12} \text{ m}$ ;  $1 \text{ \AA} = 100 \text{ pm}$ ).

### SAMPLE EXERCISE 7.1 | Bond Lengths in a Molecule

Natural gas used in home heating and cooking is odorless. Because natural gas leaks pose the danger of explosion or suffocation, various smelly substances are added to the gas to allow detection of a leak. One such substance is methyl mercaptan,  $\text{CH}_3\text{SH}$ , whose structure is shown in the margin. Use Figure 7.7 to predict the lengths of the C—S, C—H, and S—H bonds in this molecule.

#### SOLUTION

**Analyze and Plan:** We are given three bonds and the list of bonding atomic radii. We will assume that each bond length is the sum of the radii of the two atoms involved.

**Solve:** Using radii for C, S, and H from Figure 7.7, we predict

$$\begin{aligned}\text{C—S bond length} &= \text{radius of C} + \text{radius of S} \\ &= 0.77 \text{ \AA} + 1.02 \text{ \AA} = 1.79 \text{ \AA}\end{aligned}$$

$$\text{C—H bond length} = 0.77 \text{ \AA} + 0.37 \text{ \AA} = 1.14 \text{ \AA}$$

$$\text{S—H bond length} = 1.02 \text{ \AA} + 0.37 \text{ \AA} = 1.39 \text{ \AA}$$

**Check:** The experimentally determined bond lengths in methyl mercaptan (taken from the chemical literature) are C—S = 1.82 Å, C—H = 1.10 Å, and S—H = 1.33 Å. (In general, the lengths of bonds involving hydrogen show larger deviations from the values predicted by the sum of the atomic radii than do those bonds involving larger atoms.)

**Comment:** Notice that the estimated bond lengths using bonding atomic radii are close, but not exact matches, to the experimental bond lengths. Atomic radii must be used with some caution in estimating bond lengths. In Chapter 8 we will examine some of the average lengths of common types of bonds.

#### PRACTICE EXERCISE

Using Figure 7.7, predict which will be greater, the P—Br bond length in  $\text{PBr}_3$  or the As—Cl bond length in  $\text{AsCl}_3$ .

*Answer:* P—Br

## Periodic Trends in Atomic Radii

If we examine the “relief map” of atomic radii shown in Figure 7.7, we observe two interesting trends in the data:

1. Within each column (group), atomic radius tends to increase from top to bottom. This trend results primarily from the increase in the principal quantum number ( $n$ ) of the outer electrons. As we go down a column, the outer electrons have a greater probability of being farther from the nucleus, causing the atom to increase in size.
2. Within each row (period), atomic radius tends to decrease from left to right. The major factor influencing this trend is the increase in the effective nuclear charge ( $Z_{\text{eff}}$ ) as we move across a row. The increasing effective nuclear charge steadily draws the valence electrons closer to the nucleus, causing the atomic radius to decrease.

### GIVE IT SOME THOUGHT

In section 7.2 we said that the effective nuclear charge generally increases when you move down a column of the periodic table, whereas in Chapter 6 we saw that the “size” of an orbital increases as the principal quantum number increases. With respect to atomic radii, do these trends work together or against each other? Which effect is larger?

### SAMPLE EXERCISE 7.2 | Atomic Radii

Referring to a periodic table, arrange (as much as possible) the following atoms in order of increasing size:  ${}_{15}\text{P}$ ,  ${}_{16}\text{S}$ ,  ${}_{33}\text{As}$ ,  ${}_{34}\text{Se}$ . (Atomic numbers are given for the elements to help you locate them quickly in the periodic table.)

#### SOLUTION

**Analyze and Plan:** We are given the chemical symbols for four elements. We can use their relative positions in the periodic table and the two periodic trends just described to predict the relative order of their atomic radii.

**Solve:** Notice that P and S are in the same row of the periodic table, with S to the right of P. Therefore, we expect the radius of S to be smaller than that of P. (Radii decrease as we move from left to right.) Likewise, the radius of Se is expected to be smaller than that of As. We also notice that As is directly below P and that Se is directly below S. We expect, therefore, that the radius of As is greater than that of P and the radius of Se is greater than that of S. From these observations, we predict  $\text{S} < \text{P}$ ,  $\text{P} < \text{As}$ ,  $\text{S} < \text{Se}$ , and  $\text{Se} < \text{As}$ . We can therefore conclude that S has the smallest radii of the four elements and that As has the largest radius.

Using just the two trends described above, we cannot determine whether P or Se has the larger radius. To go from P to Se in the periodic table, we must move down (radius tends to increase) and to the right (radius tends to decrease). In Figure 7.7 we see that the radius of Se (1.16 Å) is greater than that of P (1.06 Å). If you examine the figure carefully, you will discover that for the *s*- and *p*-block elements the increase in radius moving down a column tends to be the greater effect. There are exceptions, however.

**Check:** From Figure 7.7, we have  $\text{S} (1.02 \text{ \AA}) < \text{P} (1.06 \text{ \AA}) < \text{Se} (1.16 \text{ \AA}) < \text{As} (1.19 \text{ \AA})$ .

**Comment:** Note that the trends we have just discussed are for the *s*- and *p*-block elements. You will see in Figure 7.7 that the transition elements do not show a regular decrease upon moving from left to right across a row.

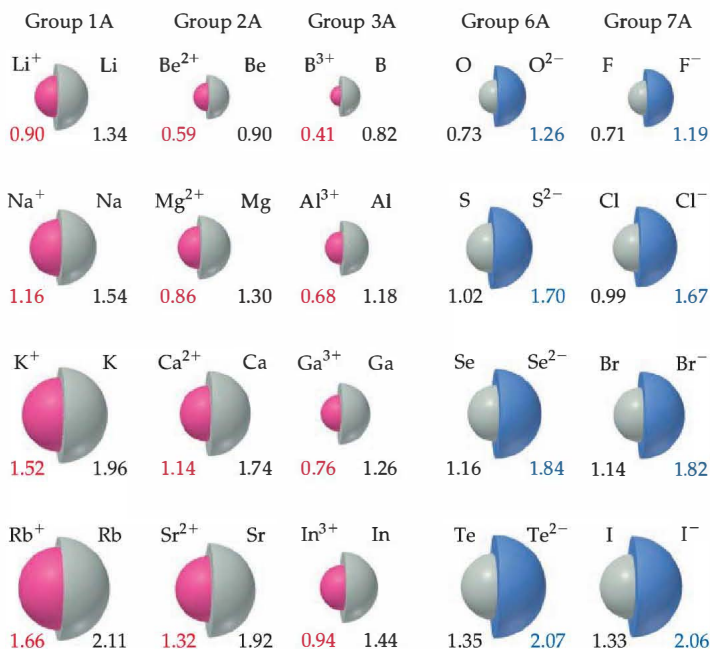

#### PRACTICE EXERCISE

Arrange the following atoms in order of increasing atomic radius:  ${}_{11}\text{Na}$ ,  ${}_{4}\text{Be}$ ,  ${}_{12}\text{Mg}$

**Answer:**  $\text{Be} < \text{Mg} < \text{Na}$

### Periodic Trends in Ionic Radii

Just as bonding atomic radii can be determined from interatomic distances in elements, ionic radii can be determined from interatomic distances in ionic compounds. Like the size of an atom, the size of an ion depends on its nuclear charge, the number of electrons it possesses, and the orbitals in which the valence electrons reside. The formation of a cation vacates the most spatially extended occupied orbitals in an atom and decreases the number of electron–electron repulsions. Therefore, *cations are smaller than their parent atoms*, as illustrated in Figure 7.8. The opposite is true of anions. When electrons are added

► **Figure 7.8 Cation and anion size.** Comparisons of the radii, in Å, of neutral atoms and ions for several of the groups of representative elements. Neutral atoms are shown in gray, cations in red, and anions in blue.

Ionic size plays a major role in determining the properties of ions in solution. For example, a small difference in ionic size is often sufficient for one metal ion to be biologically important and another not to be. To illustrate, let's examine some of the biological chemistry of the zinc ion ( $\text{Zn}^{2+}$ ) and compare it with the cadmium ion ( $\text{Cd}^{2+}$ ).

Recall from the "Chemistry and Life" box in Section 2.7 that zinc is needed in our diets in trace amounts. Zinc is an essential part of several enzymes—the proteins that facilitate or regulate the speeds of key biological reactions. For example, one of the most important zinc-containing enzymes is *carbonic anhydrase*. This enzyme is found in red blood cells. Its job is to facilitate the reaction of carbon dioxide ( $\text{CO}_2$ ) with water to form the bicarbonate ion ( $\text{HCO}_3^-$ ):

You might be surprised to know that our bodies need an enzyme for such a simple reaction. In the absence of carbonic anhydrase, however, the  $\text{CO}_2$  produced in cells when they are oxidizing glucose or other fuels in vigorous exercise would be cleared out much too slowly. About 20% of the  $\text{CO}_2$  produced by cell metabolism binds to hemoglobin and is carried to the lungs, where it is expelled. About 70% of the  $\text{CO}_2$  produced is converted to bicarbonate ion through the action of carbonic anhydrase. When the  $\text{CO}_2$  has been converted into bicarbonate ion, it diffuses into the blood plasma and eventually is passed into the lungs in the reverse of Equation 7.2. These processes are illustrated in Figure 7.9. In the absence of zinc, the carbonic anhydrase would be inactive, and serious imbalances would result in the amount of  $\text{CO}_2$  present in blood.

Zinc is also found in several other enzymes, including some found in the liver and kidneys. It is obviously essential to life. By contrast, cadmium, zinc's neighbor in group 2B, is extremely toxic to humans. But why are two elements so dif-

▲ **Figure 7.9 Ridding the body of carbon dioxide.**

Illustration of the flow of  $\text{CO}_2$  from tissues into blood vessels and eventually into the lungs. About 20% of the  $\text{CO}_2$  binds to hemoglobin and is released in the lungs. About 70% is converted by carbonic anhydrase into  $\text{HCO}_3^-$  ion, which remains in the blood plasma until the reverse reaction releases  $\text{CO}_2$  into the lungs. Small amounts of  $\text{CO}_2$  simply dissolve in the blood plasma and are released in the lungs.

ferent? Both occur as  $2+$  ions, but  $\text{Zn}^{2+}$  is smaller than  $\text{Cd}^{2+}$ . The radius of  $\text{Zn}^{2+}$  is  $0.88 \text{ \AA}$ ; that of  $\text{Cd}^{2+}$  is  $1.09 \text{ \AA}$ . Can this difference be the cause of such a dramatic reversal of biological properties? The answer is that while size is not the only factor, it is very important. In the carbonic anhydrase enzyme the  $\text{Zn}^{2+}$  ion is found electrostatically bonded to atoms on the protein, as shown in Figure 7.10. It turns out that  $\text{Cd}^{2+}$  binds in this same place preferentially over  $\text{Zn}^{2+}$ , thus displacing it. When  $\text{Cd}^{2+}$  is present instead of  $\text{Zn}^{2+}$ , however, the reaction of  $\text{CO}_2$  with water is not facilitated. More seriously,  $\text{Cd}^{2+}$  inhibits reactions that are essential to the kidneys' functioning.

*Related Exercises: 7.30, 7.91, and 7.92*

◀ **Figure 7.10 A zinc-containing enzyme.** The enzyme called carbonic anhydrase (left) catalyzes the reaction between  $\text{CO}_2$  and water to form  $\text{HCO}_3^-$ . The ribbon represents the folding of the protein chain. The "active site" of the enzyme (represented by the ball-and-stick model) is where the reaction occurs. (H atoms have been excluded from this model for clarity.) The red sphere represents the oxygen of a water molecule that is bound to the zinc ion (gold sphere) at the center of the active site. The water molecule is replaced by  $\text{CO}_2$  in the reaction. The bonds coming off the five-member rings attach the active site to the protein (nitrogen and carbon atoms are represented by blue and black spheres, respectively).

needed to remove the first electron from a neutral atom. For example, the first ionization energy for the sodium atom is the energy required for the process

The *second ionization energy*,  $I_2$ , is the energy needed to remove the second electron, and so forth, for successive removals of additional electrons. Thus,  $I_2$  for the sodium atom is the energy associated with the process

The greater the ionization energy, the more difficult it is to remove an electron.

## GIVE IT SOME THOUGHT

Light can be used to ionize atoms and ions, as in Equations 7.3 and 7.4. Which of the two processes, [7.3] or [7.4], would require shorter wavelength radiation?

## Variations in Successive Ionization Energies

Ionization energies for the elements sodium through argon are listed in Table 7.2. Notice that the values for a given element increase as successive electrons are removed:  $I_1 < I_2 < I_3$ , and so forth. This trend exists because with each successive removal, an electron is being pulled away from an increasingly more positive ion, requiring increasingly more energy.

TABLE 7.2 ■ Successive Values of Ionization Energies,  $I$ , for the Elements Sodium through Argon (kJ/mol)

Element	$I_1$	$I_2$	$I_3$	$I_4$	$I_5$	$I_6$	$I_7$
Na	495	4562	(inner-shell electrons)				
Mg	738	1451	7733				
Al	578	1817	2745	11,577			
Si	786	1577	3232	4356	16,091		
P	1012	1907	2914	4964	6274	21,267	
S	1000	2252	3357	4556	7004	8496	27,107
Cl	1251	2298	3822	5159	6542	9362	11,018
Ar	1521	2666	3931	5771	7238	8781	11,995

A second important feature shown in Table 7.2 is the sharp increase in ionization energy that occurs when an inner-shell electron is removed. For example, consider silicon, whose electron configuration is  $1s^2 2s^2 2p^6 3s^2 3p^2$  or  $[\text{Ne}]3s^2 3p^2$ . The ionization energies increase steadily from 786 kJ/mol to 4356 kJ/mol for the loss of the four electrons in the outer 3s and 3p subshells. Removal of the fifth electron, which comes from the 2p subshell, requires a great deal more energy: 16,091 kJ/mol. The large increase occurs because the 2p electron is much more likely to be found close to the nucleus than are the four  $n = 3$  electrons, and therefore the 2p electron experiences a much greater effective nuclear charge than do the 3s and 3p electrons.

## GIVE IT SOME THOUGHT

Which would you expect to be greater,  $I_1$  for a boron atom or  $I_2$  for a carbon atom?

Every element exhibits a large increase in ionization energy when electrons are removed from its noble-gas core. This observation supports the idea that only the outermost electrons, those beyond the noble-gas core, are involved in the sharing and transfer of electrons that give rise to chemical bonding and reactions. The inner electrons are too tightly bound to the nucleus to be lost from the atom or even shared with another atom.

## SAMPLE EXERCISE 7.5 | Trends in Ionization Energy

Three elements are indicated in the periodic table in the margin. Based on their locations, predict the one with the largest second ionization energy.

**SOLUTION**

**Analyze and Plan:** The locations of the elements in the periodic table allow us to predict the electron configurations. The greatest ionization energies involve removal of core electrons. Thus, we should look first for an element with only one electron in the outermost occupied shell.

**Solve:** The element in group 1A (Na), indicated by the red box, has only one valence electron. The second ionization energy of this element is associated, therefore, with the removal of a core electron. The other elements indicated, S (green box) and Ca (blue box), have two or more valence electrons. Thus, Na should have the largest second ionization energy.

**Check:** If we consult a chemistry handbook, we find the following values for the second ionization energies ( $I_2$ ) of the respective elements: Ca (1,145 kJ/mol) < S (2,252 kJ/mol) < Na (4,562 kJ/mol).

**PRACTICE EXERCISE**

Which will have the greater third ionization energy, Ca or S?

**Answer:** Ca

**Periodic Trends in First Ionization Energies**

We have seen that the ionization energy for a given element increases as we remove successive electrons. What trends do we observe in ionization energy as we move from one element to another in the periodic table? Figure 7.11 shows a graph of  $I_1$  versus atomic number for the first 54 elements. The important trends are as follows:

**▲ Figure 7.11 First ionization energy versus atomic number.**

The red dots mark the beginning of a period (alkali metals), the blue dots mark the end of a period (noble gases), and the black dots indicate s- and p-block elements, while green dots are used to represent the transition metals.

The periodic trends in the first ionization energies of the s- and p-block elements are further illustrated in Figure 7.12.

In general, smaller atoms have higher ionization energies. The same factors that influence atomic size also influence ionization energies. The energy needed to remove an electron from the outermost occupied shell depends on both the effective nuclear charge and the average distance of the electron from the nucleus. Either increasing the effective nuclear charge or decreasing the distance from the nucleus increases the attraction between the electron and the nucleus.

▲ **Figure 7.12 Trends in first ionization energy.** First ionization energies for the  $s$ - and  $p$ -block elements in the first six periods. The ionization energy generally increases from left to right and decreases from top to bottom. The ionization energy of astatine has not been determined.

▲ **Figure 7.13  $2p$  orbital filling in nitrogen and oxygen.** The presence of a fourth electron in the  $2p$  orbitals of oxygen leads to an extra repulsion associated with putting two electrons in a single orbital. This repulsion is responsible for the lower first ionization energy of oxygen.

As this attraction increases, it becomes more difficult to remove the electron and, thus, the ionization energy increases. As we move across a period, there is both an increase in effective nuclear charge and a decrease in atomic radius, causing the ionization energy to increase. As we move down a column, however, the atomic radius increases, while the effective nuclear charge increases rather gradually. Thus, the attraction between the nucleus and the electron decreases, causing the ionization energy to decrease.

The irregularities within a given row are somewhat subtler but still readily explained. For example, the decrease in ionization energy from beryllium ( $[\text{He}]2s^2$ ) to boron ( $[\text{He}]2s^22p^1$ ), shown in Figures 7.11 and 7.12, occurs because the third valence electron of B must occupy the  $2p$  subshell, which is empty for Be. Recall that, as we discussed earlier, the  $2p$  subshell is at a higher energy than the  $2s$  subshell (Figure 6.23). The decrease in ionization energy when moving from nitrogen ( $[\text{He}]2s^22p^3$ ) to oxygen ( $[\text{He}]2s^22p^4$ ) is because of the repulsion of paired electrons in the  $p^4$  configuration, as shown in Figure 7.13 ◀. Remember that according to Hund's rule, each electron in the  $p^3$  configuration resides in a different  $p$  orbital, which minimizes the electron–electron repulsion among the three  $2p$  electrons. ∞ (Section 6.8)

### ■ SAMPLE EXERCISE 7.6 | Periodic Trends in Ionization Energy

Referring to a periodic table, arrange the following atoms in order of increasing first ionization energy: Ne, Na, P, Ar, K.

#### SOLUTION

**Analyze and Plan:** We are given the chemical symbols for five elements. To rank them according to increasing first ionization energy, we need to locate each element in the periodic table. We can then use their relative positions and the trends in first ionization energy to predict their order.

**Solve:** Ionization energy increases as we move left to right across a row. It decreases as we move from the top of a group to the bottom. Because Na, P, and Ar are in the same row of the periodic table, we expect  $I_1$  to vary in the order  $\text{Na} < \text{P} < \text{Ar}$ .

Because Ne is above Ar in group 8A, we expect Ne to have the greater first ionization energy:  $\text{Ar} < \text{Ne}$ . Similarly, K is the alkali metal directly below Na in group 1A, and so we expect  $I_1$  for K to be less than that of Na:  $\text{K} < \text{Na}$ .

From these observations, we conclude that the ionization energies follow the order

**Check:** The values shown in Figure 7.12 confirm this prediction.

#### ■ PRACTICE EXERCISE

Which has the lowest first ionization energy, B, Al, C, or Si? Which has the highest first ionization energy?

*Answer:* Al lowest, C highest

## Electron Configurations of Ions

When electrons are removed from an atom to form a cation, they are always removed first from the occupied orbitals having the largest principal quantum

number,  $n$ . For example, when one electron is removed from a lithium atom ( $1s^2 2s^1$ ), it is the  $2s^1$  electron that is removed:

Likewise, when two electrons are removed from Fe ( $[\text{Ar}]3d^6 4s^2$ ), the  $4s^2$  electrons are the ones removed:

If an additional electron is removed, forming  $\text{Fe}^{3+}$ , it now comes from a  $3d$  orbital because all the orbitals with  $n = 4$  are empty:

It may seem odd that the  $4s$  electrons are removed before the  $3d$  electrons in forming transition-metal cations. After all, in writing electron configurations, we added the  $4s$  electrons before the  $3d$  ones. In writing electron configurations for atoms, however, we are going through an imaginary process in which we move through the periodic table from one element to another. In doing so, we are adding both an electron to an orbital and a proton to the nucleus to change the identity of the element. In ionization, we do not reverse this process because no protons are being removed.

If there is more than one occupied subshell for a given value of  $n$  the electrons are first removed from the orbital with the highest value of  $l$ . For example a tin atom loses its  $5p$  electrons before it loses its  $5s$  electrons:

When electrons are added to an atom to form an anion, they are added to the empty or partially filled orbital having the lowest value of  $n$ . For example, when an electron is added to a fluorine atom to form the  $\text{F}^-$  ion, the electron goes into the one remaining vacancy in the  $2p$  subshell:

### GIVE IT SOME THOUGHT

Would  $\text{Cr}^{3+}$  and  $\text{V}^{2+}$  have the same or different electron configurations?

#### SAMPLE EXERCISE 7.7 | Electron Configurations of Ions

Write the electron configuration for (a)  $\text{Ca}^{2+}$  (b)  $\text{Co}^{3+}$ , and (c)  $\text{S}^{2-}$ .

#### SOLUTION

**Analyze and Plan:** We are asked to write electron configurations for three ions. To do so, we first write the electron configuration of the parent atom. We then remove electrons to form cations or add electrons to form anions. Electrons are first removed from the orbitals having the highest value of  $n$ . They are added to the empty or partially filled orbitals having the lowest value of  $n$ .

#### Solve:

(a) Calcium (atomic number 20) has the electron configuration

To form a  $2+$  ion, the two outer electrons must be removed, giving an ion that is isoelectronic with Ar:

(b) Cobalt (atomic number 27) has the electron configuration

To form a  $3+$  ion, three electrons must be removed. As discussed in the text preceding this Sample Exercise, the  $4s$  electrons are removed before the  $3d$  electrons. Consequently, the electron configuration for  $\text{Co}^{3+}$  is

(c) Sulfur (atomic number 16) has the electron configuration

To form a  $2-$  ion, two electrons must be added. There is room for two additional electrons in the  $3p$  orbitals. Thus, the  $\text{S}^{2-}$  electron configuration is

**Comment:** Remember that many of the common ions of the  $s$ - and  $p$ -block elements, such as  $\text{Ca}^{2+}$  and  $\text{S}^{2-}$ , have the same number of electrons as the closest noble gas.  (Section 2.7)

### PRACTICE EXERCISE

Write the electron configuration for (a)  $\text{Ga}^{3+}$ , (b)  $\text{Cr}^{3+}$ , and (c)  $\text{Br}^-$ .

**Answers:** (a)  $[\text{Ar}]3d^{10}$ , (b)  $[\text{Ar}]3d^3$ , (c)  $[\text{Ar}]3d^{10}4s^2 4p^6 = [\text{Kr}]$

## 7.5 ELECTRON AFFINITIES

The first ionization energy of an atom is a measure of the energy change associated with removing an electron from the atom to form a positively charged ion. For example, the first ionization energy of  $\text{Cl}(\text{g})$ , 1251 kJ/mol, is the energy change associated with the process

The positive value of the ionization energy means that energy must be put into the atom to remove the electron.

In addition, most atoms can gain electrons to form negatively charged ions. The energy change that occurs when an electron is added to a gaseous atom is called the **electron affinity** because it measures the attraction, or *affinity*, of the atom for the added electron. For most atoms, energy is released when an electron is added. For example, the addition of an electron to a chlorine atom is accompanied by an energy change of  $-349$  kJ/mol, the negative sign indicating that energy is released during the process. We therefore say that the electron affinity of Cl is  $-349$  kJ/mol:\*

It is important to understand the difference between ionization energy and electron affinity: Ionization energy measures the ease with which an atom *loses* an electron, whereas electron affinity measures the ease with which an atom *gains* an electron.

The greater the attraction between a given atom and an added electron, the more negative the atom's electron affinity will be. For some elements, such as the noble gases, the electron affinity has a positive value, meaning that the anion is higher in energy than are the separated atom and electron:

The fact that the electron affinity is a positive number means that an electron will not attach itself to an Ar atom; the  $\text{Ar}^-$  ion is unstable and does not form.

\*Two sign conventions are used for electron affinity. In most introductory texts, including this one, the thermodynamic sign convention is used: a negative sign indicates that the addition of an electron is an exothermic process, as in the electron affinity given for chlorine,  $-349$  kJ/mol. Historically, however, electron affinity has been defined as the energy released when an electron is added to a gaseous atom or ion. Because  $349$  kJ/mol is released when an electron is added to  $\text{Cl}(\text{g})$ , the electron affinity by this convention would be  $+349$  kJ/mol.

TABLE 7.3 ■ Characteristic Properties of Metals and Nonmetals

Metals	Nonmetals
Have a shiny luster; various colors, although most are silvery	Do not have a luster; various colors
Solids are malleable and ductile	Solids are usually brittle; some are hard, some are soft
Good conductors of heat and electricity	Poor conductors of heat and electricity
Most metal oxides are ionic solids that are basic	Most nonmetal oxides are molecular substances that form acidic solutions
Tend to form cations in aqueous solution	Tend to form anions or oxyanions in aqueous solution

▲ **Figure 7.16 The luster of metals.** Metallic objects are readily recognized by their characteristic shiny luster.

at the top right corner, and the metalloids lie between the metals and nonmetals. Hydrogen, which is located at the top left corner, is a nonmetal. This is why we set off hydrogen from the remaining group 1A elements in Figure 7.15 by inserting a space between the H box and the Li box. Some of the distinguishing properties of metals and nonmetals are summarized in Table 7.3 ▲.

The more an element exhibits the physical and chemical properties of metals, the greater its **metallic character**. As indicated in Figure 7.15, metallic character generally increases as we proceed down a column of the periodic table and increases as we proceed from right to left in a row. Let's now examine the close relationships that exist between electron configurations and the properties of metals, nonmetals, and metalloids.

### Metals

Most metallic elements exhibit the shiny luster that we associate with metals (Figure 7.16 ◀). Metals conduct heat and electricity. In general they are malleable (can be pounded into thin sheets) and ductile (can be drawn into wires). All are solids at room temperature except mercury (melting point =  $-39^\circ\text{C}$ ), which is a liquid. Two metals melt at slightly above room temperature, cesium at  $28.4^\circ\text{C}$  and gallium at  $29.8^\circ\text{C}$ . At the other extreme, many metals melt at very high temperatures. For example, chromium melts at  $1900^\circ\text{C}$ .

*Metals tend to have low ionization energies and therefore tend to form positive ions relatively easily.* As a result, metals are oxidized (lose electrons) when they undergo chemical reactions. This fact is illustrated in Figure 7.17 ▼, where the first ionization energies of the metals, nonmetals, and metalloids are compared.

Among the fundamental atomic properties (radius, electron configuration, electron affinity, and so forth), the first ionization energy is the best indicator of whether an element will behave as a metal or a nonmetal. The relative ease of oxidation of common metals was discussed earlier, in Section 4.4. As we noted there, many metals are oxidized by a variety of common substances, including  $\text{O}_2$  and acids.

◀ **Figure 7.17 A comparison of the first ionization energies of metals vs. nonmetals.** Values of first ionization energy for metals are markedly lower than those of nonmetals. The red circles correspond to metallic elements, the blue squares to nonmetals, and the black triangles to metalloids. The dashed line at 925 kJ/mol separates the metals from the nonmetals.

1A												7A		8A	N O B L E			
H <sup>+</sup>	2A										3A		4A	5A		6A	H <sup>-</sup>	
Li <sup>+</sup>															N <sup>3-</sup>	O <sup>2-</sup>	F <sup>-</sup>	G A S E S
Na <sup>+</sup>	Mg <sup>2+</sup>	Transition metals										Al <sup>3+</sup>			P <sup>3-</sup>	S <sup>2-</sup>	Cl <sup>-</sup>	
K <sup>+</sup>	Ca <sup>2+</sup>	Sc <sup>3+</sup>	Ti <sup>4+</sup>	V <sup>5+</sup>	Cr <sup>3+</sup>	Mn <sup>2+</sup> Mn <sup>4+</sup>	Fe <sup>2+</sup> Fe <sup>3+</sup>	Co <sup>2+</sup> Co <sup>3+</sup>	Ni <sup>2+</sup>	Cu <sup>+</sup> Cu <sup>2+</sup>	Zn <sup>2+</sup>					Se <sup>2-</sup>	Br <sup>-</sup>

Cs <sup>+</sup>	Ba <sup>2+</sup>								Pt <sup>2+</sup>	Au <sup>+</sup> Au <sup>3+</sup>	Hg <sup>2+</sup> Hg <sup>2+</sup>		Pb <sup>2+</sup> Pb <sup>4+</sup>	Bi <sup>3+</sup> Bi <sup>5+</sup>				

▲ **Figure 7.18 Representative oxidation states.** Oxidation states found in ionic compounds, including some examples of higher oxidation states adopted by *p*-block metals. Notice that the steplike line that divides metals from nonmetals also separates cations from anions.

Figure 7.18▲ shows the oxidation states of some representative ions of both metals and nonmetals. As we noted in Section 2.7, the charge on any alkali metal ion is always 1+, and that on any alkaline earth metal is always 2+ in their compounds. For atoms belonging to either of these groups, the outer *s* electrons are easily lost, yielding a noble-gas electron configuration. For metals belonging to groups with partially occupied *p* orbitals (Groups 3A–7A), the observed cations are formed either by losing only the outer *p* electrons (such as Sn<sup>2+</sup>) or the outer *s* and *p* electrons (such as Sn<sup>4+</sup>). The charge on transition-metal ions does not follow an obvious pattern. One of the characteristic features of the transition metals is their ability to form more than one positive ion. For example, iron may be 2+ in some compounds and 3+ in others.

### GIVE IT SOME THOUGHT

Based on periodic trends discussed in this chapter, can you see a general relationship between the trends in metallic character and those for ionization energy?

*Compounds of metals with nonmetals tend to be ionic substances.* For example, most metal oxides and halides are ionic solids. To illustrate, the reaction between nickel metal and oxygen produces nickel oxide, an ionic solid containing Ni<sup>2+</sup> and O<sup>2-</sup> ions:

The oxides are particularly important because of the great abundance of oxygen in our environment.

*Most metal oxides are basic.* Those that dissolve in water react to form metal hydroxides, as in the following examples:

Metal oxide + water  $\longrightarrow$  metal hydroxide

The basicity of metal oxides is due to the oxide ion, which reacts with water according to the net ionic equation

► **Figure 7.19 Metal oxides react with acids.** (a) Nickel oxide (NiO), nitric acid (HNO<sub>3</sub>), and water. (b) NiO is insoluble in water, but reacts with HNO<sub>3</sub> to give a green solution of the salt Ni(NO<sub>3</sub>)<sub>2</sub>.

Metal oxides also demonstrate their basicity by reacting with acids to form a salt plus water, as illustrated in Figure 7.19 ▲:

In contrast, we will soon see that nonmetal oxides are acidic, dissolving in water to form acidic solutions and reacting with bases to form salts.

#### ■ SAMPLE EXERCISE 7.8 | Metal Oxides

(a) Would you expect scandium oxide to be a solid, liquid, or gas at room temperature? (b) Write the balanced chemical equation for the reaction of scandium oxide with nitric acid.

#### SOLUTION

**Analyze and Plan:** We are asked about one physical property of scandium oxide—its state at room temperature—and one chemical property—how it reacts with nitric acid.

#### Solve:

(a) Because scandium oxide is the oxide of a metal, we would expect it to be an ionic solid. Indeed it is, with the very high melting point of 2485 °C. (b) In its compounds, scandium has a 3+ charge, Sc<sup>3+</sup>; the oxide ion is O<sup>2-</sup>. Consequently, the formula of scandium oxide is Sc<sub>2</sub>O<sub>3</sub>. Metal oxides tend to be basic and therefore to react with acids to form a salt plus water. In this case the salt is scandium nitrate, Sc(NO<sub>3</sub>)<sub>3</sub>. The balanced chemical equation is

#### ■ PRACTICE EXERCISE

Write the balanced chemical equation for the reaction between copper(II) oxide and sulfuric acid.

**Answer:**  $\text{CuO}(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow \text{CuSO}_4(aq) + \text{H}_2\text{O}(l)$

▼ **Figure 7.20 The diversity of nonmetals.** Nonmetallic elements are diverse in their appearances. Shown here are (clockwise from top left) sulfur, bromine, phosphorus, iodine, and carbon.

## Nonmetals

*Nonmetals vary greatly in appearance* (Figure 7.20 ◀). They are not lustrous and generally are poor conductors of heat and electricity. Their melting points are generally lower than those of metals (although diamond, a form of carbon, melts at 3570 °C). Under ordinary conditions, seven nonmetals exist as diatomic molecules. Five of these are gases (H<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, F<sub>2</sub>, and Cl<sub>2</sub>), one is a liquid (Br<sub>2</sub>), and one is a volatile solid (I<sub>2</sub>). Excluding the noble gases, the remaining nonmetals are solids that can be either hard, such as diamond, or soft, such as sulfur.

Because of their electron affinities, nonmetals tend to gain electrons when they react with metals. For example, the reaction of aluminum with bromine produces aluminum bromide, an ionic compound containing the aluminum ion,  $\text{Al}^{3+}$ , and the bromide ion,  $\text{Br}^-$ :

A nonmetal typically will gain enough electrons to fill its outermost occupied  $p$  subshell, giving a noble-gas electron configuration. For example, the bromine atom gains one electron to fill its  $4p$  subshell:

Compounds composed entirely of nonmetals are typically molecular substances. For example, the oxides, halides, and hydrides of the nonmetals are molecular substances that tend to be gases, liquids, or low-melting solids at room temperature.

Most nonmetal oxides are acidic; those that dissolve in water react to form acids, as in the following examples:

The reaction of carbon dioxide with water (Figure 7.21 ▼) accounts for the acidity of carbonated water and, to some extent, rainwater. Because sulfur is present in oil and coal, combustion of these common fuels produces sulfur dioxide and sulfur trioxide. These substances dissolve in water to produce *acid rain*, a major pollution problem in many parts of the world. Like acids, most nonmetal oxides dissolve in basic solutions to form a salt plus water:

### GIVE IT SOME THOUGHT

A compound  $\text{ACl}_3$  (A is an element) has a melting point of  $-112^\circ\text{C}$ . Would you expect the compound to be a molecular or ionic substance? If you were told that element A was either scandium (Sc) or phosphorus (P), which do you think would be a more likely choice?

(a)

(b)

◀ **Figure 7.21 The reaction of  $\text{CO}_2$  with water.** (a) The water has been made slightly basic and contains a few drops of bromthymol blue, an acid–base indicator that is blue in basic solution. (b) Upon the addition of a piece of solid carbon dioxide,  $\text{CO}_2(s)$ , the color changes to yellow, indicating an acidic solution. The mist is due to water droplets condensed from the air by the cold  $\text{CO}_2$  gas.

**SAMPLE EXERCISE 7.9** | Nonmetal Oxides

Write the balanced chemical equations for the reactions of solid selenium dioxide with (a) water, (b) aqueous sodium hydroxide.

**SOLUTION**

**Analyze and Plan:** We first note that selenium (Se) is a nonmetal. We therefore need to write chemical equations for the reaction of a nonmetal oxide, first with water and then with a base, NaOH. Nonmetal oxides are acidic, reacting with water to form an acid and with bases to form a salt and water.

**Solve:**

(a) Selenium dioxide is  $\text{SeO}_2$ . Its reaction with water is like that of carbon dioxide (Equation 7.14):

(It does not matter that  $\text{SeO}_2$  is a solid and  $\text{CO}_2$  is a gas under ambient conditions; the point is that both are water-soluble nonmetal oxides.)

(b) The reaction with sodium hydroxide is like the reaction summarized by Equation 7.16:

**PRACTICE EXERCISE**

Write the balanced chemical equation for the reaction of solid tetraphosphorus hexoxide with water.

*Answer:*  $\text{P}_4\text{O}_6(\text{s}) + 6 \text{H}_2\text{O}(\text{l}) \longrightarrow 4 \text{H}_3\text{PO}_3(\text{aq})$

▲ **Figure 7.22 Elemental silicon.** Silicon is an example of a metalloid. Although it looks metallic, silicon is brittle and is a poor thermal and electrical conductor as compared to metals. Large crystals of silicon are sliced into thin wafers for use in integrated circuits.

▼ **Figure 7.23 Alkali metals.** Sodium and the other alkali metals are soft enough to be cut with a knife. The shiny metallic surface quickly tarnishes as the metal reacts with oxygen in the air.

## Metalloids

Metalloids have properties intermediate between those of metals and those of nonmetals. They may have *some* characteristic metallic properties but lack others. For example, silicon *looks* like a metal (Figure 7.22 ◀), but it is brittle rather than malleable and is a much poorer conductor of heat and electricity than are metals. Compounds of metalloids can have characteristics of the compounds of metals or nonmetals, depending on the specific compound.

Several of the metalloids, most notably silicon, are electrical semiconductors and are the principal elements used in the manufacture of integrated circuits and computer chips. One of the reasons metalloids such as silicon can be used for integrated circuits is the fact that their electrical conductivity is intermediate between that of metals and nonmetals. Very pure silicon is an electrical insulator, but its conductivity can be dramatically increased with the addition of specific impurities (dopants). This modification provides a mechanism for controlling the electrical conductivity by controlling the chemical composition. We will return to this point in Chapter 12.

## 7.7 GROUP TRENDS FOR THE ACTIVE METALS

Our discussion of atomic radius, ionization energy, electron affinity, and metallic character gives some idea of the way the periodic table can be used to organize and remember facts. As we have seen, elements in a group possess general similarities. However, trends also exist as we move through a group. In this section we will use the periodic table and our knowledge of electron configurations to examine the chemistry of the **alkali metals** (group 1A) and the **alkaline earth metals** (group 2A).

### Group 1A: The Alkali Metals

The alkali metals are soft metallic solids (Figure 7.23 ◀). All have characteristic metallic properties such as a silvery, metallic luster and high thermal and electrical conductivities. The name *alkali* comes from an Arabic word meaning “ashes.” Many compounds of sodium and potassium, two alkali metals, were isolated from wood ashes by early chemists.

TABLE 7.4 ■ Some Properties of the Alkali Metals

Element	Electron Configuration	Melting Point (°C)	Density (g/cm <sup>3</sup> )	Atomic Radius (Å)	I <sub>1</sub> (kJ/mol)
Lithium	[He]2s <sup>1</sup>	181	0.53	1.34	520
Sodium	[Ne]3s <sup>1</sup>	98	0.97	1.54	496
Potassium	[Ar]4s <sup>1</sup>	63	0.86	1.96	419
Rubidium	[Kr]5s <sup>1</sup>	39	1.53	2.11	403
Cesium	[Xe]6s <sup>1</sup>	28	1.88	2.25	376

Sodium and potassium are relatively abundant in Earth's crust, in seawater, and in biological systems. We all have sodium ions in our bodies. However, ingesting too much sodium can raise our blood pressure. Potassium is also prevalent in our bodies; a 140-pound person contains about 130 g of potassium, as K<sup>+</sup> ions in intracellular fluids. Plants require potassium for growth and development (Figure 7.24 ▶).

Some of the physical and chemical properties of the alkali metals are given in Table 7.4 ▲. The elements have low densities and melting points, and these properties vary in a fairly regular way with increasing atomic number. We can also see some of the usual trends as we move down the group, such as increasing atomic radius and decreasing first ionization energy. For each row of the periodic table, the alkali metal has the lowest I<sub>1</sub> value (Figure 7.11), which reflects the relative ease with which its outer s electron can be removed. As a result, the alkali metals are all very reactive, readily losing one electron to form ions carrying a 1+ charge. ∞ (Section 4.4)

The alkali metals exist in nature only as compounds. The metals combine directly with most nonmetals. For example, they react with hydrogen to form hydrides and with sulfur to form sulfides:

(The symbol M in Equations 7.17 and 7.18 represents any one of the alkali metals.) In hydrides of the alkali metals (LiH, NaH, and so forth), hydrogen is present as H<sup>-</sup>, called the **hydride ion**. The hydride ion, which is a hydrogen atom that has *gained* an electron, is distinct from the hydrogen ion, H<sup>+</sup>, formed when a hydrogen atom *loses* its electron.

The alkali metals react vigorously with water, producing hydrogen gas and a solution of an alkali metal hydroxide:

These reactions are very exothermic. In many cases enough heat is generated to ignite the H<sub>2</sub>, producing a fire or sometimes even an explosion (Figure 7.25 ▼).

▲ Figure 7.24 Elements in fertilizers. Fertilizers contain large quantities of potassium, phosphorus, and nitrogen to meet the needs of growing plants.

◀ Figure 7.25 The alkali metals react vigorously with water. (a) The reaction of lithium is evidenced by the bubbling of escaping hydrogen gas. (b) The reaction of sodium is more rapid and is so exothermic that the hydrogen gas produced burns in air. (c) Potassium reacts almost explosively.

► **Figure 7.26** Flame tests. (a) Li (crimson red), (b) Na (yellow), and (c) K (lilac).

This reaction is most violent for the heavier members of the group, in keeping with their weaker hold on the single valence electron.

The reactions between the alkali metals and oxygen are more complex. When oxygen reacts with metals, metal oxides, which contain the  $O^{2-}$  ion, are usually formed. Indeed, lithium shows this reactivity:

When dissolved in water,  $\text{Li}_2\text{O}$  and other soluble metal oxides react with water to form hydroxide ions from the reaction of  $O^{2-}$  ions with  $\text{H}_2\text{O}$  (Equation 7.11).

In contrast, the other alkali metals all react with oxygen to form metal peroxides, which contain the  $O_2^{2-}$  ion. For example, sodium forms sodium peroxide,  $\text{Na}_2\text{O}_2$ .

Potassium, rubidium, and cesium also form compounds that contain the  $O_2^-$  ion, which we call the *superoxide ion*. For example, potassium forms potassium superoxide,  $\text{KO}_2$ :

You should be aware that the reactions shown in Equations 7.21 and 7.22 are somewhat surprising; in most cases, the reaction of oxygen with a metal forms the metal oxide.

As is evident from Equations 7.19 through 7.22, the alkali metals are extremely reactive toward water and oxygen. Because of this, the metals are usually stored submerged in a liquid hydrocarbon, such as mineral oil or kerosene.

Although alkali metal ions are colorless, each emits a characteristic color when placed in a flame (Figure 7.26▲). The ions are reduced to gaseous metal atoms in the central region of the flame. The high temperature of the flame then excites the valence electron to a higher-energy orbital, causing the atom to be in an excited state. The atom then emits energy in the form of visible light as the electron falls back into the lower-energy orbital and the atom returns to its ground state. Sodium, for instance, gives a yellow flame because of emission at 589 nm. This wavelength is produced when the excited valence electron drops from the  $3p$  subshell to the lower-energy  $3s$  subshell. The characteristic yellow emission of sodium is the basis for sodium vapor lamps (Figure 7.27◀).

▲ **Figure 7.27** Light from sodium. Sodium vapor lamps, which are used for commercial and highway lighting, have a yellow glow because of the emission from excited sodium atoms.

### GIVE IT SOME THOUGHT

Cesium metal tends to be the most reactive of the stable alkali metals (francium, element number 87, is radioactive and has not been extensively studied). What *atomic* property of Cs is most responsible for its high reactivity?

**SAMPLE EXERCISE 7.10** | Reactions of an Alkali Metal

Write a balanced equation that predicts the reaction of cesium metal with (a)  $\text{Cl}_2(\text{g})$ , (b)  $\text{H}_2\text{O}(\text{l})$ , (c)  $\text{H}_2(\text{g})$ .

**SOLUTION**

**Analyze and Plan:** Cesium is an alkali metal (atomic number 55). We therefore expect that its chemistry will be dominated by oxidation of the metal to  $\text{Cs}^+$  ions. Further, we recognize that Cs is far down the periodic table, which means it will be among the most active of all metals and will probably react with all three of the substances listed.

**Solve:** The reaction between Cs and  $\text{Cl}_2$  is a simple combination reaction between two elements, one a metal and the other a nonmetal, forming the ionic compound  $\text{CsCl}$ :

By analogy to Equations 7.19 and 7.17, respectively, we predict the reactions of cesium with water and hydrogen to proceed as follows:

All three of these reactions are redox reactions where cesium forms a  $\text{Cs}^+$  ion in the product. The chloride ( $\text{Cl}^-$ ), hydroxide ( $\text{OH}^-$ ), and hydride ( $\text{H}^-$ ) ions are all  $1-$  ions, which means the final products have 1:1 stoichiometry with  $\text{Cs}^+$ .

**PRACTICE EXERCISE**

Write a balanced equation for the reaction between potassium metal and elemental sulfur.

**Answer:**  $2 \text{K}(\text{s}) + \text{S}(\text{s}) \longrightarrow \text{K}_2\text{S}(\text{s})$

**Group 2A: The Alkaline Earth Metals**

Like the alkali metals, the group 2A elements are all solids at room temperature and have typical metallic properties, some of which are listed in Table 7.5. Compared with the alkali metals, the alkaline earth metals are harder and more dense, and they melt at higher temperatures.

The first ionization energies of the alkaline earth elements are low, but they are not as low as those of the alkali metals. Consequently, the alkaline earth metals are less reactive than their alkali metal neighbors. As we noted in Section 7.4, the ease with which the elements lose electrons decreases as we move across the periodic table from left to right and increases as we move down a group. Thus, beryllium and magnesium, the lightest members of the alkaline earth metals, are the least reactive.

The trend of increasing reactivity within the group is shown by the way the alkaline earth metals behave in the presence of water. Beryllium does not react with water or steam, even when heated red-hot. Magnesium reacts slowly with liquid water and more readily with steam to form magnesium oxide and hydrogen:

Calcium and the elements below it react readily with water at room temperature (although more slowly than the alkali metals adjacent to them in the

**TABLE 7.5** ■ Some Properties of the Alkaline Earth Metals

Element	Electron Configuration	Melting Point ( $^{\circ}\text{C}$ )	Density ( $\text{g}/\text{cm}^3$ )	Atomic Radius ( $\text{\AA}$ )	$I_1$ ( $\text{kJ}/\text{mol}$ )
Beryllium	$[\text{He}]2s^2$	1287	1.85	0.90	899
Magnesium	$[\text{Ne}]3s^2$	650	1.74	1.30	738
Calcium	$[\text{Ar}]4s^2$	842	1.55	1.74	590
Strontium	$[\text{Kr}]5s^2$	777	2.63	1.92	549
Barium	$[\text{Xe}]6s^2$	727	3.51	1.98	503

The alkali metal ions tend to play a rather unexciting role in most chemical reactions in general chemistry. As noted in Section 4.2, all salts of the alkali metal ions are soluble, and the ions are spectators in most aqueous reactions (except for those involving the alkali metals in their elemental form, such as in Equations 7.17 through 7.22). However, the alkali metal ions play an important role in human physiology. Sodium and potassium ions, for example, are major components of blood plasma and intracellular fluid, respectively, with average concentrations of 0.1 M. These electrolytes serve as vital charge carriers in normal cellular function. We will see in Chapter 20 that these ions are also two of the principal ions involved in regulation of the heart.

In contrast, the lithium ion ( $\text{Li}^+$ ) has no known function in normal human physiology. Since the discovery of lithium in 1817, however, people thought salts of the element possessed almost mystical healing powers. There were even claims that lithium ions were an ingredient in ancient “fountain of youth” formulas. In 1927, Mr. C. L. Grigg began marketing a soft drink that contained lithium. The original unwieldy name of the beverage was “Bib-Label Lithiated Lemon-Lime Soda,” which was soon changed to the simpler and more familiar name Seven Up® (Figure 7.28 ▶).

Because of concerns of the Food and Drug Administration, lithium was removed from Seven Up® during the early 1950s. At nearly the same time, psychiatrists discovered that the lithium ion has a remarkable therapeutic effect on the mental disorder called *bipolar affective disorder*, or *manic-depressive illness*. Over 1 million Americans suffer from this psychosis, undergoing severe mood swings from deep depression to a manic euphoria. The lithium ion smooths these mood swings, allowing the bipolar patient to function more effectively in daily life.

The antipsychotic action of  $\text{Li}^+$  was discovered by accident during the late 1940s by Australian psychiatrist John Cade as he was researching the use of uric acid—a component of urine—to treat manic-depressive illness. He administered

the acid to manic laboratory animals in the form of its most soluble salt, lithium urate, and found that many of the manic symptoms seemed to disappear. Later studies showed that uric acid has no role in the therapeutic effects observed; rather, the seemingly innocuous  $\text{Li}^+$  ions were responsible. Because lithium overdose can cause severe side effects in humans, including kidney failure and death, lithium salts were not approved as antipsychotic drugs for humans until 1970. Today  $\text{Li}^+$  is usually administered orally in the form of  $\text{Li}_2\text{CO}_3$ , which is the active ingredient in prescription drugs such as Eskalith®. Lithium drugs are effective for about 70% of the bipolar patients who take it.

In this age of sophisticated drug design and biotechnology, the simple lithium ion is still the most effective treatment of this destructive psychological disorder. Remarkably, in spite of intensive research, scientists still do not fully understand the biochemical action of lithium that leads to its therapeutic effects. Because of its similarity to the  $\text{Na}^+$  ion, the  $\text{Li}^+$  ion is incorporated into blood plasma, where it can affect the behavior of both nerve cells and muscle cells. The  $\text{Li}^+$  ion has a smaller radius than the  $\text{Na}^+$  ion (Figure 7.8), so its interaction with molecules in cells is somewhat different. Other studies indicate that  $\text{Li}^+$  alters the function of certain neurotransmitters, which might lead to its effectiveness as an antipsychotic drug.

▲ **Figure 7.28 Lithium no more.** The soft drink Seven Up® originally contained lithium citrate, the lithium salt of citric acid. The lithium was claimed to give the beverage healthful benefits, including “an abundance of energy, enthusiasm, a clear complexion, lustrous hair, and shining eyes!” The lithium was removed from the beverage in the early 1950s, about the same time that the antipsychotic action of  $\text{Li}^+$  was discovered.

▲ **Figure 7.29 Elemental calcium solution.** Calcium metal reacts with water to form hydrogen gas and aqueous calcium hydroxide,  $\text{Ca}(\text{OH})_2(\text{aq})$ .

periodic table), as shown in Figure 7.29 ◀. The reaction between calcium and water, for example, is

The reactions represented in Equations 7.23 and 7.24 illustrate the dominant pattern in the reactivity of the alkaline earth elements: they tend to lose their two outer *s* electrons and form 2+ ions. For example, magnesium reacts with chlorine at room temperature to form  $\text{MgCl}_2$  and burns with dazzling brilliance in air to give  $\text{MgO}$  (Figure 3.5):

In the presence of  $\text{O}_2$ , magnesium metal is protected from many chemicals by a thin surface coating of water-insoluble  $\text{MgO}$ . Thus, even though Mg is high in the activity series  $\rightleftharpoons$  (Section 4.4), it can be incorporated into lightweight structural alloys used in, for example, automobile wheels. The heavier alkaline earth metals (Ca, Sr, and Ba) are even more reactive toward nonmetals than is magnesium.

The heavier alkaline earth ions give off characteristic colors when strongly heated in a flame. The colored flame produced by calcium is brick red, that of strontium is crimson red, and that of barium is green. Strontium salts produce the brilliant red color in fireworks, and barium salts produce the green color (Figure 7.30 ▶).

Both magnesium and calcium are essential for living organisms (Figure 2.24). Calcium is particularly important for growth and maintenance of bones and teeth (Figure 7.31 ▶). In humans 99% of the calcium is found in the skeletal system.

◀ **Figure 7.30 Fireworks display.** The colors in a fireworks display originate from the characteristic emissions of elements, including the alkaline earths. In this display the crimson color comes from strontium, while the green color comes from barium.

▲ **Figure 7.31 Calcium in the body.** This X-ray photograph shows the bone structure of the human hand. The primary mineral in bone and teeth is hydroxyapatite,  $\text{Ca}_5(\text{PO}_4)_3\text{OH}$ , in which calcium is present as  $\text{Ca}^{2+}$ .

### GIVE IT SOME THOUGHT

Calcium carbonate,  $\text{CaCO}_3$ , is often used as a dietary calcium supplement for bone health. Although  $\text{CaCO}_3(\text{s})$  is insoluble in water (Table 4.1), it can be taken orally to allow for the delivery of  $\text{Ca}^{2+}(\text{aq})$  ions to the musculoskeletal system. Why is this the case? [Hint: Recall the reactions of metal carbonates that were discussed in Section 4.3.]

## 7.8 GROUP TRENDS FOR SELECTED NONMETALS

### Hydrogen

Hydrogen, the first element in the periodic table, has a  $1s^1$  electron configuration, and for this reason its usual position in the table is above the alkali metals. However, hydrogen does not truly belong to any particular group. Unlike the alkali metals, hydrogen is a nonmetal that occurs as a colorless diatomic gas,  $\text{H}_2(\text{g})$ , under most conditions. Nevertheless, hydrogen can be metallic under tremendous pressures. The interiors of the planets Jupiter and Saturn, for example, are believed to consist of a dense core of rock and ice surrounded by a thick shell of metallic hydrogen. The metallic hydrogen is in turn surrounded by a layer of liquid molecular hydrogen that gradually transforms to a mixture of gaseous hydrogen and helium upon moving closer to the surface. The Cassini–Huygens satellite mission, launched in 1997, has provided a wealth of new information regarding Saturn and its largest moon, Titan, including their chemical compositions. The spacecraft successfully entered orbit around Saturn in June 2004, and in January 2005 the Huygens probe descended through Titan’s atmosphere (Figure 7.32 ▶).

Owing to the complete absence of nuclear shielding of its sole electron, the ionization energy of hydrogen, 1312 kJ/mol, is more than double that of any of the alkali metals (Figure 7.11). In fact, hydrogen’s ionization energy is comparable to the  $I_1$  values of other nonmetals, such as oxygen and chlorine. As a result, hydrogen does not lose its valence electron as easily as do the alkali metals. Whereas the alkali metals readily lose their valence electron to nonmetals to form ionic compounds, hydrogen shares its electron with nonmetals and thereby forms molecular compounds. The reactions between hydrogen and nonmetals can be quite exothermic, as evidenced by the combustion reaction between hydrogen and oxygen to form water (Figure 5.13):

▲ **Figure 7.32 Exploring Saturn.** This panoramic view of Saturn was taken from the Cassini spacecraft. From this perspective Saturn shelters the spacecraft from the Sun’s blinding glare.

We have also seen (Equation 7.17) that hydrogen reacts with active metals to form solid metal hydrides that contain the hydride ion,  $\text{H}^-$ . The fact that hydrogen can gain an electron further illustrates that it is not truly a member of the alkali metal family. In fact, in terms of chemical reactivity, hydrogen has more in common with the halogens (Group 7A) than with the alkali metals.

In addition to its ability to form covalent bonds and metal hydrides, probably the most important characteristic of hydrogen is its ability to lose its electron to form a cation. Indeed, the aqueous chemistry of hydrogen is dominated by the  $\text{H}^+(\text{aq})$  ion, which we first encountered in Chapter 4.  $\rightleftharpoons$  (Section 4.1) We will study this important ion in greater detail in Chapter 16.

### Group 6A: The Oxygen Group

As we proceed down group 6A, there is a change from nonmetallic to metallic character (Figure 7.15). Oxygen, sulfur, and selenium are typical nonmetals. Tellurium has some metallic properties and is classified as a metalloid. Polonium, which is radioactive and quite rare, is a metal.

Oxygen is a colorless gas at room temperature; all of the other members of group 6A are solids. Some of the physical properties of the group 6A elements are given in Table 7.6  $\blacktriangledown$ .

As we saw in Section 2.6, oxygen is encountered in two molecular forms,  $\text{O}_2$  and  $\text{O}_3$ . The  $\text{O}_2$  form is the more common one. People generally mean  $\text{O}_2$  when they say “oxygen,” although the name *dioxygen* is more descriptive. The  $\text{O}_3$  form is called **ozone**. The two forms of oxygen are examples of *allotropes*. Allotropes are different forms of the same element in the same state. (In this case both forms are gases.) About 21% of dry air consists of  $\text{O}_2$  molecules. Ozone is present in very small amounts in the upper atmosphere and in polluted air. It is also formed from  $\text{O}_2$  in electrical discharges, such as in lightning storms:

This reaction is strongly endothermic, telling us that  $\text{O}_3$  is less stable than  $\text{O}_2$ .

It is interesting to consider the differences in physical and chemical properties of the allotropes of oxygen. Although both  $\text{O}_2$  and  $\text{O}_3$  are colorless and therefore do not absorb visible light,  $\text{O}_3$  absorbs certain wavelengths of ultraviolet light that  $\text{O}_2$  does not. Because of this difference, the presence of ozone in the upper atmosphere is beneficial, filtering out harmful UV light  $\rightleftharpoons$  (Section 18.3). Ozone and dioxygen also have different chemical properties. Ozone, which has a pungent odor, is a powerful oxidizing agent. Because of this property ozone is sometimes added to water to kill bacteria or used in low levels to help to purify air. However, the reactivity of ozone also makes its presence in polluted air near Earth’s surface detrimental to human health.

Oxygen has a great tendency to attract electrons from other elements (to *oxidize* them). Oxygen in combination with a metal is almost always present as the oxide ion,  $\text{O}^{2-}$ . This ion has a noble-gas configuration and is particularly stable. As shown in Equation 7.27, the formation of nonmetal oxides is also often very exothermic and thus energetically favorable.

TABLE 7.6 ■ Some Properties of the Group 6A Elements

Element	Electron Configuration	Melting Point ( $^\circ\text{C}$ )	Density	Atomic Radius ( $\text{\AA}$ )	$I_1$ (kJ/mol)
Oxygen	$[\text{He}]2s^2 2p^4$	-218	1.43 g/L	0.73	1314
Sulfur	$[\text{Ne}]3s^2 3p^4$	115	1.96 g/cm <sup>3</sup>	1.02	1000
Selenium	$[\text{Ar}]3d^{10} 4s^2 4p^4$	221	4.82 g/cm <sup>3</sup>	1.16	941
Tellurium	$[\text{Kr}]4d^{10} 5s^2 5p^4$	450	6.24 g/cm <sup>3</sup>	1.35	869
Polonium	$[\text{Xe}]4f^{14} 5d^{10} 6s^2 6p^4$	254	9.20 g/cm <sup>3</sup>	—	812

In our discussion of the alkali metals, we noted two less common oxygen anions—the peroxide ( $\text{O}_2^{2-}$ ) ion and the superoxide ( $\text{O}_2^-$ ) ion. Compounds of these ions often react with themselves to produce an oxide and  $\text{O}_2$ . For example, aqueous hydrogen peroxide,  $\text{H}_2\text{O}_2$ , slowly decomposes into water and  $\text{O}_2$  at room temperature:

For this reason, bottles of aqueous hydrogen peroxide are topped with caps that are able to release the  $\text{O}_2(\text{g})$  produced before the pressure inside becomes too great (Figure 7.33▶).

After oxygen, the most important member of group 6A is sulfur. This element also exists in several allotropic forms, the most common and stable of which is the yellow solid having the molecular formula  $\text{S}_8$ . This molecule consists of an eight-membered ring of sulfur atoms, as shown in Figure 7.34▼. Even though solid sulfur consists of  $\text{S}_8$  rings, we usually write it simply as  $\text{S}(\text{s})$  in chemical equations to simplify the stoichiometric coefficients.

Like oxygen, sulfur has a tendency to gain electrons from other elements to form sulfides, which contain the  $\text{S}^{2-}$  ion. In fact, most sulfur in nature is present as metal sulfides. Sulfur is below oxygen in the periodic table, and the tendency of sulfur to form sulfide anions is not as great as that of oxygen to form oxide ions. As a result, the chemistry of sulfur is more complex than that of oxygen. In fact, sulfur and its compounds (including those in coal and petroleum) can be burned in oxygen. The main product is sulfur dioxide, a major pollutant:

We will discuss the environmental aspects of sulfur oxide chemistry in greater depth in Chapter 18.

◀ **Figure 7.34 Elemental sulfur.** At room temperature, the most common allotropic form of sulfur is an eight-member ring,  $\text{S}_8$ .

▶ **Figure 7.33 Hydrogen peroxide solution.** Bottles of this common antiseptic are topped with a cap that allows any excess pressure created by  $\text{O}_2(\text{g})$  to be released from the bottle. Hydrogen peroxide is often stored in dark-colored or opaque bottles to minimize exposure to light, which accelerates its decomposition.

## Group 7A: The Halogens

The group 7A elements are known as the **halogens**, after the Greek words *halos* and *gennao*, meaning “salt formers.” Some of the properties of these elements are given in Table 7.7▼. Astatine, which is both extremely rare and radioactive, is omitted because many of its properties are not yet known.

Unlike the group 6A elements, all the halogens are typical nonmetals. Their melting and boiling points increase with increasing atomic number. Fluorine and chlorine are gases at room temperature, bromine is a liquid, and iodine is a solid. Each element consists of diatomic molecules:  $\text{F}_2$ ,  $\text{Cl}_2$ ,  $\text{Br}_2$ , and  $\text{I}_2$ . Fluorine gas is pale yellow; chlorine gas is yellow-green; bromine liquid is reddish

**TABLE 7.7** ■ Some Properties of the Halogens

Element	Electron Configuration	Melting Point ( $^\circ\text{C}$ )	Density	Atomic Radius ( $\text{\AA}$ )	$I_1$ (kJ/mol)
Fluorine	$[\text{He}]2s^22p^5$	-220	1.69 g/L	0.71	1681
Chlorine	$[\text{Ne}]3s^23p^5$	-102	3.12 g/L	0.99	1251
Bromine	$[\text{Ar}]3d^{10}4s^24p^5$	-7.3	3.12 g/cm <sup>3</sup>	1.14	1140
Iodine	$[\text{Kr}]4d^{10}5s^25p^5$	114	4.94 g/cm <sup>3</sup>	1.33	1008

▲ **Figure 7.35 Elemental halogens.** All three of these elements—from left to right, iodine ( $I_2$ ), bromine ( $Br_2$ ), and chlorine ( $Cl_2$ )—exist as diatomic molecules.

brown and readily forms a reddish brown vapor; and solid iodine is grayish black and readily forms a violet vapor (Figure 7.35 ◀).

The halogens have highly negative electron affinities (Figure 7.14). Thus, it is not surprising that the chemistry of the halogens is dominated by their tendency to gain electrons from other elements to form halide ions,  $X^-$ . (In many equations  $X$  is used to indicate any one of the halogen elements.) Fluorine and chlorine are more reactive than bromine and iodine. In fact, fluorine removes electrons from almost any substance with which it comes into contact, including water, and usually does so very exothermically, as in the following equations:

As a result, fluorine gas is difficult and dangerous to use in the laboratory, requiring specialized equipment.

Chlorine is the most industrially useful of the halogens. In 2005, total production was 22 billion pounds, making it the eighth most produced chemical in the United States. Unlike fluorine, chlorine reacts slowly with water to form relatively stable aqueous solutions of HCl and HOCl (hypochlorous acid):

Chlorine is often added to drinking water and swimming pools, where the HOCl(aq) that is generated serves as a disinfectant.

The halogens react directly with most metals to form ionic halides. The halogens also react with hydrogen to form gaseous hydrogen halide compounds:

These compounds are all very soluble in water and dissolve to form the hydrohalic acids. As we discussed in Section 4.3, HCl(aq), HBr(aq), and HI(aq) are strong acids, whereas HF(aq) is a weak acid.

### GIVE IT SOME THOUGHT

Can you use data in Table 7.7 to provide estimates for the atomic radius and first ionization energy of an astatine atom?

## Group 8A: The Noble Gases

The group 8A elements, known as the **noble gases**, are all nonmetals that are gases at room temperature. They are all *monatomic* (that is, they consist of single atoms rather than molecules). Some physical properties of the noble-gas elements are listed in Table 7.8 ◀. The high radioactivity of radon (Rn, atomic number 86) has limited the study of its reaction chemistry and some of its properties.

The noble gases have completely filled  $s$  and  $p$  subshells. All elements of group 8A have large first ionization energies, and we see the expected decrease as we move down the column. Because the noble gases possess such stable electron configurations, they are exceptionally unreactive. In fact, until the early

**TABLE 7.8** ■ Some Properties of the Noble Gases

Element	Electron Configuration	Boiling Point (K)	Density (g/L)	Atomic Radius* (Å)	$I_1$ (kJ/mol)
Helium	$1s^2$	4.2	0.18	0.32	2372
Neon	$[He]2s^22p^6$	27.1	0.90	0.69	2081
Argon	$[Ne]3s^23p^6$	87.3	1.78	0.97	1521
Krypton	$[Ar]3d^{10}4s^24p^6$	120	3.75	1.10	1351
Xenon	$[Kr]4d^{10}5s^25p^6$	165	5.90	1.30	1170
Radon	$[Xe]4f^{14}5d^{10}6s^26p^6$	211	9.73	1.45	1037

\*Only the heaviest of the noble-gas elements form chemical compounds. Thus, the atomic radii for the lighter noble-gas elements are estimated values.

1960s the elements were called the *inert gases* because they were thought to be incapable of forming chemical compounds. In 1962, Neil Bartlett at the University of British Columbia reasoned that the ionization energy of Xe might be low enough to allow it to form compounds. In order for this to happen, Xe would have to react with a substance with an extremely high ability to remove electrons from other substances, such as fluorine. Bartlett synthesized the first noble-gas compound by combining Xe with the fluorine-containing compound  $\text{PtF}_6$ . Xenon also reacts directly with  $\text{F}_2(\text{g})$  to form the molecular compounds  $\text{XeF}_2$ ,  $\text{XeF}_4$ , and  $\text{XeF}_6$  (Figure 7.36 ▶). Krypton has a higher  $I_1$  value than xenon and is therefore less reactive. In fact, only a single stable compound of krypton is known,  $\text{KrF}_2$ . In 2000, Finnish scientists reported the first neutral molecule that contains argon, the  $\text{HArF}$  molecule, which is stable only at low temperatures.

▲ **Figure 7.36** A compound of xenon. Crystals of  $\text{XeF}_4$ , which is one of the very few compounds that contain a group 8A element.

### ■ SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

The element bismuth (Bi, atomic number 83) is the heaviest member of group 5A. A salt of the element, bismuth subsalicylate, is the active ingredient in Pepto-Bismol<sup>®</sup>, an over-the-counter medication for gastric distress.

- The covalent atomic radii of thallium (Tl) and lead (Pb) are 1.48 Å and 1.47 Å, respectively. Using these values and those in Figure 7.7, predict the covalent atomic radius of the element bismuth (Bi). Explain your answer.
- What accounts for the general increase in atomic radius going down the group 5A elements?
- Another major use of bismuth has been as an ingredient in low-melting metal alloys, such as those used in fire sprinkler systems and in typesetting. The element itself is a brittle white crystalline solid. How do these characteristics fit with the fact that bismuth is in the same periodic group with such nonmetallic elements as nitrogen and phosphorus?
- $\text{Bi}_2\text{O}_3$  is a basic oxide. Write a balanced chemical equation for its reaction with dilute nitric acid. If 6.77 g of  $\text{Bi}_2\text{O}_3$  is dissolved in dilute acidic solution to make 0.500 L of solution, what is the molarity of the solution of  $\text{Bi}^{3+}$  ion?
- $^{209}\text{Bi}$  is the heaviest stable isotope of any element. How many protons and neutrons are present in this nucleus?
- The density of Bi at 25 °C is 9.808 g/cm<sup>3</sup>. How many Bi atoms are present in a cube of the element that is 5.00 cm on each edge? How many moles of the element are present?

### SOLUTION

(a) Note that there is a gradual decrease in radius of the elements in Groups 3A–5A as we proceed across the fifth period, that is, in the series In–Sn–Sb. Therefore, it is reasonable to expect a decrease of about 0.02 Å as we move from Pb to Bi, leading to an estimate of 1.45 Å. The tabulated value is 1.46 Å.

(b) The general increase in radius with increasing atomic number in the group 5A elements occurs because additional shells of electrons are being added, with corresponding increases in nuclear charge. The core electrons in each case largely shield the outermost electrons from the nucleus, so the effective nuclear charge does not vary greatly as we go to higher atomic numbers. However, the principal quantum number,  $n$ , of the outermost electrons steadily increases, with a corresponding increase in orbital radius.

(c) The contrast between the properties of bismuth and those of nitrogen and phosphorus illustrates the general rule that there is a trend toward increased metallic character as we move down in a given group. Bismuth, in fact, is a metal. The increased metallic character occurs because the outermost electrons are more readily lost in bonding, a trend that is consistent with its lower ionization energy.

(d) Following the procedures described in Section 4.2 for writing molecular and net ionic equations, we have the following:

In the net ionic equation, nitric acid is a strong acid and  $\text{Bi}(\text{NO}_3)_3$  is a soluble salt, so we need show only the reaction of the solid with the hydrogen ion forming the  $\text{Bi}^{3+}(\text{aq})$  ion and water.

To calculate the concentration of the solution, we proceed as follows (Section 4.5):

$$\frac{6.77 \text{ g Bi}_2\text{O}_3}{0.500 \text{ L soln}} \times \frac{1 \text{ mol Bi}_2\text{O}_3}{466.0 \text{ g Bi}_2\text{O}_3} \times \frac{2 \text{ mol Bi}^{3+}}{1 \text{ mol Bi}_2\text{O}_3} = \frac{0.0581 \text{ mol Bi}^{3+}}{\text{L soln}} = 0.0581 \text{ M}$$

(e) We can proceed as in Section 2.3. Bismuth is element 83; there are therefore 83 protons in the nucleus. Because the atomic mass number is 209, there are  $209 - 83 = 126$  neutrons in the nucleus.

(f) We proceed as in Sections 1.4 and 3.4: the volume of the cube is  $(5.00)^3 \text{ cm}^3 = 125 \text{ cm}^3$ . Then we have

$$125 \text{ cm}^3 \text{ Bi} \times \frac{9.808 \text{ g Bi}}{1 \text{ cm}^3} \times \frac{1 \text{ mol Bi}}{209.0 \text{ g Bi}} = 5.87 \text{ mol Bi}$$

$$5.87 \text{ mol Bi} \times \frac{6.022 \times 10^{23} \text{ atom Bi}}{1 \text{ mol Bi}} = 3.54 \times 10^{24} \text{ atoms Bi}$$

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 7.1** The periodic table was first developed by Mendeleev and Meyer on the basis of the similarity in chemical and physical properties exhibited by certain elements. Moseley established that each element has a unique atomic number, which added more order to the periodic table. We now recognize that elements in the same column of the periodic table have the same number of electrons in their **valence orbitals**. This similarity in valence electronic structure leads to the similarities among elements in the same group. The differences among elements in the same group arise because their valence orbitals are in different shells.

**Section 7.2** Many properties of atoms are due to the average distance of the outer electrons from the nucleus and to the **effective nuclear charge** experienced by these electrons. The core electrons are very effective in screening the outer electrons from the full charge of the nucleus, whereas electrons in the same shell do not screen each other effectively. As a result, the effective nuclear charge experienced by valence electrons increases as we move left to right across a period.

**Section 7.3** The size of an atom can be gauged by its **bonding atomic radius**, based on measurements of the distances separating atoms in their chemical compounds. In general, atomic radii increase as we go down a column in the periodic table and decrease as we proceed left to right across a row.

Cations are smaller than their parent atoms; anions are larger than their parent atoms. For ions of the same charge, size increases going down a column of the periodic table. An **isoelectronic series** is a series of ions that has the same number of electrons. For such a series, size decreases with increasing nuclear charge as the electrons are attracted more strongly to the nucleus.

**Section 7.4** The first **ionization energy** of an atom is the minimum energy needed to remove an electron from the atom in the gas phase, forming a cation. The second ionization energy is the energy needed to remove a second electron, and so forth. Ionization energies show a

sharp increase after all the valence electrons have been removed, because of the much higher effective nuclear charge experienced by the core electrons. The first ionization energies of the elements show periodic trends that are opposite those seen for atomic radii, with smaller atoms having higher first ionization energies. Thus, first ionization energies decrease as we go down a column and increase as we proceed left to right across a row.

We can write electron configurations for ions by first writing the electron configuration of the neutral atom and then removing or adding the appropriate number of electrons. Electrons are removed first from the orbitals with the largest value of  $n$ . If there are two valence orbitals with the same value of  $n$  (such as  $4s$  and  $4p$ ), then the electrons are lost first from the orbital with a higher value of  $l$  (in this case,  $4p$ ). Electrons are added to orbitals in the reverse order.

**Section 7.5** The **electron affinity** of an element is the energy change upon adding an electron to an atom in the gas phase, forming an anion. A negative electron affinity means that the anion is stable; a positive electron affinity means that the anion is not stable relative to the separated atom and electron, in which case its exact value cannot be measured. In general, electron affinities become more negative as we proceed from left to right across the periodic table. The halogens have the most-negative electron affinities. The electron affinities of the noble gases are positive because the added electron would have to occupy a new, higher-energy subshell.

**Section 7.6** The elements can be categorized as metals, nonmetals, and metalloids. Most elements are metals; they occupy the left side and the middle of the periodic table. Nonmetals appear in the upper-right section of the table. Metalloids occupy a narrow band between the metals and nonmetals. The tendency of an element to exhibit the properties of metals, called the **metallic character**, increases as we proceed down a column and decreases as we proceed from left to right across a row.

Metals have a characteristic luster, and they are good conductors of heat and electricity. When metals react with

nonmetals, the metal atoms are oxidized to cations and ionic substances are generally formed. Most metal oxides are basic; they react with acids to form salts and water.

Nonmetals lack metallic luster and are generally poor conductors of heat and electricity. Several are gases at room temperature. Compounds composed entirely of nonmetals are generally molecular. Nonmetals usually form anions in their reactions with metals. Nonmetal oxides are acidic; they react with bases to form salts and water. Metalloids have properties that are intermediate between those of metals and nonmetals.

**Section 7.7** The periodic properties of the elements can help us understand the properties of groups of the representative elements. The **alkali metals** (group 1A) are soft metals with low densities and low melting points. They have the lowest ionization energies of the elements. As a result, they are very reactive toward nonmetals, easily losing their outer  $s$  electron to form  $1+$  ions. The **alkaline earth metals** (group 2A) are harder and more dense and have higher melting points than the alkali metals. They are also very reactive toward nonmetals, although not as reactive as the alkali metals. The alkaline earth metals readily lose their two outer  $s$  electrons to form  $2+$  ions. Both alkali and alkaline earth metals react with hydrogen to form ionic substances that contain the **hydride ion**,  $\text{H}^-$ .

**Section 7.8** Hydrogen is a nonmetal with properties that are distinct from any of the groups of the periodic table. It forms molecular compounds with other nonmetals, such as oxygen and the halogens.

Oxygen and sulfur are the most important elements in group 6A. Oxygen is usually found as a diatomic molecule,  $\text{O}_2$ . **Ozone**,  $\text{O}_3$ , is an important allotrope of oxygen. Oxygen has a strong tendency to gain electrons from other elements, thus oxidizing them. In combination with metals, oxygen is usually found as the oxide ion,  $\text{O}^{2-}$ , although salts of the peroxide ion,  $\text{O}_2^{2-}$ , and superoxide ion,  $\text{O}_2^-$ , are sometimes formed. Elemental sulfur is most commonly found as  $\text{S}_8$  molecules. In combination with metals, it is most often found as the sulfide ion,  $\text{S}^{2-}$ .

The **halogens** (group 7A) are nonmetals that exist as diatomic molecules. The halogens have the most negative electron affinities of the elements. Thus their chemistry is dominated by a tendency to form  $1-$  ions, especially in reactions with metals.

The **noble gases** (group 8A) are nonmetals that exist as monatomic gases. They are very unreactive because they have completely filled  $s$  and  $p$  subshells. Only the heaviest noble gases are known to form compounds, and they do so only with very active nonmetals, such as fluorine.

## KEY SKILLS

- Understand the meaning of effective nuclear charge,  $Z_{\text{eff}}$ , and how  $Z_{\text{eff}}$  depends upon nuclear charge and electron configuration.
- Use the periodic table to predict the trends in atomic radii, ionic radii, ionization energy, and electron affinity.
- Understand how the radius of an atom changes upon losing electrons to form a cation or gaining electrons to form an anion.
- Understand how the ionization energy changes as we remove successive electrons. Recognize the jump in ionization energy that occurs when the ionization corresponds to removing a core electron.
- Be able to write the electron configurations of ions.
- Understand how irregularities in the periodic trends for electron affinity can be related to electron configuration.
- Recognize the differences in chemical and physical properties of metals and nonmetals, including the basicity of metal oxides and the acidity of nonmetal oxides.
- Understand how the atomic properties, such as ionization energy and electron configuration, are related to the chemical reactivity and physical properties of the alkali and alkaline earth metals (groups 1A and 2A).
- Be able to write balanced equations for the reactions of the group 1A and 2A metals with water, oxygen, hydrogen, and the halogens.
- Understand and recognize the unique characteristics of hydrogen.
- Understand how the atomic properties (such as ionization energy, electron configuration, and electron affinity) of group 6A, 7A, and 8A elements are related to their chemical reactivity and physical properties.

## KEY EQUATIONS

- $Z_{\text{eff}} = Z - S$  [7.1] Estimating effective nuclear charge

## VISUALIZING CONCEPTS

- 7.1 We can draw an analogy between the attraction of an electron to a nucleus and seeing a lightbulb—in essence, the more nuclear charge the electron “sees,” the greater the attraction. (a) Within this analogy, discuss how the shielding by core electrons is analogous to putting a frosted-glass lampshade between the lightbulb and your eyes, as shown in the illustration. (b) Explain how we could mimic moving to the right in a row of the periodic table by changing the wattage of the lightbulb. (c) How would you change the wattage of the bulb and/or the frosted glass to mimic the effect of moving down a column of the periodic table? [Section 7.2]

- 7.2 Fluorine has atomic number 9. If we represent the radius of a fluorine atom with the billiard ball illustrated here, would the analogy be more appropriate for the bonding or nonbonding atomic radius? If we used the same billiard ball to illustrate the concept of fluorine’s bonding atomic radius, would we overestimate or underestimate the bonding atomic radius? Explain. [Section 7.3]

- 7.3 Consider the  $A_2X_4$  molecule depicted below, where A and X are elements. The A—A bond length in this molecule is  $d_1$ , and the four A—X bond lengths are each  $d_2$ . (a) In terms of  $d_1$  and  $d_2$ , how could you define the bonding atomic radii of atoms A and X? (b) In terms of  $d_1$  and  $d_2$ , what would you predict for the X—X bond length of an  $X_2$  molecule? [Section 7.3]

- 7.4 Make a simple sketch of the shape of the main part of the periodic table, as shown. (a) Ignoring H and He, write a single straight arrow from the element with the smallest bonding atomic radius to the element with the largest. (b) Ignoring H and He, write a single straight arrow from the element with the smallest first ionization energy to the element with the largest. (c) What significant observation can you make from the arrows you drew in parts (a) and (b)? [Sections 7.3 and 7.4]

- 7.5 In the chemical process called *electron transfer*, an electron is transferred from one atom or molecule to another (We will talk about electron transfer extensively in Chapter 20.) A simple electron transfer reaction is

In terms of the ionization energy and electron affinity of atom A, what is the energy change for this reaction? For a representative nonmetal such as chlorine, is this process exothermic? For a representative metal such as sodium, is this process exothermic? [Sections 7.4 and 7.5]

- 7.6 An element X reacts with  $F_2(g)$  to form the molecular product shown below. (a) Write a balanced equation for this reaction (do not worry about the phases for X and the product). (b) Do you think that X is a metal or nonmetal? Explain. [Section 7.6]

## EXERCISES

## Periodic Table; Effective Nuclear Charge

- 7.7 Why did Mendeleev leave blanks in his early version of the periodic table? How did he predict the properties of the elements that belonged in those blanks?
- 7.8 The prefix *eka-* comes from the Sanskrit word for one. Mendeleev used this prefix to indicate that the unknown element was one place away from the known element that followed the prefix. For example, *eka-silicon*, which we now call germanium, is one element below silicon. Mendeleev also predicted the existence of *eka-manganese*, which was not experimentally confirmed until 1937 because this element is radioactive and does not occur in nature. Based on the periodic table shown in Figure 7.2, what do we now call the element Mendeleev called *eka-manganese*?
- 7.9 In Chapter 1 we learned that silicon is the second most abundant element in Earth's crust, accounting for more than one-fourth of the mass of the crust (Figure 1.6). Yet we see that silicon is not among the elements that have been known since ancient times (Figure 7.2), whereas iron, which accounts for less than 5% of Earth's crust, has been known since prehistoric times. Given silicon's abundance how do you account for its relatively late discovery?
- 7.10 (a) During the period from about 1800 to about 1865, the atomic weights of many elements were accurately measured. Why was this important to Mendeleev's formulation of the periodic table? (b) What property of the atom did Moseley associate with the wavelength of X-rays emitted from an element in his experiments? (c) Why are chemical and physical properties of the elements more closely related to atomic number than they are to atomic weight?
- 7.11 (a) What is meant by the term *effective nuclear charge*? (b) How does the effective nuclear charge experienced by the valence electrons of an atom vary going from left to right across a period of the periodic table?
- 7.12 (a) How is the concept of effective nuclear charge used to simplify the numerous electron-electron repulsions in a many-electron atom? (b) Which experiences a greater effective nuclear charge in a Be atom, the 1s electrons or the 2s electrons? Explain.
- 7.13 Detailed calculations show that the value of  $Z_{\text{eff}}$  for Na and K atoms is 2.51+ and 3.49+, respectively. (a) What value do you estimate for  $Z_{\text{eff}}$  experienced by the outermost electron in both Na and K by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (b) What values do you estimate for  $Z_{\text{eff}}$  using Slater's rules? (c) Which approach gives a more accurate estimate of  $Z_{\text{eff}}$ ? (d) Does either method of approximation account for the gradual increase in  $Z_{\text{eff}}$  that occurs upon moving down a group?
- 7.14 Detailed calculations show that the value of  $Z_{\text{eff}}$  for Si and Cl atoms is 4.29+ and 6.12+, respectively. (a) What value do you estimate for  $Z_{\text{eff}}$  experienced by the outermost electron in both Si and Cl by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (b) What values do you estimate for  $Z_{\text{eff}}$  using Slater's rules? (c) Which approach gives a more accurate estimate of  $Z_{\text{eff}}$ ? (d) Which method of approximation more accurately accounts for the steady increase in  $Z_{\text{eff}}$  that occurs upon moving left to right across a period?
- 7.15 Which will experience the greater effective nuclear charge, the electrons in the  $n = 3$  shell in Ar or the  $n = 3$  shell in Kr? Which will be closer to the nucleus? Explain.
- 7.16 Arrange the following atoms in order of increasing effective nuclear charge experienced by the electrons in the  $n = 3$  electron shell: K, Mg, P, Rh, and Ti. Explain the basis for your order.

## Atomic and Ionic Radii

- 7.17 (a) Because an exact outer boundary cannot be measured or even calculated for an atom, how are atomic radii determined? (b) What is the difference between a bonding radius and a nonbonding radius? (c) For a given element, which one is larger?
- 7.18 (a) Why does the quantum mechanical description of many-electron atoms make it difficult to define a precise atomic radius? (b) When nonbonded atoms come up against one another, what determines how closely the nuclear centers can approach?
- 7.19 The distance between W atoms in tungsten metal is 2.74 Å. What is the atomic radius of a tungsten atom in this environment? (This radius is called the *metallic radius*.)
- 7.20 Based on the radii presented in Figure 7.7, predict the distance between Si atoms in solid silicon.
- 7.21 Estimate the As—I bond length from the data in Figure 7.7, and compare your value to the experimental As—I bond length in arsenic triiodide, AsI<sub>3</sub>, 2.55 Å.
- 7.22 The experimental Bi—I bond length in bismuth triiodide, BiI<sub>3</sub>, is 2.81 Å. Based on this value and data in Figure 7.7, predict the atomic radius of Bi.
- 7.23 How do the sizes of atoms change as we move (a) from left to right across a row in the periodic table, (b) from top to bottom in a group in the periodic table? (c) Arrange the following atoms in order of increasing atomic radius: F, P, S, As.

- 7.24 (a) Among the nonmetallic elements, the change in atomic radius in moving one place left or right in a row is smaller than the change in moving one row up or down. Explain these observations. (b) Arrange the following atoms in order of increasing atomic radius: Si, Al, Ge, Ga.
- 7.25 Using only the periodic table, arrange each set of atoms in order of increasing radius: (a) Ca, Mg, Be; (b) Ga, Br, Ge; (c) Al, Ti, Si.
- 7.26 Using only the periodic table, arrange each set of atoms in order of increasing radius: (a) Ba, Ca, Na; (b) Sn, Sb, As; (c) Al, Be, Si.
- 7.27 (a) Why are monatomic cations smaller than their corresponding neutral atoms? (b) Why are monatomic anions larger than their corresponding neutral atoms? (c) Why does the size of ions increase as one proceeds down a column in the periodic table?
- 7.28 Explain the following variations in atomic or ionic radii: (a)  $I^- > I > I^+$ , (b)  $Ca^{2+} > Mg^{2+} > Be^{2+}$ , (c)  $Fe > Fe^{2+} > Fe^{3+}$ .
- 7.29 Consider a reaction represented by the following spheres:

Which sphere represents a metal and which a nonmetal? Explain.

- 7.30 Consider the following spheres:

Which one represents Ca, which  $Ca^{2+}$ , and which  $Mg^{2+}$ ?

- 7.31 (a) What is an isoelectronic series? (b) Which neutral atom is isoelectronic with each of the following ions:  $Al^{3+}$ ,  $Ti^{4+}$ ,  $Br^-$ ,  $Sn^{2+}$ .

- 7.32 Some ions do not have a corresponding neutral atom that has the same electron configuration. For each of the following ions identify the neutral atom that has the same number of electrons and determine if this atom has the same electron configuration. If such an atom does not exist explain why: (a)  $Cl^-$ , (b)  $Sc^{3+}$ , (c)  $Fe^{2+}$ , (d)  $Zn^{2+}$ , (e)  $Sn^{4+}$ .
- 7.33 Consider the isoelectronic ions  $F^-$  and  $Na^+$ . (a) Which ion is smaller? (b) Using Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant,  $S$ , calculate  $Z_{eff}$  for the 2p electrons in both ions. (c) Repeat this calculation using Slater's rules to estimate the screening constant,  $S$ . (d) For isoelectronic ions, how are effective nuclear charge and ionic radius related?
- 7.34 Consider the isoelectronic ions  $Cl^-$  and  $K^+$ . (a) Which ion is smaller? (b) Use Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute nothing to the screening constant,  $S$ , calculate  $Z_{eff}$  for these two ions. (c) Repeat this calculation using Slater's rules to estimate the screening constant,  $S$ . (d) For isoelectronic ions how are effective nuclear charge and ionic radius related?

- 7.35 Consider S, Cl, and K and their most common ions. (a) List the atoms in order of increasing size. (b) List the ions in order of increasing size. (c) Explain any differences in the orders of the atomic and ionic sizes.

- 7.36 For each of the following sets of atoms and ions, arrange the members in order of increasing size: (a)  $Se^{2-}$ ,  $Te^{2-}$ , Se; (b)  $Co^{3+}$ ,  $Fe^{2+}$ ,  $Fe^{3+}$ ; (c) Ca,  $Ti^{4+}$ ,  $Sc^{3+}$ ; (d)  $Be^{2+}$ ,  $Na^+$ , Ne.

- 7.37 For each of the following statements, provide an explanation: (a)  $O^{2-}$  is larger than O; (b)  $S^{2-}$  is larger than  $O^{2-}$ ; (c)  $S^{2-}$  is larger than  $K^+$ ; (d)  $K^+$  is larger than  $Ca^{2+}$ .

- 7.38 In the ionic compounds LiF, NaCl, KBr, and RbI, the measured cation-anion distances are 2.01 Å (Li-F), 2.82 Å (Na-Cl), 3.30 Å (K-Br), and 3.67 Å (Rb-I), respectively. (a) Predict the cation-anion distance using the values of ionic radii given in Figure 7.8. (b) Is the agreement between the prediction and the experiment perfect? If not, why not? (c) What estimates of the cation-anion distance would you obtain for these four compounds using *bonding atomic radii*? Are these estimates as accurate as the estimates using ionic radii?

## Ionization Energies; Electron Affinities

- 7.39 Write equations that show the processes that describe the first, second, and third ionization energies of a boron atom.
- 7.40 Write equations that show the process for (a) the first two ionization energies of tin and (b) the fourth ionization energy of titanium.
- 7.41 (a) Why are ionization energies always positive quantities? (b) Why does F have a larger first ionization energy than O? (c) Why is the second ionization energy of an atom always greater than its first ionization energy?
- 7.42 (a) Why does Li have a larger first ionization energy than Na? (b) The difference between the third and fourth ionization energies of scandium is much larger than the difference between the third and fourth ionization energies of titanium. Why? (c) Why does Li have a much larger second ionization energy than Be?
- 7.43 (a) What is the general relationship between the size of an atom and its first ionization energy? (b) Which element in the periodic table has the largest ionization energy? Which has the smallest?
- 7.44 (a) What is the trend in first ionization energies as one proceeds down the group 7A elements? Explain how this trend relates to the variation in atomic radii. (b) What is the trend in first ionization energies as one moves across the fourth period from K to Kr? How does this trend compare with the trend in atomic radii?
- 7.45 Based on their positions in the periodic table, predict which atom of the following pairs will have the larger first ionization energy: (a) Cl, Ar; (b) Be, Ca; (c) K, Co; (d) S, Ge; (e) Sn, Te.

- 7.46 For each of the following pairs, indicate which element has the larger first ionization energy: (a) Ti, Ba; (b) Ag, Cu; (c) Ge, Cl; (d) Pb, Sb. (In each case use electron configuration and effective nuclear charge to explain your answer.)
- 7.47 Write the electron configurations for the following ions: (a)  $\text{In}^{3+}$ , (b)  $\text{Sb}^{3+}$ , (c)  $\text{Te}^{2-}$ , (d)  $\text{Te}^{6+}$ , (e)  $\text{Hg}^{2+}$ , (f)  $\text{Rh}^{3+}$ .
- 7.48 Write electron configurations for the following ions, and determine which have noble-gas configurations: (a)  $\text{Cr}^{3+}$ , (b)  $\text{N}^{3-}$ , (c)  $\text{Sc}^{3+}$ , (d)  $\text{Cu}^{2+}$ , (e)  $\text{Ti}^{+}$ , (f)  $\text{Au}^{+}$ .
- 7.49 Write the electron configuration for (a) the  $\text{Ni}^{2+}$  ion and (b) the  $\text{Sn}^{2+}$  ion. How many unpaired electrons does each contain?
- 7.50 Identify the element whose ions have the following electron configurations: (a) a  $2+$  ion with  $[\text{Ar}]3d^9$ , (b) a  $1+$  ion with  $[\text{Xe}]4f^{14}5d^{10}6s^2$ . How many unpaired electrons does each ion contain?
- 7.51 The first ionization energy of Ar and the electron affinity of Ar are both positive values. What is the significance of the positive value in each case?
- 7.52 The electron affinity of lithium is a negative value, whereas the electron affinity of beryllium is a positive value. Use electron configurations to account for this observation.
- 7.53 While the electron affinity of bromine is a negative quantity, it is positive for Kr. Use the electron configurations of the two elements to explain the difference.
- 7.54 What is the relationship between the ionization energy of an anion with a  $1-$  charge such as  $\text{F}^{-}$  and the electron affinity of the neutral atom, F?
- 7.55 Consider the first ionization energy of neon and the electron affinity of fluorine. (a) Write equations, including electron configurations, for each process. (b) These two quantities will have opposite signs. Which will be positive, and which will be negative? (c) Would you expect the magnitudes of these two quantities to be equal? If not, which one would you expect to be larger? Explain your answer.
- 7.56 Write an equation for the process that corresponds to the electron affinity of the  $\text{Mg}^{+}$  ion. Also write the electron configurations of the species involved. What is the magnitude of the energy change in the process? [Hint: The answer is in Table 7.2.]

## Properties of Metals and Nonmetals

- 7.57 How are metallic character and first ionization energy related?
- 7.58 Arrange the following pure solid elements in order of increasing electrical conductivity: Ge, Ca, S, and Si. Explain the reasoning you used.
- 7.59 If we look at groups 3A through 5A, we see two metalloids for groups 4A (Si, Ge) and 5A (As, Sb), but only one metalloid in group 3A (B). To maintain a regular geometric pattern one might expect that aluminum would also be a metalloid, giving group 3A two metalloids. What can you say about the metallic character of aluminum with respect to its neighbors based on its first ionization energy?
- 7.60 For each of the following pairs, which element will have the greater metallic character: (a) Li or Be, (b) Li or Na, (c) Sn or P, (d) Al or B?
- 7.61 Predict whether each of the following oxides is ionic or molecular:  $\text{SO}_2$ ,  $\text{MgO}$ ,  $\text{Li}_2\text{O}$ ,  $\text{P}_2\text{O}_5$ ,  $\text{Y}_2\text{O}_3$ ,  $\text{N}_2\text{O}$ , and  $\text{XeO}_3$ . Explain the reasons for your choices.
- 7.62 Some metal oxides, such as  $\text{Sc}_2\text{O}_3$ , do not react with pure water, but they do react when the solution becomes either acidic or basic. Do you expect  $\text{Sc}_2\text{O}_3$  to react when the solution becomes acidic or when it becomes basic? Write a balanced chemical equation to support your answer.
- 7.63 (a) What is meant by the terms acidic oxide and basic oxide? (b) How can we predict whether an oxide will be acidic or basic, based on its composition?
- 7.64 Arrange the following oxides in order of increasing acidity:  $\text{CO}_2$ ,  $\text{CaO}$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{SO}_3$ ,  $\text{SiO}_2$ , and  $\text{P}_2\text{O}_5$ .
- 7.65 Chlorine reacts with oxygen to form  $\text{Cl}_2\text{O}_7$ . (a) What is the name of this product (see Table 2.6)? (b) Write a balanced equation for the formation of  $\text{Cl}_2\text{O}_7(l)$  from the elements. (c) Under usual conditions,  $\text{Cl}_2\text{O}_7$  is a colorless liquid with a boiling point of  $81^\circ\text{C}$ . Is this boiling point expected or surprising? (d) Would you expect  $\text{Cl}_2\text{O}_7$  to be more reactive toward  $\text{H}^+(aq)$  or  $\text{OH}^-(aq)$ ? Explain.
- [7.66] An element X reacts with oxygen to form  $\text{XO}_2$  and with chlorine to form  $\text{XCl}_4$ .  $\text{XO}_2$  is a white solid that melts at high temperatures (above  $1000^\circ\text{C}$ ). Under usual conditions,  $\text{XCl}_4$  is a colorless liquid with a boiling point of  $58^\circ\text{C}$ . (a)  $\text{XCl}_4$  reacts with water to form  $\text{XO}_2$  and another product. What is the likely identity of the other product? (b) Do you think that element X is a metal, nonmetal, or metalloid? Explain. (c) By using a sourcebook such as the *CRC Handbook of Chemistry and Physics*, try to determine the identity of element X.
- 7.67 Write balanced equations for the following reactions: (a) barium oxide with water, (b) iron(II) oxide with perchloric acid, (c) sulfur trioxide with water, (d) carbon dioxide with aqueous sodium hydroxide.
- 7.68 Write balanced equations for the following reactions: (a) potassium oxide with water, (b) diphosphorus trioxide with water, (c) chromium(III) oxide with dilute hydrochloric acid, (d) selenium dioxide with aqueous potassium hydroxide.

## Group Trends in Metals and Nonmetals

- 7.69** Compare the elements sodium and magnesium with respect to the following properties: (a) electron configuration, (b) most common ionic charge, (c) first ionization energy, (d) reactivity toward water, (e) atomic radius. Account for the differences between the two elements.
- 7.70** (a) Compare the electron configurations and atomic radii (see Figure 7.7) of rubidium and silver. In what respects are their electronic configurations similar? Account for the difference in radii of the two elements. (b) As with rubidium, silver is most commonly found as the  $1+$  ion,  $\text{Ag}^+$ . However, silver is far less reactive. Explain these observations.
- 7.71** (a) Why is calcium generally more reactive than magnesium? (b) Why is calcium generally less reactive than potassium?
- 7.72** (a) Why is cesium more reactive toward water than is lithium? (b) One of the alkali metals reacts with oxygen to form a solid white substance. When this substance is dissolved in water, the solution gives a positive test for hydrogen peroxide,  $\text{H}_2\text{O}_2$ . When the solution is tested in a burner flame, a lilac-purple flame is produced. What is the likely identity of the metal? (c) Write a balanced chemical equation for reaction of the white substance with water.
- 7.73** Write a balanced equation for the reaction that occurs in each of the following cases: (a) Potassium metal burns in an atmosphere of chlorine gas. (b) Strontium oxide is added to water. (c) A fresh surface of lithium metal is exposed to oxygen gas. (d) Sodium metal is reacted with molten sulfur.
- 7.74** Write a balanced equation for the reaction that occurs in each of the following cases: (a) Cesium is added to water. (b) Strontium is added to water. (c) Sodium reacts with oxygen. (d) Calcium reacts with iodine.
- 7.75** (a) If we arrange the elements of the second period (Li–Ne) in order of increasing first ionization energy, where would hydrogen fit into this series? (b) If we now arrange the elements of the third period (Na–Ar) in order of increasing first ionization energy, where would lithium fit into this series? (c) Are these series consistent with the assignment of hydrogen as a nonmetal and lithium as a metal?
- 7.76** (a) As described in Section 7.7, the alkali metals react with hydrogen to form hydrides and react with halogens—for example, fluorine—to form halides. Compare the roles of hydrogen and the halogen in these reactions. In what sense are the forms of hydrogen and halogen in the products alike? (b) Write balanced equations for the reaction of fluorine with calcium and for the reaction of hydrogen with calcium. What are the similarities among the products of these reactions?
- 7.77** Compare the elements fluorine and chlorine with respect to the following properties: (a) electron configuration, (b) most common ionic charge, (c) first ionization energy, (d) reactivity toward water, (e) electron affinity, (f) atomic radius. Account for the differences between the two elements.
- 7.78** Little is known about the properties of astatine, At, because of its rarity and high radioactivity. Nevertheless, it is possible for us to make many predictions about its properties. (a) Do you expect the element to be a gas, liquid, or solid at room temperature? Explain. (b) What is the chemical formula of the compound it forms with Na?
- 7.79** Until the early 1960s the group 8A elements were called the inert gases; before that they were called the rare gases. The term rare gases was dropped after it was discovered that argon accounts for roughly 1% of Earth's atmosphere. (a) Why was the term inert gases dropped? (b) What discovery triggered this change in name? (c) What name is applied to the group now?
- 7.80** Why does xenon react with fluorine, whereas neon does not?
- 7.81** Write a balanced equation for the reaction that occurs in each of the following cases: (a) Ozone decomposes to dioxygen. (b) Xenon reacts with fluorine. (Write three different equations.) (c) Sulfur reacts with hydrogen gas. (d) Fluorine reacts with water.
- 7.82** Write a balanced equation for the reaction that occurs in each of the following cases: (a) Chlorine reacts with water. (b) Barium metal is heated in an atmosphere of hydrogen gas. (c) Lithium reacts with sulfur. (d) Fluorine reacts with magnesium metal.

## ADDITIONAL EXERCISES

- 7.83** Consider the stable elements through lead ( $Z = 82$ ). In how many instances are the atomic weights of the elements in the reverse order relative to the atomic numbers of the elements? What is the explanation for these cases?
- 7.84** (a) Which will have the lower energy, a  $4s$  or a  $4p$  electron in an As atom? (b) How can we use the concept of effective nuclear charge to explain your answer to part (a)?
- 7.85** (a) If the core electrons were totally effective at shielding the valence electrons and the valence electrons provided no shielding for each other, what would be the effective nuclear charge acting on the  $3s$  and  $3p$  valence electrons in P? (b) Repeat these calculations using Slater's rules. (c) Detailed calculations indicate that the effective nuclear charge is  $5.6+$  for the  $3s$  electrons and  $4.9+$  for the  $3p$  electrons. Why are the values for the  $3s$  and  $3p$  electrons different? (d) If you remove a single electron from a P atom, which orbital will it come from? Explain.

- 7.86 Nearly all the mass of an atom is in the nucleus, which has a very small radius. When atoms bond together (for example, two fluorine atoms in  $F_2$ ), why is the distance separating the nuclei so much larger than the radii of the nuclei?
- [7.87] Consider the change in effective nuclear charge experienced by a  $2p$  electron as we proceed from C to N. (a) Based on a simple model in which core electrons screen the valence electrons completely and valence electrons do not screen other valence electrons, what do you predict for the change in  $Z_{\text{eff}}$  from C to N? (b) What change do you predict using Slater's rules? (c) The actual change in  $Z_{\text{eff}}$  from C to N is 0.70+. Which approach to estimating  $Z_{\text{eff}}$  is more accurate? (d) The change in  $Z_{\text{eff}}$  from N to O is smaller than that from C to N. Can you provide an explanation for this observation?
- 7.88 As we move across a period of the periodic table, why do the sizes of the transition elements change more gradually than those of the representative elements?
- 7.89 In the series of group 5A hydrides, of general formula  $MH_3$ , the measured bond distances are P—H, 1.419 Å; As—H, 1.519 Å; Sb—H, 1.707 Å. (a) Compare these values with those estimated by use of the atomic radii in Figure 7.7. (b) Explain the steady increase in M—H bond distance in this series in terms of the electronic configurations of the M atoms.
- 7.90 It is possible to produce compounds of the form  $GeClH_3$ ,  $GeCl_2H_2$ , and  $GeCl_3H$ . What values do you predict for the Ge—H and Ge—Cl bond lengths in these compounds?
- 7.91 Note from the following table that the increase in atomic radius in moving from Zr to Hf is smaller than in moving from Y to La. Suggest an explanation for this effect.

Atomic Radii (Å)			
Sc	1.44	Ti	1.36
Y	1.62	Zr	1.48
La	1.69	Hf	1.50

- 7.92 The "Chemistry and Life" box on ionic size in Section 7.3 compares the ionic radii of  $Zn^{2+}$  and  $Cd^{2+}$ . (a) The 2+ ion of which other element seems the most obvious one to compare to  $Zn^{2+}$  and  $Cd^{2+}$ ? (b) With reference to Figure 2.24, is the element in part (a) essential for life? (c) Estimate the ionic radius of the 2+ ion of the element in part (a). Explain any assumptions you have made. (d) Would you expect the 2+ ion of the element in part (a) to be physiologically more similar to  $Zn^{2+}$  or to  $Cd^{2+}$ ? (e) Use a sourcebook or a Web search to determine whether the element in part (a) is toxic to humans.
- [7.93] The ionic substance strontium oxide, SrO, forms from the direct reaction of strontium metal with molecular oxygen. The arrangement of the ions in solid SrO is analogous to that in solid NaCl (see Figure 2.23) and is shown here. (a) Write a balanced equation for the formation of SrO(s) from the elements. (b) Based on the ionic radii in Figure 7.8, predict the length of the side of the

cube in the figure (the distance from the center of an atom at one corner to the center of an atom at a neighboring corner). (c) The experimental density of SrO is  $5.10 \text{ g/cm}^3$ . Given your answer to part (b), what is the number of formula units of SrO that are contained in the cube in the figure? (We will examine structures like those in the figure more closely in Chapter 11.)

- 7.94 Explain the variation in ionization energies of carbon, as displayed in the following graph:

- 7.95 Do you agree with the following statement? "A negative value for the electron affinity of an atom occurs when the outermost electrons incompletely shield one another from the nucleus." If not, change it to make it more nearly correct in your view. Apply either the statement as given or your revised statement to explain why the electron affinity of bromine is  $-325 \text{ kJ/mol}$  and that for its neighbor Kr is  $> 0$ .
- 7.96 Use orbital diagrams to illustrate what happens when an oxygen atom gains two electrons. Why is it extremely difficult to add a third electron to the atom?
- [7.97] Use electron configurations to explain the following observations: (a) The first ionization energy of phosphorus is greater than that of sulfur. (b) The electron affinity of nitrogen is lower (less negative) than those of both carbon and oxygen. (c) The second ionization energy of oxygen is greater than the first ionization energy of fluorine. (d) The third ionization energy of manganese is greater than those of both chromium and iron.

**7.98** The following table gives the electron affinities, in kJ/mol, for the group 1B and group 2B metals: (a) Why are the electron affinities of the group 2B elements greater than zero? (b) Why do the electron affinities of the group 1B elements become more negative as we move down the group? [Hint: Examine the trends in the electron affinity of other groups as we proceed down the periodic table.]

Cu -119	Zn > 0
Ag -126	Cd > 0
Au -223	Hg > 0

**7.99** Hydrogen is an unusual element because it behaves in some ways like the alkali metal elements and in other ways like a nonmetal. Its properties can be explained in part by its electron configuration and by the values for its ionization energy and electron affinity. (a) Explain why the electron affinity of hydrogen is much closer to the values for the alkali elements than for the halogens. (b) Is the following statement true? "Hydrogen has the smallest bonding atomic radius of any element that forms chemical compounds." If not, correct it. If it is, explain in terms of electron configurations. (c) Explain why the ionization energy of hydrogen is closer to the values for the halogens than for the alkali metals.

**[7.100]** The first ionization energy of the oxygen molecule is the energy required for the following process:

The energy needed for this process is 1175 kJ/mol, very similar to the first ionization energy of Xe. Would you expect  $\text{O}_2$  to react with  $\text{F}_2$ ? If so, suggest a product or products of this reaction.

**7.101** Based on your reading of this chapter, arrange the following in order of increasing melting point: K,  $\text{Br}_2$ , Mg, and  $\text{O}_2$ . Explain the factors that determine the order.

**7.102** The element strontium is used in a variety of industrial processes. It is not an extremely hazardous substance, but low levels of strontium ingestion could affect the health of children. Radioactive strontium is very hazardous; it was a by-product of nuclear weapons testing and was found widely distributed following nuclear tests. Calcium is quite common in the environment, including food products, and is frequently present in drinking water. Discuss the similarities and differences between calcium and strontium, and indicate how and why strontium might be expected to accompany calcium in water supplies, uptake by plants, and so on.

**[7.103]** There are certain similarities in properties that exist between the first member of any periodic family and the element located below it and to the right in the periodic table. For example, in some ways Li resembles Mg, Be resembles Al, and so forth. This observation is called the diagonal relationship. Using what we have learned in this chapter, offer a possible explanation for this relationship.

**[7.104]** A historian discovers a nineteenth-century notebook in which some observations, dated 1822, on a substance thought to be a new element, were recorded. Here are some of the data recorded in the notebook: Ductile, silver-white, metallic looking. Softer than lead. Unaffected by water. Stable in air. Melting point:  $153^\circ\text{C}$ . Density:  $7.3\text{ g/cm}^3$ . Electrical conductivity: 20% that of copper. Hardness: About 1% as hard as iron. When 4.20 g of the unknown is heated in an excess of oxygen, 5.08 g of a white solid is formed. The solid could be sublimed by heating to over  $800^\circ\text{C}$ . (a) Using information in the text and a handbook of chemistry, and making allowances for possible variations in numbers from current values, identify the element reported. (b) Write a balanced chemical equation for the reaction with oxygen. (c) Judging from Figure 7.2, might this nineteenth-century investigator have been the first to discover a new element?

## INTEGRATIVE EXERCISES

**[7.105]** Moseley established the concept of atomic number by studying X-rays emitted by the elements. The X-rays emitted by some of the elements have the following wavelengths:

Element	Wavelength ( $\text{\AA}$ )
Ne	14.610
Ca	3.358
Zn	1.435
Zr	0.786
Sn	0.491

(a) Calculate the frequency,  $\nu$ , of the X-rays emitted by each of the elements, in Hz. (b) Using graph paper (or

suitable computer software), plot the square root of  $\nu$  versus the atomic number of the element. What do you observe about the plot? (c) Explain how the plot in part (b) allowed Moseley to predict the existence of undiscovered elements. (d) Use the result from part (b) to predict the X-ray wavelength emitted by iron. (e) A particular element emits X-rays with a wavelength of  $0.980\text{ \AA}$ . What element do you think it is?

**[7.106]** (a) Write the electron configuration for Li, and estimate the effective nuclear charge experienced by the valence electron. (b) The energy of an electron in a one-electron atom or ion equals  $(-2.18 \times 10^{-18}\text{ J})\left(\frac{Z^2}{n^2}\right)$  where  $Z$  is the nuclear charge and  $n$  is the principal quantum number of the electron. Estimate the first ionization energy of Li. (c) Compare the result of your calculation with the

value reported in table 7.4, and explain the difference.

(d) What value of the effective nuclear charge gives the proper value for the ionization energy? Does this agree with your explanation in (c)?

- [7.107] One way to measure ionization energies is photoelectron spectroscopy (PES), a technique based on the photoelectric effect.  $\rightleftharpoons$  (Section 6.2) In PES, monochromatic light is directed onto a sample, causing electrons to be emitted. The kinetic energy of the emitted electrons is measured. The difference between the energy of the photons and the kinetic energy of the electrons corresponds to the energy needed to remove the electrons (that is, the ionization energy). Suppose that a PES experiment is performed in which mercury vapor is irradiated with ultraviolet light of wavelength 58.4 nm.
- (a) What is the energy of a photon of this light, in eV? (b) Write an equation that shows the process corresponding to the first ionization energy of Hg. (c) The kinetic energy of the emitted electrons is measured to be 10.75 eV. What is the first ionization energy of Hg, in kJ/mol? (d) With reference to Figure 7.11, determine which of the halogen elements has a first ionization energy closest to that of mercury.

- 7.108 Consider the gas-phase transfer of an electron from a sodium atom to a chlorine atom:

(a) Write this reaction as the sum of two reactions, one that relates to an ionization energy and one that relates to an electron affinity. (b) Use the result from part (a), data in this chapter, and Hess's law to calculate the enthalpy of the above reaction. Is the reaction exothermic or endothermic? (c) The reaction between sodium metal and chlorine gas is highly exothermic and produces NaCl(s), whose structure was discussed in Section 2.7. Comment on this observation relative to the calculated enthalpy for the aforementioned gas-phase reaction.

- [7.109] When magnesium metal is burned in air (Figure 3.5), two products are produced. One is magnesium oxide, MgO. The other is the product of the reaction of Mg with molecular nitrogen, magnesium nitride. When water is added to magnesium nitride, it reacts to form magnesium oxide and ammonia gas. (a) Based on the charge of the nitride ion (Table 2.5), predict the formula of magnesium nitride. (b) Write a balanced equation for the reaction of magnesium nitride with water. What is the driving force for this reaction? (c) In an experiment a piece of magnesium ribbon is burned in air in a crucible.

The mass of the mixture of MgO and magnesium nitride after burning is 0.470 g. Water is added to the crucible, further reaction occurs, and the crucible is heated to dryness until the final product is 0.486 g of MgO. What was the mass percentage of magnesium nitride in the mixture obtained after the initial burning? (d) Magnesium nitride can also be formed by reaction of the metal with ammonia at high temperature. Write a balanced equation for this reaction. If a 6.3-g Mg ribbon reacts with 2.57 g NH<sub>3</sub>(g) and the reaction goes to completion, which component is the limiting reactant? What mass of H<sub>2</sub>(g) is formed in the reaction? (e) The standard enthalpy of formation of solid magnesium nitride is -461.08 kJ/mol. Calculate the standard enthalpy change for the reaction between magnesium metal and ammonia gas.

- 7.110 (a) The experimental Bi—Br bond length in bismuth tribromide, BiBr<sub>3</sub>, is 2.63 Å. Based on this value and the data in Figure 7.7, predict the atomic radius of Bi. (b) Bismuth tribromide is soluble in acidic solution. It is formed by treating solid bismuth(III) oxide with aqueous hydrobromic acid. Write a balanced chemical equation for this reaction. (c) While bismuth(III) oxide is soluble in acidic solutions, it is insoluble in basic solutions such as NaOH(aq). Based on these properties, is bismuth characterized as a metallic, metalloid, or non-metallic element? (d) Treating bismuth with fluorine gas forms BiF<sub>5</sub>. Use the electron configuration of Bi to explain the formation of a compound with this formulation. (e) While it is possible to form BiF<sub>5</sub> in the manner just described, pentahalides of bismuth are not known for the other halogens. Explain why the pentahalide might form with fluorine, but not with the other halogens. How does the behavior of bismuth relate to the fact that xenon reacts with fluorine to form compounds, but not with the other halogens?
- 7.111 Potassium superoxide, KO<sub>2</sub>, is often used in oxygen masks (such as those used by firefighters) because KO<sub>2</sub> reacts with CO<sub>2</sub> to release molecular oxygen. Experiments indicate that 2 mol of KO<sub>2</sub>(s) react with each mole of CO<sub>2</sub>(g). (a) The products of the reaction are K<sub>2</sub>CO<sub>3</sub>(s) and O<sub>2</sub>(g). Write a balanced equation for the reaction between KO<sub>2</sub>(s) and CO<sub>2</sub>(g). (b) Indicate the oxidation number for each atom involved in the reaction in part (a). What elements are being oxidized and reduced? (c) What mass of KO<sub>2</sub>(s) is needed to consume 18.0 g CO<sub>2</sub>(g)? What mass of O<sub>2</sub>(g) is produced during this reaction?

CHAPTER  
8

# BASIC CONCEPTS OF CHEMICAL BONDING

**THE WHITE CLIFFS OF DOVER** in southeastern England are made up largely of chalk, a porous form of limestone. The mineral calcite, with a composition of  $\text{CaCO}_3$ , is the predominant chemical substance in both chalk and limestone. Much of Earth's calcite is produced by marine organisms, which combine  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  ions to form shells of  $\text{CaCO}_3$ . The presence of  $\text{CO}_3^{2-}$  ions in oceans can be traced to dissolved  $\text{CO}_2$  from the atmosphere.

### 8.1 Chemical Bonds, Lewis Symbols, and the Octet Rule

We can broadly characterize chemical bonds into three types: *ionic*, *covalent*, and *metallic*. In evaluating bonding, *Lewis symbols* provide a useful shorthand notation for keeping track of the valence electrons in atoms and ions.

### 8.2 Ionic Bonding

We will observe that in ionic substances the atoms are held together by the electrostatic attractions between ions of opposite charge. We will study the energetics of formation of ionic substances and describe the *lattice energy* of these substances.

### 8.3 Covalent Bonding

We also recognize that the atoms in molecular substances are held together by the sharing of one or more electron pairs between atoms. In general the electrons are shared in such a way that each atom attains an *octet* of electrons.

### 8.4 Bond Polarity and Electronegativity

We define *electronegativity* as the ability of an atom in a compound to attract electrons to itself. In general, electron pairs will be shared unequally between atoms of differing electronegativity, leading to *polar covalent bonds*.

### 8.5 Drawing Lewis Structures

We will see that *Lewis structures* are a simple yet powerful way of predicting the covalent bonding

patterns within molecules. In addition to the octet rule, we will see that the concept of *formal charge* can be used to identify the most favorable Lewis structure.

### 8.6 Resonance Structures

We observe that in some cases more than one equivalent Lewis structure can be drawn for a molecule or polyatomic ion. The actual structure in such cases is a blend of two or more contributing Lewis structures, called *resonance structures*.

### 8.7 Exceptions to the Octet Rule

We recognize that the octet rule is more of a guideline than an inviolate rule. Exceptions to the octet rule include molecules with an odd number of electrons; molecules where large differences in electronegativity prevent an atom from completing its octet; and, most commonly, molecules where an element from the third period or lower attains more than an octet of electrons.

### 8.8 Strengths of Covalent Bonds

We observe that bond strengths vary with the number of shared electron pairs as well as other factors. We can use *average bond enthalpy* values to estimate the enthalpies of reactions in cases where thermodynamic data such as heats of formation are unavailable.

**CALCIUM CARBONATE,  $\text{CaCO}_3$ , IS ONE OF THE MOST INTERESTING AND VERSATILE COMPOUNDS** on the planet. It accounts for roughly 4% of Earth's crust and is the major component of rocks such as limestone and marble. The white cliffs of Dover in southeastern England are one of the most

famous natural formations of  $\text{CaCO}_3$ . The cliffs consist almost entirely of a porous form of limestone called chalk.

Unlike most inorganic substances,  $\text{CaCO}_3$  is widely used by living organisms and is found in objects such as seashells, coral, eggshells, and pearls. Calcium carbonate plays a role in the complex chemistry associated with the greenhouse effect because it is formed in the oceans through the reaction between calcium ions and dissolved carbon dioxide. When limestone is heated to elevated temperatures,  $\text{CaCO}_3$  decomposes into solid  $\text{CaO}$  (the important industrial chemical called quicklime) and gaseous  $\text{CO}_2$ . Calcium carbonate undergoes the reactions that it does because the atoms in  $\text{CaCO}_3$  are held

▼ **Figure 8.1 Chemical bonds.** Examples of substances in which (a) ionic, (b) covalent, and (c) metallic bonds are found.

together by a combination of two different types of bonds. The carbon and oxygen atoms that make up the carbonate ion share valence electrons, resulting in the formation of *covalent bonds*. The oppositely charged  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  ions are held together by electrostatic attractions, which are called *ionic bonds*.

The properties of substances are determined in large part by the *chemical bonds* that hold their atoms together. What determines the type of bonding in each substance? How do the characteristics of these bonds give rise to different physical and chemical properties? The keys to answering the first question are found in the electronic structures of the atoms involved, which we discussed in Chapters 6 and 7. In this chapter and the next, we will examine the relationship between the electronic structures of atoms and the chemical bonds they form. We will also see how the properties of ionic and covalent substances arise from the distributions of electronic charge within atoms, ions, and molecules.

## 8.1 CHEMICAL BONDS, LEWIS SYMBOLS, AND THE OCTET RULE

Whenever two atoms or ions are strongly attached to each other, we say there is a **chemical bond** between them. There are three general types of chemical bonds: ionic, covalent, and metallic. Figure 8.1 ◀ shows examples of substances in which we find each of these types of attractive forces.

The term **ionic bond** refers to electrostatic forces that exist between ions of opposite charge. Ions may be formed from atoms by the transfer of one or more electrons from one atom to another. Ionic substances generally result from the interaction of metals on the left side of the periodic table with nonmetals on the right side (excluding the noble gases, group 8A). Ionic bonding will be discussed in Section 8.2.

A **covalent bond** results from the sharing of electrons between two atoms. The most familiar examples of covalent bonding are seen in the interactions of nonmetallic elements with one another. We devote much of this chapter and the next to describing and understanding covalent bonds.

**Metallic bonds** are found in metals, such as copper, iron, and aluminum. Each atom in a metal is bonded to several neighboring atoms. The bonding electrons are relatively free to move throughout the three-dimensional structure of the metal. Metallic bonds give rise to such typical metallic properties as high electrical conductivity and luster. We will examine these bonds in Chapter 23.

### Lewis Symbols

The electrons involved in chemical bonding are the *valence electrons*, which, for most atoms, are those residing in the outermost occupied shell of an atom. ∞ (Section 6.8) The American chemist G. N. Lewis (1875–1946) suggested a simple way of showing the valence electrons in an atom and tracking them in the course of bond formation, using what are now known as *Lewis electron-dot symbols*, or merely Lewis symbols.

The **Lewis symbol** for an element consists of the chemical symbol for the element plus a dot for each valence electron. Sulfur, for example, has the electron configuration  $[\text{Ne}]3s^23p^4$ ; its Lewis symbol therefore shows six valence electrons:

The dots are placed on the four sides of the atomic symbol: the top, the bottom, and the left and right sides. Each side can accommodate up to two electrons. All four sides of the symbol are equivalent, which means that the choice of which sides accommodate the fifth and sixth electrons is arbitrary.

TABLE 8.1 ■ Lewis Symbols

Element	Electron Configuration	Lewis Symbol	Element	Electron Configuration	Lewis Symbol
Li	[He]2s <sup>1</sup>	Li·	Na	[Ne]3s <sup>1</sup>	Na·
Be	[He]2s <sup>2</sup>	·Be·	Mg	[Ne]3s <sup>2</sup>	·Mg·
B	[He]2s <sup>2</sup> 2p <sup>1</sup>	·B·	Al	[Ne]3s <sup>2</sup> 3p <sup>1</sup>	·Al·
C	[He]2s <sup>2</sup> 2p <sup>2</sup>	·C·	Si	[Ne]3s <sup>2</sup> 3p <sup>2</sup>	·Si·
N	[He]2s <sup>2</sup> 2p <sup>3</sup>	·N·	P	[Ne]3s <sup>2</sup> 3p <sup>3</sup>	·P·
O	[He]2s <sup>2</sup> 2p <sup>4</sup>	·O·	S	[Ne]3s <sup>2</sup> 3p <sup>4</sup>	·S·
F	[He]2s <sup>2</sup> 2p <sup>5</sup>	·F·	Cl	[Ne]3s <sup>2</sup> 3p <sup>5</sup>	·Cl·
Ne	[He]2s <sup>2</sup> 2p <sup>6</sup>	·Ne·	Ar	[Ne]3s <sup>2</sup> 3p <sup>6</sup>	·Ar·

The electron configurations and Lewis symbols for the representative elements of the second and third rows of the periodic table are shown in Table 8.1▲. Notice that the number of valence electrons in any representative element is the same as the group number of the element. For example, the Lewis symbols for oxygen and sulfur, members of group 6A, both show six dots.

### GIVE IT SOME THOUGHT

Are all three of the following Lewis symbols for Cl correct?

## The Octet Rule

Atoms often gain, lose, or share electrons to achieve the same number of electrons as the noble gas closest to them in the periodic table. The noble gases have very stable electron arrangements, as evidenced by their high ionization energies, low affinity for additional electrons, and general lack of chemical reactivity. ∞ (Section 7.8) Because all noble gases (except He) have eight valence electrons, many atoms undergoing reactions also end up with eight valence electrons. This observation has led to a guideline known as the **octet rule**: *Atoms tend to gain, lose, or share electrons until they are surrounded by eight valence electrons.*

An octet of electrons consists of full *s* and *p* subshells in an atom. In terms of Lewis symbols, an octet can be thought of as four pairs of valence electrons arranged around the atom, as in the Lewis symbol for Ne in Table 8.1. There are many exceptions to the octet rule, but it provides a useful framework for introducing many important concepts of bonding.

## 8.2 IONIC BONDING

When sodium metal, Na(*s*), is brought into contact with chlorine gas, Cl<sub>2</sub>(*g*), a violent reaction ensues (Figure 8.2 ▼). The product of this very exothermic reaction is sodium chloride, NaCl(*s*):

Sodium chloride is composed of Na<sup>+</sup> and Cl<sup>−</sup> ions, which are arranged in a regular three-dimensional array, as shown in Figure 8.3 ▼.

The formation of Na<sup>+</sup> from Na and Cl<sup>−</sup> from Cl<sub>2</sub> indicates that an electron has been lost by a sodium atom and gained by a chlorine atom—we can envision an *electron transfer* from the Na atom to the Cl atom. Two of the atomic properties we discussed in Chapter 7 give us an indication of how readily electron transfer

### FORMATION OF SODIUM CHLORIDE

When metals and nonmetals react, electrons are transferred from the metal atoms to the nonmetal atoms, forming ions. The principal reason that ionic compounds are stable is the attraction between ions of unlike charge, which draws them together, releasing energy and causing the ions to form a solid array or lattice.

▲ Figure 8.2 Formation of sodium chloride.

▲ Figure 8.3 The crystal structure of sodium chloride. In this three-dimensional array of ions, each  $\text{Na}^+$  ion is surrounded by six  $\text{Cl}^-$  ions, and each  $\text{Cl}^-$  ion is surrounded by six  $\text{Na}^+$  ions.

occurs: the ionization energy, which indicates how easily an electron can be removed from an atom, and the electron affinity, which measures how much an atom wants to gain an electron.  $\infty$  (Sections 7.4 and 7.5) Electron transfer to form oppositely charged ions occurs when one of the atoms readily gives up an electron (low ionization energy) and the other atom readily gains an electron (high electron affinity). Thus, NaCl is a typical ionic compound because it consists of a metal of low ionization energy and a nonmetal of high electron affinity. Using Lewis electron-dot symbols (and showing a chlorine atom rather than the  $\text{Cl}_2$  molecule), we can represent this reaction as follows:

The arrow indicates the transfer of an electron from the Na atom to the Cl atom. Each ion has an octet of electrons, the octet on  $\text{Na}^+$  being the  $2s^2 2p^6$  electrons that lie below the single  $3s$  valence electron of the Na atom. We have put a bracket around the chloride ion to emphasize that all eight electrons are located on the  $\text{Cl}^-$  ion.

## GIVE IT SOME THOUGHT

Describe the electron transfers that occur in the formation of calcium oxide from elemental calcium and oxygen.

## Energetics of Ionic Bond Formation

As seen in Figure 8.2, the reaction of sodium with chlorine is *very* exothermic. In fact, Equation 8.1 is the reaction for the formation of NaCl(s) from its elements, so that the enthalpy change for the reaction is  $\Delta H_f^\circ$  for NaCl(s). In Appendix C we see that the heat of formation of other ionic substances is also quite negative. What factors make the formation of ionic compounds so exothermic?

In Equation 8.2 we represented the formation of NaCl as the transfer of an electron from Na to Cl. Recall from our discussion of ionization energies, however, that the loss of electrons from an atom is always an endothermic process.  $\infty$  (Section 7.4) Removing an electron from Na(g) to form Na<sup>+</sup>(g), for instance, requires 496 kJ/mol. Conversely, when a nonmetal gains an electron, the process is generally exothermic, as seen from the negative electron affinities of the elements.  $\infty$  (Section 7.5) Adding an electron to Cl(g), for example, releases 349 kJ/mol. If the transfer of an electron from one atom to another were the only factor in forming an ionic bond, the overall process would not be exothermic. For example, removing an electron from Na(g) and adding it to Cl(g) is an endothermic process that requires  $496 - 349 = 147$  kJ/mol. This endothermic process corresponds to the formation of sodium and chloride ions that are infinitely far apart—in other words, the positive energy change assumes that the ions are not interacting with one another, which is quite different from the situation in ionic solids.

## GIVE IT SOME THOUGHT

Consider the ionization energies of the alkali metals and the electron affinities of the halogens given in Chapter 7. Can you find any pair where the transfer of an electron from the alkali metal to the halogen would be an exothermic process?

The principal reason that ionic compounds are stable is the attraction between ions of unlike charge. This attraction draws the ions together, releasing energy and causing the ions to form a solid array, or lattice, such as that shown for NaCl in Figure 8.3. A measure of just how much stabilization results from arranging oppositely charged ions in an ionic solid is given by the **lattice energy**, which is the energy required to completely separate a mole of a solid ionic compound into its gaseous ions.

To get a picture of this process for NaCl, imagine that the structure shown in Figure 8.3 expands from within, so that the distances between the ions increase until the ions are very far apart. This process requires 788 kJ/mol, which is the value of the lattice energy:

Note that this process is highly endothermic. The reverse process—the coming together of Na(g)<sup>+</sup> and Cl(g)<sup>-</sup> to form NaCl(s)—is therefore highly exothermic  $\Delta H = -788$  kJ/mol.

Table 8.2 lists the lattice energies of NaCl and other ionic compounds. All are large positive values, indicating that the ions are strongly attracted to one another in these solids. The energy released by the

TABLE 8.2 ■ Lattice Energies for Some Ionic Compounds

Compound	Lattice Energy (kJ/mol)	Compound	Lattice Energy (kJ/mol)
LiF	1030	MgCl <sub>2</sub>	2326
LiCl	834	SrCl <sub>2</sub>	2127
LiI	730		
NaF	910	MgO	3795
NaCl	788	CaO	3414
NaBr	732	SrO	3217
NaI	682		
KF	808	ScN	7547
KCl	701		
KBr	671		
CsCl	657		
CsI	600		

attraction between ions of unlike charge more than makes up for the endothermic nature of ionization energies, making the formation of ionic compounds an exothermic process. The strong attractions also cause most ionic materials to be hard and brittle, with high melting points—for example, NaCl melts at 801 °C.

The magnitude of the lattice energy of a solid depends on the charges of the ions, their sizes, and their arrangement in the solid. We saw in Chapter 5 that the potential energy of two interacting charged particles is given by

$$E_{el} = \frac{\kappa Q_1 Q_2}{d} \quad [8.4]$$

In this equation  $Q_1$  and  $Q_2$  are the charges on the particles,  $d$  is the distance between their centers, and  $\kappa$  is a constant,  $8.99 \times 10^9 \text{ J}\cdot\text{m}/\text{C}^2$ .  $\rightleftharpoons$  (Section 5.1) Equation 8.4 indicates that the attractive interaction between two oppositely charged ions increases as the magnitudes of their charges increase and as the distance between their centers decreases. Thus, for a given arrangement of ions, the lattice energy increases as the charges on the ions increase and as their radii decrease. The magnitude of lattice energies depends predominantly on the ionic charges because ionic radii vary over only a limited range.

### SAMPLE EXERCISE 8.1 | Magnitudes of Lattice Energies

Without consulting Table 8.2, arrange the following ionic compounds in order of increasing lattice energy: NaF, CsI, and CaO.

#### SOLUTION

**Analyze:** From the formulas for three ionic compounds, we must determine their relative lattice energies.

**Plan:** We need to determine the charges and relative sizes of the ions in the compounds. We can then use Equation 8.4 qualitatively to determine the relative energies, knowing that the larger the ionic charges, the greater the energy and the farther apart the ions are, the lower the energy.

**Solve:** NaF consists of  $\text{Na}^+$  and  $\text{F}^-$  ions, CsI of  $\text{Cs}^+$  and  $\text{I}^-$  ions, and CaO of  $\text{Ca}^{2+}$  and  $\text{O}^{2-}$  ions. Because the product of the charges,  $Q_1 Q_2$ , appears in the numerator of Equation 8.4, the lattice energy will increase dramatically when the charges of the ions increase. Thus, we expect the lattice energy of CaO, which has 2+ and 2- ions, to be the greatest of the three.

The ionic charges in NaF and CsI are the same. As a result, the difference in their lattice energies will depend on the difference in the distance between the centers of the ions in their lattice. Because ionic size increases as we go down a group in the periodic table (Section 7.3), we know that  $\text{Cs}^+$  is larger than  $\text{Na}^+$  and  $\text{I}^-$  is larger than  $\text{F}^-$ . Therefore the distance between the  $\text{Na}^+$  and  $\text{F}^-$  ions in NaF will be less than the distance between the  $\text{Cs}^+$  and  $\text{I}^-$  ions in CsI. As a result, the lattice energy of NaF should be greater than that of CsI. In order of increasing energy, therefore, we have  $\text{CsI} < \text{NaF} < \text{CaO}$ .

**Check:** Table 8.2 confirms our predicted order is correct.

### PRACTICE EXERCISE

Which substance would you expect to have the greatest lattice energy,  $\text{MgF}_2$ ,  $\text{CaF}_2$ , or  $\text{ZrO}_2$ ?

*Answer:*  $\text{ZrO}_2$

## Electron Configurations of Ions of the s- and p-Block Elements

We began considering the electron configurations of ions in Section 7.4. In light of our examination of ionic bonding, we will continue with that discussion here. The energetics of ionic bond formation helps explain why many ions tend to have noble-gas electron configurations. For example, sodium readily loses one electron to form  $\text{Na}^+$ , which has the same electron configuration as Ne:

Even though lattice energy increases with increasing ionic charge, we never find ionic compounds that contain  $\text{Na}^{2+}$  ions. The second electron removed would have to come from an inner shell of the sodium atom, and removing electrons from an inner shell requires a very large amount of energy.  $\rightleftharpoons$  (Section 7.4) The increase in lattice energy is not enough to compensate for the energy needed to remove an inner-shell electron. Thus, sodium and the other group 1A metals are found in ionic substances only as  $1+$  ions.

Similarly, the addition of electrons to nonmetals is either exothermic or only slightly endothermic as long as the electrons are being added to the valence shell. Thus, a Cl atom easily adds an electron to form  $\text{Cl}^-$ , which has the same electron configuration as Ar:

To form a  $\text{Cl}^{2-}$  ion, the second electron would have to be added to the next higher shell of the Cl atom, which is energetically very unfavorable. Therefore, we never observe  $\text{Cl}^{2-}$  ions in ionic compounds. Based on these concepts, we expect that ionic compounds of the representative metals from groups 1A, 2A, and 3A will contain cations with charges of  $1+$ ,  $2+$ , and  $3+$ , respectively. Likewise, ionic compounds of the representative nonmetals of groups 5A, 6A, and 7A usually contain anions of charge  $3-$ ,  $2-$ , and  $1-$ , respectively.

### SAMPLE EXERCISE 8.2 | Charges on Ions

Predict the ion generally formed by (a) Sr, (b) S, (c) Al.

#### SOLUTION

**Analyze:** We must decide how many electrons are most likely to be gained or lost by atoms of Sr, S, and Al.

**Plan:** In each case we can use the element's position in the periodic table to predict whether it will form a cation or an anion. We can then use its electron configuration to determine the ion that is likely to be formed.

**Solve:** (a) Strontium is a metal in group 2A and will therefore form a cation. Its electron configuration is  $[\text{Kr}]5s^2$ , and so we expect that the two valence electrons can be lost easily to give an  $\text{Sr}^{2+}$  ion. (b) Sulfur is a nonmetal in group 6A and will thus tend to be found as an anion. Its electron configuration ( $[\text{Ne}]3s^2 3p^4$ ) is two electrons short of a noble-gas configuration. Thus, we expect that sulfur will form  $\text{S}^{2-}$  ions. (c) Aluminum is a metal in group 3A. We therefore expect it to form  $\text{Al}^{3+}$  ions.

**Check:** The ionic charges we predict here are confirmed in Tables 2.4 and 2.5.

### PRACTICE EXERCISE

Predict the charges on the ions formed when magnesium reacts with nitrogen.

*Answer:*  $\text{Mg}^{2+}$  and  $\text{N}^{3-}$

## Transition-Metal Ions

Because ionization energies increase rapidly for each successive electron removed, the lattice energies of ionic compounds are generally large enough to compensate for the loss of up to only three electrons from atoms. Thus, we find cations with charges of  $1+$ ,  $2+$ , or  $3+$  in ionic compounds. Most transition metals, however, have more than three electrons beyond a noble-gas core. Silver, for example, has a  $[\text{Kr}]4d^{10}5s^1$  electron configuration. Metals of group 1B (Cu, Ag, Au) often occur as  $1+$  ions (as in  $\text{CuBr}$  and  $\text{AgCl}$ ). In forming  $\text{Ag}^+$ , the 5s electron is lost, leaving a completely filled 4d subshell. As in this example, transition metals generally do not form ions that have a noble-gas configuration. The octet rule, although useful, is clearly limited in scope.

Recall from our discussion in Section 7.4 that when a positive ion is formed from an atom, electrons are always lost first from the subshell having the

## A Closer Look CALCULATION OF LATTICE ENERGIES: THE BORN-HABER CYCLE

Lattice energy is a useful concept because it relates directly to the stability of an ionic solid. Unfortunately, the lattice energy cannot be determined directly by experiment. It can, however, be calculated by envisioning the formation of an ionic compound as occurring in a series of well-defined steps. We can then use Hess's law (Section 5.6) to put these steps together in a way that gives us the lattice energy for the compound. By so doing, we construct a **Born-Haber cycle**, a thermochemical cycle named after the German scientists Max Born (1882–1970) and Fritz Haber (1868–1934), who introduced it to analyze the factors contributing to the stability of ionic compounds.

In the Born-Haber cycle for NaCl, we consider the formation of NaCl(s) from the elements Na(s) and Cl<sub>2</sub>(g) by two different routes, as shown in Figure 8.4. The enthalpy change for the direct route (red arrow) is the heat of formation of NaCl(s):

The indirect route consists of five steps, shown by the green arrows in Figure 8.4. First, we generate gaseous atoms of sodium by vaporizing sodium metal. Then we form gaseous atoms of chlorine by breaking the bonds in the Cl<sub>2</sub> molecules. The enthalpy changes for these processes are available to us as enthalpies of formation (Appendix C):

Both of these processes are endothermic; energy is required to generate gaseous sodium and chlorine atoms.

In the next two steps we remove the electron from Na(g) to form Na<sup>+</sup>(g) and then add the electron to Cl(g) to form Cl<sup>-</sup>(g). The enthalpy changes for these processes equal the first ionization energy of Na, *I*<sub>1</sub>(Na), and the electron affinity of Cl, denoted *E*(Cl), respectively:  $\rightleftharpoons$  (Sections 7.4, 7.5)

Finally, we combine the gaseous sodium and chloride ions to form solid sodium chloride. Because this process is just the reverse of the lattice energy (breaking a solid into gaseous ions), the enthalpy change is the negative of the lattice energy, the quantity that we want to determine:

The sum of the five steps in the indirect path (green arrows) gives us NaCl(s) from Na(s) and  $\frac{1}{2}$ Cl<sub>2</sub>(g). Thus, from Hess's law we know that the sum of the enthalpy changes for these five steps equals that for the direct path, indicated by the red arrow, Equation 8.5:

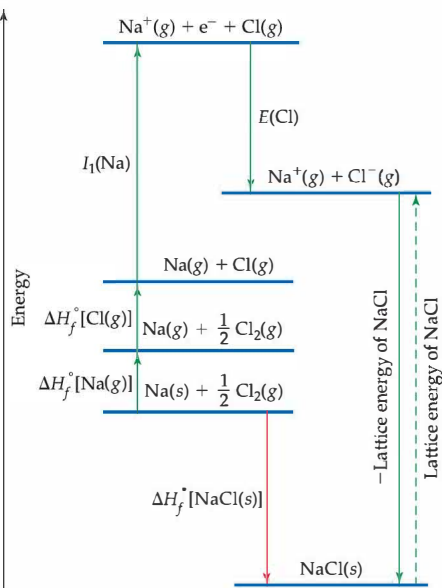

$$\Delta H_f^\circ[\text{NaCl(s)}] = \Delta H_f^\circ[\text{Na(g)}] + \Delta H_f^\circ[\text{Cl(g)}] \\ + I_1(\text{Na}) + E(\text{Cl}) - \Delta H_{\text{lattice}} \\ -411 \text{ kJ} = 108 \text{ kJ} + 122 \text{ kJ} + 496 \text{ kJ} - 349 \text{ kJ} - \Delta H_{\text{lattice}}$$

Solving for  $\Delta H_{\text{lattice}}$ :

$$\Delta H_{\text{lattice}} = 108 \text{ kJ} + 122 \text{ kJ} + 496 \text{ kJ} - 349 \text{ kJ} + 411 \text{ kJ} \\ = 788 \text{ kJ}$$

Thus, the lattice energy of NaCl is 788 kJ/mol.

**Related Exercises:** 8.26, 8.27, and 8.28

**▲ Figure 8.4 The Born-Haber cycle.** This representation shows the energetic relationships in the formation of ionic solids from the elements. By Hess's law, the enthalpy of formation of NaCl(s) from elemental sodium and chlorine (Equation 8.5) is equal to the sum of the energies of several individual steps (Equations 8.6 through 8.10).

largest value of *n*. Thus, in forming ions, transition metals lose the valence-shell *s* electrons first, then as many *d* electrons as are required to reach the charge of the ion. Let's consider Fe, which has the electron configuration [Ar]3d<sup>6</sup>4s<sup>2</sup>. In forming the Fe<sup>2+</sup> ion, the two 4s electrons are lost, leading to an [Ar]3d<sup>6</sup> configuration. Removal of an additional electron gives the Fe<sup>3+</sup> ion, whose electron configuration is [Ar]3d<sup>5</sup>.

## GIVE IT SOME THOUGHT

Which element forms a  $2+$  ion that has the electron configuration  $[\text{Kr}]4d^8$ ?

## 8.3 COVALENT BONDING

Ionic substances possess several characteristic properties. They are usually brittle substances with high melting points. They are usually crystalline. Furthermore, ionic crystals often can be cleaved; that is, they break apart along smooth, flat surfaces. These characteristics result from electrostatic forces that maintain the ions in a rigid, well-defined, three-dimensional arrangement such as that shown in Figure 8.3.

The vast majority of chemical substances do not have the characteristics of ionic materials. Most of the substances with which we come into daily contact—such as water—tend to be gases, liquids, or solids with low melting points. Many, such as gasoline, vaporize readily. Many are pliable in their solid forms—for example, plastic bags and paraffin.

For the very large class of substances that do not behave like ionic substances, we need a different model for the bonding between atoms. G. N. Lewis reasoned that atoms might acquire a noble-gas electron configuration by sharing electrons with other atoms. As we noted in Section 8.1, a chemical bond formed by sharing a pair of electrons is called a *covalent bond*.

The hydrogen molecule,  $\text{H}_2$ , provides the simplest example of a covalent bond. When two hydrogen atoms are close to each other, electrostatic interactions occur between them. The two positively charged nuclei repel each other, the two negatively charged electrons repel each other, and the nuclei and electrons attract each other, as shown in Figure 8.5. Because the  $\text{H}_2$  molecule exists as a stable entity, the attractive forces must exceed the repulsive ones. Let's take a closer look at the attractive forces that hold this molecule together.

By using quantum mechanical methods analogous to those employed for atoms  $\rightleftharpoons$  (Section 6.5), it is possible to calculate the distribution of electron density in molecules. Such a calculation for  $\text{H}_2$  shows that the attractions between the nuclei and the electrons cause electron density to concentrate between the nuclei, as shown in Figure 8.5(b). As a result, the overall electrostatic interactions are attractive. Thus, the atoms in  $\text{H}_2$  are held together principally because the two nuclei are electrostatically attracted to the concentration of negative charge between them. In essence, the shared pair of electrons in any covalent bond acts as a kind of "glue" to bind atoms together.

## GIVE IT SOME THOUGHT

If a  $\text{H}_2$  molecule is ionized to form  $\text{H}_2^+$ , it will change the bond strength. Based on the simple description of covalent bonding given above, would you expect the  $\text{H}-\text{H}$  bond in  $\text{H}_2^+$  to be weaker or stronger than the  $\text{H}-\text{H}$  bond in  $\text{H}_2$ ?

## Lewis Structures

The formation of covalent bonds can be represented using Lewis symbols for the constituent atoms. The formation of the  $\text{H}_2$  molecule from two H atoms, for example, can be represented as

In this way, each hydrogen atom acquires a second electron, achieving the stable, two-electron, noble-gas electron configuration of helium.

The formation of a bond between two Cl atoms to give a  $\text{Cl}_2$  molecule can be represented in a similar way:

**▲ Figure 8.5 The covalent bond in  $\text{H}_2$ .** (a) The attractions and repulsions among electrons and nuclei in the hydrogen molecule. (b) Electron distribution in the  $\text{H}_2$  molecule. The concentration of electron density between the nuclei leads to a net attractive force that constitutes the covalent bond holding the molecule together.

By sharing the bonding electron pair, each chlorine atom has eight electrons (an octet) in its valence shell. It thus achieves the noble-gas electron configuration of argon.

The structures shown here for  $\text{H}_2$  and  $\text{Cl}_2$  are called **Lewis structures** (or Lewis electron-dot structures). In writing Lewis structures, we usually show each electron pair shared between atoms as a line and the unshared electron pairs as dots. Written this way, the Lewis structures for  $\text{H}_2$  and  $\text{Cl}_2$  are

For the nonmetals, the number of valence electrons in a neutral atom is the same as the group number. Therefore, one might predict that 7A elements, such as F, would form one covalent bond to achieve an octet; 6A elements, such as O, would form two covalent bonds; 5A elements, such as N, would form three covalent bonds; and 4A elements, such as C, would form four covalent bonds. These predictions are borne out in many compounds. For example, consider the simple hydrogen compounds of the nonmetals of the second row of the periodic table:

Thus, the Lewis model succeeds in accounting for the compositions of many compounds of nonmetals, in which covalent bonding predominates.

### ■ SAMPLE EXERCISE 8.3 | Lewis Structure of a Compound

Given the Lewis symbols for the elements nitrogen and fluorine shown in Table 8.1, predict the formula of the stable binary compound (a compound composed of two elements) formed when nitrogen reacts with fluorine, and draw its Lewis structure.

#### SOLUTION

**Analyze:** The Lewis symbols for nitrogen and fluorine reveal that nitrogen has five valence electrons and fluorine has seven.

**Plan:** We need to find a combination of the two elements that results in an octet of electrons around each atom in the compound. Nitrogen requires three additional electrons to complete its octet, whereas fluorine requires only one. Sharing a pair of electrons between one N atom and one F atom will result in an octet of electrons for fluorine but not for nitrogen. We therefore need to figure out a way to get two more electrons for the N atom.

**Solve:** Nitrogen must share a pair of electrons with three fluorine atoms to complete its octet. Thus, the Lewis structure for the resulting compound,  $\text{NF}_3$ , is

**Check:** The Lewis structure in the center shows that each atom is surrounded by an octet of electrons. Once you are accustomed to thinking of each line in a Lewis structure as representing *two* electrons, you can just as easily use the structure on the right to check for octets.

### ■ PRACTICE EXERCISE

Compare the Lewis symbol for neon with the Lewis structure for methane,  $\text{CH}_4$ . In what important way are the electron arrangements about neon and carbon alike? In what important respect are they different?

**Answer:** Both atoms have an octet of electrons about them. However, the electrons about neon are unshared electron pairs, whereas those about carbon are shared with four hydrogen atoms.

## Multiple Bonds

The sharing of a pair of electrons constitutes a single covalent bond, generally referred to simply as a **single bond**. In many molecules, atoms attain complete octets by sharing more than one pair of electrons. When two electron pairs are shared, two lines are drawn, representing a **double bond**. In carbon dioxide, for example, bonding occurs between carbon, with four valence electrons, and oxygen, with six:

As the diagram shows, each oxygen acquires an octet of electrons by sharing two electron pairs with carbon. Carbon, on the other hand, acquires an octet of electrons by sharing two electron pairs in each of the two bonds it forms with oxygen.

A **triple bond** corresponds to the sharing of three pairs of electrons, such as in the  $\text{N}_2$  molecule:

Because each nitrogen atom possesses five electrons in its valence shell, three electron pairs must be shared to achieve the octet configuration.

The properties of  $\text{N}_2$  are in complete accord with its Lewis structure. Nitrogen is a diatomic gas with exceptionally low reactivity that results from the very stable nitrogen–nitrogen bond. Study of the structure of  $\text{N}_2$  reveals that the nitrogen atoms are separated by only 1.10 Å. The short N—N bond distance is a result of the triple bond between the atoms. From structure studies of many different substances in which nitrogen atoms share one or two electron pairs, we have learned that the average distance between bonded nitrogen atoms varies with the number of shared electron pairs:

As a general rule, the distance between bonded atoms decreases as the number of shared electron pairs increases. The distance between the nuclei of the atoms involved in a bond is called the **bond length** for the bond. We first encountered bond lengths in Section 7.3 in our discussion of atomic radii, and we will discuss them further in Section 8.8.

### GIVE IT SOME THOUGHT

The C—O bond length in carbon monoxide, CO, is 1.13 Å, whereas the C—O bond length in  $\text{CO}_2$  is 1.24 Å. Without drawing a Lewis structure, do you think that carbon monoxide has a single, double, or triple bond between the C and O atoms?

## 8.4 BOND POLARITY AND ELECTRONEGATIVITY

When two identical atoms bond, as in  $\text{Cl}_2$  or  $\text{H}_2$ , the electron pairs must be shared equally. In highly ionic compounds, on the other hand, such as NaCl, there is relatively little sharing of electrons, which means that NaCl is best described as composed of  $\text{Na}^+$  and  $\text{Cl}^-$  ions. The 3s electron of the Na atom is, in effect, transferred completely to chlorine. The bonds that are found in most substances fall somewhere between these extremes.

The concept of **bond polarity** helps describe the sharing of electrons between atoms. A **nonpolar covalent bond** is one in which the electrons are shared equally between two atoms, as in the  $\text{Cl}_2$  and  $\text{N}_2$  examples we just cited.

In a **polar covalent bond**, one of the atoms exerts a greater attraction for the bonding electrons than the other. If the difference in relative ability to attract electrons is large enough, an ionic bond is formed.

### Electronegativity

We use a quantity called electronegativity to estimate whether a given bond will be nonpolar covalent, polar covalent, or ionic. **Electronegativity** is defined as the ability of an atom *in a molecule* to attract electrons to itself. The greater an atom's electronegativity, the greater is its ability to attract electrons to itself. The electronegativity of an atom in a molecule is related to its ionization energy and electron affinity, which are properties of isolated atoms. The *ionization energy* measures how strongly a gaseous atom holds on to its electrons,  $\infty$  (Section 7.4) while the *electron affinity* is a measure of how strongly an atom attracts additional electrons.  $\infty$  (Section 7.5) An atom with a very negative electron affinity and high ionization energy will both attract electrons from other atoms and resist having its electrons attracted away; it will be highly electronegative.

Numerical estimates of electronegativity can be based on a variety of properties, not just ionization energy and electron affinity. The American chemist Linus Pauling (1901–1994) developed the first and most widely used electronegativity scale; he based his scale on thermochemical data. Figure 8.6 shows Pauling's electronegativity values for many of the elements. The values are unitless. Fluorine, the most electronegative element, has an electronegativity of 4.0. The least electronegative element, cesium, has an electronegativity of 0.7. The values for all other elements lie between these two extremes.

Within each period there is generally a steady increase in electronegativity from left to right; that is, from the most metallic to the most nonmetallic elements. With some exceptions (especially within the transition metals), electronegativity decreases with increasing atomic number in any one group. This is what we might expect because we know that ionization energies tend to decrease with increasing atomic number in a group and electron affinities do not change very much. You do not need to memorize numerical values for electronegativity. Instead, you should know the periodic trends so that you can predict which of two elements is more electronegative.

▼ **Figure 8.6** Electronegativities of the elements. Electronegativity generally increases from left to right across a period and decreases from top to bottom down a group.

### GIVE IT SOME THOUGHT

How does the *electronegativity* of an element differ from its *electron affinity*?

### Electronegativity and Bond Polarity

We can use the difference in electronegativity between two atoms to gauge the polarity of the bonding between them. Consider these three fluorine-containing compounds:

Compound	F <sub>2</sub>	HF	LiF
Electronegativity difference	4.0 – 4.0 = 0	4.0 – 2.1 = 1.9	4.0 – 1.0 = 3.0
Type of bond	Nonpolar covalent	Polar covalent	Ionic

▲ **Figure 8.7 Electron density distribution.** This computer-generated rendering shows the calculated electron-density distribution on the surface of the  $F_2$ , HF, and LiF molecules. The regions of relatively low electron density (net positive charge) appear blue, those of relatively high electron density (net negative charge) appear red, and regions that are close to electrically neutral appear green.

In  $F_2$  the electrons are shared equally between the fluorine atoms, and thus the covalent bond is *nonpolar*. In general, a nonpolar covalent bond results when the electronegativities of the bonded atoms are equal.

In HF the fluorine atom has a greater electronegativity than the hydrogen atom, with the result that the sharing of electrons is unequal—the bond is polar. In general, a polar covalent bond results when the atoms differ in electronegativity. In HF the more electronegative fluorine atom attracts electron density away from the less electronegative hydrogen atom, leaving a partial positive charge on the hydrogen atom and a partial negative charge on the fluorine atom. We can represent this charge distribution as

The  $\delta^+$  and  $\delta^-$  (read “delta plus” and “delta minus”) symbolize the partial positive and negative charges, respectively.

In LiF the electronegativity difference is very large, meaning that the electron density is shifted far toward F. The resultant bond is therefore most accurately described as *ionic*. This shift of electron density toward the more electronegative atom can be seen in the results of calculations of electron density distributions. For the three species in our example, the calculated electron density distributions are shown in Figure 8.7▲. The regions of space that have relatively higher electron density are shown in red, and those with a relatively lower electron density are shown in blue. You can see that in  $F_2$  the distribution is symmetrical, in HF it is clearly shifted toward fluorine, and in LiF the shift is even greater. These examples illustrate, therefore, that *the greater the difference in electronegativity between two atoms, the more polar their bond.*

### GIVE IT SOME THOUGHT

Based on differences in electronegativity, how would you characterize the bonding in silicon nitride,  $Si_3N_4$ ? Would you expect the bonds between Si and N to be nonpolar, polar covalent, or ionic?

#### SAMPLE EXERCISE 8.4 | Bond Polarity

In each case, which bond is more polar: (a)  $B-Cl$  or  $C-Cl$ , (b)  $P-F$  or  $P-Cl$ ? Indicate in each case which atom has the partial negative charge.

#### SOLUTION

**Analyze:** We are asked to determine relative bond polarities, given nothing but the atoms involved in the bonds.

**Plan:** Because we are not asked for quantitative answers, we can use the periodic table and our knowledge of electronegativity trends to answer the question.

**Solve:**

(a) The chlorine atom is common to both bonds. Therefore, the analysis reduces to a comparison of the electronegativities of B and C. Because boron is to the left of carbon in the periodic table, we predict that boron has the lower electronegativity. Chlorine, being on the right side of the table, has a higher electronegativity. The more polar bond will be the one between the atoms having the lowest electronegativity (boron) and the highest electronegativity (chlorine). Consequently, the B—Cl bond is more polar; the chlorine atom carries the partial negative charge because it has a higher electronegativity.

(b) In this example phosphorus is common to both bonds, and the analysis reduces to a comparison of the electronegativities of F and Cl. Because fluorine is above chlorine in the periodic table, it should be more electronegative and will form the more polar bond with P. The higher electronegativity of fluorine means that it will carry the partial negative charge.

**Check:**

(a) Using Figure 8.6: The difference in the electronegativities of chlorine and boron is  $3.0 - 2.0 = 1.0$ ; the difference between chlorine and carbon is  $3.0 - 2.5 = 0.5$ . Hence the B—Cl bond is more polar, as we had predicted.

(b) Using Figure 8.6: The difference in the electronegativities of chlorine and phosphorus is  $3.0 - 2.1 = 0.9$ ; the difference between fluorine and phosphorus is  $4.0 - 2.1 = 1.9$ . Hence the P—F bond is more polar, as we had predicted.

**PRACTICE EXERCISE**

Which of the following bonds is most polar: S—Cl, S—Br, Se—Cl, or Se—Br?

*Answer:* Se—Cl

**Dipole Moments**

The difference in electronegativity between H and F leads to a polar covalent bond in the HF molecule. As a consequence, there is a concentration of negative charge on the more electronegative F atom, leaving the less electronegative H atom at the positive end of the molecule. A molecule such as HF, in which the centers of positive and negative charge do not coincide, is said to be a **polar molecule**. Thus, we describe both bonds and entire molecules as being polar and nonpolar.

We can indicate the polarity of the HF molecule in two ways:

Recall from the preceding subsection that “ $\delta+$ ” and “ $\delta-$ ” indicate the partial positive and negative charges on the H and F atoms. In the notation on the right, the arrow denotes the shift in electron density toward the fluorine atom. The crossed end of the arrow can be thought of as a plus sign that designates the positive end of the molecule.

Polarity helps determine many of the properties of substances that we observe at the macroscopic level, in the laboratory and in everyday life. Polar molecules align themselves with respect to one another, with the negative end of one molecule and the positive end of another attracting each other. Polar molecules are likewise attracted to ions. The negative end of a polar molecule is attracted to a positive ion, and the positive end is attracted to a negative ion. These interactions account for many properties of liquids, solids, and solutions, as you will see in Chapters 11, 12, and 13.

How can we quantify the polarity of a molecule? Whenever a distance separates two electrical charges of equal magnitude but opposite sign, a **dipole** is established. The quantitative measure of the magnitude of a dipole is called its **dipole moment**, denoted  $\mu$ . If a distance  $r$  separates two equal and opposite charges  $Q+$  and  $Q-$ , the magnitude of the dipole moment is the product of  $Q$  and  $r$  (Figure 8.8  $\blacktriangleleft$ ):

$$\mu = Qr \quad [8.11]$$

**▲ Figure 8.8 Dipole and dipole moment.** When charges of equal magnitude and opposite sign  $Q+$  and  $Q-$  are separated by a distance  $r$ , a dipole is produced. The size of the dipole is given by the dipole moment,  $\mu$ , which is the product of the charge separated and the distance of separation between the charge centers:  $\mu = Qr$ .

The dipole moment increases as the magnitude of charge that is separated increases and as the distance between the charges increases. For a nonpolar molecule, such as  $F_2$ , the dipole moment is zero because there is no charge separation.

### GIVE IT SOME THOUGHT

The molecules chlorine monofluoride,  $ClF$ , and iodine monofluoride,  $IF$ , are examples of *interhalogen* compounds—compounds that contain bonds between different halogen elements. Which of these molecules will have the larger dipole moment?

Dipole moments are usually reported in *debyes* (D), a unit that equals  $3.34 \times 10^{-30}$  coulomb-meters (C·m). For molecules, we usually measure charge in units of the electronic charge  $e$ ,  $1.60 \times 10^{-19}$  C, and distance in units of angstroms. Suppose that two charges  $1+$  and  $1-$  (in units of  $e$ ) are separated by a distance of  $1.00 \text{ \AA}$ . The dipole moment produced is

$$\mu = Qr = (1.60 \times 10^{-19} \text{ C})(1.00 \text{ \AA}) \left( \frac{10^{-10} \text{ m}}{1 \text{ \AA}} \right) \left( \frac{1 \text{ D}}{3.34 \times 10^{-30} \text{ C}\cdot\text{m}} \right) = 4.79 \text{ D}$$

Measurement of the dipole moments can provide us with valuable information about the charge distributions in molecules, as illustrated in Sample Exercise 8.5.

### SAMPLE EXERCISE 8.5 | Dipole Moments of Diatomic Molecules

The bond length in the  $HCl$  molecule is  $1.27 \text{ \AA}$ . (a) Calculate the dipole moment, in debyes, that would result if the charges on the H and Cl atoms were  $1+$  and  $1-$ , respectively. (b) The experimentally measured dipole moment of  $HCl(g)$  is  $1.08 \text{ D}$ . What magnitude of charge, in units of  $e$ , on the H and Cl atoms would lead to this dipole moment?

#### SOLUTION

**Analyze and Plan:** We are asked in (a) to calculate the dipole moment of  $HCl$  that would result if there were a full charge transferred from H to Cl. We can use Equation 8.11 to obtain this result. In (b), we are given the actual dipole moment for the molecule and will use that value to calculate the actual partial charges on the H and Cl atoms.

#### Solve:

(a) The charge on each atom is the electronic charge,  $e = 1.60 \times 10^{-19} \text{ C}$ . The separation is  $1.27 \text{ \AA}$ . The dipole moment is therefore

$$\mu = Qr = (1.60 \times 10^{-19} \text{ C})(1.27 \text{ \AA}) \left( \frac{10^{-10} \text{ m}}{1 \text{ \AA}} \right) \left( \frac{1 \text{ D}}{3.34 \times 10^{-30} \text{ C}\cdot\text{m}} \right) = 6.08 \text{ D}$$

(b) We know the value of  $\mu$ ,  $1.08 \text{ D}$  and the value of  $r$ ,  $1.27 \text{ \AA}$ . We want to calculate the value of  $Q$ :

$$Q = \frac{\mu}{r} = \frac{(1.08 \text{ D}) \left( \frac{3.34 \times 10^{-30} \text{ C}\cdot\text{m}}{1 \text{ D}} \right)}{(1.27 \text{ \AA}) \left( \frac{10^{-10} \text{ m}}{1 \text{ \AA}} \right)} = 2.84 \times 10^{-20} \text{ C}$$

We can readily convert this charge to units of  $e$ :

$$\text{Charge in } e = (2.84 \times 10^{-20} \text{ C}) \left( \frac{1 e}{1.60 \times 10^{-19} \text{ C}} \right) = 0.178e$$

Thus, the experimental dipole moment indicates that the charge separation in the  $HCl$  molecule is

Because the experimental dipole moment is less than that calculated in part (a), the charges on the atoms are much less than a full electronic charge. We could have anticipated this because the  $H-Cl$  bond is polar covalent rather than ionic.

### PRACTICE EXERCISE

The dipole moment of chlorine monofluoride,  $ClF(g)$ , is  $0.88 \text{ D}$ . The bond length of the molecule is  $1.63 \text{ \AA}$ . (a) Which atom is expected to have the partial negative charge? (b) What is the charge on that atom, in units of  $e$ ?

**Answers:** (a) F, (b)  $0.11-$

**TABLE 8.3** Bond Lengths, Electronegativity Differences, and Dipole Moments of the Hydrogen Halides

Compound	Bond Length (Å)	Electronegativity Difference	Dipole Moment (D)
HF	0.92	1.9	1.82
HCl	1.27	0.9	1.08
HBr	1.41	0.7	0.82
HI	1.61	0.4	0.44

Table 8.3 ◀ presents the bond lengths and dipole moments of the hydrogen halides. Notice that as we proceed from HF to HI, the electronegativity difference decreases and the bond length increases. The first effect decreases the amount of charge separated and causes the dipole moment to decrease from HF to HI, even though the bond length is increasing. Calculations identical to those used in Sample Exercise 8.5 show that the actual charges on the atoms decrease from  $0.41+/0.41-$  in HF to  $0.057+/0.057-$

in HI. We can “visualize” the varying degree of electronic charge shift in these substances from computer-generated renderings based on calculations of electron distribution, as shown in Figure 8.9 ▼. For these molecules, the change in the electronegativity difference has a greater effect on the dipole moment than does the change in bond length.

### GIVE IT SOME THOUGHT

The bond between carbon and hydrogen is one of the most important types of bonds in chemistry. The length of a H—C bond is approximately 1.1 Å. Based on this distance and differences in electronegativity, would you predict the dipole moment of an individual H—C bond to be larger or smaller than the dipole moment of the H—I bond?

Before leaving this section let's return to the LiF molecule pictured in Figure 8.7. Under standard conditions LiF exists as an extended ionic solid with an arrangement of atoms analogous to the sodium chloride structure shown in Figure 8.3. However, it is possible to generate LiF molecules by vaporizing the solid at high temperature. The molecules have a dipole moment of 6.28 D and a bond distance of 1.53 Å. From these values we can calculate the charge on lithium and fluorine to be  $0.857+$  and  $0.857-$ , respectively. This bond is extremely polar, and the presence of such large charges strongly favors the formation of an extended ionic lattice whereby each lithium ion is surrounded by fluoride ions and vice versa.

### Differentiating Ionic and Covalent Bonding

To understand the interactions responsible for chemical bonding, it is advantageous to treat ionic and covalent bonding separately. That is the approach taken in this chapter, as well as in most undergraduate-level chemistry texts. The partitioning of bonding into ionic and covalent extremes is considered when we name chemical substances. We saw in Section 2.8 that there are two general approaches

▲ **Figure 8.9** Charge separation in the hydrogen halides. Blue represents regions of lowest electron density, red regions of highest electron density. In HF the strongly electronegative F pulls much of the electron density away from H. In HI the I, being much less electronegative than F, does not attract the shared electrons as strongly, and consequently there is far less polarization of the bond.

to naming binary compounds: one used for ionic compounds and the other for molecular ones. However, in reality there is a continuum between the extremes of ionic and covalent bonding. This lack of a well-defined separation between the two types of bonding may seem unsettling or confusing at first.

Fortunately, the simple models of ionic and covalent bonding presented in this chapter go quite a long way toward understanding and predicting the structures and properties of chemical compounds. When covalent bonding is dominant, more often than not we expect compounds to exist as molecules\*, with all of the properties we associate with molecular substances, such as relatively low melting and boiling points and non-electrolyte behavior when dissolved in water. Furthermore, we will see later that the polarity of covalent bonds has important consequence for the properties of substances. On the other hand, when ionic bonding is dominant, we expect the compounds to possess very different properties. Ionic compounds tend to be brittle, high-melting solids with extended lattice structures and they exhibit strong electrolyte behavior when dissolved in water.

There are of course exceptions to these general stereotypes, some of which we will examine later in the book. Nonetheless, the ability to quickly categorize the predominant bonding interactions in a substance as covalent or ionic imparts considerable insight into the properties of that substance. The question then becomes what is the best system for recognizing which type of bonding will be dominant?

The simplest approach one can take is to assume that the interaction between a metal and a nonmetal will be ionic, while the interaction between two nonmetals will be covalent. While this classification scheme is reasonably predictive, there are far too many exceptions to use it blindly. For example, tin is a metal and chlorine is a nonmetal, but  $\text{SnCl}_4$  is a molecular substance that exists as a colorless liquid at room temperature. It freezes at  $-33^\circ\text{C}$  and boils at  $114^\circ\text{C}$ . Clearly the bonding in this substance is better described as polar covalent than ionic. A more sophisticated approach, as outlined in the preceding discussion, is to use the difference in electronegativity as the main criterion for determining whether ionic or covalent bonding will be dominant. This approach correctly predicts the bonding in  $\text{SnCl}_4$  to be polar covalent based on an electronegativity difference of 1.2 and at the same time correctly predicts the bonding in  $\text{NaCl}$  to be predominantly ionic based on an electronegativity difference of 2.1.

Evaluating the bonding based on electronegativity difference is a useful system, but it has one shortcoming. Our electronegativity scale does not explicitly take into account changes in bonding that accompany changes in the oxidation state of the metal. For example, the electronegativity difference between manganese and oxygen is  $3.5 - 1.5 = 2.0$ , which falls in the range where the bonding is normally considered to be ionic (the electronegativity difference for  $\text{NaCl}$  was 2.1). Therefore, it is not surprising to learn that manganese (II) oxide,  $\text{MnO}$ , is a green solid that melts at  $1842^\circ\text{C}$  and has the same crystal structure as  $\text{NaCl}$ .

However, it would be incorrect to assume that the bonding between manganese and oxygen is always ionic. Manganese (VII) oxide, which has the formula  $\text{Mn}_2\text{O}_7$ , is a green liquid that freezes at  $5.9^\circ\text{C}$ , signaling that covalent rather than ionic bonding is dominant. The change in the oxidation state of manganese is responsible for the change in bonding type. As a general principle, whenever the oxidation state of the metal increases, it will lead to an increase in the degree of covalent character in the bonding. When the oxidation state of the metal becomes highly positive (roughly speaking +4 or larger), we should expect a significant degree of covalency in bonds it forms with nonmetals. In such instances you should not be surprised if a compound or polyatomic ion (such as  $\text{MnO}_4^-$  or  $\text{CrO}_4^{2-}$ ) exhibits the general properties of molecular, rather than ionic compounds.

\*There are some obvious exceptions to this rule, such as the network solids, including diamond, silicon, and germanium, where an extended structure is formed even though the bonding is clearly covalent. These examples are discussed in more detail in Section 11.8.

## GIVE IT SOME THOUGHT

You encounter two substances: one is a yellow solid that melts at 41 °C and boils at 131 °C. The other is a green solid that melts at 2320 °C. If you are told that one of the compounds is  $\text{Cr}_2\text{O}_3$  and the other is  $\text{OsO}_4$ , which one would you expect to be the yellow solid?

## 8.5 DRAWING LEWIS STRUCTURES

Lewis structures can help us understand the bonding in many compounds and are frequently used when discussing the properties of molecules. For this reason, drawing Lewis structures is an important skill that you should practice. To do so, you should follow a regular procedure. First we will outline the procedure, and then we will go through several examples.

1. *Sum the valence electrons from all atoms.* (Use the periodic table as necessary to help you determine the number of valence electrons in each atom.) For an anion, add one electron to the total for each negative charge. For a cation, subtract one electron from the total for each positive charge. Do not worry about keeping track of which electrons come from which atoms. Only the total number is important.
2. *Write the symbols for the atoms to show which atoms are attached to which, and connect them with a single bond* (a dash, representing two electrons). Chemical formulas are often written in the order in which the atoms are connected in the molecule or ion. The formula HCN, for example, tells you that the carbon atom is bonded to the H and to the N. In many polyatomic molecules and ions, the central atom is usually written first, as in  $\text{CO}_3^{2-}$  and  $\text{SF}_4$ . Remember that the central atom is generally less electronegative than the atoms surrounding it. In other cases, you may need more information before you can draw the Lewis structure.
3. *Complete the octets around all the atoms bonded to the central atom.* Remember, however, that you use only a single pair of electrons around hydrogen.
4. *Place any leftover electrons on the central atom,* even if doing so results in more than an octet of electrons around the atom. In Section 8.7 we will discuss molecules that do not adhere to the octet rule.
5. *If there are not enough electrons to give the central atom an octet, try multiple bonds.* Use one or more of the unshared pairs of electrons on the atoms bonded to the central atom to form double or triple bonds.

## SAMPLE EXERCISE 8.6 | Drawing Lewis Structures

Draw the Lewis structure for phosphorus trichloride,  $\text{PCl}_3$ .

## SOLUTION

**Analyze and Plan:** We are asked to draw a Lewis structure from a molecular formula. Our plan is to follow the five-step procedure just described.

## Solve:

First, we sum the valence electrons. Phosphorus (group 5A) has five valence electrons, and each chlorine (group 7A) has seven. The total number of valence electrons is therefore

$$5 + (3 \times 7) = 26$$

Second, we arrange the atoms to show which atom is connected to which, and we draw a single bond between them. There are various ways the atoms might be arranged. In binary (two-element) compounds, however, the first element listed in the chemical formula is generally surrounded by the remaining atoms. Thus, we begin with a skeleton structure that shows a single bond between the phosphorus atom and each chlorine atom:

(It is not crucial to place the atoms in exactly this arrangement.)

Third, we complete the octets on the atoms bonded to the central atom. Placing octets around each Cl atom accounts for 24 electrons (remember, each line in our structure represents *two* electrons):

Fourth, we place the remaining two electrons on the central atom, completing the octet around it:

This structure gives each atom an octet, so we stop at this point. (Remember that in achieving an octet, the bonding electrons are counted for both atoms.)

### ■ PRACTICE EXERCISE

- (a) How many valence electrons should appear in the Lewis structure for  $\text{CH}_2\text{Cl}_2$ ?  
 (b) Draw the Lewis structure.

### ■ SAMPLE EXERCISE 8.7 | Lewis Structures with Multiple Bonds

Draw the Lewis structure for HCN.

#### SOLUTION

Hydrogen has one valence electron, carbon (group 4A) has four, and nitrogen (group 5A) has five. The total number of valence electrons is therefore  $1 + 4 + 5 = 10$ . In principle, there are different ways in which we might choose to arrange the atoms. Because hydrogen can accommodate only one electron pair, it always has only one single bond associated with it in any compound. Therefore,  $\text{C—H—N}$  is an impossible arrangement. The remaining two possibilities are  $\text{H—C—N}$  and  $\text{H—N—C}$ . The first is the arrangement found experimentally. You might have guessed this to be the atomic arrangement because (a) the formula is written with the atoms in this order, and (b) carbon is less electronegative than nitrogen. Thus, we begin with a skeleton structure that shows single bonds between hydrogen, carbon, and nitrogen:

These two bonds account for four electrons. If we then place the remaining six electrons around N to give it an octet, we do not achieve an octet on C:

We therefore try a double bond between C and N, using one of the unshared pairs of electrons we placed on N. Again, there are fewer than eight electrons on C, and so we next try a triple bond. This structure gives an octet around both C and N:

We see that the octet rule is satisfied for the C and N atoms, and the H atom has two electrons around it. This appears to be a correct Lewis structure.

### ■ PRACTICE EXERCISE

Draw the Lewis structure for (a)  $\text{NO}^+$  ion, (b)  $\text{C}_2\text{H}_4$ .

**SAMPLE EXERCISE 8.8** | Lewis Structure for a Polyatomic Ion

Draw the Lewis structure for the  $\text{BrO}_3^-$  ion.

**SOLUTION**

Bromine (group 7A) has seven valence electrons, and oxygen (group 6A) has six. We must now add one more electron to our sum to account for the  $1^-$  charge of the ion. The total number of valence electrons is therefore  $7 + (3 \times 6) + 1 = 26$ . For oxyanions— $\text{BrO}_3^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$ ,  $\text{CO}_3^{2-}$ , and so forth—the oxygen atoms surround the central nonmetal atoms. After following this format and then putting in the single bonds and distributing the unshared electron pairs, we have

Notice here and elsewhere that the Lewis structure for an ion is written in brackets with the charge shown outside the brackets at the upper right.

**PRACTICE EXERCISE**

Draw the Lewis structure for (a)  $\text{ClO}_2^-$  ion, (b)  $\text{PO}_4^{3-}$  ion.

**Formal Charge**

When we draw a Lewis structure, we are describing how the electrons are distributed in a molecule (or polyatomic ion). In some instances we can draw several different Lewis structures that all obey the octet rule. How do we decide which one is the most reasonable? One approach is to do some “bookkeeping” of the valence electrons to determine the formal charge of each atom in each Lewis structure. The **formal charge** of any atom in a molecule is the charge the atom would have if all the atoms in the molecule had the same electronegativity (that is, if each bonding electron pair in the molecule were shared equally between its two atoms).

To calculate the formal charge on any atom in a Lewis structure, we assign the electrons to the atom as follows:

1. All unshared (nonbonding) electrons are assigned to the atom on which they are found.
2. For any bond—single, double, or triple—*half* of the bonding electrons are assigned to each atom in the bond.

The formal charge of each atom is then calculated by *subtracting the number of electrons assigned to the atom from the number of valence electrons in the isolated atom*.

Let’s illustrate this procedure by calculating the formal charges on the C and N atoms in the cyanide ion,  $\text{CN}^-$ , which has the Lewis structure

For the C atom, there are 2 nonbonding electrons and 3 electrons from the 6 in the triple bond ( $\frac{1}{2} \times 6 = 3$ ) for a total of 5. The number of valence electrons on a neutral C atom is 4. Thus, the formal charge on C is  $4 - 5 = -1$ . For N, there are 2 nonbonding electrons and 3 electrons from the triple bond. Because the number of valence electrons on a neutral N atom is 5, its formal charge is  $5 - 5 = 0$ . Thus, the formal charges on the atoms in the Lewis structure of  $\text{CN}^-$  are

Notice that the sum of the formal charges equals the overall charge on the ion,  $1-$ . The formal charges on a neutral molecule must add to zero, whereas those on an ion add to give the overall charge on the ion.

The concept of formal charge can help us choose between alternative Lewis structures. We will consider the  $\text{CO}_2$  molecule to see how this is done. As shown in Section 8.3,  $\text{CO}_2$  is represented as having two double bonds. However, we can also satisfy the octet rule by drawing a Lewis structure having one single bond and one triple bond. Calculating the formal charge for each atom in these structures, we have

	$\ddot{\text{O}}=\text{C}=\ddot{\text{O}}$	$\ddot{\text{O}}-\text{C}\equiv\text{O}:$
Valence electrons:	6 4 6	6 4 6
-(Electrons assigned to atom):	6 4 6	7 4 5
Formal charge:	0 0 0	-1 0 +1

Note that in both cases the formal charges add up to zero, as they must because  $\text{CO}_2$  is a neutral molecule. So, which is the correct structure? As a general rule, when several Lewis structures are possible, we will use the following guidelines to choose the most correct one:

1. We generally choose the Lewis structure in which the atoms bear formal charges closest to zero.
2. We generally choose the Lewis structure in which any negative charges reside on the more electronegative atoms.

Thus, the first Lewis structure of  $\text{CO}_2$  is preferred because the atoms carry no formal charges and so satisfy the first guideline.

Although the concept of formal charge helps us choose between alternative Lewis structures, it is very important that you remember that *formal charges do not represent real charges on atoms*. These charges are just a bookkeeping convention. The actual charge distributions in molecules and ions are determined not by formal charges but by a number of factors, including the electronegativity differences between atoms.

### GIVE IT SOME THOUGHT

Suppose that a Lewis structure for a neutral fluorine-containing molecule results in a formal charge on the fluorine atom of  $+1$ . What conclusion would you draw?

#### SAMPLE EXERCISE 8.9 | Lewis Structures and Formal Charges

The following are three possible Lewis structures for the thiocyanate ion,  $\text{NCS}^-$ :

(a) Determine the formal charges of the atoms in each structure. (b) Which Lewis structure is the preferred one?

#### SOLUTION

(a) Neutral N, C, and S atoms have five, four, and six valence electrons, respectively. We can determine the following formal charges in the three structures by using the rules we just discussed:

As they must, the formal charges in all three structures sum to  $1-$ , the overall charge of the ion.

## 8.6 RESONANCE STRUCTURES

We sometimes encounter molecules and ions in which the experimentally determined arrangement of atoms is not adequately described by a single Lewis structure. Consider a molecule of ozone,  $O_3$ , which is a bent molecule with two equal  $O-O$  bond lengths (Figure 8.11 ▶). Because each oxygen atom contributes 6 valence electrons, the ozone molecule has 18 valence electrons. In writing the Lewis structure, we find that we must have one  $O-O$  single bond and one  $O=O$  double bond to attain an octet of electrons about each atom:

However, this structure cannot by itself be correct because it requires that one  $O-O$  bond be different from the other, contrary to the observed structure—we would expect the  $O=O$  double bond to be shorter than the  $O-O$  single bond. ⇌ (Section 8.3) In drawing the Lewis structure, however, we could just as easily have put the  $O=O$  bond on the left:

The placement of the atoms in these two alternative but completely equivalent Lewis structures for ozone is the same, but the placement of the electrons is different. Lewis structures of this sort are called **resonance structures**. To describe the structure of ozone properly, we write both Lewis structures and use a double-headed arrow to indicate that the real molecule is described by an average of the two resonance structures:

To understand why certain molecules require more than one resonance structure, we can draw an analogy to the mixing of paint (Figure 8.12 ▶). Blue and yellow are both primary colors of paint pigment. An equal blend of blue and yellow pigments produces green pigment. We cannot describe green paint in terms of a single primary color, yet it still has its own identity. Green paint does not oscillate between its two primary colors: It is not blue part of the time and yellow the rest of the time. Similarly, molecules such as ozone cannot be described as oscillating between the two individual Lewis structures shown above.

The true arrangement of the electrons in molecules such as  $O_3$  must be considered as a blend of two (or more) Lewis structures. By analogy to the green paint, the molecule has its own identity separate from the individual resonance structures. For example, the ozone molecule always has two equivalent  $O-O$  bonds whose lengths are intermediate between the lengths of an oxygen–oxygen single bond and an oxygen–oxygen double bond. Another way of looking at it is to say that the rules for drawing Lewis structures do not allow us to have a single structure that adequately represents the ozone molecule. For example, there are no rules for drawing half-bonds. We can get around this limitation by drawing two equivalent Lewis structures that, when averaged, amount to something very much like what is observed experimentally.

### GIVE IT SOME THOUGHT

The  $O-O$  bonds in ozone are often described as “one-and-a-half” bonds. Is this description consistent with the idea of resonance?

▲ **Figure 8.11 Ozone.** Molecular structure (top) and electron-distribution diagram (bottom) for the ozone molecule,  $O_3$ .

▲ **Figure 8.12 Resonance.** Describing a molecule as a blend of different resonance structures is similar to describing a paint color as a blend of primary colors. (a) Green paint is a blend of blue and yellow. We cannot describe green as a single primary color. (b) The ozone molecule is a blend of two resonance structures. We cannot describe the ozone molecule in terms of a single Lewis structure.

As an additional example of resonance structures, consider the nitrate ion,  $\text{NO}_3^-$ , for which three equivalent Lewis structures can be drawn:

Notice that the arrangement of atoms is the same in each structure—only the placement of electrons differs. In writing resonance structures, the same atoms must be bonded to each other in all structures, so that the only differences are in the arrangements of electrons. All three Lewis structures taken together adequately describe the nitrate ion, in which all three N—O bond lengths are the same.

### GIVE IT SOME THOUGHT

In the same sense that we describe the O—O bonds in  $\text{O}_3$  as “one-and-a-half” bonds, how would you describe the N—O bonds in  $\text{NO}_3^-$ ?

In some instances all the possible Lewis structures for a species may not be equivalent to one another. Instead, one or more may represent a more stable arrangement than other possibilities. We will encounter examples of this as we proceed.

### SAMPLE EXERCISE 8.10 Resonance Structures

Which is predicted to have the shorter sulfur–oxygen bonds,  $\text{SO}_3$  or  $\text{SO}_3^{2-}$ ?

#### SOLUTION

The sulfur atom has six valence electrons, as does oxygen. Thus,  $\text{SO}_3$  contains 24 valence electrons. In writing the Lewis structure, we see that three equivalent resonance structures can be drawn:

As was the case for  $\text{NO}_3^-$ , the actual structure of  $\text{SO}_3$  is an equal blend of all three. Thus, each S—O bond distance should be about one-third of the way between that of a single and that of a double bond (see the Give It Some Thought exercise above). That is, they should be shorter than single bonds but not as short as double bonds.

The  $\text{SO}_3^{2-}$  ion has 26 electrons, which leads to a Lewis structure in which all the S—O bonds are single bonds:

There are no other reasonable Lewis structures for this ion. It can be described quite well by a single Lewis structure rather than by multiple resonance structures.

Our analysis of the Lewis structures leads us to conclude that  $\text{SO}_3$  should have the shorter S—O bonds and  $\text{SO}_3^{2-}$  the longer ones. This conclusion is correct: The experimentally measured S—O bond lengths are 1.42 Å in  $\text{SO}_3$  and 1.51 Å in  $\text{SO}_3^{2-}$ .

### PRACTICE EXERCISE

Draw two equivalent resonance structures for the formate ion,  $\text{HCO}_2^-$ .

## Resonance in Benzene

Resonance is an extremely important concept in describing the bonding in organic molecules, particularly in the ones called *aromatic* molecules. Aromatic organic molecules include the hydrocarbon called *benzene*, which has the molecular formula  $C_6H_6$  (Figure 8.13 ▶). The six C atoms of benzene are bonded in a hexagonal ring, and one H atom is bonded to each C atom.

We can write two equivalent Lewis structures for benzene, each of which satisfies the octet rule. These two structures are in resonance:

Each resonance structure shows three C—C single bonds and three C=C double bonds, but the double bonds are in different places in the two structures. The experimental structure of benzene shows that all six C—C bonds are of equal length, 1.40 Å, intermediate between the typical bond lengths for a C—C single bond (1.54 Å) and a C=C double bond (1.34 Å).

Benzene is commonly represented by omitting the hydrogen atoms attached to carbon and showing only the carbon-carbon framework with the vertices unlabeled. In this convention, the resonance in the benzene molecule is represented either by two structures separated by a double-headed arrow, as with our other examples, or by a shorthand notation in which we draw a hexagon with a circle in it:

The shorthand notation on the right reminds us that benzene is a blend of two resonance structures—it emphasizes that the C=C double bonds cannot be assigned to specific edges of the hexagon. Chemists use both representations of benzene interchangeably.

The bonding arrangement in benzene confers special stability to the molecule. As a result, literally millions of organic compounds contain the six-membered rings characteristic of benzene. Many of these compounds are important in biochemistry, in pharmaceuticals, and in the production of modern materials. We will say more about the bonding in benzene in Chapter 9 and about its unusual stability in Chapter 25.

### GIVE IT SOME THOUGHT

Each Lewis structure of benzene has three C=C double bonds. Another hydrocarbon containing three C=C double bonds is *hexatriene*,  $C_6H_8$ . A Lewis structure of hexatriene is

Would you expect hexatriene to have multiple resonance structures like benzene? If not, why is this molecule different from benzene with respect to resonance?

(a)

(b)

▲ **Figure 8.13 Benzene, an “aromatic” organic compound.**

(a) Benzene is obtained from the distillation of fossil fuels. More than 4 billion pounds of benzene is produced annually in the United States. Because benzene is a carcinogen, its use is closely regulated. (b) The benzene molecule is a regular hexagon of carbon atoms with a hydrogen atom bonded to each one.

## 8.7 EXCEPTIONS TO THE OCTET RULE

The octet rule is so simple and useful in introducing the basic concepts of bonding that you might assume it is always obeyed. In Section 8.2, however, we noted its limitation in dealing with ionic compounds of the transition metals. The octet rule also fails in many situations involving covalent bonding. These exceptions to the octet rule are of three main types:

1. Molecules and polyatomic ions containing an odd number of electrons
2. Molecules and polyatomic ions in which an atom has fewer than an octet of valence electrons
3. Molecules and polyatomic ions in which an atom has more than an octet of valence electrons

### Odd Number of Electrons

In the vast majority of molecules and polyatomic ions, the total number of valence electrons is even, and complete pairing of electrons occurs. However, in a few molecules and polyatomic ions, such as  $\text{ClO}_2$ ,  $\text{NO}$ ,  $\text{NO}_2$ , and  $\text{O}_2^-$ , the number of valence electrons is odd. Complete pairing of these electrons is impossible, and an octet around each atom cannot be achieved. For example,  $\text{NO}$  contains  $5 + 6 = 11$  valence electrons. The two most important Lewis structures for this molecule are

### GIVE IT SOME THOUGHT

Which of the Lewis structures shown above for  $\text{NO}$  would be preferred based on analysis of the formal charges?

### Less than an Octet of Valence Electrons

A second type of exception occurs when there are fewer than eight valence electrons around an atom in a molecule or polyatomic ion. This situation is also relatively rare (with the exception of hydrogen and helium as we have already discussed), most often encountered in compounds of boron and beryllium. As an example, let's consider boron trifluoride,  $\text{BF}_3$ . If we follow the first four steps of the procedure at the beginning of Section 8.5 for drawing Lewis structures, we obtain the structure

There are only six electrons around the boron atom. In this Lewis structure the formal charges on both the B and the F atoms are zero. We could complete the octet around boron by forming a double bond (step 5). In so doing, we see that there are three equivalent resonance structures (the formal charges on each atom are shown in red):

These Lewis structures force a fluorine atom to share additional electrons with the boron atom, which is inconsistent with the high electronegativity of fluorine. In fact, the formal charges tell us that this is an unfavorable situation.

In each of the Lewis structures, the F atom involved in the B=F double bond has a formal charge of +1, while the less electronegative B atom has a formal charge of -1. Thus, the Lewis structures in which there is a B=F double bond are less important than the one in which there are fewer than an octet of valence electrons around boron:

We usually represent  $\text{BF}_3$  solely by the leftmost resonance structure, in which there are only six valence electrons around boron. The chemical behavior of  $\text{BF}_3$  is consistent with this representation. In particular,  $\text{BF}_3$  reacts very energetically with molecules having an unshared pair of electrons that can be used to form a bond with boron. For example,  $\text{BF}_3$  reacts with ammonia,  $\text{NH}_3$ , to form the compound  $\text{NH}_3\text{BF}_3$ :

In this stable compound, boron has an octet of valence electrons. We will consider reactions of this type in more detail in Chapter 16 when we study Lewis acids and bases. [⇌ \(Section 16.11\)](#)

### More than an Octet of Valence Electrons

The third and largest class of exceptions consists of molecules or polyatomic ions in which there are more than eight electrons in the valence shell of an atom. When we draw the Lewis structure for  $\text{PCl}_5$ , for example, we are forced to “expand” the valence shell and place ten electrons around the central phosphorus atom:

Other examples of molecules and ions with “expanded” valence shells are  $\text{SF}_4$ ,  $\text{AsF}_6^-$ , and  $\text{ICl}_4^-$ . The corresponding molecules with a second-period atom as the central atom, such as  $\text{NCl}_5$  and  $\text{OF}_4$ , do *not* exist. Let’s take a look at why expanded valence shells are observed only for elements in period 3 and beyond in the periodic table.

Elements of the second period have only the  $2s$  and  $2p$  valence orbitals available for bonding. Because these orbitals can hold a maximum of eight electrons, we never find more than an octet of electrons around elements from the second period. Elements from the third period and beyond, however, have  $ns$ ,  $np$ , and unfilled  $nd$  orbitals that can be used in bonding. For example, the orbital diagram for the valence shell of a phosphorus atom is

Although third-period elements often satisfy the octet rule, as in  $\text{PCl}_3$ , they also often exceed an octet by seeming to use their empty  $d$  orbitals to accommodate additional electrons.\*

Size also plays an important role in determining whether an atom in a molecule or polyatomic ion can accommodate more than eight electrons in its valence shell. The larger the central atom is, the larger the number of atoms that can surround it. The number of molecules and ions with expanded valence shells therefore increases with increasing size of the central atom. The size of the surrounding atoms is also important. Expanded valence shells occur most often when the central atom is bonded to the smallest and most electronegative atoms, such as F, Cl, and O.

### SAMPLE EXERCISE 8.11 | Lewis Structure for an Ion with an Expanded Valence Shell

Draw the Lewis structure for  $\text{ICl}_4^-$ .

#### SOLUTION

Iodine (group 7A) has seven valence electrons. Each chlorine (group 7A) also has seven. An extra electron is added to account for the  $1-$  charge of the ion. Therefore, the total number of valence electrons is

$$7 + 4(7) + 1 = 36$$

The I atom is the central atom in the ion. Putting eight electrons around each Cl atom (including a pair of electrons between I and each Cl to represent the single bond between these atoms) requires  $8 \times 4 = 32$  electrons.

We are thus left with  $36 - 32 = 4$  electrons to be placed on the larger iodine:

Iodine has 12 valence electrons around it, four more than needed for an octet.

#### PRACTICE EXERCISE

(a) Which of the following atoms is never found with more than an octet of valence electrons around it: S, C, P, Br? (b) Draw the Lewis structure for  $\text{XeF}_2$ .

Answers: (a) C, (b)

At times you may see Lewis structures written with an expanded valence shell even though structures can be written with an octet. For example, consider the following Lewis structures for the phosphate ion,  $\text{PO}_4^{3-}$ :

The formal charges on the atoms are shown in red. In the Lewis structure shown on the left, the P atom obeys the octet rule. In the Lewis structure shown on the right, the P atom has an expanded valence shell of five electron pairs<sup>†</sup> leading to smaller formal charges on the atoms. Which Lewis structure is a better representation of the bonding in  $\text{PO}_4^{3-}$ ? Theoretical calculations based on quantum

\*Based on theoretical calculations, some chemists have questioned whether valence  $d$  orbitals are actually used in the bonding of molecules and ions with expanded valence shells. Nevertheless, the presence of valence  $d$  orbitals in period 3 and beyond provides the simplest explanation of this phenomenon, especially within the scope of a general chemistry textbook.

<sup>†</sup>The Lewis structure shown on the right has four equivalent resonance forms. Only one is shown for clarity.

mechanics suggest that the structure on the left is the best single Lewis structure for the phosphate ion. In general, when choosing between alternative Lewis structures, if it is possible to draw a Lewis structure where the octet rule is satisfied without using multiple bonds, that structure will be preferred.

## 8.8 STRENGTHS OF COVALENT BONDS

The stability of a molecule is related to the strengths of the covalent bonds it contains. The strength of a covalent bond between two atoms is determined by the energy required to break that bond. It is easiest to relate bond strength to the enthalpy change in reactions in which bonds are broken. [☞ \(Section 5.4\)](#) The **bond enthalpy** is the enthalpy change,  $\Delta H$ , for the breaking of a particular bond in one mole of a gaseous substance. For example, the bond enthalpy for the bond between chlorine atoms in the  $\text{Cl}_2$  molecule is the enthalpy change when 1 mol of  $\text{Cl}_2$  is dissociated into chlorine atoms:

We use the designation  $D(\text{bond type})$  to represent bond enthalpies.

It is relatively simple to assign bond enthalpies to bonds that are found in diatomic molecules, such as the  $\text{Cl}-\text{Cl}$  bond in  $\text{Cl}_2$ ,  $D(\text{Cl}-\text{Cl})$ , or the  $\text{H}-\text{Br}$  bond in  $\text{HBr}$ ,  $D(\text{H}-\text{Br})$ . The bond enthalpy is just the energy required to break the diatomic molecule into its component atoms. Many important bonds, such as the  $\text{C}-\text{H}$  bond, exist only in polyatomic molecules. For these types of bonds, we usually use *average* bond enthalpies. For example, the enthalpy change for the following process in which a methane molecule is decomposed to its five atoms (a process called *atomization*) can be used to define an average bond enthalpy for the  $\text{C}-\text{H}$  bond,  $D(\text{C}-\text{H})$ :

Because there are four equivalent  $\text{C}-\text{H}$  bonds in methane, the heat of atomization is equal to the sum of the bond enthalpies of the four  $\text{C}-\text{H}$  bonds. Therefore, the average  $\text{C}-\text{H}$  bond enthalpy for  $\text{CH}_4$  is  $D(\text{C}-\text{H}) = (1660/4) \text{ kJ/mol} = 415 \text{ kJ/mol}$ .

The bond enthalpy for a given set of atoms, say  $\text{C}-\text{H}$ , depends on the rest of the molecule of which the atom pair is a part. However, the variation from one molecule to another is generally small, which supports the idea that bonding electron pairs are localized between atoms. If we consider  $\text{C}-\text{H}$  bond enthalpies in many different compounds, we find that the average bond enthalpy is  $413 \text{ kJ/mol}$ , which compares closely with the  $415 \text{ kJ/mol}$  value calculated from  $\text{CH}_4$ .

### GIVE IT SOME THOUGHT

The hydrocarbon *ethane*,  $\text{C}_2\text{H}_6$ , was first introduced in Section 2.9. How could you use the enthalpy of atomization of  $\text{C}_2\text{H}_6(g)$  along with the value of  $D(\text{C}-\text{H})$  to provide an estimate for  $D(\text{C}-\text{C})$ ?

Table 8.4  $\blacktriangledown$  lists several average bond enthalpies. *The bond enthalpy is always a positive quantity*; energy is always required to break chemical bonds. Conversely, energy is always released when a bond forms between two gaseous atoms or molecular fragments. The greater the bond enthalpy is, the stronger the bond.

TABLE 8.4 ■ Average Bond Enthalpies (kJ/mol)

Single Bonds							
C—H	413	N—H	391	O—H	463	F—F	155
C—C	348	N—N	163	O—O	146		
C—N	293	N—O	201	O—F	190	Cl—F	253

C—F	485	N—Cl	200	O—I	234		
C—Cl	328	N—Br	243			Br—F	237
C—Br	276			S—H	339	Br—Cl	218
C—I	240	H—H	436	S—F	327	Br—Br	193
C—S	259	H—F	567	S—Cl	253		
		H—Cl	431	S—Br	218	I—Cl	208
Si—H	323	H—Br	366	S—S	266	I—Br	175
Si—Si	226	H—I	299			I—I	151
Si—C	301						
Si—O	368						
Si—Cl	464						
Multiple Bonds							
C=C	614	N=N	418	O <sub>2</sub>	495		
C≡C	839	N≡N	941				
C=N	615	N=O	607	S=O	523		
C≡N	891			S=S	418		
C=O	799						
C≡O	1072						

A molecule with strong chemical bonds generally has less tendency to undergo chemical change than does one with weak bonds. This relationship between strong bonding and chemical stability helps explain the chemical form in which many elements are found in nature. For example, Si—O bonds are among the strongest ones that silicon forms. It should not be surprising, therefore, that SiO<sub>2</sub> and other substances containing Si—O bonds (silicates) are so common; it is estimated that over 90% of Earth's crust is composed of SiO<sub>2</sub> and silicates.

### Bond Enthalpies and the Enthalpies of Reactions

We can use average bond enthalpies to estimate the enthalpies of reactions in which bonds are broken and new bonds are formed. This procedure allows us to estimate quickly whether a given reaction will be endothermic ( $\Delta H > 0$ ) or exothermic ( $\Delta H < 0$ ) even if we do not know  $\Delta H_f^\circ$  for all the chemical species involved.

Our strategy for estimating reaction enthalpies is a straightforward application of Hess's law.  $\rightleftharpoons$  (Section 5.6) We use the fact that breaking bonds is always an endothermic process, and bond formation is always exothermic. We therefore imagine that the reaction occurs in two steps: (1) We supply enough energy to break those bonds in the reactants that are not present in the products. In this step the enthalpy of the system is increased by the sum of the bond enthalpies of the bonds that are broken. (2) We form the bonds in the products that were not present in the reactants. This step releases energy and therefore lowers the enthalpy of the system by the sum of the bond enthalpies of the bonds that are formed. The enthalpy of the reaction,  $\Delta H_{\text{rxn}}$ , is estimated as the sum of the bond enthalpies of the bonds broken minus the sum of the bond enthalpies of the bonds formed:

$$\Delta H_{\text{rxn}} = \sum(\text{bond enthalpies of bonds broken}) - \sum(\text{bond enthalpies of bonds formed}) \quad [8.12]$$

◀ **Figure 8.14 Using bond enthalpies to calculate  $\Delta H_{\text{rxn}}$ .** Average bond enthalpies are used to estimate  $\Delta H_{\text{rxn}}$  for the reaction in Equation 8.13. Breaking the C—H and Cl—Cl bonds produces a positive enthalpy change ( $\Delta H_1$ ), whereas making the C—Cl and H—Cl bonds causes a negative enthalpy change ( $\Delta H_2$ ). The values of  $\Delta H_1$  and  $\Delta H_2$  are estimated from the values in Table 8.4. From Hess's law,  $\Delta H_{\text{rxn}} = \Delta H_1 + \Delta H_2$ .

Consider, for example, the gas-phase reaction between methane,  $\text{CH}_4$ , and chlorine to produce methyl chloride,  $\text{CH}_3\text{Cl}$ , and hydrogen chloride,  $\text{HCl}$ :

Our two-step procedure is outlined in Figure 8.14▲. We note that in the course of this reaction the following bonds are broken and made:

*Bonds broken:* 1 mol C—H, 1 mol Cl—Cl

*Bonds made:* 1 mol C—Cl, 1 mol H—Cl

We first supply enough energy to break the C—H and Cl—Cl bonds, which will raise the enthalpy of the system. We then form the C—Cl and H—Cl bonds, which will release energy and lower the enthalpy of the system. By using Equation 8.12 and the data in Table 8.4, we estimate the enthalpy of the reaction as

$$\begin{aligned} \Delta H_{\text{rxn}} &= [D(\text{C}-\text{H}) + D(\text{Cl}-\text{Cl}) - [D(\text{C}-\text{Cl}) + D(\text{H}-\text{Cl})]] \\ &= (413 \text{ kJ} + 242 \text{ kJ}) - (328 \text{ kJ} + 431 \text{ kJ}) = -104 \text{ kJ} \end{aligned}$$

The reaction is exothermic because the bonds in the products (especially the H—Cl bond) are stronger than the bonds in the reactants (especially the Cl—Cl bond).

We usually use bond enthalpies to estimate  $\Delta H_{\text{rxn}}$  only if we do not have the needed  $\Delta H_f^\circ$  values readily at hand. For the above reaction, we cannot calculate  $\Delta H_{\text{rxn}}$  from  $\Delta H_f^\circ$  values and Hess's law because the value of  $\Delta H_f^\circ$  for  $\text{CH}_3\text{Cl}(\text{g})$  is not given in Appendix C. If we obtain the value of  $\Delta H_f^\circ$  for  $\text{CH}_3\text{Cl}(\text{g})$  from another source (such as the *CRC Handbook of Chemistry and Physics*) and use Equation 5.31, we find that  $\Delta H_{\text{rxn}} = -99.8 \text{ kJ}$  for the reaction in Equation 8.13. Thus, the use of average bond enthalpies provides a reasonably accurate estimate of the actual reaction enthalpy change.

It is important to remember that bond enthalpies are derived for *gaseous* molecules and that they are often *averaged* values. Nonetheless, average bond enthalpies are useful for estimating reaction enthalpies quickly, especially for gas-phase reactions.

## Chemistry Put to Work

## EXPLOSIVES AND ALFRED NOBEL

Enormous amounts of energy can be stored in chemical bonds. Perhaps the most graphic illustration of this fact is seen in certain molecular substances that are used as explosives. Our discussion of bond enthalpies allows us to examine more closely some of the properties of such explosive substances.

An explosive must have the following characteristics: (1) It must decompose very exothermically; (2) the products of its decomposition must be gaseous, so that a tremendous gas pressure accompanies the decomposition; (3) its decomposition must occur very rapidly; and (4) it must be stable enough so that it can be detonated predictably. The combination of the first three effects leads to the violent evolution of heat and gases.

To give the most exothermic reaction, an explosive should have weak chemical bonds and should decompose into molecules with very strong bonds. Looking at bond enthalpies (Table 8.4), the  $\text{N}\equiv\text{N}$ ,  $\text{C}\equiv\text{O}$ , and  $\text{C}=\text{O}$  bonds are among the strongest. Not surprisingly, explosives are usually designed to produce the gaseous products  $\text{N}_2(\text{g})$ ,  $\text{CO}(\text{g})$ , and  $\text{CO}_2(\text{g})$ . Water vapor is nearly always produced as well.

Many common explosives are organic molecules that contain nitro ( $\text{NO}_2$ ) or nitrate ( $\text{NO}_3$ ) groups attached to a carbon skeleton. The Lewis structures of two of the most familiar explosives, nitroglycerin and trinitrotoluene (TNT), are

shown here (resonance structures are not shown for clarity). TNT contains the six-membered ring characteristic of benzene.

Nitroglycerin

Trinitrotoluene (TNT)

### SAMPLE EXERCISE 8.12 Using Average Bond Enthalpies

Using Table 8.4, estimate  $\Delta H$  for the following reaction (where we explicitly show the bonds involved in the reactants and products):

#### SOLUTION

**Analyze:** We are asked to estimate the enthalpy change for a chemical process by using average bond enthalpies for the bonds that are broken in the reactants and formed in the products.

**Plan:** Among the reactants, we must break six  $\text{C}-\text{H}$  bonds and a  $\text{C}-\text{C}$  bond in  $\text{C}_2\text{H}_6$ ; we also break  $\frac{7}{2} \text{O}_2$  bonds. Among the products, we form four  $\text{C}=\text{O}$  bonds (two in each  $\text{CO}_2$ ) and six  $\text{O}-\text{H}$  bonds (two in each  $\text{H}_2\text{O}$ ).

**Solve:** Using Equation 8.12 and data from Table 8.4, we have

$$\begin{aligned} \Delta H &= 6D(\text{C}-\text{H}) + D(\text{C}-\text{C}) + \frac{7}{2}D(\text{O}_2) - 4D(\text{C}=\text{O}) - 6D(\text{O}-\text{H}) \\ &= 6(413 \text{ kJ}) + 348 \text{ kJ} + \frac{7}{2}(495 \text{ kJ}) - (4(799 \text{ kJ}) + 6(463 \text{ kJ})) \\ &= 4558 \text{ kJ} - 5974 \text{ kJ} \\ &= -1416 \text{ kJ} \end{aligned}$$

**Check:** This estimate can be compared with the value of  $-1428 \text{ kJ}$  calculated from more accurate thermochemical data; the agreement is good.

#### PRACTICE EXERCISE

Using Table 8.4, estimate  $\Delta H$  for the reaction

**Answer:**  $-86 \text{ kJ}$

Nitroglycerin is a pale yellow, oily liquid. It is highly *shock-sensitive*: Merely shaking the liquid can cause its explosive decomposition into nitrogen, carbon dioxide, water, and oxygen gases:

The large bond enthalpies of the  $\text{N}_2$  molecules (941 kJ/mol),  $\text{CO}_2$  molecules ( $2 \times 799$  kJ/mol), and water molecules ( $2 \times 463$  kJ/mol) make this reaction enormously exothermic. Nitroglycerin is an exceptionally unstable explosive because it is in nearly perfect *explosive balance*: With the exception of a small amount of  $\text{O}_2(g)$  produced, the only products are  $\text{N}_2$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$ . Note also that, unlike combustion reactions (Section 3.2), explosions are entirely self-contained. No other reagent, such as  $\text{O}_2(g)$ , is needed for the explosive decomposition.

Because nitroglycerin is so unstable, it is difficult to use as a controllable explosive. The Swedish inventor Alfred Nobel (Figure 8.15) found that mixing nitroglycerin with an absorbent solid material such as diatomaceous earth or cellulose gives a solid explosive (*dynamite*) that is much safer than liquid nitroglycerin.

*Related Exercises: 8.93 and 8.94*

**▲ Figure 8.15 Alfred Nobel (1833–1896), the Swedish inventor of dynamite.** By many accounts Nobel's discovery that nitroglycerin could be made more stable by absorbing it onto cellulose was an accident. This discovery made Nobel a very wealthy man. He was also a complex and lonely man, however, who never married, was frequently ill, and suffered from chronic depression. He had invented the most powerful military explosive to date, but he strongly supported international peace movements. His will stated that his fortune be used to establish prizes awarding those who "have conferred the greatest benefit on mankind," including the promotion of peace and "fraternity between nations." The Nobel Prize is probably the most coveted award that a scientist, writer, or peace advocate can receive.

## Bond Enthalpy and Bond Length

Just as we can define an average bond enthalpy, we can also define an average bond length for a number of common bond types. Some of these are listed in Table 8.5. Of particular interest is the relationship among bond enthalpy, bond length, and the number of bonds between the atoms. For example, we can use data in Tables 8.4 and 8.5 to compare the bond lengths and bond enthalpies of carbon–carbon single, double, and triple bonds:

C—C	C=C	C≡C
1.54 Å	1.34 Å	1.20 Å
348 kJ/mol	614 kJ/mol	839 kJ/mol

As the number of bonds between the carbon atoms increases, the bond enthalpy increases and the bond length decreases; that is, the carbon atoms are held more closely and more tightly together. In general, *as the number of bonds between two atoms increases, the bond grows shorter and stronger.*

**TABLE 8.5** ■ Average Bond Lengths for Some Single, Double, and Triple Bonds

Bond	Bond Length (Å)	Bond	Bond Length (Å)
C—C	1.54	N—N	1.47
C=C	1.34	N=N	1.24
C≡C	1.20	N≡N	1.10
C—N	1.43	N—O	1.36
C=N	1.38	N=O	1.22
C≡N	1.16		
		O—O	1.48
C—O	1.43	O=O	1.21
C=O	1.23		
C≡O	1.13		

**SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

Phosgene, a substance used in poisonous gas warfare during World War I, is so named because it was first prepared by the action of sunlight on a mixture of carbon monoxide and chlorine gases. Its name comes from the Greek words *phos* (light) and *genes* (born of). Phosgene has the following elemental composition: 12.14% C, 16.17% O, and 71.69% Cl by mass. Its molar mass is 98.9 g/mol. (a) Determine the molecular formula of this compound. (b) Draw three Lewis structures for the molecule that satisfy the octet rule for each atom. (The Cl and O atoms bond to C.) (c) Using formal charges, determine which Lewis structure is the most important one. (d) Using average bond enthalpies, estimate  $\Delta H$  for the formation of gaseous phosgene from  $\text{CO}(g)$  and  $\text{Cl}_2(g)$ .

**SOLUTION**

(a) The empirical formula of phosgene can be determined from its elemental composition.  $\Leftrightarrow$  (Section 3.5) Assuming 100 g of the compound and calculating the number of moles of C, O, and Cl in this sample, we have

$$(12.14 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.01 \text{ g C}} \right) = 1.011 \text{ mol C}$$

$$(16.17 \text{ g O}) \left( \frac{1 \text{ mol O}}{16.00 \text{ g O}} \right) = 1.011 \text{ mol O}$$

$$(71.69 \text{ g Cl}) \left( \frac{1 \text{ mol Cl}}{35.45 \text{ g Cl}} \right) = 2.022 \text{ mol Cl}$$

The ratio of the number of moles of each element, obtained by dividing each number of moles by the smallest quantity, indicates that there is one C and one O for each two Cl in the empirical formula,  $\text{COCl}_2$ .

The molar mass of the empirical formula is  $12.01 + 16.00 + 2(35.45) = 98.91 \text{ g/mol}$ , the same as the molar mass of the molecule. Thus,  $\text{COCl}_2$  is the molecular formula.

(b) Carbon has four valence electrons, oxygen has six, and chlorine has seven, giving  $4 + 6 + 2(7) = 24$  electrons for the Lewis structures. Drawing a Lewis structure with all single bonds does not give the central carbon atom an octet. Using multiple bonds, three structures satisfy the octet rule:

(c) Calculating the formal charges on each atom gives

The first structure is expected to be the most important one because it has the lowest formal charges on each atom. Indeed, the molecule is usually represented by this Lewis structure.

(d) Writing the chemical equation in terms of the Lewis structures of the molecules, we have

Thus, the reaction involves breaking a  $\text{C}\equiv\text{O}$  bond and a  $\text{Cl--Cl}$  bond and forming a  $\text{C=O}$  bond and two  $\text{C--Cl}$  bonds. Using bond enthalpies from Table 8.4, we have

$$\begin{aligned} \Delta H &= D(\text{C}\equiv\text{O}) + D(\text{Cl--Cl}) - (D(\text{C=O}) + 2D(\text{C--Cl})) \\ &= 1072 \text{ kJ} + 242 \text{ kJ} - (799 \text{ kJ} + 2(328 \text{ kJ})) = -141 \text{ kJ} \end{aligned}$$

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Introduction and Section 8.1** In this chapter we have focused on the interactions that lead to the formation of **chemical bonds**. We classify these bonds into three broad groups: **ionic bonds**, which result from the electrostatic forces that exist between ions of opposite charge; **covalent bonds**, which result from the sharing of electrons by two atoms; and **metallic bonds**, which result from a delocalized sharing of electrons in metals. The formation of bonds involves interactions of the outermost electrons of atoms, their valence electrons. The valence electrons of an atom can be represented by electron-dot symbols, called **Lewis symbols**. The tendencies of atoms to gain, lose, or share their valence electrons often follow the **octet rule**, which can be viewed as an attempt by atoms to achieve a noble-gas electron configuration.

**Section 8.2** Ionic bonding results from the transfer of electrons from one atom to another, leading to the formation of a three-dimensional lattice of charged particles. The stabilities of ionic substances result from the strong electrostatic attractions between an ion and the surrounding ions of opposite charge. The magnitude of these interactions is measured by the **lattice energy**, which is the energy needed to separate an ionic lattice into gaseous ions. Lattice energy increases with increasing charge on the ions and with decreasing distance between the ions. The **Born–Haber cycle** is a useful thermochemical cycle in which we use Hess’s law to calculate the lattice energy as the sum of several steps in the formation of an ionic compound.

**Section 8.3** A covalent bond results from the sharing of electrons. We can represent the electron distribution in molecules by means of **Lewis structures**, which indicate how many valence electrons are involved in forming bonds and how many remain as unshared electron pairs. The octet rule helps determine how many bonds will be formed between two atoms. The sharing of one pair of electrons produces a **single bond**; the sharing of two or three pairs of electrons between two atoms produces **double** or **triple bonds**, respectively. Double and triple bonds are examples of multiple bonding between atoms. The **bond length** between two bonded atoms is the distance between the two nuclei. The bond length decreases as the number of bonds between the atoms increases.

**Section 8.4** In covalent bonds, the electrons may not necessarily be shared equally between two atoms. **Bond polarity** helps describe unequal sharing of electrons in a bond. In a **nonpolar covalent bond** the electrons in the bond are shared equally by the two atoms; in a **polar covalent bond** one of the atoms exerts a greater attraction for the electrons than the other.

**Electronegativity** is a numerical measure of the ability of an atom to compete with other atoms for the electrons shared between them. Fluorine is the most electronegative

element, meaning it has the greatest ability to attract electrons from other atoms. Electronegativity values range from 0.7 for Cs to 4.0 for F. Electronegativity generally increases from left to right in a row of the periodic table, and decreases going down a column. The difference in the electronegativities of bonded atoms can be used to determine the polarity of a bond. The greater the electronegativity difference the more polar the bond.

A **polar molecule** is one whose centers of positive and negative charge do not coincide. Thus, a polar molecule has a positive side and a negative side. This separation of charge produces a **dipole**, the magnitude of which is given by the **dipole moment**, which is measured in debyes (D). Dipole moments increase with increasing amount of charge separated and increasing distance of separation. Any diatomic molecule X—Y in which X and Y have different electronegativities is a polar molecule.

Most bonding interactions lie between the extremes of covalent and ionic bonding. While it is generally true that the bonding between a metal and a nonmetal is predominantly ionic, exceptions to this guideline are not uncommon when the difference in electronegativity of the atoms is relatively small or when the oxidation state of the metal becomes large.

**Sections 8.5 and 8.6** If we know which atoms are connected to one another, we can draw Lewis structures for molecules and ions by a simple procedure. Once we do so, we can determine the **formal charge** of each atom in a Lewis structure, which is the charge that the atom would have if all atoms had the same electronegativity. Most acceptable Lewis structures will have low formal charges with any negative formal charges residing on more electronegative atoms.

Sometimes a single Lewis structure is inadequate to represent a particular molecule (or ion). In such situations, we describe the molecule by using two or more **resonance structures** for the molecule. The molecule is envisioned as a blend of these multiple resonance structures. Resonance structures are important in describing the bonding in molecules such as ozone,  $O_3$ , and the organic molecule benzene,  $C_6H_6$ .

**Section 8.7** The octet rule is not obeyed in all cases. Exceptions occur when (a) a molecule has an odd number of electrons, (b) it is not possible to complete an octet around an atom without forcing an unfavorable distribution of electrons, or (c) a large atom is surrounded by a sufficiently large number of small electronegative atoms that it has more than an octet of electrons around it. In this last case we envision using the unfilled *d* orbitals of the large atom to “expand” the valence shell of the atom. Expanded valence shells are observed for atoms in the third row and beyond in the periodic table, for which low-energy *d* orbitals are available.

**Section 8.8** The strength of a covalent bond is measured by its **bond enthalpy**, which is the molar enthalpy change upon breaking a particular bond. Average bond enthalpies can be determined for a wide variety of covalent bonds. The strengths of covalent bonds increase with the number of electron pairs shared between two atoms.

We can use bond enthalpies to estimate the enthalpy change during chemical reactions in which bonds are broken and new bonds formed. The average bond length between two atoms decreases as the number of bonds between the atoms increases, consistent with the bond being stronger as the number of bonds increases.

## KEY SKILLS

- Write Lewis symbols for atoms and ions.
- Understand lattice energy and be able to arrange compounds in order of increasing lattice energy based on the charges and sizes of the ions involved.
- Use atomic electron configurations and the octet rule to write Lewis structures for molecules to determine their electron distribution.
- Use electronegativity differences to identify nonpolar covalent, polar covalent, and ionic bonds.
- Calculate charge separation in diatomic molecules based on the experimentally measured dipole moment and bond distance.
- Calculate formal charges from Lewis structures and use those formal charges to identify the most favorable Lewis structures.
- Recognize molecules where resonance structures are needed to describe the bonding.
- Recognize exceptions to the octet rule and draw accurate Lewis structures even when the octet rule is not obeyed.
- Understand the relationship between bond type (single, double, and triple), bond strength (or enthalpy) and bond length.
- Use bond enthalpies to estimate enthalpy changes for reactions involving gas phase reactants and products.

## KEY EQUATIONS

$$E_{el} = \frac{\kappa Q_1 Q_2}{d} \quad [8.4]$$

$$\mu = Qr \quad [8.11]$$

$$\Delta H_{rxn} = \sum(\text{bond enthalpies of bonds broken}) - \sum(\text{bond enthalpies of bonds formed}) \quad [8.12]$$

The potential energy of two interacting charges

The dipole moment of two charges of equal magnitude but opposite sign, separated by a distance  $r$

The enthalpy change as a function of bond enthalpies for reactions involving gas phase molecules.

## VISUALIZING CONCEPTS

8.1 For each of these Lewis symbols, indicate the group in the periodic table in which the element X belongs:

8.2 Illustrated at right are four ions—A, B, X, and Y—showing their relative ionic radii. The ions shown in red carry positive charges: a 2+ charge for A and a 1+ charge for B. Ions shown in blue carry negative charges: a 1− charge for X and a 2− charge for Y. (a) Which combinations of these ions produce ionic compounds where there is a 1:1 ratio of cations and anions? (b) Among those compounds, which combination of ions leads to the ionic compound having the largest lattice energy? (c) Which combination of ions leads to the ionic compound having the smallest lattice energy? [Section 8.2]

8.3 The orbital diagram below shows the valence electrons for a 2+ ion of an element. (a) What is the element? (b) What is the electron configuration of an atom of this element? [Section 8.2]

3d

- 8.4 In the Lewis structure shown below, A, D, E, Q, X, and Z represent elements in the first two rows of the periodic table (H—Ne). Identify all six elements so that the formal charges of all atoms are zero. [Section 8.3]

- 8.5 The partial Lewis structure below is for a hydrocarbon molecule. In the full Lewis structure, each carbon atom satisfies the octet rule, and there are no unshared electron pairs in the molecule. The carbon-carbon bonds are labeled 1, 2, and 3. (a) Determine where the hydrogen atoms are in the molecule. (b) Rank the carbon-carbon bonds in order of increasing bond length. (c) Rank the carbon-carbon bonds in order of increasing bond enthalpy. [Section 8.3 and 8.8]

- 8.6 Consider the Lewis structure for the polyatomic oxyanion shown below, where X is an element from the 3rd period (Na—Ar). By changing the overall charge,  $n$ , from 1− to 2− to 3− we get three different polyatomic ions. For each of these ions (a) Identify the central atom, X. (b) Determine the formal charge of the central atom, X. (c) Draw a Lewis structure that makes the formal charge on the central atom equal to zero. (d) If the Lewis structure you drew in part (c) differs from the Lewis structure shown below, which one do you think is the best one (if you were able to choose only a single Lewis structure)? [Sections 8.5, 8.6, and 8.7]

## EXERCISES

### Lewis Symbols

- 8.7 (a) What are valence electrons? (b) How many valence electrons does a nitrogen atom possess? (c) An atom has the electron configuration  $1s^2 2s^2 2p^6 3s^2 3p^2$ . How many valence electrons does the atom have?
- 8.8 (a) What is the octet rule? (b) How many electrons must a sulfur atom gain to achieve an octet in its valence shell? (c) If an atom has the electron configuration  $1s^2 2s^2 2p^3$ , how many electrons must it gain to achieve an octet?
- 8.9 Write the electron configuration for phosphorus. Identify the valence electrons in this configuration and the nonvalence electrons. From the standpoint of chemical reactivity, what is the important difference between them?
- 8.10 (a) Write the electron configuration for the element titanium, Ti. How many valence electrons does this atom possess? (b) Hafnium, Hf, is also found in group 4B. Write the electron configuration for Hf. (c) Both Ti and Hf behave as though they possess the same number of valence electrons. Which of the subshells in the electron configuration of Hf behave as valence orbitals? Which behave as core orbitals?
- 8.11 Write the Lewis symbol for atoms of each of the following elements: (a) Al, (b) Br, (c) Ar, (d) Sr.
- 8.12 What is the Lewis symbol for each of the following atoms or ions: (a) Ca, (b) P, (c)  $\text{Mg}^{2+}$ , (d)  $\text{S}^{2-}$ ?

### Ionic Bonding

- 8.13 Using Lewis symbols, diagram the reaction between magnesium and oxygen atoms to give the ionic substance MgO.
- 8.14 Use Lewis symbols to represent the reaction that occurs between Ca and F atoms.
- 8.15 Predict the chemical formula of the ionic compound formed between the following pairs of elements: (a) Al and F, (b) K and S, (c) Y and O, (d) Mg and N.
- 8.16 Which ionic compound is expected to form from combining the following pairs of elements: (a) barium and fluorine, (b) cesium and chlorine, (c) lithium and nitrogen, (d) aluminum and oxygen?
- 8.17 Write the electron configuration for each of the following ions, and determine which ones possess noble-gas configurations: (a)  $\text{Sr}^{2+}$ , (b)  $\text{Ti}^{2+}$ , (c)  $\text{Se}^{2-}$ , (d)  $\text{Ni}^{2+}$ , (e)  $\text{Br}^-$ , (f)  $\text{Mn}^{3+}$ .
- 8.18 Write electron configurations for the following ions, and determine which have noble-gas configurations: (a)  $\text{Zn}^{2+}$ , (b)  $\text{Te}^{2-}$ , (c)  $\text{Sc}^{3+}$ , (d)  $\text{Rh}^{3+}$ , (e)  $\text{Ti}^+$ , (f)  $\text{Bi}^{3+}$ .
- 8.19 (a) Define the term *lattice energy*. (b) Which factors govern the magnitude of the lattice energy of an ionic compound?
- 8.20 NaCl and KF have the same crystal structure. The only difference between the two is the distance that separates cations and anions. (a) The lattice energies of NaCl and KF are given in Table 8.2. Based on the lattice energies, would you expect the Na—Cl or the K—F distance to be longer? (b) Use the ionic radii given in Figure 7.8 to estimate the Na—Cl and K—F distances. Does this estimate agree with the prediction you made based upon the lattice energies?
- 8.21 The ionic substances KF, CaO, and ScN are isoelectronic (they have the same number of electrons). Examine the lattice energies for these substances in Table 8.2, and account for the trends you observe.
- 8.22 (a) Does the lattice energy of an ionic solid increase or decrease (i) as the charges of the ions increase, (ii) as the sizes of the ions increase? (b) Using a periodic table,

arrange the following substances according to their expected lattice energies, listing them from lowest lattice energy to the highest:  $\text{ScN}$ ,  $\text{KBr}$ ,  $\text{MgO}$ ,  $\text{NaF}$ . Compare your list with the data in Table 8.2.

- 8.23** The lattice energies of  $\text{KBr}$  and  $\text{CsCl}$  are nearly equal (Table 8.2). What can you conclude from this observation?
- 8.24** Explain the following trends in lattice energy: (a)  $\text{CaF}_2 > \text{BaF}_2$ ; (b)  $\text{NaCl} > \text{RbBr} > \text{CsBr}$ ; (c)  $\text{BaO} > \text{KF}$ .
- 8.25** Energy is required to remove two electrons from  $\text{Ca}$  to form  $\text{Ca}^{2+}$  and is required to add two electrons to  $\text{O}$  to form  $\text{O}^{2-}$ . Why, then, is  $\text{CaO}$  stable relative to the free elements?
- 8.26** Construct a Born–Haber cycle for the formation of the hypothetical compound  $\text{NaCl}_2$ , where the sodium ion

has a  $2+$  charge (the 2nd ionization energy for sodium is given in Table 7.2). (a) How large would the lattice energy need to be for the formation of  $\text{NaCl}_2$  to be exothermic? (b) If we were to estimate the lattice energy of  $\text{NaCl}_2$  to be roughly equal to that of  $\text{MgCl}_2$  (2326 kJ/mol from Table 8.2), what value would you obtain for the standard enthalpy of formation,  $\Delta H_f^\circ$ , of  $\text{NaCl}_2$ ?

- 8.27** Use data from Appendix C, Figure 7.12, and Figure 7.14 to calculate the lattice energy of  $\text{RbCl}$ . Is this value greater than or less than the lattice energy of  $\text{NaCl}$ ? Explain.
- 8.28** (a) Based on the lattice energies of  $\text{MgCl}_2$  and  $\text{SrCl}_2$  given in Table 8.2, what is the range of values that you would expect for the lattice energy of  $\text{CaCl}_2$ ? (b) Using data from Appendix C, Figure 7.12, and Figure 7.14 and the value of the second ionization energy for  $\text{Ca}$ , 1145 kJ/mol, calculate the lattice energy of  $\text{CaCl}_2$ .

## Covalent Bonding, Electronegativity, and Bond Polarity

- 8.29** (a) What is meant by the term *covalent bond*? (b) Give three examples of covalent bonding. (c) A substance  $\text{XY}$ , formed from two different elements, boils at  $-33^\circ\text{C}$ . Is  $\text{XY}$  likely to be a covalent or an ionic substance? Explain.
- 8.30** Which of these elements is unlikely to form covalent bonds:  $\text{S}$ ,  $\text{H}$ ,  $\text{K}$ ,  $\text{Ar}$ ,  $\text{Si}$ ? Explain your choices.
- 8.31** Using Lewis symbols and Lewis structures, diagram the formation of  $\text{SiCl}_4$  from  $\text{Si}$  and  $\text{Cl}$  atoms.
- 8.32** Use Lewis symbols and Lewis structures to diagram the formation of  $\text{PF}_3$  from  $\text{P}$  and  $\text{F}$  atoms.
- 8.33** (a) Construct a Lewis structure for  $\text{O}_2$  in which each atom achieves an octet of electrons. (b) Explain why it is necessary to form a double bond in the Lewis structure. (c) The bond in  $\text{O}_2$  is shorter than the  $\text{O}-\text{O}$  bond in compounds that contain an  $\text{O}-\text{O}$  single bond. Explain this observation.
- 8.34** (a) Construct a Lewis structure for hydrogen peroxide,  $\text{H}_2\text{O}_2$ , in which each atom achieves an octet of electrons. (b) Do you expect the  $\text{O}-\text{O}$  bond in  $\text{H}_2\text{O}_2$  to be longer or shorter than the  $\text{O}-\text{O}$  bond in  $\text{O}_2$ ?
- 8.35** (a) What is meant by the term electronegativity? (b) On the Pauling scale what is the range of electronegativity values for the elements? (c) Which element has the greatest electronegativity? (d) Which element has the smallest electronegativity?
- 8.36** (a) What is the trend in electronegativity going from left to right in a row of the periodic table? (b) How do electronegativity values generally vary going down a column in the periodic table? (c) How do periodic trends in electronegativity relate to those for ionization energy and electron affinity?
- 8.37** Using only the periodic table as your guide, select the most electronegative atom in each of the following sets: (a)  $\text{Se}$ ,  $\text{Rb}$ ,  $\text{O}$ ,  $\text{In}$ ; (b)  $\text{Al}$ ,  $\text{Ca}$ ,  $\text{C}$ ,  $\text{Si}$ ; (c)  $\text{Ge}$ ,  $\text{As}$ ,  $\text{P}$ ,  $\text{Sn}$ ; (d)  $\text{Li}$ ,  $\text{Rb}$ ,  $\text{Be}$ ,  $\text{Sr}$ .
- 8.38** By referring only to the periodic table, select (a) the most electronegative element in group 6A; (b) the least elec-

tronegative element in the group Al, Si, P; (c) the most electronegative element in the group Ga, P, Cl, Na; (d) the element in the group K, C, Zn, F, that is most likely to form an ionic compound with Ba.

- 8.39** Which of the following bonds are polar: (a)  $\text{B}-\text{F}$ , (b)  $\text{Cl}-\text{Cl}$ , (c)  $\text{Se}-\text{O}$ , (d)  $\text{H}-\text{I}$ ? Which is the more electronegative atom in each polar bond?
- 8.40** Arrange the bonds in each of the following sets in order of increasing polarity: (a)  $\text{C}-\text{F}$ ,  $\text{O}-\text{F}$ ,  $\text{Be}-\text{F}$ ; (b)  $\text{O}-\text{Cl}$ ,  $\text{S}-\text{Br}$ ,  $\text{C}-\text{P}$ ; (c)  $\text{C}-\text{S}$ ,  $\text{B}-\text{F}$ ,  $\text{N}-\text{O}$ .
- 8.41** The dipole moment and bond distance measured for the highly reactive gas phase  $\text{OH}$  molecule are 1.78 D and 0.98 Å, respectively. (a) Given these values calculate the effective charges on the H and O atoms of the  $\text{OH}$  molecule in units of the electronic charges  $e$ . (b) Is this bond more or less polar than the  $\text{H}-\text{Cl}$  bond in an  $\text{HCl}$  molecule? (c) Is that what you would have expected based on electronegativities?
- 8.42** The iodine monobromide molecule,  $\text{IBr}$ , has a bond length of 2.49 Å and a dipole moment of 1.21 D. (a) Which atom of the molecule is expected to have a negative charge? Explain. (b) Calculate the effective charges on the I and Br atoms in  $\text{IBr}$ , in units of the electronic charge  $e$ .
- 8.43** In the following pairs of binary compounds determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound: (a)  $\text{SiF}_4$  and  $\text{LaF}_3$ , (b)  $\text{FeCl}_2$  and  $\text{ReCl}_6$ , (c)  $\text{PbCl}_4$  and  $\text{RbCl}$ .
- 8.44** In the following pairs of binary compounds determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound: (a)  $\text{TiCl}_4$  and  $\text{CaF}_2$ , (b)  $\text{ClF}_3$  and  $\text{VF}_3$ , (c)  $\text{SbCl}_5$  and  $\text{AlF}_3$ .

## Lewis Structures; Resonance Structures

- 8.45 Draw Lewis structures for the following: (a)  $\text{SiH}_4$ , (b)  $\text{CO}$ , (c)  $\text{SF}_2$ , (d)  $\text{H}_2\text{SO}_4$  (H is bonded to O), (e)  $\text{ClO}_2^-$  (f)  $\text{NH}_2\text{OH}$ .
- 8.46 Write Lewis structures for the following: (a)  $\text{H}_2\text{CO}$  (both H atoms are bonded to C), (b)  $\text{H}_2\text{O}_2$ , (c)  $\text{C}_2\text{F}_6$  (contains a C—C bond), (d)  $\text{AsO}_3^{3-}$ , (e)  $\text{H}_2\text{SO}_3$  (H is bonded to O), (f)  $\text{C}_2\text{H}_2$ .
- 8.47 (a) When talking about atoms in a Lewis structure, what is meant by the term *formal charge*? (b) Does the formal charge of an atom represent the actual charge on that atom? Explain. (c) How does the formal charge of an atom in a Lewis structure differ from the oxidation number of the atom?
- 8.48 (a) Write a Lewis structure for the phosphorus trifluoride molecule,  $\text{PF}_3$ . Is the octet rule satisfied for all the atoms in your structure? (b) Determine the oxidation numbers of the P and F atoms. (c) Determine the formal charges of the P and F atoms. (d) Is the oxidation number for the P atom the same as its formal charge? Explain why or why not.
- 8.49 Write Lewis structures that obey the octet rule for each of the following, and assign oxidation numbers and formal charges to each atom: (a)  $\text{NO}^+$ , (b)  $\text{POCl}_3$  (P is bonded to the three Cl atoms and to the O), (c)  $\text{ClO}_4^-$ , (d)  $\text{HClO}_3$  (H is bonded to O).
- 8.50 For each of the following molecules or ions of sulfur and oxygen, write a single Lewis structure that obeys the octet rule, and calculate the oxidation numbers and formal charges on all the atoms: (a)  $\text{SO}_2$ , (b)  $\text{SO}_3$ , (c)  $\text{SO}_3^{2-}$ . (d) Arrange these molecules/ions in order of increasing S—O bond distance.
- 8.51 (a) Write one or more appropriate Lewis structures for the nitrite ion,  $\text{NO}_2^-$ . (b) With what allotrope of oxygen

is it isoelectronic? (c) What would you predict for the lengths of the bonds in  $\text{NO}_2^-$  relative to N—O single bonds?

- 8.52 Consider the nityl cation,  $\text{NO}_2^+$ . (a) Write one or more appropriate Lewis structures for this ion. (b) Are resonance structures needed to describe the structure? (c) With what familiar molecule is it isoelectronic?
- 8.53 Predict the ordering of the C—O bond lengths in  $\text{CO}$ ,  $\text{CO}_2$ , and  $\text{CO}_3^{2-}$ .
- 8.54 Based on Lewis structures, predict the ordering of N—O bond lengths in  $\text{NO}^+$ ,  $\text{NO}_2^-$ , and  $\text{NO}_3^-$ .
- 8.55 (a) Use the concept of resonance to explain why all six C—C bonds in benzene are equal in length. (b) Are the C—C bond lengths in benzene shorter than C—C single bonds? Are they shorter than C=C double bonds?
- 8.56 Mothballs are composed of naphthalene,  $\text{C}_{10}\text{H}_8$ , a molecule of which consists of two six-membered rings of carbon fused along an edge, as shown in this incomplete Lewis structure:

- (a) Write two complete Lewis structures for naphthalene. (b) The observed C—C bond lengths in the molecule are intermediate between C—C single and C=C double bonds. Explain. (c) Represent the resonance in naphthalene in a way analogous to that used to represent it in benzene.

## Exceptions to the Octet Rule

- 8.57 (a) State the octet rule. (b) Does the octet rule apply to ionic as well as to covalent compounds? Explain, using examples as appropriate.
- 8.58 Considering the nonmetals, what is the relationship between the group number for an element (carbon, for example, belongs to group 4A; see the periodic table on the inside front cover) and the number of single covalent bonds that element needs to form to conform to the octet rule?
- 8.59 What is the most common exception to the octet rule? Give two examples.
- 8.60 For elements in the third row of the periodic table and beyond, the octet rule is often not obeyed. What factors are usually cited to explain this fact?
- 8.61 Draw the Lewis structures for each of the following ions or molecules. Identify those that do not obey the octet rule, and explain why they do not. (a)  $\text{SO}_3^{2-}$ , (b)  $\text{AlH}_3$ , (c)  $\text{N}_3^-$ , (d)  $\text{CH}_2\text{Cl}_2$ , (e)  $\text{SbF}_5$ .

- 8.62 Draw the Lewis structures for each of the following molecules or ions. Which do not obey the octet rule? (a)  $\text{NH}_4^+$ , (b)  $\text{SCN}^-$ , (c)  $\text{PCl}_3$ , (d)  $\text{TeF}_4$ , (e)  $\text{XeF}_2$ .

- 8.63 In the vapor phase,  $\text{BeCl}_2$  exists as a discrete molecule. (a) Draw the Lewis structure of this molecule, using only single bonds. Does this Lewis structure satisfy the octet rule? (b) What other resonance forms are possible that satisfy the octet rule? (c) Using formal charges, select the resonance form from among all the Lewis structures that is most important in describing  $\text{BeCl}_2$ .
- 8.64 (a) Describe the molecule chlorine dioxide,  $\text{ClO}_2$ , using three possible resonance structures. (b) Do any of these resonance structures satisfy the octet rule for every atom in the molecule? Why or why not? (c) Using formal charges, select the resonance structure(s) that is (are) most important.

## Bond Enthalpies

8.65 Using the bond enthalpies tabulated in Table 8.4, estimate  $\Delta H$  for each of the following gas-phase reactions:

8.66 Using bond enthalpies (Table 8.4), estimate  $\Delta H$  for the following gas-phase reactions:

8.67 Using bond enthalpies (Table 8.4), estimate  $\Delta H$  for each of the following reactions:

[8.68] Use bond enthalpies (Table 8.4) to estimate the enthalpy change for each of the following reactions:

8.69 Ammonia is produced directly from nitrogen and hydrogen by using the Haber process. The chemical reaction is

(a) Use bond enthalpies (Table 8.4) to estimate the enthalpy change for the reaction, and tell whether this reaction is exothermic or endothermic. (b) Compare the enthalpy change you calculate in (a) to the true enthalpy change as obtained using  $\Delta H_f^\circ$  values.

8.70 (a) Use bond enthalpies to estimate the enthalpy change for the reaction of hydrogen with ethene:

(b) Calculate the standard enthalpy change for this reaction, using heats of formation. Why does this value differ from that calculated in (a)?

8.71 Given the following bond-dissociation energies, calculate the average bond enthalpy for the Ti—Cl bond.

	$\Delta H$ (kJ/mol)
$\text{TiCl}_4(\text{g}) \longrightarrow \text{TiCl}_3(\text{g}) + \text{Cl}(\text{g})$	335
$\text{TiCl}_3(\text{g}) \longrightarrow \text{TiCl}_2(\text{g}) + \text{Cl}(\text{g})$	423
$\text{TiCl}_2(\text{g}) \longrightarrow \text{TiCl}(\text{g}) + \text{Cl}(\text{g})$	444
$\text{TiCl}(\text{g}) \longrightarrow \text{Ti}(\text{g}) + \text{Cl}(\text{g})$	519

[8.72] (a) Using average bond enthalpies, predict which of the following reactions will be most exothermic:

(b) Explain the trend, if any, that exists between reaction exothermicity and the extent to which the carbon atom is bonded to oxygen.

## ADDITIONAL EXERCISES

8.73 How many elements in the periodic table are represented by a Lewis symbol with a single dot? Are all these elements in the same group? Explain.

8.74 (a) Explain the following trend in lattice energy:  $\text{BeH}_2$ , 3205 kJ/mol;  $\text{MgH}_2$ , 2791 kJ/mol;  $\text{CaH}_2$ , 2410 kJ/mol;  $\text{SrH}_2$ , 2250 kJ/mol;  $\text{BaH}_2$ , 2121 kJ/mol. (b) The lattice energy of  $\text{ZnH}_2$  is 2870 kJ/mol. Based on the data given in part (a), the radius of the  $\text{Zn}^{2+}$  ion is expected to be closest to that of which group 2A element?

8.75 Based on data in Table 8.2, estimate (within 30 kJ/mol) the lattice energy for (a)  $\text{LiBr}$ , (b)  $\text{CsBr}$ , (c)  $\text{CaCl}_2$ .

8.76 Would you expect  $\text{AlN}$  to have a lattice energy that is larger or smaller than  $\text{ScN}$ ? Explain.

[8.77] From the ionic radii given in Figure 7.8, calculate the potential energy of a  $\text{Ca}^{2+}$  and  $\text{O}^{2-}$  ion pair that are just touching (the magnitude of the electronic charge is given on the back inside cover). Calculate the energy of a mole of such pairs. How does this value compare with

the lattice energy of CaO (Table 8.2)? Explain the difference.

- [8.78] From Equation 8.4 and the ionic radii given in Figure 7.8, calculate the potential energy of the following pairs of ions. Assume that the ions are separated by a distance equal to the sum of their ionic radii: (a)  $\text{Na}^+$ ,  $\text{Br}^-$ ; (b)  $\text{Rb}^+$ ,  $\text{Br}^-$ ; (c)  $\text{Sr}^{2+}$ ,  $\text{S}^{2-}$ .
- 8.79 (a) How does a polar molecule differ from a nonpolar one? (b) Atoms X and Y have different electronegativities. Will the diatomic molecule X—Y necessarily be polar? Explain. (c) What factors affect the size of the dipole moment of a diatomic molecule?
- 8.80 Which of the following molecules or ions contain polar bonds: (a)  $\text{P}_4$ , (b)  $\text{H}_2\text{S}$ , (c)  $\text{NO}_2^-$ , (d)  $\text{S}_2^{2-}$ ?
- 8.81 To address energy and environmental issues, there is great interest in powering vehicles with hydrogen rather than gasoline. One of the most attractive aspects of the “hydrogen economy” is the fact that in principle the only emission would be water. However, two daunting obstacles must be overcome before this vision can become a reality. First, an economical method of producing hydrogen must be found. Second, a safe, lightweight, and compact way of storing hydrogen must be found. The hydrides of light metals are attractive for hydrogen storage because they can store a high weight percentage of hydrogen in a small volume. One of the most attractive hydrides is  $\text{NaAlH}_4$ , which can release 5.6% of its mass as  $\text{H}_2$  upon decomposing to  $\text{NaH}(\text{s})$ ,  $\text{Al}(\text{s})$ , and  $\text{H}_2(\text{g})$ .  $\text{NaAlH}_4$  possesses both covalent bonds, which hold polyatomic anions together, and ionic bonds. (a) Write a balanced equation for the decomposition of  $\text{NaAlH}_4$ . (b) Which element in  $\text{NaAlH}_4$  is the most electronegative? Which one is the least electronegative? (c) Based on electronegativity differences, what do you think is the identity of the polyatomic anion? Draw a Lewis structure for this ion.
- 8.82 For the following collection of nonmetallic elements, O, P, Te, I, B, (a) which two would form the most polar single bond? (b) Which two would form the longest single bond? (c) Which two would be likely to form a compound of formula  $\text{XY}_2$ ? (d) Which combinations of elements would likely yield a compound of empirical formula  $\text{X}_2\text{Y}_3$ ? In each case explain your answer.
- 8.83 You and a partner are asked to complete a lab entitled “Oxides of Ruthenium” that is scheduled to extend over two lab periods. The first lab, which is to be completed by your partner, is devoted to carrying out compositional analysis. In the second lab, you are to determine melting points. Upon going to lab you find two unlabeled vials, one containing a soft yellow substance and the other a black powder. You also find the following notes in your partner’s notebook—*Compound 1*: 76.0% Ru and 24.0% O (by mass), *Compound 2*: 61.2% Ru and 38.8% O (by mass). (a) What is the empirical formula for Compound 1? (b) What is the empirical formula for Compound 2? (c) Upon determining the melting points of these two compounds, you find that the yellow compound melts at 25 °C, while the black powder does not melt up to the maximum temperature of your apparatus, 1200 °C. What is the identity of the yellow compound? What is the identity of the black compound? Be sure to use the appropriate naming convention depending upon whether the compound is better described as a molecular or ionic compound.
- 8.84 You and a partner are asked to complete a lab entitled “Fluorides of Group 6B Metals” that is scheduled to extend over two lab periods. The first lab, which is to be completed by your partner, is devoted to carrying out compositional analysis. In the second lab, you are to determine melting points. Upon going to lab you find two unlabeled vials, one containing a colorless liquid and the other a green powder. You also find the following notes in your partner’s notebook—*Compound 1*: 47.7% Cr and 52.3% F (by mass), *Compound 2*: 45.7% Mo and 54.3% F (by mass). (a) What is the empirical formula for Compound 1? (b) What is the empirical formula for Compound 2? (c) Upon determining the melting points of these two compounds you find that the colorless liquid solidifies at 18 °C, while the green powder does not melt up to the maximum temperature of your apparatus, 1200 °C. What is the identity of the colorless liquid? What is the identity of the green powder? Be sure to use the appropriate naming convention depending upon whether the compound is better described as a molecular or ionic compound.
- [8.85] (a) Triazine,  $\text{C}_3\text{H}_3\text{N}_3$ , is like benzene except that in triazine every other C—H group is replaced by a nitrogen atom. Draw the Lewis structure(s) for the triazine molecule. (b) Estimate the carbon–nitrogen bond distances in the ring.
- [8.86] Using the electronegativities of Br and Cl, estimate the partial charges on the atoms in the Br—Cl molecule. Using these partial charges and the atomic radii given in Figure 7.7, estimate the dipole moment of the molecule. The measured dipole moment is 0.57 D.
- 8.87 Although  $\text{I}_3^-$  is known,  $\text{F}_3^-$  is not. Using Lewis structures, explain why  $\text{F}_3^-$  does not form.
- 8.88 Calculate the formal charge on the indicated atom in each of the following molecules or ions: (a) the central oxygen atom in  $\text{O}_3$ , (b) phosphorus in  $\text{PF}_6^-$ , (c) nitrogen in  $\text{NO}_2$ , (d) iodine in  $\text{ICl}_3$ , (e) chlorine in  $\text{HClO}_4$  (hydrogen is bonded to O).
- 8.89 (a) Determine the formal charge on the chlorine atom in the hypochlorite ion,  $\text{ClO}^-$ , and the perchlorate ion,  $\text{ClO}_4^-$ , using resonance structures where the Cl atom has an octet. (b) What are the oxidation numbers of chlorine in  $\text{ClO}^-$  and in  $\text{ClO}_4^-$ ? (c) Is it uncommon for the formal charge and the oxidation state to be different? Explain. (d) Perchlorate is a much stronger oxidizing agent than hypochlorite. Would you expect there to be any relationship between the oxidizing power of the oxyanion and either the oxidation state or the formal charge of chlorine?
- 8.90 The following three Lewis structures can be drawn for  $\text{N}_2\text{O}$ :
- $$:\text{N}\equiv\text{N}-\ddot{\text{O}}: \longleftrightarrow :\ddot{\text{N}}-\text{N}\equiv\text{O}: \longleftrightarrow :\ddot{\text{N}}=\text{N}=\ddot{\text{O}}:$$
- (a) Using formal charges, which of these three resonance forms is likely to be the most important? (b) The N—N bond length in  $\text{N}_2\text{O}$  is 1.12 Å, slightly longer than a typical N≡N bond; and the N—O bond length is 1.19 Å, slightly shorter than a typical N=O bond. (See Table 8.5.) Rationalize these observations in terms of the resonance structures shown previously and your conclusion for (a).

- 8.91** An important reaction for the conversion of natural gas to other useful hydrocarbons is the conversion of methane to ethane.

In practice, this reaction is carried out in the presence of oxygen, which converts the hydrogen produced to water.

Use bond enthalpies (Table 8.4) to estimate  $\Delta H$  for these two reactions. Why is the conversion of methane to ethane more favorable when oxygen is used?

- 8.92** Two compounds are isomers if they have the same chemical formula but a different arrangement of atoms. Use bond enthalpies (Table 8.4) to estimate  $\Delta H$  for each of the following gas-phase isomerization reactions, and indicate which isomer has the lower enthalpy:

- [8.93] With reference to the “Chemistry Put to Work” box on explosives, (a) use bond enthalpies to estimate the enthalpy change for the explosion of 1.00 g of nitroglycerin. (b) Write a balanced equation for the decomposition of TNT.

Assume that, upon explosion, TNT decomposes into  $\text{N}_2(\text{g})$ ,  $\text{CO}_2(\text{g})$ ,  $\text{H}_2\text{O}(\text{g})$ , and  $\text{C}(\text{s})$ .

- [8.94] The “plastic” explosive C-4, often used in action movies, contains the molecule *cyclotrimethylenetrinitramine*, which is often called RDX (for Royal Demolition eXplosive):

Cyclotrimethylenetrinitramine (RDX)

- (a) Complete the Lewis structure for the molecule by adding unshared electron pairs where they are needed. (b) Does the Lewis structure you drew in part (a) have any resonance structures? If so, how many? (c) The molecule causes an explosion by decomposing into  $\text{CO}(\text{g})$ ,  $\text{N}_2(\text{g})$ , and  $\text{H}_2\text{O}(\text{g})$ . Write a balanced equation for the decomposition reaction. (d) With reference to Table 8.4, which is the weakest type of bond in the molecule? (e) Use average bond enthalpies to estimate the enthalpy change when 5.0 g of RDX decomposes.
- 8.95** The bond lengths of carbon-carbon, carbon-nitrogen, carbon-oxygen, and nitrogen-nitrogen single, double, and triple bonds are listed in Table 8.5. Plot bond enthalpy (Table 8.4) versus bond length for these bonds. What do you conclude about the relationship between bond length and bond enthalpy? What do you conclude about the relative strengths of C—C, C—N, C—O, and N—N bonds?
- 8.96** Use the data in Table 8.5 and the following data: S—S distance in  $\text{S}_8 = 2.05 \text{ \AA}$ ; S—O distance in  $\text{SO}_2 = 1.43 \text{ \AA}$  to answer the following questions: (a) Predict the bond length in a S—N single bond. (b) Predict the bond length in a S—O single bond. (c) Why is the S—O bond length in  $\text{SO}_2$  considerably shorter than your predicted value for the S—O single bond? (d) When elemental sulfur,  $\text{S}_8$ , is carefully oxidized, a compound  $\text{S}_8\text{O}$  is formed, in which one of the sulfur atoms in the  $\text{S}_8$  ring is bonded to an oxygen atom. The S—O bond length in this compound is  $1.48 \text{ \AA}$ . In light of this information, write Lewis structures that can account for the observed S—O bond length. Does the sulfur bearing the oxygen in this compound obey the octet rule?

## INTEGRATIVE EXERCISES

- 8.97** The  $\text{Ti}^{2+}$  ion is isoelectronic with the Ca atom. (a) Are there any differences in the electron configurations of  $\text{Ti}^{2+}$  and Ca? (b) With reference to Figure 6.25, comment on the changes in the ordering of the  $4s$  and  $3d$  subshells in Ca and  $\text{Ti}^{2+}$ . (c) Will Ca and  $\text{Ti}^{2+}$  have the same number of unpaired electrons? Explain.
- [8.98] (a) Write the chemical equations that are used in calculating the lattice energy of  $\text{SrCl}_2(\text{s})$  via a Born-Haber cycle. (b) The second ionization energy of Sr(g) is  $1064 \text{ kJ/mol}$ . Use this fact along with data in Appendix C, Figure 7.12, Figure 7.14, and Table 8.2 to calculate  $\Delta H_f^\circ$  for  $\text{SrCl}_2(\text{s})$ .
- [8.99] The electron affinity of oxygen is  $-141 \text{ kJ/mol}$ , corresponding to the reaction
- $$\text{O}(\text{g}) + \text{e}^- \longrightarrow \text{O}^-(\text{g})$$
- The lattice energy of  $\text{K}_2\text{O}(\text{s})$  is  $2238 \text{ kJ/mol}$ . Use these data along with data in Appendix C and Figure 7.12 to calculate the “second electron affinity” of oxygen, corresponding to the reaction
- $$\text{O}^-(\text{g}) + \text{e}^- \longrightarrow \text{O}^{2-}(\text{g})$$

- 8.100** The reaction of indium, In, with sulfur leads to three binary compounds, which we will assume to be purely ionic. The three compounds have the following properties:

Compound	Mass % In	Melting Point (°C)
A	87.7	653
B	78.2	692
C	70.5	1050

- (a) Determine the empirical formulas of compounds A, B, and C. (b) Give the oxidation state of In in each of the three compounds. (c) Write the electron configuration for the In ion in each compound. Do any of these configurations correspond to a noble-gas configuration? (d) In which compound is the ionic radius of In expected to be smallest? Explain. (e) The melting point of ionic compounds often correlates with the lattice energy. Explain the trends in the melting points of compounds A, B, and C in these terms.
- [8.101]** One scale for electronegativity is based on the concept that the electronegativity of any atom is proportional to the ionization energy of the atom minus its electron affinity: electronegativity =  $k(\text{IE} - \text{EA})$ , where  $k$  is a proportionality constant. (a) How does this definition explain why the electronegativity of F is greater than that of Cl even though Cl has the greater electron affinity? (b) Why are both ionization energy and electron affinity relevant to the notion of electronegativity? (c) By using data in Chapter 7, determine the value of  $k$  that would lead to an electronegativity of 4.0 for F under this definition. (d) Use your result from part (c) to determine the electronegativities of Cl and O using this scale. Do these values follow the trend shown in Figure 8.6?
- 8.102** The compound chloral hydrate, known in detective stories as knockout drops, is composed of 14.52% C, 1.83% H, 64.30% Cl, and 19.35% O by mass and has a molar mass of 165.4 g/mol. (a) What is the empirical formula of this substance? (b) What is the molecular formula of this substance? (c) Draw the Lewis structure of the molecule, assuming that the Cl atoms bond to a single C atom and that there are a C—C bond and two C—O bonds in the compound.
- 8.103** Barium azide is 62.04% Ba and 37.96% N. Each azide ion has a net charge of  $1-$ . (a) Determine the chemical formula of the azide ion. (b) Write three resonance structures for the azide ion. (c) Which structure is most important? (d) Predict the bond lengths in the ion.
- 8.104** Acetylene ( $\text{C}_2\text{H}_2$ ) and nitrogen ( $\text{N}_2$ ) both contain a triple bond, but they differ greatly in their chemical properties. (a) Write the Lewis structures for the two substances. (b) By referring to Appendix C, look up the enthalpies of formation of acetylene and nitrogen and compare their reactivities. (c) Write balanced chemical equations for the complete oxidation of  $\text{N}_2$  to form  $\text{N}_2\text{O}_5(\text{g})$  and of acetylene to form  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ . (d) Calculate the enthalpy of oxidation per mole of  $\text{N}_2$  and  $\text{C}_2\text{H}_2$  (the enthalpy of formation of  $\text{N}_2\text{O}_5(\text{g})$  is 11.30 kJ/mol). How do these comparative values relate to your response to part (b)? Both  $\text{N}_2$  and  $\text{C}_2\text{H}_2$  possess triple bonds with quite high bond enthalpies (Table 8.4). What aspect of chemical bonding in these molecules or in the oxidation products seems to account for the difference in chemical reactivities?
- [8.105]** Under special conditions, sulfur reacts with anhydrous liquid ammonia to form a binary compound of sulfur and nitrogen. The compound is found to consist of 69.6% S and 30.4% N. Measurements of its molecular mass yield a value of  $184.3 \text{ g mol}^{-1}$ . The compound occasionally detonates on being struck or when heated rapidly. The sulfur and nitrogen atoms of the molecule are joined in a ring. All the bonds in the ring are of the same length. (a) Calculate the empirical and molecular formulas for the substance. (b) Write Lewis structures for the molecule, based on the information you are given. (Hint: You should find a relatively small number of dominant Lewis structures.) (c) Predict the bond distances between the atoms in the ring. (Note: The S—S distance in the  $\text{S}_8$  ring is 2.05 Å.) (d) The enthalpy of formation of the compound is estimated to be  $480 \text{ kJ mol}^{-1}$ .  $\Delta H_f^\circ$  of  $\text{S}(\text{g})$  is  $222.8 \text{ kJ mol}^{-1}$ . Estimate the average bond enthalpy in the compound.
- [8.106]** A common form of elemental phosphorus is the tetrahedral  $\text{P}_4$  molecule, where all four phosphorus atoms are equivalent:

- At room temperature phosphorus is a solid. (a) Do you think there are any unshared pairs of electrons in the  $\text{P}_4$  molecule? (b) How many P—P bonds are there in the molecule? (c) Can you draw a Lewis structure for a linear  $\text{P}_4$  molecule that satisfies the octet rule? (d) Using formal charges, what can you say about the stability of the linear molecule vs. that of the tetrahedral molecule?
- [8.107]** Consider benzene ( $\text{C}_6\text{H}_6$ ) in the gas phase. (a) Write the reaction for breaking all the bonds in  $\text{C}_6\text{H}_6(\text{g})$ , and use data in Appendix C to determine the enthalpy change for this reaction. (b) Write a reaction that corresponds to breaking all the carbon-carbon bonds in  $\text{C}_6\text{H}_6(\text{g})$ . (c) By combining your answers to parts (a) and (b) and using the average bond enthalpy for C—H from Table 8.4, calculate the average bond enthalpy for the carbon-carbon bonds in  $\text{C}_6\text{H}_6(\text{g})$ . (d) Comment on your answer from part (c) as compared to the values for C—C single bonds and C=C double bonds in Table 8.4.
- 8.108** Average bond enthalpies are generally defined for gas-phase molecules. Many substances are liquids in their standard state.  $\rightleftharpoons$  (Section 5.7) By using appropriate thermochemical data from Appendix C, calculate average bond enthalpies in the liquid state for the following bonds, and compare these values to the gas-phase values given in Table 8.4: (a) Br—Br, from  $\text{Br}_2(\text{l})$ ; (b) C—Cl, from  $\text{CCl}_4(\text{l})$ ; (c) O—O, from  $\text{H}_2\text{O}_2(\text{l})$  (assume that the O—H bond enthalpy is the same as in the gas phase). (d) What can you conclude about the process of breaking bonds in the liquid as compared to the gas phase? Explain the difference in the  $\Delta H$  values between the two phases.

MOLECULAR GEOMETRY  
AND BONDING THEORIES

**THE ANTICANCER DRUG**  
**TAXOL<sup>®</sup>** was originally isolated  
from the bark of the Pacific  
yew tree. Chemists have now  
learned how to synthesize this  
important pharmaceutical in  
the laboratory without  
harvesting these slow-growing  
and relatively rare trees.

## WHAT'S AHEAD

---

### 9.1 Molecular Shapes

We begin by discussing how *molecular geometries* are described and by examining some common geometries exhibited by molecules.

### 9.2 The VSEPR Model

We next consider how molecular geometries can be predicted using a simple model (the *valence-shell electron-pair repulsion*, or *VSEPR*, model), which is based on Lewis structures and the repulsions between regions of high electron density.

### 9.3 Molecular Shape and Molecular Polarity

Once we know the type of bonds in a molecule and the geometry of the molecule, we can determine whether the molecule is *polar* or *nonpolar*.

### 9.4 Covalent Bonding and Orbital Overlap

We recognize that electrons are shared between atoms in a covalent bond. In *valence-bond theory*, the bonding electrons are visualized as originating in atomic orbitals on two different atoms. The covalent bond between the atoms arises when these orbitals overlap in space.

### 9.5 Hybrid Orbitals

To account for molecular shape, we consider how the orbitals of one atom mix with one another, or *hybridize*, to create *hybrid orbitals* suitable for bonding within molecules.

### 9.6 Multiple Bonds

We consider that overlapping atomic orbitals that underlie covalent bonding in a molecule can overlap in multiple ways, based on geometry, to produce *sigma* ( $\sigma$ ) and *pi* ( $\pi$ ) bonds between atoms. Single bonds generally consist of one sigma bond between the bonded atoms; multiple bonds involve one sigma and one or more pi bonds.

### 9.7 Molecular Orbitals

We evaluate a more sophisticated treatment of bonding that uses *molecular orbital theory*, which introduces the concepts of *bonding* and *antibonding molecular orbitals* arising from atomic orbitals.

### 9.8 Second-Row Diatomic Molecules

We consider how molecular orbital theory is used to construct *energy level diagrams* for second-row diatomic molecules.

**WE SAW IN CHAPTER 8 THAT LEWIS STRUCTURES** help us understand the compositions of molecules and their covalent bonds.

However, Lewis structures do not show one of the most important aspects of molecules—their overall shapes.

Molecules have shapes and sizes that are defined by the

angles and distances between the nuclei of their component atoms. Indeed, chemists often refer to molecular *architecture* when describing the distinctive shapes and sizes of molecules.

The shape and size of a molecule of a particular substance, together with the strength and polarity of its bonds, largely determine the properties of that substance. Some of the most dramatic examples of the important roles of molecular shape and size are seen in biochemical reactions and in substances produced by living species. For example, the chapter-opening photograph shows a Pacific yew tree, a species that grows along the Pacific coast of the northwestern United States and Canada. In 1967 two chemists isolated from the

bark of the Pacific yew small amounts of a molecule that was found to be among the most effective treatments for breast and ovarian cancer. This molecule, now known as the pharmaceutical Taxol<sup>®</sup>, has a complex molecular architecture that leads to its powerful therapeutic effectiveness. Even a small modification to the shape and size of the molecule decreases its effectiveness and can lead to the formation of a substance toxic to humans. Chemists now know how to synthesize the drug in the laboratory, which has made it more available and has saved the slow-growing Pacific yew tree from possible extinction. Before the drug was synthesized, six trees had to be harvested to provide the Taxol<sup>®</sup> necessary to treat one cancer patient.

Our first goal in this chapter is to learn the relationship between two-dimensional Lewis structures and three-dimensional molecular shapes. Armed with this knowledge, we can then examine more closely the nature of covalent bonds. The lines that are used to depict bonds in Lewis structures provide important clues about the orbitals that molecules use in bonding. By examining these orbitals, we can gain a greater understanding of the behavior of molecules. You will find that the material in this chapter will help you in later discussions of the physical and chemical properties of substances.

## 9.1 MOLECULAR SHAPES

In Chapter 8 we used Lewis structures to account for the formulas of covalent compounds.  $\infty$  (Section 8.5) Lewis structures, however, do not indicate the shapes of molecules; they simply show the number and types of bonds between atoms. For example, the Lewis structure of  $\text{CCl}_4$  tells us only that four Cl atoms are bonded to a central C atom:

The Lewis structure is drawn with the atoms all in the same plane. As shown in Figure 9.1  $\blacktriangleleft$ , however, the actual three-dimensional arrangement of the atoms shows the Cl atoms at the corners of a *tetrahedron*, a geometric object with four corners and four faces, each of which is an equilateral triangle.

The overall shape of a molecule is determined by its **bond angles**, the angles made by the lines joining the nuclei of the atoms in the molecule. The bond angles of a molecule, together with the bond lengths  $\infty$  (Section 8.8), accurately define the shape and size of the molecule. In  $\text{CCl}_4$  the bond angles are defined as the angles between the C—Cl bonds. You should be able to see that there are six Cl—C—Cl angles in  $\text{CCl}_4$ , and they all have the same value— $109.5^\circ$ , which is characteristic of a tetrahedron. In addition, all four C—Cl bonds are the same length ( $1.78 \text{ \AA}$ ). Thus, the shape and size of  $\text{CCl}_4$  are completely described by stating that the molecule is tetrahedral with C—Cl bonds of length  $1.78 \text{ \AA}$ .

In our discussion of the shapes of molecules, we will begin with molecules (and ions) that, like  $\text{CCl}_4$ , have a single central atom bonded to two or more atoms of the same type. Such molecules conform to the general formula  $\text{AB}_n$ , in which the central atom A is bonded to  $n$  B atoms. Both  $\text{CO}_2$  and  $\text{H}_2\text{O}$  are  $\text{AB}_2$  molecules, for example, whereas  $\text{SO}_3$  and  $\text{NH}_3$  are  $\text{AB}_3$  molecules, and so on.

The possible shapes of  $\text{AB}_n$  molecules depend on the value of  $n$ . We observe only a few general shapes for a given value of  $n$ . Those commonly found for  $\text{AB}_2$  and  $\text{AB}_3$  molecules are shown in Figure 9.2  $\blacktriangleright$ . Therefore, an  $\text{AB}_2$  molecule must be either linear (bond angle =  $180^\circ$ ) or bent (bond angle  $\neq 180^\circ$ ). For example,  $\text{CO}_2$  is linear, and  $\text{SO}_2$  is bent. For  $\text{AB}_3$  molecules, the two most common

**▲ Figure 9.1 Tetrahedral geometry.** (a) A tetrahedron is an object with four faces and four vertices. Each face is an equilateral triangle. (b) The geometry of the  $\text{CCl}_4$  molecule. Each C—Cl bond in the molecule points toward a vertex of a tetrahedron. All of the C—Cl bonds are the same length, and all of the Cl—C—Cl bond angles are the same. This type of drawing of  $\text{CCl}_4$  is called a ball-and-stick model. (c) A representation of  $\text{CCl}_4$ , called a space-filling model. It shows the relative sizes of the atoms, but the geometry is somewhat harder to see.

◀ **Figure 9.2 Shapes of  $AB_2$  and  $AB_3$  molecules.** Top:  $AB_2$  molecules can be either linear or bent. Bottom: Three possible shapes for  $AB_3$  molecules.

shapes place the B atoms at the corners of an equilateral triangle. If the A atom lies in the same plane as the B atoms, the shape is called *trigonal planar*. If the A atom lies above the plane of the B atoms, the shape is called *trigonal pyramidal* (a pyramid with an equilateral triangle as its base). For example,  $SO_3$  is trigonal planar, and  $NF_3$  is trigonal pyramidal. Some  $AB_3$  molecules, such as  $ClF_3$ , exhibit the more unusual *T shape* shown in Figure 9.2.

The shape of any particular  $AB_n$  molecule can usually be derived from one of the five basic geometric structures shown in Figure 9.3 ▶. Starting with a tetrahedron, for example, we can remove atoms successively from the corners as shown in Figure 9.4 ▼. When an atom is removed from one corner of the tetrahedron, the remaining fragment has a trigonal-pyramidal geometry, such as that found for  $NF_3$ . When two atoms are removed, a bent geometry results.

Why do so many  $AB_n$  molecules have shapes related to the basic structures in Figure 9.3, and can we predict these shapes? When A is a representative element (one of the elements from the *s* block or *p* block of the periodic table), we can answer these questions by using the **valence-shell electron-pair repulsion (VSEPR) model**. Although the name is rather imposing, the model is quite simple. It has useful predictive capabilities, as we will see in Section 9.2.

▼ **Figure 9.3 Shapes of  $AB_n$  molecules.** For molecules whose formula is of the general form  $AB_n$ , there are five fundamental shapes.

◀ **Figure 9.4 Derivatives from the  $AB_n$  geometries.** Additional molecular shapes can be obtained by removing corner atoms from the basic shapes shown in Figure 9.3. Here we begin with a tetrahedron and successively remove corners, producing first a trigonal-pyramidal geometry and then a bent geometry, each having ideal bond angles of 109.5°. Molecular shape is meaningful only when there are at least three atoms. If there are only two, they must be arranged next to each other, and no special name is given to describe the molecule.

(a) Two balloons adopt a linear arrangement.

(b) Three balloons adopt a trigonal-planar arrangement.

(c) Four balloons adopt a tetrahedral arrangement.

▲ **Figure 9.5 A balloon analogy for electron domains.** Balloons tied together at their ends naturally adopt their lowest-energy arrangement.

### GIVE IT SOME THOUGHT

One of the common shapes for  $AB_4$  molecules is *square planar*: All five atoms lie in the same plane, the B atoms lie at the corners of a square, and the A atom is at the center of the square. Which of the shapes in Figure 9.3 could lead to a square-planar geometry upon the removal of one or more atoms?

## 9.2 THE VSEPR MODEL

Imagine tying two identical balloons together at their ends. As shown in Figure 9.5(a), the balloons naturally orient themselves to point away from each other; that is, they try to “get out of each other’s way” as much as possible. If we add a third balloon, the balloons orient themselves toward the vertices of an equilateral triangle as shown in Figure 9.5(b). If we add a fourth balloon, they adopt a tetrahedral shape [Figure 9.5(c)]. We see that an optimum geometry exists for each number of balloons.

In some ways the electrons in molecules behave like the balloons shown in Figure 9.5. We have seen that a single covalent bond is formed between two atoms when a pair of electrons occupies the space between the atoms.  $\infty$  (Section 8.3) A **bonding pair** of electrons thus defines a region in which the electrons will most likely be found. We will refer to such a region as an **electron domain**. Likewise, a **nonbonding pair** (or **lone pair**) of electrons defines an electron domain that is located principally on one atom. For example, the Lewis structure of  $NH_3$  has four electron domains around the central nitrogen atom (three bonding pairs and one nonbonding pair):

Each multiple bond in a molecule also constitutes a single electron domain. Thus, the following resonance structure for  $O_3$  has three electron domains around the central oxygen atom (a single bond, a double bond, and a nonbonding pair of electrons):

In general, *each nonbonding pair, single bond, or multiple bond produces an electron domain around the central atom.*

### GIVE IT SOME THOUGHT

An  $AB_3$  molecule has the resonance structure

Does this Lewis structure follow the octet rule? How many electron domains are there around the A atom?

The VSEPR model is based on the idea that electron domains are negatively charged and therefore repel one another. Like the balloons in Figure 9.5, electron domains try to stay out of one another’s way. *The best arrangement of a given number of electron domains is the one that minimizes the repulsions among them.* In fact, the analogy between electron domains and balloons is so close that the same preferred geometries are found in both cases. Like the balloons in

**TABLE 9.1** ■ Electron-Domain Geometries as a Function of the Number of Electron Domains

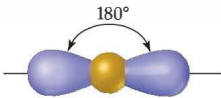

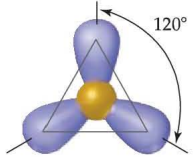

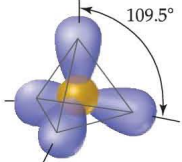

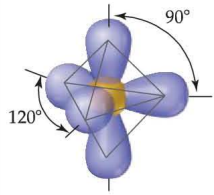

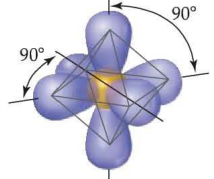

Number of Electron Domains	Arrangement of Electron Domains	Electron-Domain Geometry	Predicted Bond Angles
2		Linear	180°
3		Trigonal planar	120°
4		Tetrahedral	109.5°
5		Trigonal bipyramidal	120° 90°
6		Octahedral	90°

Figure 9.5, two electron domains are arranged *linearly*, three domains are arranged in a *trigonal-planar* fashion, and four are arranged *tetrahedrally*. These arrangements, together with those for five electron domains (*trigonal bipyramidal*) and six electron domains (*octahedral*), are summarized in Table 9.1 ▲. If you compare the geometries in Table 9.1 with those in Figure 9.3, you will see that they are the same. *The shapes of different AB<sub>n</sub> molecules or ions depend on the number of electron domains surrounding the central A atom.*

The arrangement of electron domains about the central atom of an AB<sub>n</sub> molecule or ion is called its **electron-domain geometry**. In contrast, the **molecular geometry** is the arrangement of *only the atoms* in a molecule or ion—any nonbonding pairs are not part of the description of the molecular geometry. In the VSEPR model, we predict the electron-domain geometry. From knowing how many domains are due to nonbonding pairs, we can then predict the molecular geometry of a molecule or ion from its electron-domain geometry.

▲ **Figure 9.6 The molecular geometry of  $\text{NH}_3$ .** The geometry is predicted by first drawing the Lewis structure, then using the VSEPR model to determine the electron-domain geometry, and finally focusing on the atoms themselves to describe the molecular geometry.

When all the electron domains in a molecule arise from bonds, the molecular geometry is identical to the electron-domain geometry. When, however, one or more of the domains involve nonbonding pairs of electrons, we must remember to ignore those domains when predicting molecular shape. Consider the  $\text{NH}_3$  molecule, which has four electron domains around the nitrogen atom (Figure 9.6 ▲). We know from Table 9.1 that the repulsions among four electron domains are minimized when the domains point toward the vertices of a tetrahedron, so the electron-domain geometry of  $\text{NH}_3$  is tetrahedral. We know from the Lewis structure of  $\text{NH}_3$  that one of the electron domains is due to a nonbonding pair of electrons, which will occupy one of the four vertices of the tetrahedron. Hence the molecular geometry of  $\text{NH}_3$  is trigonal pyramidal, as shown in Figure 9.6. Notice that the tetrahedral arrangement of the four electron domains leads us to predict the trigonal-pyramidal molecular geometry.

We can generalize the steps we follow in using the VSEPR model to predict the shapes of molecules or ions:

1. Draw the *Lewis structure* of the molecule or ion, and count the total number of electron domains around the central atom. Each nonbonding electron pair, each single bond, each double bond, and each triple bond counts as an electron domain.
2. Determine the *electron-domain geometry* by arranging the electron domains about the central atom so that the repulsions among them are minimized, as shown in Table 9.1.
3. Use the arrangement of the bonded atoms to determine the *molecular geometry*.

Figure 9.6 shows how these steps are applied to predict the geometry of the  $\text{NH}_3$  molecule. Because the trigonal-pyramidal molecular geometry is based on tetrahedral electron-domain geometry, the *ideal bond angles* are  $109.5^\circ$ . As we will soon see, bond angles deviate from the ideal angles when the surrounding atoms and electron domains are not identical.

Let's apply these steps to determine the shape of the  $\text{CO}_2$  molecule. We first draw its Lewis structure, which reveals two electron domains (two double bonds) around the central carbon:

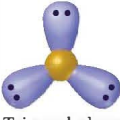

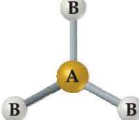

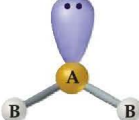

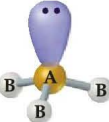

Two electron domains will arrange themselves to give a linear electron-domain geometry (Table 9.1). Because neither domain is a nonbonding pair of electrons, the molecular geometry is also linear, and the  $\text{O}-\text{C}-\text{O}$  bond angle is  $180^\circ$ .

Table 9.2 ► summarizes the possible molecular geometries when an  $\text{AB}_n$  molecule has four or fewer electron domains about A. These geometries are important because they include all the commonly occurring shapes found for molecules or ions that obey the octet rule.

**TABLE 9.2** ■ Electron-Domain Geometries and Molecular Shapes for Molecules with Two, Three, and Four Electron Domains around the Central Atom

Number of Electron Domains	Electron-Domain Geometry	Bonding Domains	Nonbonding Domains	Molecular Geometry	Example
2	 Linear	2	0	 Linear	$\ddot{\text{O}}=\text{C}=\ddot{\text{O}}$
3	 Trigonal planar	3	0	 Trigonal planar	
		2	1	 Bent	
4	 Tetrahedral	4	0	 Tetrahedral	
		3	1	 Trigonal pyramidal	
		2	2	 Bent	

**SAMPLE EXERCISE 9.1** | Using the VSEPR Model

Use the VSEPR model to predict the molecular geometry of (a)  $\text{O}_3$ , (b)  $\text{SnCl}_3^-$ .

**SOLUTION**

**Analyze:** We are given the molecular formulas of a molecule and a polyatomic ion, both conforming to the general formula  $\text{AB}_n$ , and both having a central atom from the  $p$  block of the periodic table.

**Plan:** To predict the molecular geometries of these species, we first draw their Lewis structures and then count the number of electron domains around the central atom. The number of electron domains gives the electron-domain geometry. We then obtain the molecular geometry from the arrangement of the domains that are due to bonds.

**Solve:**

(a) We can draw two resonance structures for  $O_3$ :

Because of resonance, the bonds between the central O atom and the outer O atoms are of equal length. In both resonance structures the central O atom is bonded to the two outer O atoms and has one nonbonding pair. Thus, there are three electron domains about the central O atoms. (Remember that a double bond counts as a single electron domain.) The arrangement of three electron domains is trigonal planar (Table 9.1). Two of the domains are from bonds, and one is due to a nonbonding pair. So, the molecule has a bent shape with an ideal bond angle of  $120^\circ$  (Table 9.2).

As this example illustrates, when a molecule exhibits resonance, any one of the resonance structures can be used to predict the molecular geometry.

(b) The Lewis structure for the  $SnCl_3^-$  ion is

The central Sn atom is bonded to the three Cl atoms and has one nonbonding pair. Therefore, the Sn atom has four electron domains around it. The resulting electron-domain geometry is tetrahedral (Table 9.1) with one of the corners occupied by a nonbonding pair of electrons. The molecular geometry is therefore trigonal pyramidal (Table 9.2), like that of  $NH_3$ .

**PRACTICE EXERCISE**

Predict the electron-domain geometry and the molecular geometry for (a)  $SeCl_2$ , (b)  $CO_3^{2-}$ .

**Answers:** (a) tetrahedral, bent; (b) trigonal planar, trigonal planar

▲ **Figure 9.7** Relative “sizes” of bonding and nonbonding electron domains.

### The Effect of Nonbonding Electrons and Multiple Bonds on Bond Angles

We can refine the VSEPR model to predict and explain slight distortions of molecules from the ideal geometries summarized in Table 9.2. For example, consider methane ( $CH_4$ ), ammonia ( $NH_3$ ), and water ( $H_2O$ ). All three have tetrahedral electron-domain geometries, but their bond angles differ slightly:

Notice that the bond angles decrease as the number of nonbonding electron pairs increases. A bonding pair of electrons is attracted by both nuclei of the bonded atoms. By contrast, a nonbonding pair is attracted primarily by only one nucleus. Because a nonbonding pair experiences less nuclear attraction, its electron domain is spread out more in space than is the electron domain for a bonding pair, as shown in Figure 9.7. Nonbonding pairs of electrons, therefore, take up more space than bonding pairs. As a result, the electron domains for nonbonding electron pairs exert greater repulsive forces on adjacent electron domains and tend to compress the bond angles. Using the analogy in Figure 9.5, we can envision the domains for nonbonding electron pairs as represented by balloons that are slightly larger and slightly fatter than those for bonding pairs.

Because multiple bonds contain a higher electronic-charge density than single bonds, multiple bonds also represent larger electron domains (“fatter balloons”). Consider the Lewis structure of phosgene,  $COCl_2$ :

Because three electron domains surround the central carbon atom, we might expect a trigonal-planar geometry with  $120^\circ$  bond angles. The double bond, however, seems to act much like a nonbonding pair of electrons, reducing the Cl—C—Cl bond angle from the ideal angle of  $120^\circ$  to an actual angle of  $111.4^\circ$ :

In general, *electron domains for multiple bonds exert a greater repulsive force on adjacent electron domains than do electron domains for single bonds.*

### GIVE IT SOME THOUGHT

One of the resonance structures of the nitrate ion,  $\text{NO}_3^-$ , is

The bond angles in this ion are exactly  $120^\circ$ . Is this observation consistent with the above discussion of the effect of multiple bonds on bond angles?

## Molecules with Expanded Valence Shells

So far, our discussion of the VSEPR model has considered molecules with no more than an octet of electrons around the central atom. Recall, however, that when the central atom of a molecule is from the third period of the periodic table and beyond, that atom may have more than four electron pairs around it. [∞ \(Section 8.7\)](#) Molecules with five or six electron domains around the central atom display a variety of molecular geometries based on the *trigonal-bipyramidal* (five electron domains) or the *octahedral* (six electron domains) electron-domain geometries, as shown in Table 9.3 ▼.

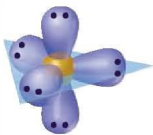

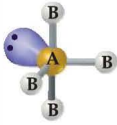

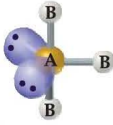

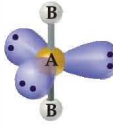

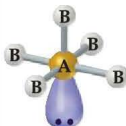

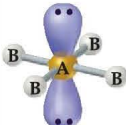

The most stable electron-domain geometry for five electron domains is the trigonal bipyramid (two trigonal pyramids sharing a base). Unlike the arrangements we have seen to this point, the electron domains in a trigonal bipyramid can point toward two geometrically distinct types of positions. Two of the five domains point toward *axial positions*, and the remaining three domains point toward *equatorial positions* (Figure 9.8 ►). Each axial domain makes a  $90^\circ$  angle with any equatorial domain. Each equatorial domain makes a  $120^\circ$  angle with either of the other two equatorial domains and a  $90^\circ$  angle with either axial domain.

Suppose a molecule has five electron domains, one or more of which originates from a nonbonding pair. Will the electron domains from the nonbonding pairs occupy axial or equatorial positions? To answer this question, we must determine which location minimizes the repulsions between the electron domains. Repulsions between domains are much greater when they are situated  $90^\circ$  from each other than when they are at  $120^\circ$ . An equatorial domain is  $90^\circ$  from only two other domains (the two axial domains). By contrast, an axial domain is situated  $90^\circ$  from *three* other domains (the three equatorial domains). Hence, an equatorial domain experiences less repulsion than an axial domain. Because the domains from nonbonding pairs exert larger repulsions than those from bonding pairs, they always occupy the equatorial positions in a trigonal bipyramid.

▲ **Figure 9.8 Trigonal-bipyramidal geometry.** Five electron domains arrange themselves around a central atom as a trigonal bipyramid. The three *equatorial* electron domains define an equilateral triangle. The two *axial* domains lie above and below the plane of the triangle. If a molecule has nonbonding electron domains, they will occupy the equatorial positions.

**TABLE 9.3** ■ Electron-Domain Geometries and Molecular Shapes for Molecules with Five and Six Electron Domains around the Central Atom

Total Electron Domains	Electron-Domain Geometry	Bonding Domains	Nonbonding Domains	Molecular Geometry	Example
5	 Trigonal bipyramidal	5	0	 Trigonal bipyramidal	PCl <sub>5</sub>
		4	1	 Seesaw	SF <sub>4</sub>
		3	2	 T-shaped	ClF <sub>3</sub>
		2	3	 Linear	XeF <sub>2</sub>
6	 Octahedral	6	0	 Octahedral	SF <sub>6</sub>
		5	1	 Square pyramidal	BrF <sub>5</sub>
		4	2	 Square planar	XeF <sub>4</sub>

## GIVE IT SOME THOUGHT

It might seem that a square planar geometry of four electron domains around a central atom would be more favorable than a tetrahedron. Can you rationalize why the tetrahedron is preferred, based on angles between electron domains?

The most stable electron-domain geometry for six electron domains is the *octahedron*. As shown in Figure 9.9, an octahedron is a polyhedron with eight faces and six vertices, each of which is an equilateral triangle. If an atom has six electron domains around it, that atom can be visualized as being at the center of the octahedron with the electron domains pointing toward the six vertices. All the bond angles in an octahedron are  $90^\circ$ , and all six vertices are equivalent. Therefore, if an atom has five bonding electron domains and one nonbonding domain, we can put the nonbonding domain at any of the six vertices of the octahedron. The result is always a *square-pyramidal* molecular geometry. When there are two nonbonding electron domains, however, their repulsions are minimized by pointing them toward opposite sides of the octahedron, producing a *square-planar* molecular geometry, as shown in Table 9.3.

**▲ Figure 9.9 An octahedron.** The octahedron is an object with eight faces and six vertices. Each face is an equilateral triangle.

### SAMPLE EXERCISE 9.2 | Molecular Geometries of Molecules with Expanded Valence Shells

Use the VSEPR model to predict the molecular geometry of (a)  $\text{SF}_4$ , (b)  $\text{IF}_5$ .

#### SOLUTION

**Analyze:** The molecules are of the  $\text{AB}_n$  type with a central atom from the  $p$  block of the periodic table.

**Plan:** We can predict their structures by first drawing Lewis structures and then using the VSEPR model to determine the electron-domain geometry and molecular geometry.

#### Solve:

(a) The Lewis structure for  $\text{SF}_4$  is

The sulfur has five electron domains around it: four from the  $\text{S}-\text{F}$  bonds and one from the nonbonding pair. Each domain points toward a vertex of a trigonal bipyramid. The domain from the nonbonding pair will point toward an equatorial position. The four bonds point toward the remaining four positions, resulting in a molecular geometry that is described as seesaw-shaped:

**Comment:** The experimentally observed structure is shown on the right. We can infer that the nonbonding electron domain occupies an equatorial position, as predicted. The axial and equatorial  $\text{S}-\text{F}$  bonds are slightly bent back away from the nonbonding domain, suggesting that the bonding domains are “pushed” by the nonbonding domain, which is larger and has greater repulsion (Figure 9.7).

(b) The Lewis structure of  $\text{IF}_5$  is

The iodine has six electron domains around it, one of which is from a nonbonding pair. The electron-domain geometry is therefore octahedral, with one position occupied by the nonbonding pair. The resulting molecular geometry is therefore *square pyramidal* (Table 9.3):

**Comment:** Because the domain for the nonbonding pair is larger than the other domains, the four  $\text{F}$  atoms in the base of the pyramid are tipped up slightly toward the  $\text{F}$  atom on top. Experimentally, we find that the angle between the base and top  $\text{F}$  atoms is  $82^\circ$ , smaller than the ideal  $90^\circ$  angle of an octahedron.

#### PRACTICE EXERCISE

Predict the electron-domain geometry and molecular geometry of (a)  $\text{ClF}_3$ , (b)  $\text{ICl}_4^-$ .

**Answers:** (a) trigonal bipyramidal, T-shaped; (b) octahedral, square planar

## Shapes of Larger Molecules

Although the structures of the molecules and ions we have already considered contain only a single central atom, the VSEPR model can be extended to more complex molecules. Consider the acetic acid molecule, with the following Lewis structure:

Acetic acid has three interior atoms: the left C atom, the central C atom, and the right-most O atom. We can use the VSEPR model to predict the geometry about each of these atoms individually:

▲ **Figure 9.10** Ball-and-stick (top) and space-filling (bottom) representations of acetic acid,  $\text{CH}_3\text{COOH}$ .

	$\begin{array}{c} \text{H} \\   \\ \text{H}-\text{C} \\   \\ \text{H} \end{array}$	$\begin{array}{c} \text{:O:} \\ // \\ \text{C} \end{array}$	$\begin{array}{c} \ddot{\text{O}}-\text{H} \end{array}$
Number of electron domains	4	3	4
Electron-domain geometry	Tetrahedral	Trigonal planar	Tetrahedral
Predicted bond angles	$109.5^\circ$	$120^\circ$	$109.5^\circ$

The leftmost C has four electron domains (all from bonding pairs), and so the geometry around that atom is tetrahedral. The central C has three electron domains (counting the double bond as one domain). Thus, the geometry around that atom is trigonal planar. The O atom has four electron domains (two from bonding pairs and two from nonbonding pairs), so its electron-domain geometry is tetrahedral, and the molecular geometry around O is bent. The bond angles about the central C atom and the O atom are expected to deviate slightly from the ideal values of  $120^\circ$  and  $109.5^\circ$  because of the spatial demands of multiple bonds and nonbonding electron pairs. The structure of the acetic acid molecule is shown in Figure 9.10 ◀.

### ■ SAMPLE EXERCISE 9.3 | Predicting Bond Angles

Eyedrops for dry eyes usually contain a water-soluble polymer called *poly(vinyl alcohol)*, which is based on the unstable organic molecule called *vinyl alcohol*:

Predict the approximate values for the  $\text{H}-\text{O}-\text{C}$  and  $\text{O}-\text{C}-\text{C}$  bond angles in vinyl alcohol.

#### SOLUTION

**Analyze:** We are given a molecular structure and asked to determine two bond angles in the structure.

**Plan:** To predict a particular bond angle, we consider the middle atom of the angle and determine the number of electron domains surrounding that atom. The ideal angle corresponds to the electron-domain geometry around the atom. The angle will be compressed somewhat by nonbonding electrons or multiple bonds.

**Solve:** For the  $\text{H}-\text{O}-\text{C}$  bond angle, the middle O atom has four electron domains (two bonding and two nonbonding). The electron-domain geometry around O is therefore tetrahedral, which gives an ideal angle of  $109.5^\circ$ . The  $\text{H}-\text{O}-\text{C}$  angle will be compressed somewhat by the nonbonding pairs, so we expect this angle to be slightly less than  $109.5^\circ$ .

To predict the O—C—C bond angle, we must examine the leftmost C atom, which is the central atom for this angle. There are three atoms bonded to this C atom and no nonbonding pairs, and so it has three electron domains about it. The predicted electron-domain geometry is trigonal planar, resulting in an ideal bond angle of  $120^\circ$ . Because of the larger size of the C=C domain, however, the O—C—C bond angle should be slightly greater than  $120^\circ$ .

### PRACTICE EXERCISE

Predict the H—C—H and C—C—C bond angles in the following molecule, called *propyne*:

Answers:  $109.5^\circ$ ,  $180^\circ$

## 9.3 MOLECULAR SHAPE AND MOLECULAR POLARITY

We now have a sense of the shapes that molecules adopt and why they do so. We will spend the rest of this chapter looking more closely at the ways in which electrons are shared to form the bonds between atoms in molecules. We will begin by returning to a topic that we first discussed in Section 8.4, namely *bond polarity* and *dipole moments*.

Recall that bond polarity is a measure of how equally the electrons in a bond are shared between the two atoms of the bond: As the difference in electronegativity between the two atoms increases, so does the bond polarity.  $\Rightarrow$  (Section 8.4) We saw that the dipole moment of a diatomic molecule is a quantitative measure of the amount of charge separation in the molecule. The charge separation in molecules has a significant effect on physical and chemical properties. We will see in Chapter 11, for example, how molecular polarity affects boiling points, melting points, and other physical properties.

For a molecule that consists of more than two atoms, *the dipole moment depends on both the polarities of the individual bonds and the geometry of the molecule*. For each bond in the molecule, we can consider the **bond dipole**, which is the dipole moment that is due only to the two atoms in that bond. Consider the linear  $\text{CO}_2$  molecule, for example. As shown in Figure 9.11(a)  $\blacktriangleright$ , each C=O bond is polar, and because the C=O bonds are identical, the bond dipoles are equal in magnitude. A plot of the electron density of the  $\text{CO}_2$  molecule, shown in Figure 9.11(b), clearly shows that the bonds are polar: On the oxygen atoms, regions of high electron density (red) are at the ends of the molecule. On the carbon atom, regions of low electron density (blue) are in the center. But what can we say about the *overall* dipole moment of the  $\text{CO}_2$  molecule?

Bond dipoles and dipole moments are *vector* quantities; that is, they have both a magnitude and a direction. The *overall* dipole moment of a polyatomic molecule is the vector sum of its bond dipoles. Both the magnitudes *and* the directions of the bond dipoles must be considered when summing these vectors. The two bond dipoles in  $\text{CO}_2$ , although equal in magnitude, are exactly opposite in direction. Adding them together is the same as adding two numbers that are equal in magnitude but opposite in sign, such as  $100 + (-100)$ . The bond dipoles, like the numbers, “cancel” each other. Therefore, the overall dipole moment of  $\text{CO}_2$  is zero, even though the individual bonds are polar. Thus, the geometry of the molecule dictates that the overall dipole moment be zero, making  $\text{CO}_2$  a *nonpolar* molecule.

**▲ Figure 9.11**  $\text{CO}_2$ , a nonpolar molecule. (a) The overall dipole moment of a molecule is the sum of its bond dipoles. In  $\text{CO}_2$  the bond dipoles are equal in magnitude, but exactly oppose each other. The overall dipole moment is zero, therefore, making the molecule nonpolar. (b) The electron-density model shows that the regions of higher electron density (red) are at the ends of the molecule while the region of lower electron density (blue) is at the center.

▲ **Figure 9.12 The dipole moment of a bent molecule.** (a) In H<sub>2</sub>O the bond dipoles are equal in magnitude, but do not exactly oppose each other. The molecule has a nonzero dipole moment overall, making the molecule polar. (b) The electron-density model shows that one end of the molecule has more electron density (the oxygen end) while the other end has less electron density (the hydrogens).

Now let's consider H<sub>2</sub>O, which is a bent molecule with two polar bonds (Figure 9.12 ◀). Again, the two bonds in the molecule are identical, and the bond dipoles are equal in magnitude. Because the molecule is bent, however, the bond dipoles do not directly oppose each other and therefore do not cancel each other. Hence, the H<sub>2</sub>O molecule has an overall nonzero dipole moment ( $\mu = 1.85$  D). Because H<sub>2</sub>O has a nonzero dipole moment, it is a *polar* molecule. The oxygen atom carries a partial negative charge, and the hydrogen atoms each have a partial positive charge, as shown by the electron-density model in Figure 9.12(b).

### GIVE IT SOME THOUGHT

The molecule O=C=S has a Lewis structure analogous to that of CO<sub>2</sub> and is a linear molecule. Will it necessarily have a zero dipole moment like that of CO<sub>2</sub>?

Figure 9.13 ▼ shows examples of polar and nonpolar molecules, all of which have polar bonds. The molecules in which the central atom is symmetrically surrounded by identical atoms (BF<sub>3</sub> and CCl<sub>4</sub>) are nonpolar. For AB<sub>*n*</sub> molecules in which all the B atoms are the same, certain symmetrical shapes—linear (AB<sub>2</sub>), trigonal planar (AB<sub>3</sub>), tetrahedral and square planar (AB<sub>4</sub>), trigonal bipyramidal (AB<sub>5</sub>), and octahedral (AB<sub>6</sub>)—must lead to nonpolar molecules even though the individual bonds might be polar.

► **Figure 9.13 Molecules containing polar bonds.** Two of these molecules have a zero dipole moment because their bond dipoles cancel one another, while the other molecules are polar.

### SAMPLE EXERCISE 9.4 | Polarity of Molecules

Predict whether the following molecules are polar or nonpolar: (a) BrCl, (b) SO<sub>2</sub>, (c) SF<sub>6</sub>.

#### SOLUTION

**Analyze:** We are given the molecular formulas of several substances and asked to predict whether the molecules are polar.

**Plan:** If the molecule contains only two atoms, it will be polar if the atoms differ in electronegativity. If the molecule contains three or more atoms, its polarity depends on both its molecular geometry and the polarity of its bonds. Thus, we must draw a Lewis structure for each molecule containing three or more atoms and determine its molecular geometry. We then use the relative electronegativities of the atoms in each bond to determine the direction of the bond dipoles. Finally, we see if the bond dipoles cancel each other to give a nonpolar molecule or reinforce each other to give a polar one.

**Solve:**

(a) Chlorine is more electronegative than bromine. All diatomic molecules with polar bonds are polar molecules. Consequently, BrCl will be polar, with chlorine carrying the partial negative charge:

The actual dipole moment of BrCl, as determined by experimental measurement, is  $\mu = 0.57 \text{ D}$ .

(b) Because oxygen is more electronegative than sulfur,  $\text{SO}_2$  has polar bonds. Three resonance forms can be written for  $\text{SO}_2$ :

For each of these, the VSEPR model predicts a bent geometry. Because the molecule is bent, the bond dipoles do not cancel, and the molecule is polar:

Experimentally, the dipole moment of  $\text{SO}_2$  is  $\mu = 1.63 \text{ D}$ .

(c) Fluorine is more electronegative than sulfur, so the bond dipoles point toward fluorine. The six S—F bonds are arranged octahedrally around the central sulfur:

Because the octahedral geometry is symmetrical, the bond dipoles cancel, and the molecule is nonpolar, meaning that  $\mu = 0$ .

**PRACTICE EXERCISE**

Determine whether the following molecules are polar or nonpolar: (a)  $\text{NF}_3$ , (b)  $\text{BCl}_3$ .

*Answers:* (a) polar because polar bonds are arranged in a trigonal-pyramidal geometry, (b) nonpolar because polar bonds are arranged in a trigonal-planar geometry

## 9.4 COVALENT BONDING AND ORBITAL OVERLAP

The VSEPR model provides a simple means for predicting the shapes of molecules. However, it does not explain why bonds exist between atoms. In developing theories of covalent bonding, chemists have approached the problem from another direction, using quantum mechanics. How can we use atomic orbitals to explain bonding and to account for the geometries of molecules? The marriage of Lewis's notion of electron-pair bonds and the idea of atomic orbitals leads to a model of chemical bonding called **valence-bond theory**. By extending this approach to include the ways in which atomic orbitals can mix with one another, we obtain a picture that corresponds nicely to the VSEPR model.

In the Lewis theory, covalent bonding occurs when atoms share electrons, which concentrates electron density between the nuclei. In the valence-bond theory, we visualize the buildup of electron density between two nuclei as occurring when a valence atomic orbital of one atom shares space, or *overlaps*, with that of another atom. The overlap of orbitals allows two electrons of opposite spin to share the common space between the nuclei, forming a covalent bond.

**▲ Figure 9.14 The overlap of orbitals to form covalent bonds.** (a) The bond in  $\text{H}_2$  results from the overlap of two  $1s$  orbitals from two H atoms. (b) The bond in  $\text{HCl}$  results from the overlap of a  $1s$  orbital of H and one of the lobes of a  $3p$  orbital of Cl. (c) The bond in  $\text{Cl}_2$  results from the overlap of two  $3p$  orbitals from two Cl atoms.

The coming together of two H atoms to form  $\text{H}_2$  is depicted in Figure 9.14(a)▲. Each atom has a single electron in a  $1s$  orbital. As the orbitals overlap, electron density is concentrated between the nuclei. Because the electrons in the overlap region are simultaneously attracted to both nuclei, they hold the atoms together, forming a covalent bond.

The idea of orbital overlap producing a covalent bond applies equally well to other molecules. In  $\text{HCl}$ , for example, chlorine has the electron configuration  $[\text{Ne}]3s^23p^5$ . All the valence orbitals of chlorine are full except one  $3p$  orbital, which contains a single electron. This electron pairs with the single electron of H to form a covalent bond. Figure 9.14(b) shows the overlap of the  $3p$  orbital of Cl with the  $1s$  orbital of H. Likewise, we can explain the covalent bond in the  $\text{Cl}_2$  molecule in terms of the overlap of the  $3p$  orbital of one atom with the  $3p$  orbital of another, as shown in Figure 9.14(c).

There is always an optimum distance between the two bonded nuclei in any covalent bond. Figure 9.15▼ shows how the potential energy of the system changes as two H atoms come together to form an  $\text{H}_2$  molecule. At infinite distance, the atoms do not “feel” each other and so the energy approaches zero. As the distance between the atoms decreases, the overlap between their  $1s$  orbitals increases. Because of the resultant increase in electron density between the nuclei, the potential energy of the system decreases. That is, the strength of the bond increases, as shown by the decrease in the energy on the curve. However, the curve also shows that as the atoms come very close together, the energy increases sharply. This increase, which becomes significant at short internuclear distances, is due mainly to the electrostatic repulsion between the nuclei. The internuclear distance, or bond length, is the distance that corresponds to the minimum of the potential-energy curve. The potential energy at this minimum corresponds to the bond strength. Thus, the observed bond length is the distance at which the attractive forces between unlike charges (electrons and nuclei) are balanced by the repulsive forces between like charges (electron–electron and nucleus–nucleus).

**► Figure 9.15 Formation of the  $\text{H}_2$  molecule.** Plot of the change in potential energy as two hydrogen atoms come together to form the  $\text{H}_2$  molecule. The minimum in the energy, at  $0.74 \text{ \AA}$ , represents the equilibrium bond distance. The energy at that point,  $-436 \text{ kJ/mol}$ , corresponds to the energy change for formation of the  $\text{H}-\text{H}$  bond.

### GIVE IT SOME THOUGHT

If you could put pressure on the hydrogen molecule so that its bond length decreased, would its bond strength increase or decrease? (Refer to Figure 9.15).

## 9.5 HYBRID ORBITALS

The VSEPR model, simple as it is, does a surprisingly good job at predicting molecular shape, despite the fact that it has no obvious relationship to the filling and shapes of atomic orbitals. For example, based on the shapes and orientations of the  $2s$  and  $2p$  orbitals on a carbon atom, it is not obvious why a  $\text{CH}_4$  molecule should have a tetrahedral geometry. How can we reconcile the notion that covalent bonds are formed from the overlap of atomic orbitals with the molecular geometries that come from the VSEPR model?

To explain geometries, we assume that the atomic orbitals on an atom (usually the central atom) mix to form new orbitals called **hybrid orbitals**. The shape of any hybrid orbital is different from the shapes of the original atomic orbitals. The process of mixing atomic orbitals is called **hybridization**. The total number of atomic orbitals on an atom remains constant, however, and so the number of hybrid orbitals on an atom equals the number of atomic orbitals that are mixed.

Let's examine the common types of hybridization. As we do so, notice the connection between the type of hybridization and the five basic electron-domain geometries predicted by the VSEPR model: linear, trigonal planar, tetrahedral, trigonal bipyramidal, and octahedral.

### $sp$ Hybrid Orbitals

To illustrate the process of hybridization, consider the  $\text{BeF}_2$  molecule, which is generated when solid  $\text{BeF}_2$  is heated to high temperatures. The Lewis structure of  $\text{BeF}_2$  is

The VSEPR model correctly predicts that  $\text{BeF}_2$  is linear with two identical  $\text{Be—F}$  bonds. How can we use valence-bond theory to describe the bonding? The electron configuration of F ( $1s^2 2s^2 2p^5$ ) indicates there is an unpaired electron in a  $2p$  orbital. This  $2p$  electron can be paired with an unpaired electron from the Be atom to form a polar covalent bond. Which orbitals on the Be atom, however, overlap with those on the F atoms to form the  $\text{Be—F}$  bonds?

The orbital diagram for a ground-state Be atom is

Because it has no unpaired electrons, the Be atom in its ground state is incapable of forming bonds with the fluorine atoms. The Be atom could form two bonds, however, by “promoting” one of the  $2s$  electrons to a  $2p$  orbital:

The Be atom now has two unpaired electrons and can therefore form two polar covalent bonds with the F atoms. The two bonds would not be identical, however, because a  $2s$  orbital would be used to form one of the bonds and a  $2p$  orbital would be used for the other. Therefore, although the promotion of an electron allows two  $\text{Be—F}$  bonds to form, we still have not explained the structure of  $\text{BeF}_2$ .

▲ **Figure 9.16 Formation of  $sp$  hybrid orbitals.** One  $s$  orbital and one  $p$  orbital can hybridize to form two equivalent  $sp$  hybrid orbitals. The two hybrid orbitals have their large lobes pointing in opposite directions,  $180^\circ$  apart.

We can solve this dilemma by “mixing” the  $2s$  orbital with one of the  $2p$  orbitals to generate two new orbitals, as shown in Figure 9.16 ▲. Like  $p$  orbitals, each of the new orbitals has two lobes. Unlike  $p$  orbitals, however, one lobe is much larger than the other. The two new orbitals are identical in shape, but their large lobes point in opposite directions. These two new orbitals are hybrid orbitals. Because we have hybridized one  $s$  and one  $p$  orbital, we call each hybrid an  $sp$  hybrid orbital. According to the valence-bond model, a linear arrangement of electron domains implies  $sp$  hybridization.

For the Be atom of  $\text{BeF}_2$ , we write the orbital diagram for the formation of two  $sp$  hybrid orbitals as follows:

▲ **Figure 9.17 Formation of two equivalent Be—F bonds in  $\text{BeF}_2$ .** Each  $sp$  hybrid orbital on Be overlaps with a  $2p$  orbital on F to form a bond. The two bonds are equivalent to each other and form an angle of  $180^\circ$ .

The electrons in the  $sp$  hybrid orbitals can form two-electron bonds with the two fluorine atoms (Figure 9.17 ◀). Because the  $sp$  hybrid orbitals are equivalent but point in opposite directions,  $\text{BeF}_2$  has two identical bonds and a linear geometry. The remaining two  $2p$  orbitals remain unhybridized.

### GIVE IT SOME THOUGHT

Suppose that the two unhybridized  $2p$  orbitals on Be were used to make the Be—F bonds in  $\text{BeF}_2$ . Would the two bonds be equivalent to each other? What would be the expected F—Be—F bond angle?

### $sp^2$ and $sp^3$ Hybrid Orbitals

Whenever we mix a certain number of atomic orbitals, we get the same number of hybrid orbitals. Each of these hybrid orbitals is equivalent to the others but points in a different direction. Thus, mixing one  $2s$  and one  $2p$  orbital yields two equivalent  $sp$  hybrid orbitals that point in opposite directions (Figure 9.16). Other combinations of atomic orbitals can be hybridized to obtain different geometries. In  $\text{BF}_3$ , for example, mixing the  $2s$  and two of the  $2p$  orbitals yields three equivalent  $sp^2$  (pronounced “s-p-two”) hybrid orbitals (Figure 9.18 ▶).

The three  $sp^2$  hybrid orbitals lie in the same plane,  $120^\circ$  apart from one another (Figure 9.18). They are used to make three equivalent bonds with the three fluorine atoms, leading to the trigonal-planar geometry of  $\text{BF}_3$ . Notice that an unfilled  $2p$  orbital remains unhybridized. This unhybridized orbital will be important when we discuss double bonds in Section 9.6.

### GIVE IT SOME THOUGHT

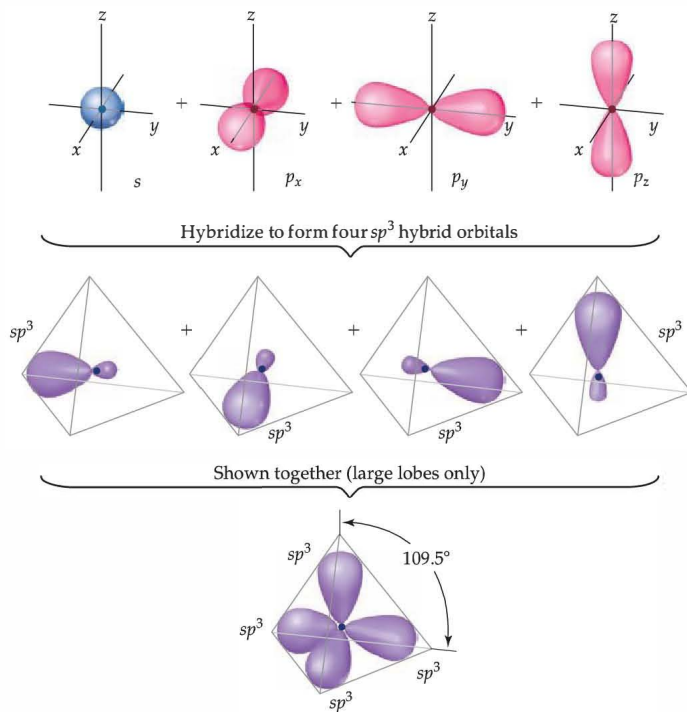

In an  $sp^2$  hybridized atom, what is the orientation of the unhybridized  $p$  orbital relative to the three  $sp^2$  hybrid orbitals?

◀ **Figure 9.18 Formation of  $sp^2$  hybrid orbitals.** One  $s$  orbital and two  $p$  orbitals can hybridize to form three equivalent  $sp^2$  hybrid orbitals. The large lobes of the hybrid orbitals point toward the corners of an equilateral triangle.

An  $s$  orbital can also mix with all three  $p$  orbitals in the same subshell. For example, the carbon atom in  $\text{CH}_4$  forms four equivalent bonds with the four hydrogen atoms. We envision this process as resulting from the mixing of the  $2s$  and all three  $2p$  atomic orbitals of carbon to create four equivalent  $sp^3$  (pronounced “ $s$ - $p$ -three”) hybrid orbitals. Each  $sp^3$  hybrid orbital has a large lobe that points toward a vertex of a tetrahedron, as shown in Figure 9.19 ▼.

◀ **Figure 9.19 Formation of  $sp^3$  hybrid orbitals.** One  $s$  orbital and three  $p$  orbitals can hybridize to form four equivalent  $sp^3$  hybrid orbitals. The large lobes of the hybrid orbitals point toward the corners of a tetrahedron.

▲ **Figure 9.20 Valence-bond description of H<sub>2</sub>O.** The bonding in a water molecule can be envisioned as  $sp^3$  hybridization of the orbitals on O. Two of the four hybrid orbitals overlap with  $1s$  orbitals of H to form covalent bonds. The other two hybrid orbitals are occupied by nonbonding pairs of electrons.

These hybrid orbitals can be used to form two-electron bonds by overlap with the atomic orbitals of another atom, such as H. Using valence-bond theory, we can describe the bonding in CH<sub>4</sub> as the overlap of four equivalent  $sp^3$  hybrid orbitals on C with the  $1s$  orbitals of the four H atoms to form four equivalent bonds.

The idea of hybridization is used in a similar way to describe the bonding in molecules containing nonbonding pairs of electrons. In H<sub>2</sub>O, for example, the electron-domain geometry around the central O atom is approximately tetrahedral. Thus, the four electron pairs can be envisioned as occupying  $sp^3$  hybrid orbitals. Two of the hybrid orbitals contain nonbonding pairs of electrons, while the other two are used to form bonds with hydrogen atoms, as shown in Figure 9.20 ◀.

### Hybridization Involving $d$ Orbitals

With the exception of H and He, all atoms have one  $s$  and three  $p$  orbitals in their valence shell. Because the number of hybrid orbitals must be equal to the number of atomic orbitals that mix to form the hybrids, this fact would seem to limit the maximum number of hybrid orbitals to four. How, then, can we apply the concept of hybridization to molecules where the central atom has more than an octet of electrons around it, such as PF<sub>5</sub> and SF<sub>6</sub>? To do so we turn to the unfilled  $d$  orbitals with the same value of the principal quantum number,  $n$ . Mixing one  $s$  orbital, three  $p$  orbitals, and one  $d$  orbital leads to five  $sp^3d$  hybrid orbitals. These hybrid orbitals are directed toward the vertices of a trigonal bipyramid.

Similarly, mixing one  $s$  orbital, three  $p$  orbitals, and two  $d$  orbitals gives six  $sp^3d^2$  hybrid orbitals that are directed toward the vertices of an octahedron. The use of  $d$  orbitals in constructing hybrid orbitals nicely corresponds to the notion of an expanded valence shell. ∞(Section 8.7) Keep in mind, however, that only atoms in the third period and beyond (atoms beyond Ne) possess vacant  $d$  orbitals that can be used to form hybrid orbitals of this type. The geometric arrangements characteristic of hybrid orbitals are summarized in Table 9.4 ▶.

### Hybrid Orbital Summary

Overall, hybrid orbitals provide a convenient model for using valence-bond theory to describe covalent bonds in molecules with geometries that conform to the electron-domain geometries predicted by the VSEPR model. The picture of hybrid orbitals has limited predictive value. When we know the electron-domain geometry, however, we can employ hybridization to describe the atomic orbitals used by the central atom in bonding.

The following steps allow us to predict the hybrid orbitals used by an atom in bonding:

1. Draw the *Lewis structure* for the molecule or ion.
2. Determine the electron-domain geometry using the *VSEPR model*.
3. Specify the *hybrid orbitals* needed to accommodate the electron pairs based on their geometric arrangement (Table 9.4).

These steps are illustrated in Figure 9.21 ▼, which shows how the hybridization employed by N in NH<sub>3</sub> is determined.

▼ **Figure 9.21 Bonding in NH<sub>3</sub>.** The hybrid orbitals used by N in the NH<sub>3</sub> molecule are predicted by first drawing the Lewis structure, then using the VSEPR model to determine the electron-domain geometry, and then specifying the hybrid orbitals that correspond to that geometry. This is essentially the same procedure as that used to determine molecular structure (Figure 9.6), except we focus on the orbitals used to make bonds and to hold nonbonding pairs.

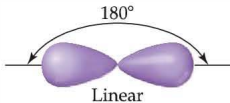

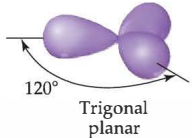

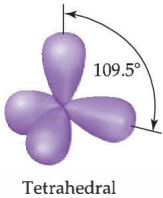

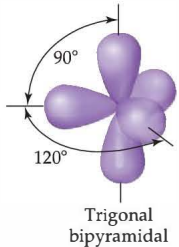

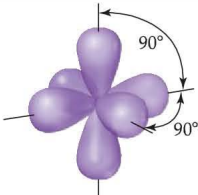

TABLE 9.4 ■ Geometric Arrangements Characteristic of Hybrid Orbital Sets

Atomic Orbital Set	Hybrid Orbital Set	Geometry	Examples
$s, p$	Two $sp$	 <p>Linear</p>	$\text{BeF}_2, \text{HgCl}_2$
$s, p, p$	Three $sp^2$	 <p>Trigonal planar</p>	$\text{BF}_3, \text{SO}_3$
$s, p, p, p$	Four $sp^3$	 <p>Tetrahedral</p>	$\text{CH}_4, \text{NH}_3, \text{H}_2\text{O}, \text{NH}_4^+$
$s, p, p, p, d$	Five $sp^3d$	 <p>Trigonal bipyramidal</p>	$\text{PF}_5, \text{SF}_4, \text{BrF}_3$
$s, p, p, p, d, d$	Six $sp^3d^2$	 <p>Octahedral</p>	$\text{SF}_6, \text{ClF}_5, \text{XeF}_4, \text{PF}_6^-$

**SAMPLE EXERCISE 9.5** | Hybridization

Indicate the hybridization of orbitals employed by the central atom in (a)  $\text{NH}_2^-$ , (b)  $\text{SF}_4$  (see Sample Exercise 9.2).

**SOLUTION**

**Analyze:** We are given two chemical formulas—one for a polyatomic anion and one for a molecular compound—and asked to describe the type of hybrid orbitals surrounding the central atom in each case.

**Plan:** To determine the hybrid orbitals used by an atom in bonding, we must know the electron-domain geometry around the atom. Thus, we first draw the Lewis structure to determine the number of electron domains around the central atom. The hybridization conforms to the number and geometry of electron domains around the central atom as predicted by the VSEPR model.

**Solve:**

(a) The Lewis structure of  $\text{NH}_2^-$  is

Because there are four electron domains around N, the electron-domain geometry is tetrahedral. The hybridization that gives a tetrahedral electron-domain geometry is  $sp^3$  (Table 9.4). Two of the  $sp^3$  hybrid orbitals contain nonbonding pairs of electrons, and the other two are used to make bonds with the hydrogen atoms.

(b) The Lewis structure and electron-domain geometry of  $\text{SF}_4$  are shown in Sample Exercise 9.2. The S atom has five electron domains around it, giving rise to a trigonal-bipyramidal electron-domain geometry. With an expanded octet of ten electrons, a  $d$  orbital on the sulfur must be used. The trigonal-bipyramidal electron-domain geometry corresponds to  $sp^3d$  hybridization (Table 9.4). One of the hybrid orbitals that points in an equatorial direction contains a nonbonding pair of electrons; the other four are used to form the S—F bonds.

### PRACTICE EXERCISE

Predict the electron-domain geometry and the hybridization of the central atom in (a)  $\text{SO}_3^{2-}$  (b)  $\text{SF}_6$ .

**Answers:** (a) tetrahedral,  $sp^3$ ; (b) octahedral,  $sp^3d^2$

▲ **Figure 9.22 The  $\pi$  bond.** When two  $p$  orbitals overlap in a sideways fashion, the result is a  $\pi$  bond. Note that the two regions of overlap constitute a single  $\pi$  bond.

## 9.6 MULTIPLE BONDS

In the covalent bonds we have considered thus far, the electron density is concentrated along the line connecting the nuclei (the *internuclear axis*). In other words, the line joining the two nuclei passes through the middle of the overlap region. These bonds are called **sigma ( $\sigma$ ) bonds**. The overlap of two  $s$  orbitals as in  $\text{H}_2$  [Figure 9.14(a)], the overlap of an  $s$  and a  $p$  orbital as in  $\text{HCl}$  [Figure 9.14(b)], the overlap between two  $p$  orbitals as in  $\text{Cl}_2$  [Figure 9.14(c)], and the overlap of a  $p$  orbital with an  $sp$  hybrid orbital as in  $\text{BeF}_2$  (Figure 9.17) are all examples of  $\sigma$  bonds.

To describe multiple bonding, we must consider a second kind of bond that results from the overlap between two  $p$  orbitals oriented perpendicularly to the internuclear axis (Figure 9.22 ◀). This sideways overlap of  $p$  orbitals produces a **pi ( $\pi$ ) bond**. A  $\pi$  bond is a covalent bond in which the overlap regions lie above and below the internuclear axis. Unlike in a  $\sigma$  bond, in a  $\pi$  bond there is no probability of finding the electron on the internuclear axis. Because the  $p$  orbitals in a  $\pi$  bond overlap sideways rather than directly facing each other, the total overlap in a  $\pi$  bond tends to be less than that in a  $\sigma$  bond. Consequently,  $\pi$  bonds are generally weaker than  $\sigma$  bonds.

In almost all cases, single bonds are  $\sigma$  bonds. A double bond consists of one  $\sigma$  bond and one  $\pi$  bond, and a triple bond consists of one  $\sigma$  bond and two  $\pi$  bonds:

To see how these ideas are used, consider ethylene ( $\text{C}_2\text{H}_4$ ), which possesses a  $\text{C}=\text{C}$  double bond. The bond angles in ethylene are all approximately  $120^\circ$  (Figure 9.23 ►), suggesting that each carbon atom uses  $sp^2$  hybrid orbitals (Figure 9.18) to form  $\sigma$  bonds with the other carbon and with two hydrogens. Because carbon has four valence electrons, after  $sp^2$  hybridization one electron in each of the carbon atoms remains in the *unhybridized*  $2p$  orbital. The unhybridized  $2p$  orbital is directed perpendicular to the plane that contains the three  $sp^2$  hybrid orbitals.

Each  $sp^2$  hybrid orbital on a carbon atom contains one electron. Figure 9.24 ► shows how the four  $\text{C}-\text{H}$   $\sigma$  bonds are formed by overlap of  $sp^2$  hybrid orbitals on C with the  $1s$  orbitals on each H atom. We use eight electrons to form these four electron-pair bonds. The  $\text{C}-\text{C}$   $\sigma$  bond is formed by the overlap of two  $sp^2$  hybrid orbitals, one on each carbon atom, and requires two more electrons. Thus ten of the 12 valence electrons in the  $\text{C}_2\text{H}_4$  molecule are used to form five  $\sigma$  bonds.

The remaining two valence electrons reside in the unhybridized  $2p$  orbitals, one electron on each carbon atom. These two  $2p$  orbitals can overlap with each other in a sideways fashion, as shown in Figure 9.25 ▼. The resultant electron density is concentrated above and below the  $\text{C}-\text{C}$  bond axis, which means this is a  $\pi$  bond (Figure 9.22). Thus, the  $\text{C}=\text{C}$  double bond in ethylene consists of one  $\sigma$  bond and one  $\pi$  bond.

Although we cannot experimentally observe a  $\pi$  bond directly (all we can observe are the positions of the atoms), the structure of ethylene provides strong support for its presence. First, the  $\text{C}-\text{C}$  bond length in ethylene (1.34 Å) is much shorter than in compounds with  $\text{C}-\text{C}$  single bonds (1.54 Å), consistent with the presence of a stronger  $\text{C}=\text{C}$  double bond. Second, all six atoms in  $\text{C}_2\text{H}_4$  lie in the same plane. The  $2p$  orbitals that make up the  $\pi$  bond can achieve a good overlap only when the two  $\text{CH}_2$  fragments lie in the same plane. If the  $\pi$  bond were absent, there would be no reason for the two  $\text{CH}_2$  fragments of ethylene to lie in the same plane. Because  $\pi$  bonds require that portions of a molecule be planar, they can introduce rigidity into molecules.

▲ **Figure 9.23 The molecular geometry of ethylene.** Ethylene,  $\text{C}_2\text{H}_4$ , has one  $\text{C}-\text{C}$   $\sigma$  bond and one  $\text{C}-\text{C}$   $\pi$  bond.

▲ **Figure 9.24 Hybridization in ethylene.** The  $\sigma$  bonding framework is formed from  $sp^2$  hybrid orbitals on the carbon atoms. The unhybridized  $2p$  orbitals on the C atoms are used to make a  $\pi$  bond.

### GIVE IT SOME THOUGHT

The molecule called *diazine* has the formula  $\text{N}_2\text{H}_2$  and the Lewis structure

Would you expect diazine to be a linear molecule (all four atoms on the same line)? If not, would you expect the molecule to be planar (all four atoms in the same plane)?

▲ **Figure 9.25 The  $\pi$  bond in ethylene.** The unhybridized  $2p$  orbitals on each C atom overlap to form a  $\pi$  bond. The electron density in the  $\pi$  bond is above and below the bond axis, whereas in the  $\sigma$  bonds the electron density lies directly along the bond axes. As noted in Figure 9.22, the two lobes constitute one  $\pi$  bond.

▲ **Figure 9.26** Formation of two  $\pi$  bonds. In acetylene,  $\text{C}_2\text{H}_2$ , the overlap of two sets of unhybridized carbon  $2p$  orbitals leads to the formation of two  $\pi$  bonds.

Triple bonds can also be explained using hybrid orbitals. Acetylene ( $\text{C}_2\text{H}_2$ ), for example, is a linear molecule containing a triple bond:  $\text{H}-\text{C}\equiv\text{C}-\text{H}$ . The linear geometry suggests that each carbon atom uses  $sp$  hybrid orbitals to form  $\sigma$  bonds with the other carbon and one hydrogen. Each carbon atom thus has two remaining unhybridized  $2p$  orbitals at right angles to each other and to the axis of the  $sp$  hybrid set (Figure 9.26 ◀). These  $p$  orbitals overlap to form a pair of  $\pi$  bonds. Thus, the triple bond in acetylene consists of one  $\sigma$  bond and two  $\pi$  bonds.

Although it is possible to make  $\pi$  bonds from  $d$  orbitals, the only  $\pi$  bonds we will consider are those formed by the overlap of  $p$  orbitals. These  $\pi$  bonds can form only if unhybridized  $p$  orbitals are present on the bonded atoms. Therefore, only atoms having  $sp$  or  $sp^2$  hybridization can be involved in such  $\pi$  bonding. Further, double and triple bonds (and hence  $\pi$  bonds) are more common in molecules made up of small atoms from the second period, especially C, N, and O. Larger atoms, such as S, P, and Si, form  $\pi$  bonds less readily.

### ■ SAMPLE EXERCISE 9.6 | Describing $\sigma$ and $\pi$ Bonds in a Molecule

Formaldehyde has the Lewis structure

Describe how the bonds in formaldehyde are formed in terms of overlaps of appropriate hybridized and unhybridized orbitals.

#### SOLUTION

**Analyze:** We are asked to describe the bonding in formaldehyde in terms of orbital overlaps.

**Plan:** Single bonds will be of the  $\sigma$  type, whereas double bonds will consist of one  $\sigma$  bond and one  $\pi$  bond. The ways in which these bonds form can be deduced from the geometry of the molecule, which we predict using the VSEPR model.

**Solve:** The C atom has three electron domains around it, which suggests a trigonal planar geometry with bond angles of about  $120^\circ$ . This geometry implies  $sp^2$  hybrid orbitals on C (Table 9.4). These hybrids are used to make the two C—H and one C—O  $\sigma$  bonds to C. There remains an unhybridized  $2p$  orbital on carbon, perpendicular to the plane of the three  $sp^2$  hybrids.

The O atom also has three electron domains around it, and so we will assume that it has  $sp^2$  hybridization as well. One of these hybrids participates in the C—O  $\sigma$  bond, while the other two hybrids hold the two nonbonding electron pairs of the O atom. Like the C atom, therefore, the O atom has an unhybridized  $2p$  orbital that is perpendicular to the plane of the molecule. The unhybridized  $2p$  orbitals on the C and O atoms overlap to form a C—O  $\pi$  bond, as illustrated in Figure 9.27 ▼.

▲ **Figure 9.27** Formation of  $\sigma$  and  $\pi$  bonds in formaldehyde,  $\text{H}_2\text{CO}$ .

**PRACTICE EXERCISE**

Consider the acetonitrile molecule:

(a) Predict the bond angles around each carbon atom; (b) describe the hybridization at each of the carbon atoms; (c) determine the total number of  $\sigma$  and  $\pi$  bonds in the molecule.

**Answers:** (a) approximately  $109^\circ$  around the left C and  $180^\circ$  on the right C; (b)  $sp^3$ ,  $sp$ ; (c) five  $\sigma$  bonds and two  $\pi$  bonds

### Resonance Structures, Delocalization, and $\pi$ Bonding

In the molecules we have discussed thus far in this section, the bonding electrons are *localized*. By this we mean that the  $\sigma$  and  $\pi$  electrons are associated totally with the two atoms that form the bond. In many molecules, however, we cannot adequately describe the bonding as being entirely localized. This situation arises particularly in molecules that have two or more resonance structures involving  $\pi$  bonds.

One molecule that cannot be described with localized  $\pi$  bonds is benzene ( $\text{C}_6\text{H}_6$ ), which has two resonance structures:  (Section 8.6)

To describe the bonding in benzene using hybrid orbitals, we first choose a hybridization scheme consistent with the geometry of the molecule. Because each carbon is surrounded by three atoms at  $120^\circ$  angles, the appropriate hybrid set is  $sp^2$ . Six localized C—C  $\sigma$  bonds and six localized C—H  $\sigma$  bonds are formed from the  $sp^2$  hybrid orbitals, as shown in Figure 9.28(a) . This leaves a  $2p$  orbital on each carbon that is oriented perpendicularly to the plane of the molecule. The situation is very much like that in ethylene, except we now have six carbon  $2p$  orbitals arranged in a ring [Figure 9.28(b)]. Each of the unhybridized  $2p$  orbitals is occupied by one electron, leaving a total of six electrons to be accounted for by  $\pi$  bonding.

We could envision using the unhybridized  $2p$  orbitals of benzene to form three localized  $\pi$  bonds. As shown in Figure 9.29(a)  and (b), there are two equivalent ways to make these localized bonds, and each corresponds to one of the resonance structures of the molecule. A representation that reflects *both* resonance structures has the

 **Figure 9.28** The  $\sigma$  and  $\pi$  bond networks in benzene,  $\text{C}_6\text{H}_6$ . (a) The C—C and C—H  $\sigma$  bonds all lie in the plane of the molecule and are formed by using carbon  $sp^2$  hybrid orbitals. (b) Each carbon atom has an unhybridized  $2p$  orbital that lies perpendicular to the molecular plane. These six  $2p$  orbitals form the  $\pi$  orbitals of benzene.

(a)  $\sigma$  bonds(b)  $2p$  atomic orbitals(a) Localized  $\pi$  bonds(b) Localized  $\pi$  bonds(c) Delocalized  $\pi$  bonds

 **Figure 9.29** Delocalized  $\pi$  bonds. The six  $2p$  orbitals of benzene, shown in Figure 9.28(b), can be used to make C—C  $\pi$  bonds. (a, b) Two equivalent ways to make localized  $\pi$  bonds. These  $\pi$  bonds correspond to the two resonance structures for benzene. (c) A representation of the smearing out, or delocalization, of the three C—C  $\pi$  bonds among the six C atoms.

six  $\pi$  electrons “smeared out” among all six carbon atoms, as shown in Figure 9.29(c). Notice how this figure corresponds to the “circle-in-a-hexagon” drawing we often use to represent benzene. This model leads to the description of each carbon-carbon bond as having identical bond lengths that are between the length of a C—C single bond (1.54 Å) and the length of a C=C double bond (1.34 Å), consistent with the observed bond lengths in benzene (1.40 Å).

Because we cannot describe the  $\pi$  bonds in benzene as individual electron-pair bonds between neighboring atoms, we say that the  $\pi$  bonds are **delocalized** among the six carbon atoms. Delocalization of the electrons in its  $\pi$  bonds gives benzene a special stability, as we will discuss in Section 25.3. Delocalization of  $\pi$  bonds is also responsible for the color of many organic molecules. A final important point to remember about delocalized  $\pi$  bonds is the constraint they place upon the geometry of a molecule. For optimal overlap of the unhybridized  $p$  orbitals, all of the atoms involved in the delocalized  $\pi$  bonding network should lie in the same plane. This location imparts a certain rigidity to the molecule that is absent in molecules containing only  $\sigma$  bonds (see the “Chemistry and Life” box on vision). If you take a course in organic chemistry, you will see many examples of how electron delocalization influences the properties of organic molecules.

### ■ SAMPLE EXERCISE 9.7 | Delocalized Bonding

Describe the bonding in the nitrate ion,  $\text{NO}_3^-$ . Does this ion have delocalized  $\pi$  bonds?

#### SOLUTION

**Analyze:** Given the chemical formula for a polyatomic anion, we are asked to describe the bonding and determine whether the ion has delocalized  $\pi$  bonds.

**Plan:** Our first step in describing the bonding in  $\text{NO}_3^-$  is to construct appropriate Lewis structures. If there are multiple resonance structures that involve the placement of the double bonds in different locations, that suggests that the  $\pi$  component of the double bonds is delocalized.

**Solve:** In Section 8.6 we saw that  $\text{NO}_3^-$  has three resonance structures:

In each of these structures the electron-domain geometry at nitrogen is trigonal planar, which implies  $sp^2$  hybridization of the N atom. The  $sp^2$  hybrid orbitals are used to construct the three N—O  $\sigma$  bonds that are present in each of the resonance structures.

The unhybridized  $2p$  orbital on the N atom can be used to make  $\pi$  bonds. For any one of the three resonance structures shown, we might imagine a single localized N—O  $\pi$  bond formed by the overlap of the unhybridized  $2p$  orbital on N and a  $2p$  orbital on one of the O atoms, as shown in Figure 9.30(a) ◀. Because each resonance structure contributes equally to the observed structure of  $\text{NO}_3^-$ , however, we represent the  $\pi$  bonding as spread out, or delocalized, over the three N—O bonds, as shown in Figure 9.30(b).

### ■ PRACTICE EXERCISE

Which of the following molecules or ions will exhibit delocalized bonding:  $\text{SO}_3$ ,  $\text{SO}_3^{2-}$ ,  $\text{H}_2\text{CO}$ ,  $\text{O}_3$ ,  $\text{NH}_4^+$ ?

**Answer:**  $\text{SO}_3$  and  $\text{O}_3$ , as indicated by the presence of two or more resonance structures involving  $\pi$  bonding for each of these molecules

▲ **Figure 9.30** Localized and delocalized  $\pi$  bonds in  $\text{NO}_3^-$ .

In recent years scientists have begun to understand the complex chemistry of vision. Vision begins when light is focused by the lens of the eye onto the retina, the layer of cells lining the interior of the eyeball. The retina contains *photoreceptor* cells called rods and cones (Figure 9.31 ▽). The human retina contains about 3 million cones and 100 million rods. The rods are sensitive to dim light and are used in night vision. The cones are sensitive to colors. The tops of the rods and cones contain a molecule called *rhodopsin*. Rhodopsin consists of a protein, called *opsin*, bonded to a reddish purple pigment called *retinal*. Structural changes around a double bond in the retinal portion of the molecule trigger a series of chemical reactions that result in vision.

Double bonds between atoms are stronger than single bonds between the same atoms (Table 8.4). For example, a C=C double bond is stronger (614 kJ/mol) than a C—C single bond (348 kJ/mol), though not twice as strong. Our recent discussions now allow us to appreciate another aspect of double bonds: the stiffness or rigidity that they introduce into molecules.

Imagine taking the —CH<sub>2</sub> group of the ethylene molecule and rotating it relative to the other —CH<sub>2</sub> group as shown in

▲ Figure 9.31 Inside the eye. A color-enhanced scanning electron micrograph of the rods (yellow) and cones (blue) in the retina of the human eye.

▲ Figure 9.33 The chemical basis of vision. When rhodopsin absorbs visible light, the  $\pi$  component of the double bond shown in red breaks, allowing rotation that produces a change in molecular geometry.

Figure 9.32 ▽. This rotation destroys the overlap of  $p$  orbitals, breaking the  $\pi$  bond, a process that requires considerable energy. Thus, the presence of a double bond restricts the rotation of the bonds in a molecule. In contrast, molecules can rotate almost freely around the bond axis in single ( $\sigma$ ) bonds because this motion has no effect on the orbital overlap for a  $\sigma$  bond. This rotation allows molecules with single bonds to twist and fold almost as if their atoms were attached by hinges.

Our vision depends on the rigidity of double bonds in retinal. In its normal form, retinal is held rigid by its double bonds, as shown on the left in Figure 9.33 ▽. Light entering the eye is absorbed by rhodopsin, and the energy is used to break the  $\pi$ -bond portion of the indicated double bond. The molecule then rotates around this bond, changing its geometry. The retinal then separates from the opsin, triggering the reactions that produce a nerve impulse that the brain interprets as the sensation of vision. It takes as few as five closely spaced molecules reacting in this fashion to produce the sensation of vision. Thus, only five photons of light are necessary to stimulate the eye.

The retinal slowly reverts to its original form and reattaches to the opsin. The slowness of this process helps explain why intense bright light causes temporary blindness. The light causes all the retinal to separate from opsin, leaving no further molecules to absorb light.

Related Exercises: 9.99 and 9.100

▲ Figure 9.32 Rotation about the carbon-carbon double bond in ethylene. The overlap of the  $p$  orbitals that form the  $\pi$  bond is lost in the rotation. For this reason, rotation about double bonds requires the absorption of energy.

## General Conclusions

On the basis of the examples we have seen, we can draw a few helpful conclusions for using the concept of hybrid orbitals to describe molecular structures:

1. Every pair of bonded atoms shares one or more pairs of electrons. The lines we draw in Lewis structures represent two electrons each. In every bond at least one pair of electrons is localized in the space between the atoms in a  $\sigma$  bond. The appropriate set of hybrid orbitals used to form the  $\sigma$  bonds between an atom and its neighbors is determined by the observed geometry of the molecule. The correlation between the set of hybrid orbitals and the geometry about an atom is given in Table 9.4.
2. The electrons in  $\sigma$  bonds are localized in the region between two bonded atoms and do not make a significant contribution to the bonding between any other two atoms.
3. When atoms share more than one pair of electrons, one pair is used to form a  $\sigma$  bond; the additional pairs form  $\pi$  bonds. The centers of charge density in a  $\pi$  bond lie above and below the internuclear axis.
4. Molecules with two or more resonance structures can have  $\pi$  bonds that extend over more than two bonded atoms. Electrons in  $\pi$  bonds that extend over more than two atoms are delocalized.

## 9.7 MOLECULAR ORBITALS

Valence-bond theory and hybrid orbitals allow us to move in a straightforward way from Lewis structures to rationalizing the observed geometries of molecules in terms of atomic orbitals. For example, we can use this theory to understand why methane has the formula  $\text{CH}_4$ , how the carbon and hydrogen atomic orbitals are used to form electron-pair bonds, and why the arrangement of the C—H bonds about the central carbon is tetrahedral. This model, however, does not explain all aspects of bonding. It is not successful, for example, in describing the excited states of molecules, which we must understand to explain how molecules absorb light, giving them color.

Some aspects of bonding are better explained by a more sophisticated model called **molecular orbital theory**. In Chapter 6 we saw that electrons in atoms can be described by wave functions, which we call atomic orbitals. In a similar way, molecular orbital theory describes the electrons in molecules by using specific wave functions called **molecular orbitals**. Chemists use the abbreviation **MO** for molecular orbital.

Molecular orbitals have many of the same characteristics as atomic orbitals. For example, an MO can hold a maximum of two electrons (with opposite spins), it has a definite energy, and we can visualize its electron-density distribution by using a contour representation, as we did when we discussed atomic orbitals. Unlike atomic orbitals, however, MOs are associated with the entire molecule, not with a single atom.

▼ **Figure 9.34** The molecular orbitals of  $\text{H}_2$ . The combination of two H  $1s$  atomic orbitals forms two molecular orbitals (MOs) of  $\text{H}_2$ . In the bonding MO,  $\sigma_{1s}$ , the atomic orbitals combine constructively, leading to a buildup of electron density between the nuclei. In the antibonding MO,  $\sigma_{1s}^*$ , the orbitals combine destructively in the bonding region. Note that the  $\sigma_{1s}^*$  MO has a node between the two nuclei.

### The Hydrogen Molecule

To appreciate the approach taken in MO theory, we will begin with the simplest molecule: the hydrogen molecule,  $\text{H}_2$ . We will use the two  $1s$  atomic orbitals (one on each H atom) to “build” molecular orbitals for the  $\text{H}_2$  molecule. Whenever two atomic orbitals overlap, two molecular orbitals form. Thus, the overlap of the  $1s$  orbitals of two hydrogen atoms to form  $\text{H}_2$  produces two MOs (Figure 9.34 ◀). One of the molecular orbitals lies lower in energy from the two atomic orbitals from which it was made; the other molecular orbital lies higher in energy.

▲ **Figure 9.35 Energy-level diagrams for H<sub>2</sub> and He<sub>2</sub>.** (a) The two electrons in the H<sub>2</sub> molecule occupy the  $\sigma_{1s}$  bonding MO. (b) In the (hypothetical) He<sub>2</sub> molecule, both the  $\sigma_{1s}$  bonding MO and the  $\sigma_{1s}^*$  antibonding MO are occupied by two electrons.

The lower-energy MO of H<sub>2</sub> concentrates electron density between the two hydrogen nuclei and is called the **bonding molecular orbital**. This sausage-shaped MO results from summing the two atomic orbitals so that the atomic orbital wave functions combine in the region between the two nuclei. Because an electron in this MO is attracted to both nuclei, the electron is more stable (it has lower energy) than it is in the 1s atomic orbital of an isolated hydrogen atom. Further, because this bonding MO concentrates electron density between the nuclei, it holds the atoms together in a covalent bond.

The higher-energy MO in Figure 9.34 has very little electron density between the nuclei and is called the **antibonding molecular orbital**. Instead of combining in the region between the nuclei, the atomic orbital wave functions cancel each other in this region, leaving the greatest electron density on opposite sides of the nuclei. Thus, this MO excludes electrons from the very region in which a bond must be formed. An electron in this MO is repelled from the bonding region and is therefore less stable (it has higher energy) than it is in the 1s atomic orbital of a hydrogen atom.

The electron density in both the bonding MO and the antibonding MO of H<sub>2</sub> is centered about the internuclear axis. MOs of this type are called **sigma ( $\sigma$ ) molecular orbitals** (by analogy to the  $\sigma$  bonds that were defined in Section 9.6). The bonding sigma MO of H<sub>2</sub> is labeled  $\sigma_{1s}$ ; the subscript indicates that the MO is formed from two 1s orbitals. The antibonding sigma MO of H<sub>2</sub> is labeled  $\sigma_{1s}^*$  (read “sigma-star-one-s”); the asterisk denotes that the MO is antibonding.

The interaction between two 1s atomic orbitals and the molecular orbitals that result can be represented by an **energy-level diagram** (also called a **molecular orbital diagram**), such as those in Figure 9.35 ▲. Such diagrams show the interacting atomic orbitals in the left and right columns and the MOs in the middle column. Note that the bonding molecular orbital,  $\sigma_{1s}$ , is lower in energy than the atomic 1s orbitals, whereas the antibonding orbital,  $\sigma_{1s}^*$ , is higher in energy than the 1s orbitals. Like atomic orbitals, each MO can accommodate two electrons with their spins paired (Pauli exclusion principle). ∞ (Section 6.7) The molecular orbital diagram of the H<sub>2</sub> molecule is shown in Figure 9.35(a). Each H atom brings one electron to the molecule, so there are two electrons in H<sub>2</sub>. These two electrons occupy the lower-energy bonding ( $\sigma_{1s}$ ) MO, and their spins are paired. Electrons occupying a bonding molecular orbital are called *bonding electrons*. Because the  $\sigma_{1s}$  MO is lower in energy than the isolated 1s atomic orbitals, the H<sub>2</sub> molecule is more stable than the two separate H atoms. By analogy with atomic electron configurations, the electron configurations for molecules can also be written with superscripts to indicate electron occupancy. The electron configuration for H<sub>2</sub>, then, is  $\sigma_{1s}^2$ .

In contrast, the hypothetical He<sub>2</sub> molecule requires four electrons to fill its molecular orbitals, as in Figure 9.35(b). Because only two electrons can be put in the  $\sigma_{1s}$  MO, the other two electrons must be placed in the  $\sigma_{1s}^*$  MO. The electron configuration of He<sub>2</sub> is  $\sigma_{1s}^2\sigma_{1s}^{*2}$ . The energy decrease from the two electrons in the bonding MO is offset by the energy increase from the two electrons in the antibonding MO.\* Hence, He<sub>2</sub> is an unstable molecule. Molecular orbital theory correctly predicts that hydrogen forms diatomic molecules but helium does not.

### Bond Order

In molecular orbital theory the stability of a covalent bond is related to its **bond order**, defined as half the difference between the number of bonding electrons and the number of antibonding electrons:

$$\text{Bond order} = \frac{1}{2} (\text{no. of bonding electrons} - \text{no. of antibonding electrons})$$

We take half the difference because we are used to thinking of bonds as pairs of electrons. A bond order of 1 represents a single bond, a bond order of 2 represents a double bond, and a bond order of 3 represents a triple bond. Because MO theory also treats molecules containing an odd number of electrons, bond orders of 1/2, 3/2, or 5/2 are possible.

Because H<sub>2</sub> has two bonding electrons and zero antibonding electrons [Figure 9.35(a)], it has a bond order of 1. Because He<sub>2</sub> has two bonding and two antibonding electrons [Figure 9.35(b)], it has a bond order of 0. A bond order of 0 means that no bond exists.

### GIVE IT SOME THOUGHT

Suppose light is used to excite one of the electrons in the H<sub>2</sub> molecule from the  $\sigma_{1s}$  MO to the  $\sigma_{1s}^*$  MO. Would you expect the H atoms to remain bonded to each other, or would the molecule fall apart?

▲ **Figure 9.36** Energy-level diagram for the He<sub>2</sub><sup>+</sup> ion.

### SAMPLE EXERCISE 9.8 | Bond Order

What is the bond order of the He<sub>2</sub><sup>+</sup> ion? Would you expect this ion to be stable relative to the separated He atom and He<sup>+</sup> ion?

#### SOLUTION

**Analyze:** We will determine the bond order for the He<sub>2</sub><sup>+</sup> ion and use it to predict whether the ion is stable.

**Plan:** To determine the bond order, we must determine the number of electrons in the molecule and how these electrons populate the available MOs. The valence electrons of He are in the 1s orbital, and the 1s orbitals combine to give an MO diagram like that for H<sub>2</sub> or He<sub>2</sub> (Figure 9.35). If the bond order is greater than 0, we expect a bond to exist, and the ion is stable.

**Solve:** The energy-level diagram for the He<sub>2</sub><sup>+</sup> ion is shown in Figure 9.36 ◀. This ion has three electrons. Two are placed in the bonding orbital, the third in the antibonding orbital. Thus, the bond order is

$$\text{Bond order} = \frac{1}{2} (2 - 1) = \frac{1}{2}$$

Because the bond order is greater than 0, we predict the He<sub>2</sub><sup>+</sup> ion to be stable relative to the separated He and He<sup>+</sup>. Formation of He<sub>2</sub><sup>+</sup> in the gas phase has been demonstrated in laboratory experiments.

### PRACTICE EXERCISE

Determine the bond order of the H<sub>2</sub><sup>-</sup> ion.

*Answer:*  $\frac{1}{2}$

\*In fact, antibonding MOs are slightly more unfavorable than bonding MOs are favorable. Thus, whenever there is an equal number of electrons in bonding and antibonding orbitals, the energy of the molecule is slightly higher than that for the separated atoms and no bond is formed.

## 9.8 SECOND-ROW DIATOMIC MOLECULES

Just as we treated the bonding in  $H_2$  by using molecular orbital theory, we can consider the MO description of other diatomic molecules. Initially we will restrict our discussion to *homonuclear* diatomic molecules (those composed of two identical atoms) of elements in the second row of the periodic table. As we will see, the procedure for determining the distribution of electrons in these molecules closely follows the one we used for  $H_2$ .

Second-row atoms have valence  $2s$  and  $2p$  orbitals, and we need to consider how they interact to form MOs. The following rules summarize some of the guiding principles for the formation of MOs and for how they are populated by electrons:

1. The number of MOs formed equals the number of atomic orbitals combined.
2. Atomic orbitals combine most effectively with other atomic orbitals of similar energy.
3. The effectiveness with which two atomic orbitals combine is proportional to their overlap. That is, as the overlap increases, the energy of the bonding MO is lowered and the energy of the antibonding MO is raised.
4. Each MO can accommodate, at most, two electrons, with their spins paired (Pauli exclusion principle).
5. When MOs of the same energy are populated, one electron enters each orbital (with the same spin) before spin pairing occurs (Hund's rule).

### Molecular Orbitals for $Li_2$ and $Be_2$

Lithium, the first element of the second period, has a  $1s^2 2s^1$  electron configuration. When lithium metal is heated above its boiling point ( $1342\text{ }^\circ\text{C}$ ),  $Li_2$  molecules are found in the vapor phase. The Lewis structure for  $Li_2$  indicates a  $Li-Li$  single bond. We will now use MOs to describe the bonding in  $Li_2$ .

Because the  $1s$  and  $2s$  orbitals of  $Li$  are so different in energy, we may assume that the  $1s$  orbital on one  $Li$  atom interacts only with the  $1s$  orbital on the other atom (rule 2). Likewise, the  $2s$  orbitals interact only with each other. The resulting energy-level diagram is shown in Figure 9.37. Notice that combining four atomic orbitals produces four MOs (rule 1).

The  $1s$  orbitals of  $Li$  combine to form  $\sigma_{1s}$  and  $\sigma_{1s}^*$  bonding and antibonding MOs, as they did for  $H_2$ . The  $2s$  orbitals interact with one another in exactly the same way, producing bonding ( $\sigma_{2s}$ ) and antibonding ( $\sigma_{2s}^*$ ) MOs. Because the  $2s$  orbitals of  $Li$  extend farther from the nucleus than the  $1s$  orbitals do, the  $2s$  orbitals overlap more effectively. As a result, the energy separation between the  $\sigma_{2s}$  and  $\sigma_{2s}^*$  orbitals is greater than that for the  $1s$ -based MOs. The  $1s$  orbitals of  $Li$  are so much lower in energy than the  $2s$  orbitals, however, that the  $\sigma_{1s}^*$  antibonding MO is still well below the  $\sigma_{2s}$  bonding MO.

Each  $Li$  atom has three electrons, so six electrons must be placed in the MOs of  $Li_2$ . As shown in Figure 9.37, these electrons occupy the  $\sigma_{1s}$ ,  $\sigma_{1s}^*$ , and  $\sigma_{2s}$  MOs, each with two electrons. There are four electrons in bonding orbitals and two in antibonding orbitals, so the bond order equals  $\frac{1}{2}(4 - 2) = 1$ . The molecule has a single bond, in agreement with its Lewis structure.

Because both the  $\sigma_{1s}$  and  $\sigma_{1s}^*$  MOs of  $Li_2$  are completely filled, the  $1s$  orbitals contribute almost nothing to the bonding. The single bond in  $Li_2$  is due essentially to the interaction of the valence  $2s$  orbitals on the  $Li$  atoms. This example

▲ Figure 9.37 Energy-level diagram for the  $Li_2$  molecule.

illustrates the general rule that *core electrons usually do not contribute significantly to bonding in molecule formation*. The rule is equivalent to using only the valence electrons when drawing Lewis structures. Thus, we need not consider further the  $1s$  orbitals while discussing the other second-row diatomic molecules.

The MO description of  $\text{Be}_2$  follows readily from the energy-level diagram for  $\text{Li}_2$ . Each Be atom has four electrons ( $1s^2 2s^2$ ), so we must place eight electrons in molecular orbitals. Thus, we completely fill the  $\sigma_{1s}$ ,  $\sigma_{1s}^*$ ,  $\sigma_{2s}$ , and  $\sigma_{2s}^*$  MOs. We have an equal number of bonding and antibonding electrons, so the bond order equals 0. Consistent with this analysis,  $\text{Be}_2$  does not exist.

### GIVE IT SOME THOUGHT

Would you expect  $\text{Be}_2^+$  to be a stable ion?

### Molecular Orbitals from $2p$ Atomic Orbitals

Before we can consider the remaining second-row molecules, we must look at the MOs that result from combining  $2p$  atomic orbitals. The interactions between  $p$  orbitals are shown in Figure 9.38 ▼, where we have arbitrarily chosen the internuclear axis to be the  $z$ -axis. The  $2p_z$  orbitals face each other in a “head-to-head” fashion. Just as we did for the  $s$  orbitals, we can combine the  $2p_z$  orbitals in two ways. One combination concentrates electron density between the nuclei and is therefore a bonding molecular orbital. The other combination excludes electron density from the bonding region; it is an antibonding molecular orbital. In each of these MOs the electron density lies along the line through the nuclei, so they are  $\sigma$  molecular orbitals:  $\sigma_{2p}$  and  $\sigma_{2p}^*$ .

The other  $2p$  orbitals overlap sideways and thus concentrate electron density above and below a line connecting the nuclei. MOs of this type are called **pi ( $\pi$ ) molecular orbitals**, by analogy to  $\pi$  bonds we saw in Section 9.6. We get one  $\pi$  bonding MO by combining the  $2p_x$  atomic orbitals and another from the  $2p_y$  atomic orbitals. These two  $\pi_{2p}$  molecular orbitals have the same energy; in other words, they are degenerate. Likewise, we get two degenerate  $\pi_{2p}^*$  antibonding MOs. The  $\pi_{2p}^*$  orbitals are mutually perpendicular to each other, like the  $2p$  orbitals from which they were made. These  $\pi_{2p}^*$  orbitals have four lobes, pointing away from the two nuclei, as shown in the Figure 9.38. The  $2p_z$  orbitals on two atoms point directly at each other. Hence, the overlap of two  $2p_z$  orbitals is greater than that for two  $2p_x$  or  $2p_y$  orbitals. From rule 3 we therefore expect the  $\sigma_{2p}$  MO to be lower in energy (more stable) than the  $\pi_{2p}$  MOs. Similarly, the  $\sigma_{2p}^*$  MO should be higher in energy (less stable) than the  $\pi_{2p}^*$  MOs.

◀ **Figure 9.38** Contour representations of the molecular orbitals formed by  $2p$  orbitals. Each time we combine two atomic orbitals, we obtain two MOs: one bonding and one antibonding.

## A Closer Look

## PHASES IN ATOMIC AND MOLECULAR ORBITALS

Our discussion of atomic orbitals in Chapter 6 and molecular orbitals in this chapter highlights some of the most important applications of quantum mechanics in chemistry. In the quantum mechanical treatment of electrons in atoms and molecules, we are mainly interested in obtaining two characteristics of the electrons—namely, their energies and their distribution in space. Recall that solving Schrödinger's wave equation yields the electron's energy,  $E$ , and wave function,  $\psi$ , but that  $\psi$  itself does not have a direct physical meaning.  $\infty$  (Section 6.5) The contour representations of atomic and molecular orbitals that we have presented thus far are based on the square of the wave function,  $\psi^2$  (the *probability density*), which gives the probability of finding the electron at a given point in space.

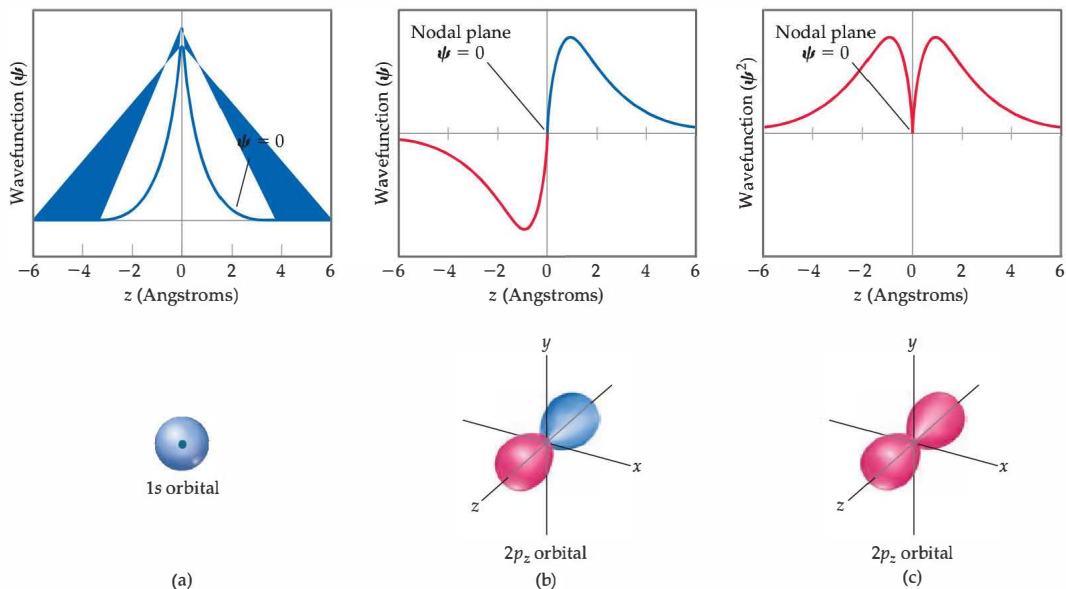

Because probability densities are squares of functions, their values must be nonnegative (zero or positive) at all points in space. However, the functions themselves can have negative values. Consider, for example, the simple sine function, plotted in Figure 9.39. From the drawing on the top, you can see that the sine function has negative values for  $x$  between 0 and  $-\pi$ , and positive values for  $x$  between 0 and  $+\pi$ . We say that the *phase* of the sine function is negative between 0 and  $-\pi$  and positive between 0 and  $+\pi$ . If we square the sine function (bottom graph), we get two peaks that look the same on each side of the origin. Both of the peaks are positive because squaring a negative number produces a positive number—we lose the phase information of the function upon squaring it.

The wave functions for the atomic orbitals are much more complicated than the simple sine function, but like the sine function they can have phases. Consider, for example, the representations of the 1s orbital in Figure 9.40. The 1s orbital is plotted a bit differently than we saw in Chapter 6. The origin

◀ **Figure 9.39**  
**Phases in the sine function.** (a) A full cycle of a sine wave ( $y = \sin x$ ) has two equivalent halves that are opposite in sign (phase). The origin is a node. (b) Squaring the sine function ( $y = \sin^2 x$ ) produces two equivalent positive peaks. The origin is still a node.

▼ **Figure 9.40** **Phases in  $s$  and  $p$  atomic orbital wavefunctions.** (a) The wave function for a 1s orbital is plotted on top, with its contour representation below. The 1s orbital has no nodes. (b) The wave function for a 2p orbital is plotted on top, with its contour representation below. The 2p orbital has a node, and the phase of the wave function changes on either side of the node. In the contour picture, this change of phase is represented by two colors for the two lobes of the orbital. (c) The square of the wave function gives the probability density for the 2p orbital. The square of the wave function is plotted on top, with the contour representation below. The contour representation has only one color to denote that the phase information has been lost by squaring the wavefunction.

1s orbital

(a)

 $2p_z$  orbital

(b)

 $2p_z$  orbital

(c)

is the point where the nucleus is, and the wave function for the  $1s$  orbital extends from the origin in space. The plot shows the value of the wave function,  $\psi$  for a slice taken along the  $z$ -axis. Below the plot is a contour representation of the  $1s$  orbital. Notice that the value of the  $1s$  wave function is always a positive number. Thus, it has only one phase. Notice also that the wave function never goes to zero. It therefore has no nodes, as we saw in Chapter 6.

In Figure 9.40b we see a similar set of representations for the  $2p_z$  orbital. Now the wave function changes sign upon crossing through  $z = 0$ . Notice that the two halves of the wave have the same shape except that one has positive values and the other negative values; the wave function changes phase upon crossing through the origin. Mathematically the  $2p_z$  wave function is equal to zero whenever  $z = 0$ . This corresponds to any point on the  $xy$  plane, so we say that the  $xy$  plane is a *nodal plane* of the  $2p_z$  orbital. The wave function for a  $p$  orbital is much like a sine function because it has two equal parts that have opposite phases. Figure 9.40b gives a typical representation used by chemists of the wave function for a  $p_z$  orbital.\* The two different colors for the lobes indicate the different signs or phases of the orbital. Like the sine function, the origin is a node.

What happens if we square the  $2p_z$  wave function? Figure 9.40c shows that when we square the wave function of the  $2p_z$  orbital, we get two peaks that look the same on each side of the origin. Both of the peaks are positive because squaring a negative number produces a positive number—we lose the phase information of the function upon squaring it, just as we did for the sine function. When we square the wave function for the  $p_x$  orbital, we get the probability density for the orbital, which is given as a contour representation in Figure 9.40c. For this function, both lobes have the same phase and therefore the same color. We use this representation throughout most of this book.

The lobes of the wave functions for the  $d$  orbitals also have different phases. For example, the wave function for a  $d_{xy}$  orbital has four lobes that alternate in phase, as shown in Figure 9.41. The wave functions for the other  $d$  orbitals likewise have lobes of alternating phase.

Why do we need to consider the additional complexity that is introduced by considering the sign or phase of the wave function? While it is true that the phase of the wave function is not necessary to visualize the shape of an atomic orbital in an isolated atom, it does become important when we consider overlap of orbitals in molecular orbital theory. Let's use the sine function as an example again. If you add two sine functions together that are of the same phase, they add

*constructively*, resulting in increased amplitude as shown in the accompanying figure. On the other hand, if you add two sine functions together that are of the opposite phase, they add *destructively* and cancel each other.

The idea of constructive and destructive interactions of wave functions is key to understanding the origin of bonding and antibonding molecular orbitals that arise from combining or overlapping of atomic orbitals. For example, the wave function of the  $\sigma_{1s}$  MO of  $H_2$  is generated by adding the wave function for the  $1s$  orbital on one atom to the wave function for the  $1s$  orbital on the other atom, with both orbitals having the same phase. We can say that the atomic wave functions overlap *constructively* in this case, to increase the electron density between the two atoms (Figure 9.42a). The wave function of the  $\sigma_{1s}^*$  MO of  $H_2$  is generated by adding the wave function for a  $1s$  orbital on one atom to the wave function for a  $1s$  orbital on the other atom, but with the two orbitals having opposite phases. This amounts to subtracting  $1s$  orbital from the other. The atomic orbital wave functions overlap *destructively* in this case, to create a region of zero electron density between the two atoms—a node. Chemists generally sketch the wave functions by simply drawing the contour representations of the  $1s$  orbitals in different colors to denote the two phases (Figure 9.42b).

◀ **Figure 9.41** Phases in  $d$  orbitals. The wave function for the  $d_{xy}$  orbital has lobes of alternating sign.

▲ **Figure 9.42** Molecular orbitals from atomic orbital wave functions. (a) The mixing of two  $1s$  orbitals that are of the same phase produces a  $\sigma_{1s}$  MO. (b) The mixing of two  $1s$  orbitals that are opposite in phase produces a  $\sigma_{1s}^*$  MO.

\*The mathematical development of this three-dimensional function (and its square) is beyond the scope of this book, and, as is typically done by chemists, we have used lobes that are the same shape as in Figure 6.23.

Notice how this wave function has similarities to both the sine function and to a  $p$  orbital—in each of these cases we have two parts of the function of opposite phase separated by a node. When we square the wave function of the  $\sigma_{1s}^*$  MO, we get the probability density representation given in Figure 9.34—notice that we once again lose the phase information when we look at the probability density.

Our brief discussion has given you only an introduction to the mathematical subtleties of atomic and molecular orbitals. Chemists use the wave functions of atomic and molecular orbitals to understand many aspects of chemical bonding and spectroscopy. You will probably see orbitals drawn in color to show phases if you take a course in organic chemistry. *Related Exercises: 9.89, 9.103, 9.105*

## Electron Configurations for $B_2$ Through $Ne_2$

So far, we have independently considered the MOs that result from  $s$  orbitals (Figure 9.34) and from  $p$  orbitals (Figure 9.38). We can combine these results to construct an energy-level diagram (Figure 9.43) for homonuclear diatomic molecules of the elements boron through neon, all of which have valence  $2s$  and  $2p$  atomic orbitals. The following features of the diagram are notable:

1. The  $2s$  atomic orbitals are lower in energy than the  $2p$  atomic orbitals.  $\Leftarrow$  (Section 6.7) Consequently, both of the molecular orbitals that result from the  $2s$  orbitals, the bonding  $\sigma_{2s}$  and antibonding  $\sigma_{2s}^*$ , are lower in energy than the lowest-energy MO derived from the  $2p$  atomic orbitals.
2. The overlap of the two  $2p_z$  orbitals is greater than that of the two  $2p_x$  or  $2p_y$  orbitals. As a result, the bonding  $\sigma_{2p}$  MO is lower in energy than the  $\pi_{2p}$  MOs, and the antibonding  $\sigma_{2p}^*$  MO is higher in energy than the  $\pi_{2p}^*$  MOs.
3. Both the  $\pi_{2p}$  and  $\pi_{2p}^*$  molecular orbitals are *doubly degenerate*; that is, there are two degenerate MOs of each type.

Before we can add electrons to the energy-level diagram in Figure 9.43, we must consider one more effect. We have constructed the diagram assuming there is no interaction between the  $2s$  orbital on one atom and the  $2p$  orbitals on the other. In fact, such interactions can and do take place. Figure 9.44 shows the overlap of a  $2s$  orbital on one of the atoms with a  $2p_z$  orbital on the other. These interactions affect the energies of the  $\sigma_{2s}$  and  $\sigma_{2p}$  molecular orbitals in such a way that these MOs move further apart in energy, the  $\sigma_{2s}$  falling and the  $\sigma_{2p}$  rising in energy (Figure 9.45). These  $2s$ – $2p$  interactions are strong enough that the energetic ordering of the MOs can be altered: For  $B_2$ ,  $C_2$ , and  $N_2$ , the  $\sigma_{2p}$  MO is above the  $\pi_{2p}$  MOs in energy. For  $O_2$ ,  $F_2$ , and  $Ne_2$ , the  $\sigma_{2p}$  MO is below the  $\pi_{2p}$  MOs.

Given the energy ordering of the molecular orbitals, it is a simple matter to determine the electron configurations for the second-row diatomic molecules  $B_2$  through  $Ne_2$ . For example, a boron atom has three valence electrons. (Remember that we are ignoring the inner-shell  $1s$  electrons.) Thus, for  $B_2$  we must place six electrons in MOs. Four of these electrons fully occupy the  $\sigma_{2s}$  and  $\sigma_{2s}^*$  MOs, leading to no net bonding. The last two electrons are put in the  $\pi_{2p}$  bonding MOs; one electron is put in one  $\pi_{2p}$  MO and the other electron is put in the other  $\pi_{2p}$  MO, with the two electrons having the same spin. Therefore,  $B_2$  has a bond order of 1. Each time we move one element to the right in the second row, two more electrons must be placed in the diagram. For example, on moving to  $C_2$ , we have two more electrons than in  $B_2$ , and these electrons are placed in the

▲ **Figure 9.43** Energy-level diagram for MOs of second-row homonuclear diatomic molecules. The diagram assumes no interaction between the  $2s$  atomic orbital on one atom and the  $2p$  atomic orbitals on the other atom, and experiment shows that it fits only for  $O_2$ ,  $F_2$ , and  $Ne_2$ .

▲ **Figure 9.44** Interaction of  $2s$  and  $2p$  atomic orbitals. The  $2s$  orbital on one atom of a diatomic molecule can overlap with the  $2p_z$  orbital on the other atom. These  $2s$ – $2p$  interactions can alter the energetic ordering of the MOs of the molecule.

► **Figure 9.45 The effect of 2s–2p interactions.** When the 2s and 2p orbitals interact, the  $\sigma_{2s}$  MO falls in energy and the  $\sigma_{2p}$  MO rises in energy. For  $O_2$ ,  $F_2$ , and  $Ne_2$ , the interaction is small, and the  $\sigma_{2p}$  MO remains below the  $\pi_{2p}$  MOs, as in Figure 9.43. For  $B_2$ ,  $C_2$ , and  $N_2$ , the 2s–2p interaction is great enough that the  $\sigma_{2p}$  MO rises above the  $\pi_{2p}$  MOs, as shown on the right.

$\pi_{2p}$  MOs, completely filling them. The electron configurations and bond orders for the diatomic molecules  $B_2$  through  $Ne_2$  are given in Figure 9.46 ▼.

### Electron Configurations and Molecular Properties

The way a substance behaves in a magnetic field provides an important insight into the arrangements of its electrons. Molecules with one or more unpaired electrons are attracted into a magnetic field. The more unpaired electrons in a species, the stronger the force of attraction will be. This type of magnetic behavior is called **paramagnetism**.

Substances with no unpaired electrons are weakly repelled from a magnetic field. This property is called **diamagnetism**. Diamagnetism is a much weaker effect than paramagnetism. A straightforward method for measuring the

▲ **Figure 9.47 Determining the magnetic properties of a sample.** The response of a sample to a magnetic field indicates whether it is diamagnetic or paramagnetic. Paramagnetism is a much stronger effect than diamagnetism.

magnetic properties of a substance, illustrated in Figure 9.47 ▲, involves weighing the substance in the presence and absence of a magnetic field. If the substance is paramagnetic, it will appear to weigh more in the magnetic field; if it is diamagnetic, it will appear to weigh less. The magnetic behaviors observed for the diatomic molecules of the second-row elements agree with the electron configurations shown in Figure 9.46.

### GIVE IT SOME THOUGHT

Figure 9.46 indicates that the  $C_2$  molecule is diamagnetic. Would that be expected if the  $\sigma_{2p}$  MO were lower in energy than the  $\pi_{2p}$  MOs?

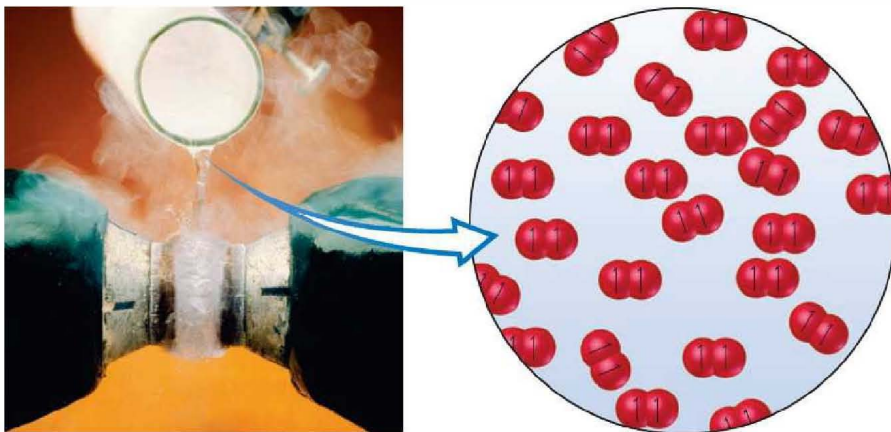

The electron configurations can also be related to the bond distances and bond enthalpies of the molecules.  $\rightleftharpoons$  (Section 8.8) As bond orders increase, bond distances decrease and bond enthalpies increase.  $N_2$ , for example, whose bond order is 3, has a short bond distance and a large bond enthalpy. The  $N_2$  molecule does not react readily with other substances to form nitrogen compounds. The high bond order of the molecule helps explain its exceptional stability. We should also note, however, that molecules with the same bond orders do *not* have the same bond distances and bond enthalpies. Bond order is only one factor influencing these properties. Other factors include the nuclear charges and the extent of orbital overlap.

Bonding in the dioxygen molecule,  $O_2$ , is especially interesting. Its Lewis structure shows a double bond and complete pairing of electrons:

The short O—O bond distance (1.21 Å) and the relatively high bond enthalpy (495 kJ/mol) are in agreement with the presence of a double bond. However, the molecule contains two unpaired electrons. The paramagnetism of  $O_2$  is demonstrated in Figure 9.48 ▼. Although the Lewis structure fails to account for the paramagnetism of  $O_2$ , molecular orbital theory correctly predicts that two unpaired electrons are in the  $\pi_{2p}^*$  orbital of the molecule (Figure 9.46). The MO description also correctly indicates a bond order of 2.

Going from  $O_2$  to  $F_2$ , we add two more electrons, completely filling the  $\pi_{2p}^*$  MOs. Thus,  $F_2$  is expected to be diamagnetic and have an F—F single bond, in accord with its Lewis structure. Finally, the addition of two more electrons to make  $Ne_2$  fills all the bonding and antibonding MOs. Therefore, the bond order of  $Ne_2$  is zero, and the molecule is not expected to exist.

▲ **Figure 9.48 Paramagnetism of  $O_2$ .** Liquid  $O_2$  being poured between the poles of a magnet. Because each  $O_2$  molecule contains two unpaired electrons,  $O_2$  is paramagnetic. It is therefore attracted into the magnetic field and “sticks” between the magnetic poles.

### ■ SAMPLE EXERCISE 9.9 | Molecular Orbitals of a Second-Row Diatomic Ion

Predict the following properties of  $O_2^+$ : (a) number of unpaired electrons, (b) bond order, (c) bond enthalpy and bond length.

#### SOLUTION

**Analyze:** Our task is to predict several properties of the cation  $O_2^+$ .

**Plan:** We will use the MO description of  $O_2^+$  to determine the desired properties. We must first determine the number of electrons in  $O_2^+$  and then draw its MO energy diagram. The unpaired electrons are those without a partner of opposite spin. The bond order is one-half the difference between the number of bonding and antibonding electrons. After calculating the bond order, we can use the data in Figure 9.46 to estimate the bond enthalpy and bond length.

#### Solve:

- (a) The  $O_2^+$  ion has 11 valence electrons, one fewer than  $O_2$ . The electron removed from  $O_2$  to form  $O_2^+$  is one of the two unpaired  $\pi^*_p$  electrons (see Figure 9.46). Therefore,  $O_2^+$  has just one unpaired electron.  
 (b) The molecule has eight bonding electrons (the same as  $O_2$ ) and three antibonding electrons (one fewer than  $O_2$ ). Thus, its bond order is

$$\frac{1}{2}(8 - 3) = 2\frac{1}{2}$$

- (c) The bond order of  $O_2^+$  is between that for  $O_2$  (bond order 2) and  $N_2$  (bond order 3). Thus, the bond enthalpy and bond length should be about midway between those for  $O_2$  and  $N_2$ , approximately 700 kJ/mol and 1.15 Å, respectively. The experimental bond enthalpy and bond length of the ion are 625 kJ/mol and 1.123 Å, respectively.

### ■ PRACTICE EXERCISE

Predict the magnetic properties and bond orders of (a) the peroxide ion,  $O_2^{2-}$ ; (b) the acetylide ion,  $C_2^{2-}$ .

**Answers:** (a) diamagnetic, 1; (b) diamagnetic, 3

## Heteronuclear Diatomic Molecules

The same principles we have used in developing an MO description of homonuclear diatomic molecules can be extended to *heteronuclear* diatomic molecules—those in which the two atoms in the molecule are not the same. We will conclude this section on MO theory with a brief discussion of the MOs of a fascinating heteronuclear diatomic molecule—the nitric oxide, NO, molecule.

The NO molecule controls several important human physiological functions. Our bodies use it, for example, to relax muscles, to kill foreign cells, and to reinforce memory. The 1998 Nobel Prize in Physiology or Medicine was awarded to three scientists for their research that uncovered the importance of NO as a “signalling” molecule in the cardiovascular system. NO also functions as a neurotransmitter and is implicated in many other biological pathways. That NO plays such an important role in human metabolism was unsuspected before 1987 because NO has an odd number of electrons and is highly reactive. The molecule has 11 valence electrons, and two possible Lewis structures can be drawn. The Lewis structure with the lower formal charges places the odd electron on the N atom:

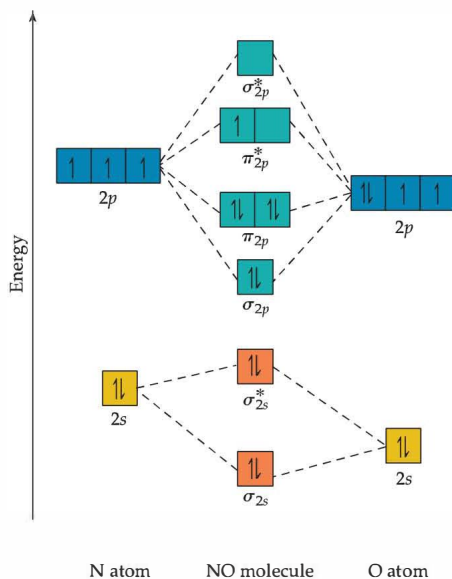

Both structures indicate the presence of a double bond, but when compared with the molecules in Figure 9.46, the experimental bond length of NO (1.15 Å) suggests a bond order greater than two. How do we treat NO using the MO model?

If the atoms in a heteronuclear diatomic molecule do not differ too greatly in their electronegativities, the description of their MOs will resemble those for homonuclear diatomics, with one important modification: The atomic energies of the more electronegative atom will be lower in energy than those of the less electronegative element. The MO diagram for NO is shown in Figure 9.49. You can see that the 2s and 2p atomic orbitals of oxygen are slightly lower than those of nitrogen because oxygen is more electronegative than nitrogen. We see that the MO energy-level diagram is much like that of a homonuclear diatomic molecule—because the 2s and 2p orbitals on the two atoms interact, the same types of MOs are produced.

There is one other important change in the MOs when we consider heteronuclear molecules. The MOs that result are still a mix of the atomic orbitals from both atoms, but in general *an MO will have a greater contribution from the atomic orbital to which it is closer in energy*. In the case of NO, for example, the  $\sigma_{2s}$  bonding MO is closer in energy to the O 2s atomic orbital. As a result, the  $\sigma_{2s}$  MO has a slightly greater contribution from O than from N—the orbital is no longer an equal mixture of the two atoms, as was the case for the homonuclear diatomic molecules. Similarly, the  $\sigma_{2s}^*$  antibonding MO is weighted more heavily toward the N atom because that MO is closest in energy to the N 2s atomic orbital.

We complete the MO diagram for NO by filling the MOs in Figure 9.49 with the 11 valence electrons. We see that there are eight bonding and three antibonding electrons, giving a bond order of  $\frac{1}{2}(8 - 3) = 2\frac{1}{2}$ , which agrees better with experiment than the Lewis structures do. The unpaired electron resides in one of the  $\pi_{2p}^*$  MOs, which are more heavily weighted toward the N atom. Thus, the Lewis structure that places the unpaired electron on nitrogen (the one preferred on the basis of formal charge) is a more accurate description of the true electron distribution in the molecule.

▲ Figure 9.49 The MO energy-level diagram for NO.

## Chemistry Put to Work

## ORBITALS AND ENERGY

If you were asked to identify the major technological challenge for the twenty-first century, you might say “energy.” The development of sustainable energy sources is crucial to meet the needs of future generations of people on our planet. Currently, the majority of the world, in one way or another, relies on exothermic combustion reactions of oil, coal, or natural gas to provide heat and ultimately power. Oil, coal, and natural gas are examples of “fossil fuels”—carbon-containing compounds that are the long-term decomposition products of ancient plants and animals. Fossil fuels are not renewable in the several-hundred-year timeframe in which we need them. But every day our planet receives plenty of energy from the Sun to easily power the world for millions of years. Whereas the combustion of fossil fuels results in release of  $\text{CO}_2$  into the atmosphere, solar energy represents a renewable energy source that is potentially less harmful to the environment. One way to utilize solar energy is to convert it into electrical energy using photovoltaic solar cells. The problem with this alternative is that the current efficiency of solar cell devices is low; only about 10–15% of sunlight is converted into useful energy. Furthermore, the cost of manufacturing solar cells is relatively high.

How does solar energy conversion work? Fundamentally, we need to be able to use photons from the Sun to excite electrons in molecules and materials to different energy levels. The brilliant colors around you—those of your clothes, the photographs in this book, the foods you eat—are due to the selective absorption of light by chemicals. Light excites electrons in molecules. In a molecular orbital picture, we can envision light exciting an electron from a filled molecular orbital to an empty one at higher energy. Because the MOs have definite energies, only light of the proper wavelengths can excite electrons. The situation is analogous to that of atomic line spectra.

↔ (Section 6.3) If the appropriate wavelength for exciting electrons is in the visible portion of the electromagnetic spectrum, the substance will appear colored: Certain wavelengths of white light are absorbed; others are not. A green leaf appears green because only green light is reflected by the leaf; other wavelengths of visible light are absorbed by the leaf.

In using molecular orbital theory to discuss the absorptions of light by molecules, we can focus on two MOs in particular. The *highest occupied molecular orbital* (HOMO) is the MO of highest energy that has electrons in it. The *lowest unoccupied molecular orbital* (LUMO) is the MO of lowest energy that does not have electrons in it. In  $\text{N}_2$ , for example, the HOMO is the  $\pi_{2p}$  MO and the LUMO is the  $\pi_{2p}^*$  MO (Figure 9.46). The energy difference between the HOMO and the LUMO—known as the HOMO–LUMO gap—is related to the minimum energy needed to excite an electron in the molecule. Colorless or white substances usually have such a large HOMO–LUMO gap that visible light is not energetic enough to excite an electron to the higher level. The minimum energy

▲ **Figure 9.50 Light into electricity.** The light from a flashlight, to the left of the photograph frame, is sufficient to excite electrons from one energy level to another in this simple solar cell, producing electricity that powers the small fan. To capture more light, a red ruthenium-containing complex is added to the colorless  $\text{TiO}_2$  paste between the glass plates.

needed to excite an electron in  $\text{N}_2$  corresponds to light with a wavelength of less than 200 nm, which is far into the ultraviolet part of the spectrum (Figure 6.4). As a result,  $\text{N}_2$  cannot absorb any visible light and is therefore colorless.

The magnitude of the energy gap between filled and empty electronic states is critical for solar energy conversion. Ideally, we would like to have a substance that absorbs as many solar photons as possible and then convert the energy of those photons into a useful form of energy such as electricity. Titanium dioxide, for example, is a readily available material that can be reasonably efficient at converting light directly into electricity. However,  $\text{TiO}_2$  is white and absorbs only a small amount of the Sun’s radiant energy output. Scientists are working to make solar cells in which  $\text{TiO}_2$  is mixed with highly colored molecules, whose HOMO–LUMO gaps correspond to visible and near-infrared light. That way, the molecules can absorb more of the solar spectrum. The molecule’s HOMO must also be higher in energy than the  $\text{TiO}_2$ ’s HOMO so that the excited electrons can flow from the molecules into the  $\text{TiO}_2$ , thereby generating electricity when the device is illuminated with light and connected to an external circuit.

Figure 9.50▲ shows a simple solar cell made from ruthenium-containing molecules, which appear red, mixed with  $\text{TiO}_2$  in a paste, sandwiched between two glass plates. Light that shines from a flashlight to the left of the device generates enough current to run the small fan that is connected to it with wires.

**SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

Elemental sulfur is a yellow solid that consists of  $S_8$  molecules. The structure of the  $S_8$  molecule is a puckered, eight-membered ring (Figure 7.34). Heating elemental sulfur to high temperatures produces gaseous  $S_2$  molecules:

(a) With respect to electronic structure, which element in the second row of the periodic table is most similar to sulfur? (b) Use the VSEPR model to predict the S—S—S bond angles in  $S_8$  and the hybridization at S in  $S_8$ . (c) Use MO theory to predict the sulfur–sulfur bond order in  $S_2$ . Is the molecule expected to be diamagnetic or paramagnetic? (d) Use average bond enthalpies (Table 8.4) to estimate the enthalpy change for the reaction just described. Is the reaction exothermic or endothermic?

**SOLUTION**

(a) Sulfur is a group 6A element with an  $[Ne]3s^23p^4$  electron configuration. It is expected to be most similar electronically to oxygen (electron configuration,  $[He]2s^22p^4$ ), which is immediately above it in the periodic table. (b) The Lewis structure of  $S_8$  is

There is a single bond between each pair of S atoms and two nonbonding electron pairs on each S atom. Thus, we see four electron domains around each S atom, and we would expect a tetrahedral electron-domain geometry corresponding to  $sp^3$  hybridization.  $\rightleftharpoons$  (Sections 9.2, 9.5) Because of the nonbonding pairs, we would expect the S—S—S angles to be somewhat less than  $109^\circ$ , the tetrahedral angle. Experimentally, the S—S—S angle in  $S_8$  is  $108^\circ$ , in good agreement with this prediction. Interestingly, if  $S_8$  were a planar ring (like a stop sign), it would have S—S—S angles of  $135^\circ$ . Instead, the  $S_8$  ring puckers to accommodate the smaller angles dictated by  $sp^3$  hybridization. (c) The MOs of  $S_2$  are entirely analogous to those of  $O_2$ , although the MOs for  $S_2$  are constructed from the 3s and 3p atomic orbitals of sulfur. Further,  $S_2$  has the same number of valence electrons as  $O_2$ . Thus, by analogy to our discussion of  $O_2$ , we would expect  $S_2$  to have a bond order of 2 (a double bond) and to be paramagnetic with two unpaired electrons in the  $\pi_{3p}^*$  molecular orbitals of  $S_2$ .  $\rightleftharpoons$  (Section 9.8) (d) We are considering the reaction in which an  $S_8$  molecule falls apart into four  $S_2$  molecules. From parts (b) and (c), we see that  $S_8$  has S—S single bonds and  $S_2$  has S=S double bonds. During the course of the reaction, therefore, we are breaking eight S—S single bonds and forming four S=S double bonds. We can estimate the enthalpy of the reaction by using Equation 8.12 and the average bond enthalpies in Table 8.4:

$$\Delta H_{\text{rxn}} = 8 D(\text{S—S}) - 4 D(\text{S}=\text{S}) = 8(266 \text{ kJ}) - 4(418 \text{ kJ}) = +456 \text{ kJ}$$

Because  $\Delta H_{\text{rxn}} > 0$ , the reaction is endothermic.  $\rightleftharpoons$  (Section 5.4) The very positive value of  $\Delta H_{\text{rxn}}$  suggests that high temperatures are required to cause the reaction to occur.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 9.1** The three-dimensional shapes and sizes of molecules are determined by their **bond angles** and bond lengths. Molecules with a central atom A surrounded by  $n$  atoms B, denoted  $AB_n$ , adopt a number of different geometric shapes, depending on the value of  $n$  and on the particular atoms involved. In the

overwhelming majority of cases, these geometries are related to five basic shapes (linear, trigonal pyramidal, tetrahedral, trigonal bipyramidal, and octahedral).

**Section 9.2** The **valence-shell electron-pair repulsion (VSEPR) model** rationalizes molecular geometries based

on the repulsions between **electron domains**, which are regions about a central atom in which electrons are likely to be found. **Bonding pairs** of electrons, which are those involved in making bonds, and **nonbonding pairs** of electrons, also called lone pairs, both create electron domains around an atom. According to the VSEPR model, electron domains orient themselves to minimize electrostatic repulsions; that is, they remain as far apart as possible. Electron domains from nonbonding pairs exert slightly greater repulsions than those from bonding pairs, which leads to certain preferred positions for nonbonding pairs and to the departure of bond angles from idealized values. Electron domains from multiple bonds exert slightly greater repulsions than those from single bonds. The arrangement of electron domains around a central atom is called the **electron-domain geometry**; the arrangement of atoms is called the **molecular geometry**.

**Section 9.3** The dipole moment of a polyatomic molecule depends on the vector sum of the dipole moments associated with the individual bonds, called the **bond dipoles**. Certain molecular shapes, such as linear  $AB_2$  and trigonal planar  $AB_3$ , assure that the bond dipoles cancel, producing a nonpolar molecule, which is one whose dipole moment is zero. In other shapes, such as bent  $AB_2$  and trigonal pyramidal  $AB_3$ , the bond dipoles do not cancel and the molecule will be polar (that is, it will have a nonzero dipole moment).

**Section 9.4** Valence-bond theory is an extension of Lewis's notion of electron-pair bonds. In valence-bond theory, covalent bonds are formed when atomic orbitals on neighboring atoms **overlap** one another. The overlap region is a favorable one for the two electrons because of their attraction to two nuclei. The greater the overlap between two orbitals, the stronger will be the bond that is formed.

**Section 9.5** To extend the ideas of valence-bond theory to polyatomic molecules, we must envision mixing  $s$ ,  $p$ , and sometimes  $d$  orbitals to form **hybrid orbitals**. The process of **hybridization** leads to hybrid atomic orbitals that have a large lobe directed to overlap with orbitals on another atom to make a bond. Hybrid orbitals can also accommodate nonbonding pairs. A particular mode of hybridization can be associated with each of the five common electron-domain geometries (linear =  $sp$ ; trigonal planar =  $sp^2$ ; tetrahedral =  $sp^3$ ; trigonal bipyramidal =  $sp^3d$ ; and octahedral =  $sp^3d^2$ ).

**Section 9.6** Covalent bonds in which the electron density lies along the line connecting the atoms (the internuclear axis) are called **sigma ( $\sigma$ ) bonds**. Bonds can also be formed from the sideways overlap of  $p$  orbitals. Such a bond is called a **pi ( $\pi$ ) bond**. A double bond, such as that in  $C_2H_4$ , consists of one  $\sigma$  bond and one  $\pi$  bond; a triple bond, such as that in  $C_2H_2$ , consists of one  $\sigma$  and two  $\pi$  bonds. The formation of a  $\pi$  bond requires that molecules adopt a specific orientation; the two  $CH_2$  groups in  $C_2H_4$ , for example, must lie in the same plane. As a result, the presence of  $\pi$  bonds introduces rigidity into molecules.

In molecules that have multiple bonds and more than one resonance structure, such as  $C_6H_6$ , the  $\pi$  bonds are **delocalized**; that is, the  $\pi$  bonds are spread among several atoms.

**Section 9.7** Molecular orbital theory is another model used to describe the bonding in molecules. In this model the electrons exist in allowed energy states called **molecular orbitals (MOs)**. These orbitals can be spread among all the atoms of a molecule. Like an atomic orbital, a molecular orbital has a definite energy and can hold two electrons of opposite spin. The combination of two atomic orbitals leads to the formation of two MOs, one at lower energy, and one at higher energy relative to the energy of the atomic orbitals. The lower-energy MO concentrates charge density in the region between the nuclei and is called a **bonding molecular orbital**. The higher-energy MO excludes electrons from the region between the nuclei and is called an **antibonding molecular orbital**. Occupation of bonding MOs favors bond formation, whereas occupation of antibonding MOs is unfavorable. The bonding and antibonding MOs formed by the combination of  $s$  orbitals are **sigma ( $\sigma$ ) molecular orbitals**; like  $\sigma$  bonds, they lie on the internuclear axis.

The combination of atomic orbitals and the relative energies of the molecular orbitals are shown by an **energy-level (or molecular orbital) diagram**. When the appropriate number of electrons are put into the MOs, we can calculate the **bond order** of a bond, which is half the difference between the number of electrons in bonding MOs and the number of electrons in antibonding MOs. A bond order of 1 corresponds to a single bond, and so forth. Bond orders can be fractional numbers.

**Section 9.8** Electrons in core orbitals do not contribute to the bonding between atoms, so a molecular orbital description usually needs to consider only electrons in the outermost electron subshells. In order to describe the MOs of second-row homonuclear diatomic molecules, we need to consider the MOs that can form by the combination of  $p$  orbitals. The  $p$  orbitals that point directly at one another can form  $\sigma$  bonding and  $\sigma^*$  antibonding MOs. The  $p$  orbitals that are oriented perpendicular to the internuclear axis combine to form **pi ( $\pi$ ) molecular orbitals**. In diatomic molecules the  $\pi$  molecular orbitals occur as pairs of degenerate (same energy) bonding and antibonding MOs. The  $\sigma_{2p}$  bonding MO is expected to be lower in energy than the  $\pi_{2p}$  bonding MOs because of larger orbital overlap. This ordering is reversed in  $B_2$ ,  $C_2$ , and  $N_2$  because of interaction between the  $2s$  and  $2p$  atomic orbitals of different atoms.

The molecular orbital description of second-row diatomic molecules leads to bond orders in accord with the Lewis structures of these molecules. Further, the model predicts correctly that  $O_2$  should exhibit **paramagnetism**, an attraction of a molecule by a magnetic field due to unpaired electrons. Those molecules in which all the electrons are paired exhibit **diamagnetism**, a weak repulsion from a magnetic field.

## KEY SKILLS

- Be able to describe the three-dimensional shapes of molecules using the VSEPR model.
- Determine whether a molecule is polar or nonpolar based on its geometry and the individual bond dipole moments.
- Be able to identify the hybridization state of atoms in molecules.
- Be able to sketch how orbitals overlap to form sigma ( $\sigma$ ) and pi ( $\pi$ ) bonds.
- Be able to explain the concept of bonding and antibonding orbitals.
- Be able to draw molecular orbital energy-level diagrams and place electrons into them to obtain the bond orders and electron configurations of diatomic molecules using molecular orbital theory.
- Understand the relationships among bond order, bond strength, and bond length.

## KEY EQUATIONS

- Bond order =  $\frac{1}{2}$  (no. of bonding electrons - no. of antibonding electrons)

## VISUALIZING CONCEPTS

9.1 A certain  $AB_4$  molecule has a “seesaw” shape:

From which of the fundamental geometries shown in Figure 9.3 could you remove one or more atoms to create a molecule having this seesaw shape? [Section 9.1]

9.2 (a) If the three balloons shown on the right are all the same size, what angle is formed between the red one and the green one? (b) If additional air is added to the blue balloon so that it gets larger, what happens to the angle between the red and green balloons? (c) What aspect of the VSEPR model is illustrated by part (b)? [Section 9.2]

9.3 An  $AB_5$  molecule adopts the geometry shown below. (a) What is the name of this geometry? (b) Do you think there are any nonbonding electron pairs on atom A? Why or why not? (c) Suppose the atoms B are halogen atoms. Can you determine uniquely to which group in the periodic table atom A belongs? [Section 9.2]

9.4 The molecule shown here is *difluoromethane* ( $CH_2F_2$ ), which is used as a refrigerant called R-32. (a) Based on the structure, how many electron domains surround the C atom in this molecule? (b) Would the molecule have a nonzero dipole moment? (c) If the molecule is polar, in what direction will the overall dipole moment vector point in the molecule? [Sections 9.2 and 9.3]

9.5 The plot below shows the potential energy of two Cl atoms as a function of the distance between them. (a) To what does an energy of zero correspond in this diagram? (b) According to the valence-bond model, why does the energy decrease as the Cl atoms move from a large separation to a smaller one? (c) What is the significance of the Cl-Cl distance at the minimum point in the plot? (d) Why does the energy rise at Cl-Cl distances less than that at the minimum point in the plot? (e) How can you estimate the bond strength of the Cl-Cl bond from the plot? [Section 9.4]

9.6 Shown below are three pairs of hybrid orbitals, with each set at a characteristic angle. For each pair, determine the type or types of hybridization that could lead to hybrid orbitals at the specified angle. [Section 9.5]

- 9.7 The orbital diagram below presents the final step in the formation of hybrid orbitals by a silicon atom. What type of hybrid orbitals is produced in this hybridization? [Section 9.5]

- 9.8 Consider the hydrocarbon drawn below. (a) What is the hybridization at each carbon atom in the molecule? (b) How many  $\sigma$  bonds are there in the molecule? (c) How many  $\pi$  bonds? [Section 9.6]

- 9.9 For each of the following contour representations of molecular orbitals, identify (i) the atomic orbitals ( $s$  or  $p$ ) used to construct the MO, (ii) the type of MO ( $\sigma$  or  $\pi$ ), and (iii) whether the MO is bonding or antibonding. [Sections 9.7 and 9.8]

- 9.10 The diagram below shows the highest occupied MOs of a neutral molecule CX, where element X is in the same row of the periodic table as C. (a) Based on the number of electrons, can you determine the identity of X? (b) Would the molecule be diamagnetic or paramagnetic? (c) Consider the  $\pi_{2p}$  MOs of the molecule. Would you expect them to have a greater atomic orbital contribution from C, have a greater atomic orbital contribution from X, or be an equal mixture of atomic orbitals from the two atoms? [Section 9.8]

## EXERCISES

### Molecular Shapes; the VSEPR Model

- 9.11 An  $AB_2$  molecule is described as linear, and the A—B bond length is known. (a) Does this information completely describe the geometry of the molecule? (b) Can you tell how many nonbonding pairs of electrons are around the A atom from this information?
- 9.12 (a) Methane ( $CH_4$ ) and the perchlorate ion ( $ClO_4^-$ ) are both described as tetrahedral. What does this indicate about their bond angles? (b) The  $NH_3$  molecule is trigonal pyramidal, while  $BF_3$  is trigonal planar. Which of these molecules is flat?
- 9.13 (a) What is meant by the term *electron domain*? (b) Explain in what way electron domains behave like the balloons in Figure 9.5. Why do they do so?
- 9.14 (a) How does one determine the number of electron domains in a molecule or ion? (b) What is the difference between a *bonding electron domain* and a *nonbonding electron domain*?
- 9.15 How many nonbonding electron pairs are there in each of the following molecules: (a)  $(CH_3)_2S$ ; (b) HCN; (c)  $H_2C_2$ ; (d)  $CH_3F$ ?
- 9.16 Describe the characteristic electron-domain geometry of each of the following numbers of electron domains about a central atom: (a) 3, (b) 4, (c) 5, (d) 6.
- 9.17 What is the difference between the electron-domain geometry and the molecular geometry of a molecule? Use the water molecule as an example in your discussion.
- 9.18 An  $AB_3$  molecule is described as having a trigonal-bipyramidal electron-domain geometry. How many nonbonding domains are on atom A? Explain.
- 9.19 Give the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom: (a) four bonding domains and no nonbonding domains, (b) three bonding domains and two nonbonding domains, (c) five bonding domains and one nonbonding domain, (e) four bonding domains and two nonbonding domains.
- 9.20 What are the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom? (a) three bonding domains and no nonbonding domains, (b) three bonding domains and one nonbonding domain, (c) two bonding domains and two nonbonding domains.
- 9.21 Give the electron-domain and molecular geometries for the following molecules and ions: (a) HCN, (b)  $SO_3^{2-}$ , (c)  $SF_4$ , (d)  $PF_6^-$ , (e)  $NH_3Cl^+$ , (f)  $N_3^-$ .
- 9.22 Draw the Lewis structure for each of the following molecules or ions, and predict their electron-domain and molecular geometries: (a)  $PF_3$ , (b)  $CH_3^+$ , (c)  $BrF_3$ , (d)  $ClO_4^-$ , (e)  $XeF_2$ , (f)  $BrO_2^-$ .
- 9.23 The figure that follows shows ball-and-stick drawings of three possible shapes of an  $AF_3$  molecule. (a) For each shape, give the electron-domain geometry on which the molecular geometry is based. (b) For each shape, how many nonbonding electron domains are there on atom A? (c) Which of the following elements will lead to an  $AF_3$  molecule with the shape in (ii): Li, B, N, Al, P, Cl? (d) Name an element A that is expected to lead to the  $AF_3$  structure shown in (iii). Explain your reasoning.

- 9.24 The figure that follows contains ball-and-stick drawings of three possible shapes of an  $AF_4$  molecule. (a) For each shape, give the electron-domain geometry on which the molecular geometry is based. (b) For each shape, how many nonbonding electron domains are there on atom A? (c) Which of the following elements will lead to an  $AF_4$  molecule with the shape in (iii): Be, C, S, Se, Si, Xe? (d) Name an element A that is expected to lead to the  $AF_4$  structure shown in (i).

- 9.25 Give the approximate values for the indicated bond angles in the following molecules:

- 9.26 Give approximate values for the indicated bond angles in the following molecules:

- 9.27 Predict the trend in the F(axial)—A—F(equatorial) bond angle in the following  $AF_n$  molecules:  $PF_5$ ,  $SF_4$ , and  $ClF_3$ .

- 9.28 The three species  $NH_2^-$ ,  $NH_3$ , and  $NH_4^+$  have H—N—H bond angles of  $105^\circ$ ,  $107^\circ$ , and  $109^\circ$ , respectively. Explain this variation in bond angles.

- 9.29 (a) Explain why  $BrF_4^-$  is square planar, whereas  $BF_4^-$  is tetrahedral. (b) Water,  $H_2O$ , is a bent molecule. Predict the shape of the molecular ion formed from the water molecule if you were able to remove four electrons to make  $(H_2O)^{4+}$ .

- 9.30 (a) Explain why the following ions have different bond angles:  $ClO_2^-$  and  $NO_2^-$ . Predict the bond angle in each case. (b) Explain why the  $XeF_2$  molecule is linear and not bent.

## Polarity of Polyatomic Molecules

- 9.31 (a) Does  $SCl_2$  have a dipole moment? If so, in which direction does the net dipole point? (b) Does  $BeCl_2$  have a dipole moment? If so, in which direction does the net dipole point?

- 9.32 (a) The  $PH_3$  molecule is polar. How does this offer experimental proof that the molecule cannot be planar? (b) It turns out that ozone,  $O_3$ , has a small dipole moment. How is this possible, given that all the atoms are the same?

- 9.33 (a) Consider the  $AF_3$  molecules in Exercise 9.23. Which of these will have a nonzero dipole moment? Explain. (b) Which of the  $AF_4$  molecules in Exercise 9.24 will have a zero dipole moment?

- 9.34 (a) What conditions must be met if a molecule with polar bonds is nonpolar? (b) What geometries will give nonpolar molecules for  $AB_2$ ,  $AB_3$ , and  $AB_4$  geometries?

- 9.35 Predict whether each of the following molecules is polar or nonpolar: (a)  $IF$ , (b)  $CS_2$ , (c)  $SO_3$ , (d)  $PCl_3$ , (e)  $SF_6$ , (f)  $IF_5$ .

- 9.36 Predict whether each of the following molecules is polar or nonpolar: (a)  $CCl_4$ , (b)  $NH_3$ , (c)  $SF_4$ , (d)  $XeF_4$ , (e)  $CH_3Br$ , (f)  $GaH_3$ .

- 9.37 Dichloroethylene ( $C_2H_2Cl_2$ ) has three forms (isomers), each of which is a different substance. (a) Draw Lewis structures of the three isomers, all of which have a carbon-carbon double bond. (b) Which of these isomers has a zero dipole moment? (c) How many isomeric forms can chloroethylene,  $C_2H_3Cl$ , have? Would they be expected to have dipole moments?

- 9.38 Dichlorobenzene,  $C_6H_4Cl_2$ , exists in three forms (isomers), called *ortho*, *meta*, and *para*:

- Which of these would have a nonzero dipole moment? Explain.

## Orbital Overlap; Hybrid Orbitals

- 9.39 (a) What is meant by the term *orbital overlap*? (b) Describe what a chemical bond is in terms of electron density between two atoms.
- 9.40 Draw sketches illustrating the overlap between the following orbitals on two atoms: (a) the 2s orbital on each atom, (b) the 2p<sub>z</sub> orbital on each atom (assume both atoms are on the z-axis), (c) the 2s orbital on one atom and the 2p<sub>z</sub> orbital on the other atom.
- 9.41 Consider the bonding in an MgH<sub>2</sub> molecule. (a) Draw a Lewis structure for the molecule, and predict its molecular geometry. (b) What hybridization scheme is used in MgH<sub>2</sub>? (c) Sketch one of the two-electron bonds between an Mg hybrid orbital and an H 1s atomic orbital.
- 9.42 How would you expect the extent of overlap of atomic orbitals to vary in the series IF, ICl, IBr, and I<sub>2</sub>?
- 9.43 Fill in the following chart. If the molecule column is blank, find an example that fulfills the conditions of the rest of the row.

Molecule	Electron-domain Geometry	Hybridization of Central Atom	Dipole moment? Yes or No.
CO <sub>2</sub>			
		sp <sup>3</sup>	yes
		sp <sup>3</sup>	no
	trigonal planar		no
SF <sub>4</sub>			
	octahedral		no
		sp <sup>2</sup>	yes
	trigonal bipyramidal		no
XeF <sub>2</sub>			

## Multiple Bonds

- 9.49 (a) Draw a picture showing how two p orbitals on two different atoms can be combined to make a sigma bond. (b) Sketch a π bond that is constructed from p orbitals. (c) Which is generally stronger, a σ bond or a π bond? Explain. (d) Can two s orbitals make a π bond? Explain.
- 9.50 (a) If the valence atomic orbitals of an atom are sp hybridized, how many unhybridized p orbitals remain in the valence shell? How many π bonds can the atom form? (b) Imagine that you could hold two atoms that are bonded together, twist them, and not change the bond length. Would it be easier to twist (rotate) around a single σ bond or around a double (σ plus π) bond, or would they be the same? Explain.
- 9.51 (a) Draw Lewis structures for ethane (C<sub>2</sub>H<sub>6</sub>), ethylene (C<sub>2</sub>H<sub>4</sub>), and acetylene (C<sub>2</sub>H<sub>2</sub>). (b) What is the hybridization of the carbon atoms in each molecule? (c) Predict which molecules, if any, are planar. (d) How many σ and π bonds are there in each molecule? (e) Suppose that silicon could form molecules that are precisely the analogs of ethane, ethylene, and acetylene. How would you describe the bonding about Si in terms of hybrid

9.44 Why are there no sp<sup>4</sup> or sp<sup>5</sup> hybrid orbitals?

- 9.45 (a) Starting with the orbital diagram of a boron atom, describe the steps needed to construct hybrid orbitals appropriate to describe the bonding in BF<sub>3</sub>. (b) What is the name given to the hybrid orbitals constructed in (a)? (c) Sketch the large lobes of the hybrid orbitals constructed in part (a). (d) Are there any valence atomic orbitals of B that are left unhybridized? If so, how are they oriented relative to the hybrid orbitals?
- 9.46 (a) Starting with the orbital diagram of a sulfur atom, describe the steps needed to construct hybrid orbitals appropriate to describe the bonding in SF<sub>2</sub>. (b) What is the name given to the hybrid orbitals constructed in (a)? (c) Sketch the large lobes of the hybrid orbitals constructed in part (a). (d) Would the hybridization scheme in part (a) be appropriate for SF<sub>4</sub>? Explain.
- 9.47 Indicate the hybridization of the central atom in (a) BCl<sub>3</sub>, (b) AlCl<sub>4</sub><sup>-</sup>, (c) CS<sub>2</sub>, (d) KrF<sub>2</sub>, (e) PF<sub>6</sub><sup>-</sup>.
- 9.48 What is the hybridization of the central atom in (a) SiCl<sub>4</sub>, (b) HCN, (c) SO<sub>3</sub>, (d) ICl<sub>2</sub><sup>-</sup>, (e) BrF<sub>4</sub><sup>-</sup>?

orbitals? Does it make a difference that Si lies in the row below C in the periodic table? Explain.

- 9.52 The nitrogen atoms in N<sub>2</sub> participate in multiple bonding, whereas those in hydrazine, N<sub>2</sub>H<sub>4</sub>, do not. (a) Draw Lewis structures for both molecules. (b) What is the hybridization of the nitrogen atoms in each molecule? (c) Which molecule has a stronger N—N bond?
- 9.53 Propylene, C<sub>3</sub>H<sub>6</sub>, is a gas that is used to form the important polymer called polypropylene. Its Lewis structure is

- (a) What is the total number of valence electrons in the propylene molecule? (b) How many valence electrons are used to make σ bonds in the molecule? (c) How many valence electrons are used to make π bonds in the molecule? (d) How many valence electrons remain in nonbonding pairs in the molecule? (e) What is the hybridization at each carbon atom in the molecule?

- 9.54 Ethyl acetate,  $C_4H_8O_2$ , is a fragrant substance used both as a solvent and as an aroma enhancer. Its Lewis structure is

- (a) What is the hybridization at each of the carbon atoms of the molecule? (b) What is the total number of valence electrons in ethyl acetate? (c) How many of the valence electrons are used to make  $\sigma$  bonds in the molecule? (d) How many valence electrons are used to make  $\pi$  bonds? (e) How many valence electrons remain in non-bonding pairs in the molecule?

- 9.55 Consider the Lewis structure for glycine, the simplest amino acid:

- (a) What are the approximate bond angles about each of the two carbon atoms, and what are the hybridizations of the orbitals on each of them? (b) What are the hybridizations of the orbitals on the two oxygens and the nitrogen atom, and what are the approximate bond

angles at the nitrogen? (c) What is the total number of  $\sigma$  bonds in the entire molecule, and what is the total number of  $\pi$  bonds?

- 9.56 The compound with the following Lewis structure is acetylsalicylic acid, better known as aspirin:

- (a) What are the approximate values of the bond angles labeled 1, 2, and 3? (b) What hybrid orbitals are used about the central atom of each of these angles? (c) How many  $\sigma$  bonds are in the molecule?

- 9.57 (a) What is the difference between a localized  $\pi$  bond and a delocalized one? (b) How can you determine whether a molecule or ion will exhibit delocalized  $\pi$  bonding? (c) Is the  $\pi$  bond in  $NO_2^-$  localized or delocalized?

- 9.58 (a) Write a single Lewis structure for  $SO_3$ , and determine the hybridization at the S atom. (b) Are there other equivalent Lewis structures for the molecule? (c) Would you expect  $SO_3$  to exhibit delocalized  $\pi$  bonding? Explain.

## Molecular Orbitals

- 9.59 (a) What is the difference between hybrid orbitals and molecular orbitals? (b) How many electrons can be placed into each MO of a molecule? (c) Can antibonding molecular orbitals have electrons in them?

- 9.60 (a) If you combine two atomic orbitals on two different atoms to make a new orbital, is this a hybrid orbital or a molecular orbital? (b) If you combine two atomic orbitals on *one* atom to make a new orbital, is this a hybrid orbital or a molecular orbital? (c) Does the Pauli exclusion principle (Section 6.7) apply to MOs? Explain.

- 9.61 Consider the  $H_2^+$  ion. (a) Sketch the molecular orbitals of the ion, and draw its energy-level diagram. (b) How many electrons are there in the  $H_2^+$  ion? (c) Draw the electron configuration of the ion in terms of its MOs. (d) What is the bond order in  $H_2^+$ ? (e) Suppose that the ion is excited by light so that an electron moves from a lower-energy to a higher-energy MO. Would you expect the excited-state  $H_2^+$  ion to be stable or to fall apart? Explain.

- 9.62 (a) Sketch the molecular orbitals of the  $H_2^-$  ion, and draw its energy-level diagram. (b) Write the electron configuration of the ion in terms of its MOs. (c) Calculate the bond order in  $H_2^-$ . (d) Suppose that the ion is excited by light, so that an electron moves from a lower-energy to a higher-energy molecular orbital. Would you expect the excited-state  $H_2^-$  ion to be stable? Explain.

- 9.63 Draw a picture that shows all three  $2p$  orbitals on one atom and all three  $2p$  orbitals on another atom. (a) Imagine the atoms coming close together to bond. How many  $\sigma$  bonds can the two sets of  $2p$  orbitals make with each other? (b) How many  $\pi$  bonds can the two sets of  $2p$

orbitals make with each other? (c) How many antibonding orbitals, and of what type, can be made from the two sets of  $2p$  orbitals?

- 9.64 (a) What is the probability of finding an electron on the internuclear axis if the electron occupies a  $\pi$  molecular orbital? (b) For a homonuclear diatomic molecule, what similarities and differences are there between the  $\pi_{2p}$  MO made from the  $2p_x$  atomic orbitals and the  $\pi_{2p}$  MO made from the  $2p_y$  atomic orbitals? (c) Why are the  $\pi_{2p}$  MOs lower in energy than the  $\pi_{2p}^*$  MOs?

- 9.65 (a) What are the relationships among bond order, bond length, and bond energy? (b) According to molecular orbital theory, would either  $Be_2$  or  $Be_2^+$  be expected to exist? Explain.

- 9.66 Explain the following: (a) The peroxide ion,  $O_2^{2-}$ , has a longer bond length than the superoxide ion,  $O_2^-$ . (b) The magnetic properties of  $B_2$  are consistent with the  $\pi_{2p}$  MOs being lower in energy than the  $\sigma_{2p}$  MO. (c) The  $O_2^{2+}$  ion has a stronger O—O bond than  $O_2$  itself.

- 9.67 (a) What does the term *diamagnetism* mean? (b) How does a diamagnetic substance respond to a magnetic field? (c) Which of the following ions would you expect to be diamagnetic:  $N_2^{2-}$ ,  $O_2^{2-}$ ,  $Be_2^{2+}$ ,  $C_2^-$ ?

- 9.68 (a) What does the term *paramagnetism* mean? (b) How can one determine experimentally whether a substance is paramagnetic? (c) Which of the following ions would you expect to be paramagnetic:  $O_2^+$ ,  $N_2^{2-}$ ,  $Li_2^+$ ,  $O_2^{2-}$ ? For those ions that are paramagnetic, determine the number of unpaired electrons.

9.69 Using Figures 9.37 and 9.45 as guides, draw the molecular orbital electron configuration for (a)  $B_2^+$ , (b)  $Li_2^+$ , (c)  $N_2^+$ , (d)  $Ne_2^{2+}$ . In each case indicate whether the addition of an electron to the ion would increase or decrease the bond order of the species.

9.70 If we assume that the energy-level diagrams for homonuclear diatomic molecules shown in Figure 9.42 can be applied to heteronuclear diatomic molecules and ions, predict the bond order and magnetic behavior of (a)  $CO^+$ , (b)  $NO^-$ , (c)  $OF^+$ , (d)  $NeF^+$ .

9.71 Determine the electron configurations for  $CN^+$ ,  $CN$ , and  $CN^-$ . (a) Which species has the strongest C—N bond? (b) Which species, if any, has unpaired electrons?

9.72 (a) The nitric oxide molecule, NO, readily loses one electron to form the  $NO^+$  ion. Why is this consistent with the electronic structure of NO? (b) Predict the order of the N—O bond strengths in NO,  $NO^+$ , and  $NO^-$ , and describe the magnetic properties of each. (c) With what neutral homonuclear diatomic molecules are the  $NO^+$  and  $NO^-$  ions isoelectronic (same number of electrons)?

[9.73] Consider the molecular orbitals of the  $P_2$  molecule. Assume that the MOs of diatomics from the third row of the periodic table are analogous to those from the second row. (a) Which valence atomic orbitals of P are used

to construct the MOs of  $P_2$ ? (b) The figure below shows a sketch of one of the MOs for  $P_2$ . What is the label for this MO? (c) For the  $P_2$  molecule, how many electrons occupy the MO in the figure? (d) Is  $P_2$  expected to be diamagnetic or paramagnetic? Explain.

[9.74] The iodine bromide molecule, IBr, is an *interhalogen compound*. Assume that the molecular orbitals of IBr are analogous to the homonuclear diatomic molecule  $F_2$ .

(a) Which valence atomic orbitals of I and of Br are used to construct the MOs of IBr? (b) What is the bond order of the IBr molecule? (c) One of the valence MOs of IBr is sketched below. Why are the atomic orbital contributions to this MO different in size? (d) What is the label for the MO? (e) For the IBr molecule, how many electrons occupy the MO?

## ADDITIONAL EXERCISES

9.75 (a) What is the physical basis for the VSEPR model? (b) When applying the VSEPR model, we count a double or triple bond as a single electron domain. Why is this justified?

9.76 The molecules  $SiF_4$ ,  $SF_4$ , and  $XeF_4$  have molecular formulas of the type  $AF_4$ , but the molecules have different molecular geometries. Predict the shape of each molecule, and explain why the shapes differ.

[9.77] The vertices of a tetrahedron correspond to four alternating corners of a cube. By using analytical geometry, demonstrate that the angle made by connecting two of the vertices to a point at the center of the cube is  $109.5^\circ$ , the characteristic angle for tetrahedral molecules.

9.78 Consider the molecule  $PF_4Cl$ . (a) Draw a Lewis structure for the molecule, and predict its electron-domain geometry. (b) Which would you expect to take up more space, a P—F bond or a P—Cl bond? Explain. (c) Predict the molecular geometry of  $PF_4Cl$ . How did your answer for part (b) influence your answer here in part (c)? (d) Would you expect the molecule to distort from its ideal electron-domain geometry? If so, how would it distort?

9.79 From their Lewis structures, determine the number of  $\sigma$  and  $\pi$  bonds in each of the following molecules or ions: (a)  $CO_2$ ; (b) thiocyanate ion,  $NCS^-$ ; (c) formaldehyde,  $H_2CO$ ; (d) formic acid,  $HCOOH$ , which has one H and two O atoms attached to C.

9.80 The lactic acid molecule,  $CH_3CH(OH)COOH$ , gives sour milk its unpleasant, sour taste. (a) Draw the Lewis structure for the molecule, assuming that carbon always forms four bonds in its stable compounds. (b) How many  $\pi$  and how many  $\sigma$  bonds are in the molecule? (c) Which CO bond is shortest in the molecule? (d) What

is the hybridization of atomic orbitals around each carbon atom associated with that short bond? (e) What are the approximate bond angles around each carbon atom in the molecule?

9.81 The  $PF_3$  molecule has a dipole moment of 1.03 D, but  $BF_3$  has a dipole moment of zero. How can you explain the difference?

9.82 There are two compounds of the formula  $Pt(NH_3)_2Cl_2$ :

The compound on the right, *cisplatin*, is used in cancer therapy. The compound on the left, *transplatin*, is ineffective for cancer therapy. Both compounds have a square-planar geometry. (a) Which compound has a nonzero dipole moment? (b) The reason *cisplatin* is a good anticancer drug is that it binds tightly to DNA. Cancer cells are rapidly dividing, producing a lot of DNA. Consequently *cisplatin* kills cancer cells at a faster rate than normal cells. However, since normal cells also are making DNA, *cisplatin* also attacks healthy cells, which leads to unpleasant side effects. The way both molecules bind to DNA involves the  $Cl^-$  ions leaving the Pt ion, to be replaced by two nitrogens in DNA. Draw a picture in which a long vertical line represents a piece of DNA. Draw the  $Pt(NH_3)_2$  fragments of *cisplatin* and *transplatin* with the proper shape. Also draw them attaching to your DNA line. Can you explain from your drawing why the shape of the *cisplatin* causes it to bind to DNA more effectively than *transplatin*?

- [9.83] The O—H bond lengths in the water molecule ( $\text{H}_2\text{O}$ ) are  $0.96 \text{ \AA}$ , and the H—O—H angle is  $104.5^\circ$ . The dipole moment of the water molecule is  $1.85 \text{ D}$ . (a) In what directions do the bond dipoles of the O—H bonds point? In what direction does the dipole moment vector of the water molecule point? (b) Calculate the magnitude of the bond dipole of the O—H bonds. (Note: You will need to use vector addition to do this.) (c) Compare your answer from part (b) to the dipole moments of the hydrogen halides (Table 8.3). Is your answer in accord with the relative electronegativity of oxygen?

- [9.84] The reaction of three molecules of fluorine gas with a Xe atom produces the substance xenon hexafluoride,  $\text{XeF}_6$ :

(a) Draw a Lewis structure for  $\text{XeF}_6$ . (b) If you try to use the VSEPR model to predict the molecular geometry of  $\text{XeF}_6$ , you run into a problem. What is it? (c) What could you do to resolve the difficulty in part (b)? (d) Suggest a hybridization scheme for the Xe atom in  $\text{XeF}_6$ . (e) The molecule  $\text{IF}_7$  has a pentagonal-bipyramidal structure (five equatorial fluorine atoms at the vertices of a regular pentagon and two axial fluorine atoms). Based on the structure of  $\text{IF}_7$ , suggest a structure for  $\text{XeF}_6$ .

- [9.85] The Lewis structure for allene is

Make a sketch of the structure of this molecule that is analogous to Figure 9.27. In addition, answer the following three questions: (a) Is the molecule planar? (b) Does it have a nonzero dipole moment? (c) Would the bonding in allene be described as delocalized? Explain.

- [9.86] The azide ion,  $\text{N}_3^-$ , is linear with two N—N bonds of equal length,  $1.16 \text{ \AA}$ . (a) Draw a Lewis structure for the azide ion. (b) With reference to Table 8.5, is the observed N—N bond length consistent with your Lewis structure? (c) What hybridization scheme would you expect at each of the nitrogen atoms in  $\text{N}_3^-$ ? (d) Show which hybridized and unhybridized orbitals are involved in the formation of  $\sigma$  and  $\pi$  bonds in  $\text{N}_3^-$ . (e) It is often observed that  $\sigma$  bonds that involve an  $sp$  hybrid orbital are shorter than those that involve only  $sp^2$  or  $sp^3$  hybrid orbitals. Can you propose a reason for this? Is this observation applicable to the observed bond lengths in  $\text{N}_3^-$ ?
- [9.87] In ozone,  $\text{O}_3$ , the two oxygen atoms on the ends of the molecule are equivalent to one another. (a) What is the best choice of hybridization scheme for the atoms of ozone? (b) For one of the resonance forms of ozone, which of the orbitals are used to make bonds and which are used to hold nonbonding pairs of electrons? (c) Which of the orbitals can be used to delocalize the  $\pi$  electrons? (d) How many electrons are delocalized in the  $\pi$  system of ozone?

- 9.88 Butadiene,  $\text{C}_4\text{H}_6$ , is a planar molecule that has the following carbon—carbon bond lengths:

(a) Predict the bond angles around each of the carbon atoms, and sketch the molecule. (b) Compare the bond lengths to the average bond lengths listed in Table 8.5. Can you explain any differences?

- [9.89] The sketches below show the atomic orbital wave functions (with phases) used to construct some of the MOs of a homonuclear diatomic molecule. For each sketch, determine the MO that will result from mixing the atomic orbital wave functions as drawn. Use the same labels for the MOs as in the “Closer Look” box on phases.

- [9.90] The cyclopentadienide ion has the formula  $\text{C}_5\text{H}_5^-$ . The ion consists of a regular pentagon of C atoms, each bonded to two C neighbors, with a hydrogen atom bonded to each C atom. All the atoms lie in the same plane. (a) Draw a Lewis structure for the ion. According to your structure, do all five C atoms have the same hybridization? Explain. (b) Chemists generally view this ion as having  $sp^2$  hybridization at each C atom. Is that view consistent with your answer to part (a)? (c) Your Lewis structure should show one nonbonding pair of electrons. Under the assumption of part (b), in what type of orbital must this nonbonding pair reside? (d) Are there resonance structures equivalent to the Lewis structure you drew in part (a)? If so, how many? (e) The ion is often drawn as a pentagon enclosing a circle. Is this representation consistent with your answer to part (d)? Explain. (f) Both benzene and the cyclopentadienide ion are often described as systems containing six  $\pi$  electrons. What do you think is meant by this description?

- 9.91 Write the electron configuration for the first excited state for  $\text{N}_2$ —that is, the state with the highest-energy electron moved to the next available energy level. (a) Is the nitrogen in its first excited state diamagnetic or paramagnetic? (b) Is the N—N bond strength in the first excited state stronger or weaker compared to that in the ground state? Explain.

- 9.92 Figure 9.47 shows how the magnetic properties of a compound can be measured experimentally. When such measurements are made, the sample is generally covered by an atmosphere of pure nitrogen gas rather than air. Why do you suppose this is done?

- 9.93 Azo dyes are organic dyes that are used for many applications, such as the coloring of fabrics. Many azo dyes are derivatives of the organic substance azobenzene,  $\text{C}_{12}\text{H}_{10}\text{N}_2$ .

A closely related substance is *hydrazobenzene*,  $C_{12}H_{12}N_2$ . The Lewis structures of these two substances are

(Recall the shorthand notation used for benzene.)

- (a) What is the hybridization at the N atom in each of the substances? (b) How many unhybridized atomic orbitals are there on the N and the C atoms in each of the substances? (c) Predict the N—N—C angles in each of the substances. (d) Azobenzene is said to have greater delocalization of its  $\pi$  electrons than hydrazobenzene. Discuss this statement in light of your answers to (a) and (b). (e) All the atoms of azobenzene lie in one plane, whereas those of hydrazobenzene do not. Is this observation consistent with the statement in part (d)? (f) Azobenzene is an intense red-orange color, whereas hydrazobenzene is nearly colorless. Which molecule would be a better one to use in a solar energy conversion device? (See the “Chemistry Put to Work” box for more information about solar cells.)
- [9.94] (a) Using only the valence atomic orbitals of a hydrogen atom and a fluorine atom, how many MOs would you expect for the HF molecule? (b) How many of the MOs from part (a) would be occupied by electrons? (c) Do you think the MO diagram shown in Figure 9.49 could be used to describe the MOs of the HF molecule? Why or

why not? (d) It turns out that the difference in energies between the valence atomic orbitals of H and F are sufficiently different that we can neglect the interaction of the 1s orbital of hydrogen with the 2s orbital of fluorine. The 1s orbital of hydrogen will mix only with one 2p orbital of fluorine. Draw pictures showing the proper orientation of all three 2p orbitals on F interacting with a 1s orbital on H. Which of the 2p orbitals can actually make a bond with a 1s orbital, assuming that the atoms lie on the z-axis? (e) In the most accepted picture of HF, all the other atomic orbitals on fluorine move over at the same energy into the molecular orbital energy level diagram for HF. These are called “nonbonding orbitals.” Sketch the energy level diagram for HF using this information, and calculate the bond order. (Nonbonding electrons do not contribute to bond order.) (f) Look at the Lewis structure for HF. Where are the nonbonding electrons?

- [9.95] Carbon monoxide, CO, is isoelectronic to  $N_2$ . (a) Draw a Lewis structure for CO that satisfies the octet rule. (b) Assume that the diagram in Figure 9.49 can be used to describe the MOs of CO. What is the predicted bond order for CO? Is this answer in accord with the Lewis structure you drew in part (a)? (c) Experimentally, it is found that the highest-energy electrons in CO reside in a  $\sigma$ -type MO. Is that observation consistent with Figure 9.49? If not, what modification needs to be made to the diagram? How does this modification relate to Figure 9.45? (d) Would you expect the  $\pi_{2p}$  MOs of CO to have equal atomic orbital contributions from the C and O atoms? If not, which atom would have the greater contribution?

## INTEGRATIVE EXERCISES

- 9.96 A compound composed of 2.1% H, 29.8% N, and 68.1% O has a molar mass of approximately 50 g/mol. (a) What is the molecular formula of the compound? (b) What is its Lewis structure if H is bonded to O? (c) What is the geometry of the molecule? (d) What is the hybridization of the orbitals around the N atom? (e) How many  $\sigma$  and how many  $\pi$  bonds are there in the molecule?
- 9.97 Sulfur tetrafluoride ( $SF_4$ ) reacts slowly with  $O_2$  to form sulfur tetrafluoride monoxide ( $OSF_4$ ) according to the following unbalanced reaction:
- $$SF_4(g) + O_2(g) \longrightarrow OSF_4(g)$$
- The O atom and the four F atoms in  $OSF_4$  are bonded to a central S atom. (a) Balance the equation. (b) Write a Lewis structure of  $OSF_4$  in which the formal charges of all atoms are zero. (c) Use average bond enthalpies (Table 8.4) to estimate the enthalpy of the reaction. Is it endothermic or exothermic? (d) Determine the electron-domain geometry of  $OSF_4$ , and write two possible molecular geometries for the molecule based on this electron-domain geometry. (e) Which of the molecular geometries in part (d) is more likely to be observed for the molecule? Explain.

- [9.98] The phosphorus trihalides ( $PX_3$ ) show the following variation in the bond angle  $X—P—X$ :  $PF_3$ ,  $96.3^\circ$ ;  $PCl_3$ ,  $100.3^\circ$ ;  $PBr_3$ ,  $101.0^\circ$ ;  $PI_3$ ,  $102.0^\circ$ . The trend is generally attributed to the change in the electronegativity of the halogen. (a) Assuming that all electron domains are the same size, what value of the  $X—P—X$  angle is predicted by

the VSEPR model? (b) What is the general trend in the  $X—P—X$  angle as the electronegativity increases? (c) Using the VSEPR model, explain the observed trend in  $X—P—X$  angle as the electronegativity of X changes. (d) Based on your answer to part (c), predict the structure of  $PBrCl_4$ .

- [9.99] The molecule 2-butene,  $C_4H_8$ , can undergo a geometric change called *cis-trans isomerization*:

As discussed in the “Chemistry and Life” box on the chemistry of vision, such transformations can be induced by light and are the key to human vision. (a) What is the hybridization at the two central carbon atoms of 2-butene? (b) The isomerization occurs by rotation about the central C—C bond. With reference to Figure 9.32, explain why the  $\pi$  bond between the two central carbon atoms is destroyed halfway through the rotation from *cis*- to *trans*-2-butene. (c) Based on average bond enthalpies (Table 8.4), how much energy per molecule must be supplied to break the C—C  $\pi$  bond? (d) What is the longest wavelength of light that will provide photons of sufficient energy to break the C—C  $\pi$  bond and cause the isomerization? (e) Is the wavelength in your answer to part (d) in the visible portion of the

electromagnetic spectrum? Comment on the importance of this result for human vision.

- 9.100 (a) Compare the bond enthalpies (Table 8.4) of the carbon-carbon single, double, and triple bonds to deduce an average  $\pi$ -bond contribution to the enthalpy. What fraction of a single bond does this quantity represent? (b) Make a similar comparison of nitrogen-nitrogen bonds. What do you observe? (c) Write Lewis structures of  $N_2H_4$ ,  $N_2H_2$ , and  $N_2$ , and determine the hybridization around nitrogen in each case. (d) Propose a reason for the large difference in your observations of parts (a) and (b).
- 9.101 Use average bond enthalpies (Table 8.4) to estimate  $\Delta H$  for the atomization of benzene,  $C_6H_6$ :

Compare the value to that obtained by using  $\Delta H_f^\circ$  data given in Appendix C and Hess's law. To what do you attribute the large discrepancy in the two values?

- 9.102 For both atoms and molecules, ionization energies (Section 7.4) are related to the energies of orbitals: The lower the energy of the orbital, the greater the ionization energy. The first ionization energy of a molecule is therefore a measure of the energy of the highest occupied molecular orbital (HOMO). See the "Chemistry Put to Work" box on Orbitals and Energy. The first ionization energies of several diatomic molecules are given in electron-volts in the following table:

Molecule	$I_1$ (eV)
$H_2$	15.4
$N_2$	15.6
$O_2$	12.1
$F_2$	15.7

(a) Convert these ionization energies to kJ/mol. (b) On the same plot, graph  $I_1$  for the H, N, O, and F atoms (Figure 7.11) and  $I_1$  for the molecules listed. (c) Do the ionization energies of the molecules follow the same periodic trends as the ionization energies of the atoms? (d) Use molecular orbital energy-level diagrams to explain the trends in the ionization energies of the molecules.

- 9.103 Many compounds of the transition-metal elements contain direct bonds between metal atoms. We will assume that the  $z$ -axis is defined as the metal-metal bond axis. (a) Which of the  $3d$  orbitals (Figure 6.24) can be used to make a  $\sigma$  bond between metal atoms? (b) Sketch the  $\sigma_{3d}$  bonding and  $\sigma_{3d}^*$  antibonding MOs. (c) With reference to the "Closer Look" box on the phases of orbitals, explain why a node is generated in the  $\sigma_{3d}^*$  MO. (d) Sketch the energy-level diagram for the  $Sc_2$  molecule, assuming that only the  $3d$  orbital from part (a) is important. (e) What is the bond order in  $Sc_2$ ?
- 9.104 The organic molecules shown below are derivatives of benzene in which additional six-membered rings are "fused" at the edges of the hexagons. The compounds are shown in the usual abbreviated method for organic molecules. (a) Determine the empirical formula of benzene and of these three compounds. (b) Suppose you are given a sample of one of the compounds. Could combustion analysis be used to determine unambiguously

which of the compounds it is? (c) Naphthalene, which is the active ingredient in mothballs, is a white solid. Write a balanced equation for the combustion of naphthalene to  $CO_2(g)$  and  $H_2O(g)$ . (d) Using the Lewis structure below for naphthalene and the average bond enthalpies in Table 8.4, estimate the heat of combustion of naphthalene, in kJ/mol. (e) Would you expect naphthalene, anthracene, and tetracene to have multiple resonance structures? If so, draw the additional resonance structures for naphthalene. (f) Benzene, naphthalene, and anthracene are colorless, but tetracene is orange. What does this imply about the relative HOMO-LUMO energy gaps in these molecules? See the "Chemistry Put to Work" box on Orbitals and Energy.

Naphthalene

Anthracene

Tetracene

- 9.105 Antibonding molecular orbitals can be used to make bonds to other atoms in a molecule. For example, metal atoms can use appropriate  $d$  orbitals to overlap with the  $\pi_{2p}^*$  orbitals of the carbon monoxide molecule. This is called  $d$ - $\pi$  backbonding. (a) Draw a coordinate axis system in which the  $y$ -axis is vertical in the plane of the paper and the  $x$ -axis horizontal. Write "M" at the origin to denote a metal atom. (b) Now, on the  $x$ -axis to the right of M, draw the Lewis structure of a CO molecule, with the carbon nearest the M. The CO bond axis should be on the  $x$ -axis. (c) Draw the CO  $\pi_{2p}^*$  orbital, with phases (see the Closer Look box on phases) in the plane of the paper. Two lobes should be pointing toward M. (d) Now draw the  $d_{xy}$  orbital of M, with phases. Can you see how they will overlap with the  $\pi_{2p}^*$  orbital of CO? (e) What kind of bond is being made with the orbitals between M and C,  $\sigma$  or  $\pi$ ? (f) Predict what will happen to the strength of the CO bond in a metal-CO complex compared to CO alone.
- 9.106 You can think of the bonding in the  $Cl_2$  molecule in several ways. For example, you can picture the Cl-Cl bond containing two electrons that each come from the  $3p$  orbitals of a Cl atom that are pointing in the appropriate direction. However, you can also think about hybrid orbitals. (a) Draw the Lewis structure of the  $Cl_2$  molecule. (b) What is the hybridization of each Cl atom? (c) What kind of orbital overlap, in this view, makes the Cl-Cl bond? (d) Imagine if you could measure the positions of the lone pairs of electrons in  $Cl_2$ . How would you distinguish between the atomic orbital and hybrid orbital models of bonding using that knowledge? (e) You can also treat  $Cl_2$  using molecular orbital theory to obtain an energy level diagram similar to that for  $F_2$ . Design an experiment that could tell you if the MO picture of  $Cl_2$  is the best one, assuming you could easily measure bond lengths, bond energies, and the light absorption properties for any ionized species.

CHAPTER  
**10** GASES

A **TORNADO IS A VIOLENT** rotating column of air characterized by a funnel-shaped cloud. A tornado can be up to 100 m in diameter with wind speeds approaching 500 km/hr.

## WHAT'S AHEAD

---

### 10.1 Characteristics of Gases

We begin by comparing the distinguishing characteristics of gases with those of liquids and solids.

### 10.2 Pressure

We will then study gas *pressure*, how it is measured, and the units used to express it, as well as consider Earth's atmosphere and the pressure it exerts.

### 10.3 The Gas Laws

We consider that the state of a gas can be expressed in terms of its volume ( $V$ ), pressure ( $P$ ), temperature ( $T$ ), and quantity of gas ( $n$ ). We will examine several empirical relationships among  $V$ ,  $P$ ,  $T$ , and  $n$  that are called *gas laws*.

### 10.4 The Ideal-Gas Equation

We find that when considered together, the empirical gas laws yield the *ideal-gas equation*,  $PV = nRT$ . Although the ideal-gas equation is not obeyed exactly by any real gas, most gases come very close to obeying it at temperature and pressure conditions of greatest interest.

### 10.5 Further Applications of the Ideal-Gas Equation

We can use the ideal-gas equation to make many useful calculations, such as the calculation of the density or molar mass of a gas.

### 10.6 Gas Mixtures and Partial Pressures

We recognize that in a mixture of gases, each component exerts a pressure that is part of the total pressure. This *partial pressure* is the pressure that the component would exert if it were by itself.

### 10.7 Kinetic-Molecular Theory

We explore this theory of gases, which helps us understand the behavior of gases, including their pressure and temperature, on a molecular level. According to the theory, the atoms or molecules that make up the gas move about with an average kinetic energy that is proportional to the gas temperature.

### 10.8 Molecular Effusion and Diffusion

We next observe that the kinetic-molecular theory helps us account for such gas properties as *effusion* through tiny openings and for *diffusion*, the movement through another substance.

### 10.9 Real Gases: Deviations from Ideal Behavior

We then consider that real gases deviate from ideal behavior because the gas molecules have finite volume and because attractive forces exist between molecules. The *van der Waals equation* gives a more accurate account of real gas behavior at high pressures and low temperatures.

**IN THE PAST SEVERAL CHAPTERS** we have learned about electronic structures of atoms and about how atoms combine to form molecules and ionic substances. In everyday life, however, we do not have direct experiences with atoms. Instead, we encounter matter as collections of enormous

numbers of atoms or molecules that make up gases, liquids, and solids. Large collections of atoms and molecules in the atmosphere, for example, are responsible for our weather—the gentle breezes and the gales, the humidity and the rain. Tornadoes, such as the one shown in the chapter-opening photo, form when moist, warm air at lower elevations converges with cooler, dry air above. The resultant air flows produce winds that can approach speeds up to 500 km/hr (300 mph).

It was John Dalton's interest in the weather that motivated him to study gases and eventually to propose the atomic theory of matter. [☞ \(Section 2.1\)](#) We now know that the properties of gases, liquids, and solids are readily

understood in terms of the behavior of their component atoms, ions, and molecules. In this chapter we will examine the physical properties of gases and consider how we can understand these properties in terms of the behavior of gas molecules. In Chapter 11 we will turn our attention to the physical properties of liquids and solids.

## 10.1 CHARACTERISTICS OF GASES

In many ways gases are the most easily understood form of matter. Even though different gaseous substances may have very different *chemical* properties, they behave quite similarly as far as their *physical* properties are concerned. For example, we live in an atmosphere composed of a mixture of gases that we refer to as air. Air is a complex mixture of several substances, primarily  $\text{N}_2$  (78%) and  $\text{O}_2$  (21%), with small amounts of several other gases, including Ar (0.9%). We breathe air to absorb oxygen,  $\text{O}_2$ , which supports human life. Air also contains nitrogen,  $\text{N}_2$ , which has very different chemical properties from oxygen, yet this mixture behaves physically as one gaseous material.

Only a few elements exist as gases under ordinary conditions of temperature and pressure: The noble gases (He, Ne, Ar, Kr, and Xe) are all monatomic gases, whereas  $\text{H}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ ,  $\text{F}_2$ , and  $\text{Cl}_2$  are diatomic gases. Many molecular compounds are also gases. Table 10.1  $\blacktriangledown$  lists a few of the more common gaseous compounds. Notice that all of these gases are composed entirely of nonmetallic elements. Furthermore, all have simple molecular formulas and, therefore, low molar masses. Substances that are liquids or solids under ordinary conditions can also exist in the gaseous state, where they are often referred to as **vapors**. The substance  $\text{H}_2\text{O}$ , for example, can exist as liquid water, solid ice, or water vapor.

Gases differ significantly from solids and liquids in several respects. For example, a gas expands spontaneously to fill its container. Consequently, the volume of a gas equals the volume of the container in which it is held. Gases also are highly compressible: When pressure is applied to a gas, its volume readily decreases. Solids and liquids, on the other hand, do not expand to fill their containers, and solids and liquids are not readily compressible.

Gases form homogeneous mixtures with each other regardless of the identities or relative proportions of the component gases. The atmosphere serves as an excellent example. As a further example, when water and gasoline are mixed, the two liquids remain as separate layers. In contrast, the water vapor and gasoline vapors above the liquids form a homogeneous gas mixture.

The characteristic properties of gases arise because the individual molecules are relatively far apart. In the air we breathe, for example, the molecules take up only about 0.1% of the total volume, with the rest being empty space. Thus, each molecule behaves largely as though the others were not present.

**TABLE 10.1**  $\blacktriangle$  Some Common Compounds That Are Gases at Room Temperature

Formula	Name	Characteristics
HCN	Hydrogen cyanide	Very toxic, slight odor of bitter almonds
$\text{H}_2\text{S}$	Hydrogen sulfide	Very toxic, odor of rotten eggs
CO	Carbon monoxide	Toxic, colorless, odorless
$\text{CO}_2$	Carbon dioxide	Colorless, odorless
$\text{CH}_4$	Methane	Colorless, odorless, flammable
$\text{C}_2\text{H}_4$	Ethylene	Colorless, ripens fruit
$\text{C}_3\text{H}_8$	Propane	Colorless, odorless, bottled gas
$\text{N}_2\text{O}$	Nitrous oxide	Colorless, sweet odor, laughing gas
$\text{NO}_2$	Nitrogen dioxide	Toxic, red-brown, irritating odor
$\text{NH}_3$	Ammonia	Colorless, pungent odor
$\text{SO}_2$	Sulfur dioxide	Colorless, irritating odor

As a result, different gases behave similarly, even though they are made up of different molecules. In contrast, the individual molecules in a liquid are close together and occupy perhaps 70% of the total space. The attractive forces among the molecules keep the liquid together.

### GIVE IT SOME THOUGHT

What is the major reason that physical properties do not differ much from one gaseous substance to another?

## 10.2 PRESSURE

Among the most readily measured properties of a gas are its temperature, volume, and pressure. Many early studies of gases focused on relationships among these properties. We have already discussed volume and temperature. (Section 1.4) Let's now consider the concept of pressure.

In general terms, **pressure** conveys the idea of a force, a push that tends to move something in a given direction. Pressure,  $P$ , is, in fact, the force,  $F$ , that acts on a given area,  $A$ .

$$P = \frac{F}{A} \quad [10.1]$$

Gases exert a pressure on any surface with which they are in contact. The gas in an inflated balloon, for example, exerts a pressure on the inside surface of the balloon.

### Atmospheric Pressure and the Barometer

You and I, coconuts and nitrogen molecules, all experience an attractive force that pulls toward the center of Earth. When a coconut comes loose from its place at the top of the tree, for example, the gravitational attractive force causes it to be accelerated toward Earth, increasing in speed as its potential energy is converted into kinetic energy. (Section 5.1) The atoms and molecules of the atmosphere also experience a gravitational acceleration. Because the gas particles have such tiny masses, however, their thermal energies of motion (their kinetic energies) override the gravitational forces, so all the molecules that make up the atmosphere don't just pile up in a thin layer at Earth's surface. Nevertheless, gravity does operate, and it causes the atmosphere as a whole to press down on Earth's surface, creating an atmospheric pressure.

You can demonstrate the existence of atmospheric pressure to yourself with an empty plastic bottle of the sort used to hold water or soft drinks. If you suck on the mouth of the empty bottle, chances are you can cause it to partially cave in. When you break the partial vacuum you have created, the bottle pops out to its original shape. What causes the bottle to cave in when the pressure inside it is reduced, even by the relatively small amount you can manage with your lungs? The gas molecules in the atmosphere are exerting a force on the outside of the bottle that is greater than the force within the bottle when some of the gas has been sucked out.

We can calculate the magnitude of the atmospheric pressure as follows: The force,  $F$ , exerted by any object is the product of its mass,  $m$ , times its acceleration,  $a$ ; that is,  $F = ma$ . The acceleration given by Earth's gravity to any object located near Earth's surface is  $9.8 \text{ m/s}^2$ . Now imagine a column of air  $1 \text{ m}^2$  in cross section extending through the entire atmosphere (Figure 10.1). That column has a mass of roughly 10,000 kg. The force exerted by the column on Earth's surface is

$$F = (10,000 \text{ kg})(9.8 \text{ m/s}^2) = 1 \times 10^5 \text{ kg}\cdot\text{m/s}^2 = 1 \times 10^5 \text{ N}$$

▼ **Figure 10.1 Atmospheric pressure.** Illustration of the manner in which Earth's atmosphere exerts pressure at the surface of the planet. The mass of a column of atmosphere exactly  $1 \text{ m}^2$  in cross-sectional area and extending to the upper atmosphere exerts a force of  $1 \times 10^5 \text{ N}$ .

▲ **Figure 10.2** A mercury barometer. The pressure of the atmosphere on the surface of the mercury (represented by the blue arrow) equals the pressure of the column of mercury (red arrow).

The SI unit for force is  $\text{kg}\cdot\text{m}/\text{s}^2$  and is called the *newton* (N):  $1\text{ N} = 1\text{ kg}\cdot\text{m}/\text{s}^2$ . The pressure exerted by the column is the force divided by the cross-sectional area,  $A$ , over which the force is applied. Because our air column has a cross-sectional area of  $1\text{ m}^2$ , we have

$$P = \frac{F}{A} = \frac{1 \times 10^5 \text{ N}}{1 \text{ m}^2} = 1 \times 10^5 \text{ N}/\text{m}^2 = 1 \times 10^5 \text{ Pa} = 1 \times 10^2 \text{ kPa}$$

The SI unit of pressure is  $\text{N}/\text{m}^2$ . It is given the name **pascal** (Pa) after Blaise Pascal (1623–1662), a French mathematician and scientist who studied pressure:  $1\text{ Pa} = 1\text{ N}/\text{m}^2$ . A related unit sometimes used to report pressures is the **bar**, which equals  $10^5\text{ Pa}$ . Atmospheric pressure at sea level is about  $100\text{ kPa}$ , or  $1\text{ bar}$ . The actual atmospheric pressure at any location depends on weather conditions and altitude.

In the early part of the seventeenth century many scientists and philosophers believed that the atmosphere had no weight. Evangelista Torricelli (1608–1647), who was a student of Galileo’s, proved this untrue. He invented the *barometer* (Figure 10.2 ◀), which is made from a glass tube more than  $760\text{ mm}$  long that is closed at one end, completely filled with mercury, and inverted into a dish that contains additional mercury. (Care must be taken so that no air gets into the tube.) When the mercury-filled tube is inverted into the dish of mercury, some of the mercury flows out of the tube, but a column of mercury remains inside. Torricelli argued that the mercury surface in the dish experiences the full force, or weight, of Earth’s atmosphere, which pushes the mercury up the tube until the pressure exerted by the mercury column equals the atmospheric pressure at the base of the tube. So the height,  $h$ , of the mercury column is a measure of the atmosphere’s pressure, and it changes as the atmospheric pressure changes.

Torricelli’s proposed explanation met with fierce opposition. Some argued that there could not possibly be a vacuum at the top of the tube. They said, “Nature does not permit a vacuum!” But Torricelli also had his supporters. Blaise Pascal, for example, had one of the barometers carried to the top of Puy de Dome, a volcanic mountain in central France, and compared its readings with a duplicate barometer kept at the foot of the mountain. As the barometer ascended, the height of the mercury column diminished, as expected, because the amount of atmosphere pressing down on the surface decreases as one moves higher. These and other experiments by scientists eventually prevailed, and the idea that the atmosphere has weight became accepted over many years.

### GIVE IT SOME THOUGHT

What happens to the height of the mercury column in a mercury barometer as you move to higher altitude, and why?

**Standard atmospheric pressure**, which corresponds to the typical pressure at sea level, is the pressure sufficient to support a column of mercury  $760\text{ mm}$  high. In SI units this pressure equals  $1.01325 \times 10^5\text{ Pa}$ . Standard atmospheric pressure defines some common non-SI units used to express gas pressures, such as the **atmosphere** (atm) and the *millimeter of mercury* (mm Hg). The latter unit is also called the **torr**, after Torricelli.

$$1\text{ atm} = 760\text{ mm Hg} = 760\text{ torr} = 1.01325 \times 10^5 \text{ Pa} = 101.325\text{ kPa}$$

Note that the units mm Hg and torr are equivalent:  $1\text{ torr} = 1\text{ mm Hg}$ .

We will usually express gas pressure in units of atm, Pa (or kPa), or torr, so you should be comfortable converting gas pressures from one set of units to another.

**SAMPLE EXERCISE 10.1** | Converting Units of Pressure

(a) Convert 0.357 atm to torr. (b) Convert  $6.6 \times 10^{-2}$  torr to atm. (c) Convert 147.2 kPa to torr.

**SOLUTION**

**Analyze:** In each case we are given the pressure in one unit and asked to convert it to another unit. Our task, therefore, is to choose the appropriate conversion factors.

**Plan:** We can use dimensional analysis to perform the desired conversions.

**Solve:**

(a) To convert atmospheres to torr, we use the relationship  $760 \text{ torr} = 1 \text{ atm}$ :

$$(0.357 \text{ atm}) \left( \frac{760 \text{ torr}}{1 \text{ atm}} \right) = 271 \text{ torr}$$

Note that the units cancel in the required manner.

(b) We use the same relationship as in part (a). To get the appropriate units to cancel, we must use the conversion factor as follows:

$$(6.6 \times 10^{-2} \text{ torr}) \left( \frac{1 \text{ atm}}{760 \text{ torr}} \right) = 8.7 \times 10^{-5} \text{ atm}$$

(c) The relationship  $760 \text{ torr} = 101.325 \text{ kPa}$  allows us to write an appropriate conversion factor for this problem:

$$(147.2 \text{ kPa}) \left( \frac{760 \text{ torr}}{101.325 \text{ kPa}} \right) = 1104 \text{ torr}$$

**Check:** In each case look at the magnitude of the answer and compare it with the starting value. The torr is a much smaller unit than the atmosphere, so we expect the *numerical* answer to be larger than the starting quantity in (a) and smaller in (b). In (c) notice that there are nearly 8 torr per kPa, so the numerical answer in torr should be about 8 times larger than its value in kPa, consistent with our calculation.

**PRACTICE EXERCISE**

(a) In countries that use the metric system, such as Canada, atmospheric pressure in weather reports is given in units of kPa. Convert a pressure of 745 torr to kPa. (b) An English unit of pressure sometimes used in engineering is pounds per square inch ( $\text{lb}/\text{in}^2$ ), or psi:  $1 \text{ atm} = 14.7 \text{ lb}/\text{in}^2$ . If a pressure is reported as 91.5 psi, express the measurement in atmospheres.

**Answer:** (a) 99.3 kPa, (b) 6.22 atm

We can use various devices to measure the pressures of enclosed gases. Tire gauges, for example, measure the pressure of air in automobile and bicycle tires. In laboratories we sometimes use a device called a *manometer*. A manometer operates on a principle similar to that of a barometer, as shown in Sample Exercise 10.2.

**SAMPLE EXERCISE 10.2** | Using a Manometer to Measure Gas Pressure

On a certain day the barometer in a laboratory indicates that the atmospheric pressure is 764.7 torr. A sample of gas is placed in a flask attached to an open-end mercury manometer, shown in Figure 10.3. A meter stick is used to measure the height of the mercury above the bottom of the manometer. The level of mercury in the open-end arm of the manometer has a height of 136.4 mm, and the mercury in the arm that is in contact with the gas has a height of 103.8 mm. What is the pressure of the gas (a) in atmospheres, (b) in kPa?

**SOLUTION**

**Analyze:** We are given the atmospheric pressure (764.7 torr) and the heights of the mercury in the two arms of the manometer and asked to determine the gas pressure in the flask. We know that this pressure must be greater than atmospheric because the manometer level on the flask side (103.8 mm) is lower than that on the side open to the atmosphere (136.4 mm), as indicated in Figure 10.3.

**Plan:** We will use the difference in height between the two arms ( $h$  in Figure 10.3) to obtain the amount by which the pressure of the gas exceeds atmospheric pressure. Because an open-end mercury manometer is used, the height difference directly measures the pressure difference in mm Hg or torr between the gas and the atmosphere.

**▲ Figure 10.3** A mercury manometer. This device is sometimes employed in the laboratory to measure gas pressures near atmospheric pressure.

**Solve:**

(a) The pressure of the gas equals the atmospheric pressure plus  $h$ :

$$\begin{aligned} P_{\text{gas}} &= P_{\text{atm}} + h \\ &= 764.7 \text{ torr} + (136.4 \text{ torr} - 103.8 \text{ torr}) \\ &= 797.3 \text{ torr} \end{aligned}$$

We convert the pressure of the gas to atmospheres:

$$P_{\text{gas}} = (797.3 \text{ torr}) \left( \frac{1 \text{ atm}}{760 \text{ torr}} \right) = 1.049 \text{ atm}$$

(b) To calculate the pressure in kPa, we employ the conversion factor between atmospheres and kPa:

$$1.049 \text{ atm} \left( \frac{101.3 \text{ kPa}}{1 \text{ atm}} \right) = 106.3 \text{ kPa}$$

**Check:** The calculated pressure is a bit more than one atmosphere. This makes sense because we anticipated that the pressure in the flask would be greater than the pressure of the atmosphere acting on the manometer, which is a bit greater than one standard atmosphere.

**PRACTICE EXERCISE**

Convert a pressure of 0.975 atm into Pa and kPa.

**Answers:**  $9.88 \times 10^4$  Pa and 98.8 kPa

*Chemistry and Life*

## BLOOD PRESSURE

The human heart pumps blood to the parts of the body through arteries, and the blood returns to the heart through veins. When your blood pressure is measured, two values are reported, such as 120/80 (120 over 80), which is a normal reading. The first measurement is the *systolic pressure*, the maximum pressure when the heart is pumping. The second is the *diastolic pressure*, the pressure when the heart is in the resting part of its pumping cycle. The units associated with these pressure measurements are torr.

Blood pressure is measured using a pressure gauge attached to a closed, air-filled jacket or cuff that is applied like a tourniquet to the arm (Figure 10.4 ▶). The pressure gauge may be a mercury manometer or some other device. The air pressure in the cuff is increased using a small pump until it is above the systolic pressure and prevents the flow of blood. The air pressure inside the cuff is then slowly reduced until blood just begins to pulse through the artery, as detected by the use of a stethoscope. At this point the pressure in the cuff equals the pressure that the blood exerts inside the arteries. Reading the gauge gives the systolic pressure. The pressure in the cuff is then reduced further until the blood flows freely. The pressure at this point is the diastolic pressure.

▲ **Figure 10.4** Measuring blood pressure.

*Hypertension* is the presence of abnormally high blood pressure. The usual criterion for hypertension is a blood pressure greater than 140/90, although recent studies suggest that health risks increase for systolic readings above 120. Hypertension significantly increases the workload on the heart and places a stress on the walls of the blood vessels throughout the body. These effects increase the risk of aneurysms, heart attacks, and strokes.

### 10.3 THE GAS LAWS

Experiments with a large number of gases reveal that four variables are needed to define the physical condition, or *state*, of a gas: temperature,  $T$ , pressure,  $P$ , volume,  $V$ , and the amount of gas, which is usually expressed as the number of moles,  $n$ . The equations that express the relationships among  $T$ ,  $P$ ,  $V$ , and  $n$  are known as the *gas laws*. Because volume is easily measured, the first gas laws to be studied expressed the effect of one of the variables on volume with the remaining two variables held constant.

◀ **Figure 10.5** An application of the pressure-volume relationship. The volume of gas in this weather balloon will increase as it ascends into the high atmosphere, where the atmospheric pressure is lower than on Earth's surface.

### The Pressure-Volume Relationship: Boyle's Law

If the pressure on a balloon is decreased, the balloon expands. That is why weather balloons expand as they rise through the atmosphere (Figure 10.5▲). Conversely, when a volume of gas is compressed, the pressure of the gas increases. British chemist Robert Boyle (1627–1691) first investigated the relationship between the pressure of a gas and its volume.

To perform his gas experiments, Boyle used a J-shaped tube like that shown in Figure 10.6▶. In the tube on the left, a quantity of gas is trapped above a column of mercury. Boyle changed the pressure on the gas by adding mercury to the tube. He found that the volume of the gas decreased as the pressure increased. For example, doubling the pressure caused the gas volume to decrease to half its original value.

**Boyle's law**, which summarizes these observations, states that *the volume of a fixed quantity of gas maintained at constant temperature is inversely proportional to the pressure*. When two measurements are inversely proportional, one gets smaller as the other gets larger. Boyle's law can be expressed mathematically as

$$V = \text{constant} \times \frac{1}{P} \quad \text{or} \quad PV = \text{constant} \quad [10.2]$$

The value of the constant depends on the temperature and the amount of gas in the sample. The graph of  $V$  versus  $P$  in Figure 10.7(a)▼ shows the type of curve obtained for a given quantity of gas at a fixed temperature. A linear relationship is obtained when  $V$  is plotted versus  $1/P$  [Figure 10.7(b)].

▲ **Figure 10.6** An illustration of Boyle's experiment relating pressure and volume. In (a) the volume of the gas trapped in the J-tube is 60 mL when the gas pressure is 760 torr. When additional mercury is added, as shown in (b), the trapped gas is compressed. The volume is 30 mL when its total pressure is 1520 torr, corresponding to atmospheric pressure plus the pressure exerted by the 760-mm column of mercury.

◀ **Figure 10.7** Graphs based on Boyle's law. (a) Volume versus pressure. (b) Volume versus  $1/P$ .

▲ **Figure 10.8** An illustration of the effect of temperature on volume. As liquid nitrogen ( $-196\text{ }^{\circ}\text{C}$ ) is poured over a balloon, the gas in the balloon is cooled and its volume decreases.

▲ **Figure 10.9** Graph based on Charles's law. At constant pressure, the volume of an enclosed gas increases as the temperature increases. The dashed line is an extrapolation to temperatures at which the substance is no longer a gas.

Simple though it is, Boyle's law occupies a special place in the history of science. Boyle was the first to carry out a series of experiments in which one variable was systematically changed to determine the effect on another variable. The data from the experiments were then employed to establish an empirical relationship—a "law."

We apply Boyle's law every time we breathe. The rib cage, which can expand and contract, and the diaphragm, a muscle beneath the lungs, govern the volume of the lungs. Inhalation occurs when the rib cage expands and the diaphragm moves downward. Both of these actions increase the volume of the lungs, thus decreasing the gas pressure inside the lungs. The atmospheric pressure then forces air into the lungs until the pressure in the lungs equals atmospheric pressure. Exhalation reverses the process—the rib cage contracts and the diaphragm moves up, both of which decrease the volume of the lungs. Air is forced out of the lungs by the resulting increase in pressure.

### GIVE IT SOME THOUGHT

What happens to the volume of a gas if you double its pressure, say from 1 atm to 2 atm, while its temperature is held constant?

### The Temperature-Volume Relationship: Charles's Law

Hot-air balloons rise because air expands as it is heated. The warm air in the ballooning is less dense than the surrounding cool air at the same pressure. This difference in density causes the balloon to ascend. Conversely, a balloon will shrink when the gas in it is cooled, as seen in Figure 10.8 ◀.

The relationship between gas volume and temperature was discovered in 1787 by the French scientist Jacques Charles (1746–1823). Charles found that the volume of a fixed quantity of gas at constant pressure increases linearly with temperature. Some typical data are shown in Figure 10.9 ◀. Notice that the extrapolated (extended) line (which is dashed) passes through  $-273\text{ }^{\circ}\text{C}$ . Note also that the gas is predicted to have zero volume at this temperature. This condition is never realized, however, because all gases liquefy or solidify before reaching this temperature.

In 1848 William Thomson (1824–1907), a British physicist whose title was Lord Kelvin, proposed an absolute-temperature scale, now known as the Kelvin scale. On this scale 0 K, which is called *absolute zero*, equals  $-273.15\text{ }^{\circ}\text{C}$  (Section 1.4) In terms of the Kelvin scale, Charles's law can be stated as follows: *The volume of a fixed amount of gas maintained at constant pressure is directly proportional to its absolute temperature.* Thus, doubling the absolute temperature, say from 200 K to 400 K, causes the gas volume to double. Mathematically, Charles's law takes the following form:

$$V = \text{constant} \times T \quad \text{or} \quad \frac{V}{T} = \text{constant} \quad [10.3]$$

The value of the constant depends on the pressure and amount of gas.

### GIVE IT SOME THOUGHT

Does the volume of a fixed quantity of gas decrease to half its original value when the temperature is lowered from  $100\text{ }^{\circ}\text{C}$  to  $50\text{ }^{\circ}\text{C}$ ?

### The Quantity-Volume Relationship: Avogadro's Law

As we add gas to a balloon, the balloon expands. The volume of a gas is affected by pressure, temperature, and the amount of gas. The relationship between the quantity of a gas and its volume follows from the work of Joseph Louis Gay-Lussac (1778–1823) and Amedeo Avogadro (1776–1856).

◀ **Figure 10.10 The law of combining volumes.** Gay-Lussac's experimental observation of combining volumes is shown together with Avogadro's explanation of this phenomenon.

Gay-Lussac is one of those extraordinary figures in the history of science who could truly be called an adventurer. He was interested in lighter-than-air balloons, and in 1804 he made an ascent to 23,000 ft—an exploit that held the altitude record for several decades. To better control lighter-than-air balloons, Gay-Lussac carried out several experiments on the properties of gases. In 1808 he observed the *law of combining volumes*: At a given pressure and temperature, the volumes of gases that react with one another are in the ratios of small whole numbers. For example, two volumes of hydrogen gas react with one volume of oxygen gas to form two volumes of water vapor, as shown in Figure 10.10 ▲.

Three years later Amedeo Avogadro interpreted Gay-Lussac's observation by proposing what is now known as **Avogadro's hypothesis**: *Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules.* For example, experiments show that 22.4 L of any gas at 0 °C and 1 atm contain  $6.02 \times 10^{23}$  gas molecules (that is, 1 mol), as depicted in Figure 10.11 ►.

**Avogadro's law** follows from Avogadro's hypothesis: *The volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas.* That is,

$$V = \text{constant} \times n \quad [10.4]$$

Thus, doubling the number of moles of gas will cause the volume to double if  $T$  and  $P$  remain constant.

			
Volume	22.4 L	22.4 L	22.4 L
Pressure	1 atm	1 atm	1 atm
Temperature	0 °C	0 °C	0 °C
Mass of gas	4.00 g	28.0 g	16.0 g
Number of gas molecules	$6.02 \times 10^{23}$	$6.02 \times 10^{23}$	$6.02 \times 10^{23}$

▲ **Figure 10.11 A comparison illustrating Avogadro's hypothesis.** Note that helium gas consists of helium atoms. Each gas has the same volume, temperature, and pressure and thus contains the same number of molecules. Because a molecule of one substance differs in mass from a molecule of another, the masses of gas in the three containers differ.

### ■ SAMPLE EXERCISE 10.3 | Evaluating the Effects of Changes in $P$ , $V$ , $n$ , and $T$ on a Gas

Suppose we have a gas confined to a cylinder as shown in Figure 10.12 ►. Consider the following changes: (a) Heat the gas from 298 K to 360 K, while maintaining the piston in the position shown in the drawing. (b) Move the piston to reduce the volume of gas from 1 L to 0.5 L. (c) Inject additional gas through the gas inlet valve. Indicate how each of these changes will affect the average distance between molecules, the pressure of the gas, and the number of moles of gas present in the cylinder.

#### SOLUTION

**Analyze:** We need to think how each of three different changes in the system affects (1) the distance between molecules, (2) the pressure of the gas, and (3) the number of moles of gas in the cylinder.

**Plan:** We will use our understanding of the gas laws and the general properties of gases to analyze each situation.

#### Solve:

(a) Heating the gas while maintaining the position of the piston will cause no change in the number of molecules per unit volume. Thus, the distance between molecules and the total moles of gas remain the same. The increase in temperature, however, will cause the pressure to increase (Charles's law).

▲ **Figure 10.12 Cylinder with piston and gas inlet valve.**

(b) Moving the piston compresses the same quantity of gas into a smaller volume. The total number of molecules of gas, and thus the total number of moles, remains the same. The average distance between molecules, however, must decrease because of the smaller volume in which the gas is confined. The reduction in volume causes the pressure to increase (Boyle's law).

(c) Injecting more gas into the cylinder while keeping the volume and temperature the same will result in more molecules and thus a greater number of moles of gas. The average distance between atoms must decrease because their number per unit volume increases. Correspondingly, the pressure increases (Avogadro's law).

#### ■ PRACTICE EXERCISE

What happens to the density of a gas as (a) the gas is heated in a constant-volume container; (b) the gas is compressed at constant temperature; (c) additional gas is added to a constant-volume container?

*Answer:* (a) no change, (b) increase, (c) increase

## 10.4 THE IDEAL-GAS EQUATION

In Section 10.3 we examined three historically important gas laws that describe the relationships between the four variables,  $P$ ,  $V$ ,  $T$ , and  $n$ , that define the state of a gas. Each law was obtained by holding two variables constant to see how the remaining two variables affect each other. We can express each law as a proportionality relationship. Using the symbol  $\propto$ , which is read "is proportional to," we have

$$\text{Boyle's law:} \quad V \propto \frac{1}{P} \quad (\text{constant } n, T)$$

$$\text{Charles's law:} \quad V \propto T \quad (\text{constant } n, P)$$

$$\text{Avogadro's law:} \quad V \propto n \quad (\text{constant } P, T)$$

We can combine these relationships to make a more general gas law.

$$V \propto \frac{nT}{P}$$

If we call the proportionality constant  $R$ , we obtain

$$V = R \left( \frac{nT}{P} \right)$$

Rearranging, we have this relationship in its more familiar form:

$$PV = nRT \quad [10.5]$$

This equation is known as the **ideal-gas equation**. An **ideal gas** is a hypothetical gas whose pressure, volume, and temperature behavior are described completely by the ideal-gas equation.

The term  $R$  in the ideal-gas equation is called the **gas constant**. The value and units of  $R$  depend on the units of  $P$ ,  $V$ ,  $n$ , and  $T$ . Temperature must *always* be expressed as an absolute temperature when used in the ideal-gas equation. The quantity of gas,  $n$ , is normally expressed in moles. The units chosen for pressure and volume are most often atm and liters, respectively. However, other units can be used. In most countries other than the United States, the SI unit of Pa (or kPa) is most commonly employed. Table 10.2 ◀ shows the numerical value for  $R$  in various units. As we saw in the "A Closer Look" box on  $P$ - $V$  work in Section 5.3, the product  $PV$  has the units of energy. Therefore, the units of  $R$  can include joules or calories. In working problems with the ideal-gas equation, the units of  $P$ ,  $V$ ,  $n$ , and  $T$  must agree with the units in the gas constant. In this chapter we will most often use the value  $R = 0.08206$  L-atm/mol-K (four significant figures) or  $0.0821$  L-atm/mol-K (three significant figures) whenever we use the ideal-gas equation, consistent with the units of atm for pressure. Use of the value  $R = 8.314$  J/mol-K, consistent with the units of Pa for pressure, is also very common.

**TABLE 10.2** ■ Numerical Values of the Gas Constant,  $R$ , in Various Units

Units	Numerical Value
L-atm/mol-K	0.08206
J/mol-K*	8.314
cal/mol-K	1.987
m <sup>3</sup> -Pa/mol-K*	8.314
L-torr/mol-K	62.36

\*SI unit

Suppose we have 1.000 mol of an ideal gas at 1.000 atm and 0.00 °C (273.15 K). According to the ideal-gas equation, the volume of the gas is

$$V = \frac{nRT}{P} = \frac{(1.000 \text{ mol})(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(273.15 \text{ K})}{1.000 \text{ atm}} = 22.41 \text{ L}$$

The conditions 0 °C and 1 atm are referred to as the **standard temperature and pressure (STP)**. Many properties of gases are tabulated for these conditions. The volume occupied by one mole of ideal gas at STP, 22.41 L, is known as the *molar volume* of an ideal gas at STP.

### GIVE IT SOME THOUGHT

How many molecules are in 22.41 L of an ideal gas at STP?

The ideal-gas equation accounts adequately for the properties of most gases under a wide variety of circumstances. The equation is not exactly correct, however, for any real gas. Thus, the measured volume,  $V$ , for given conditions of  $P$ ,  $n$ , and  $T$ , might differ from the volume calculated from  $PV = nRT$ . To illustrate, the measured molar volumes of real gases at STP are compared with the calculated volume of an ideal gas in Figure 10.13. While these real gases do not match the ideal gas behavior exactly, the differences are so small that we can ignore them for all but the most accurate work. We will have more to say about the differences between ideal and real gases in Section 10.9.

▼ **Figure 10.13 Comparison of molar volumes at STP.** One mole of an ideal gas at STP occupies a volume of 22.41 L. One mole of various real gases at STP occupies close to this ideal volume.

### SAMPLE EXERCISE 10.4 | Using the Ideal-Gas Equation

Calcium carbonate,  $\text{CaCO}_3(\text{s})$ , decomposes upon heating to give  $\text{CaO}(\text{s})$  and  $\text{CO}_2(\text{g})$ . A sample of  $\text{CaCO}_3$  is decomposed, and the carbon dioxide is collected in a 250-mL flask. After the decomposition is complete, the gas has a pressure of 1.3 atm at a temperature of 31 °C. How many moles of  $\text{CO}_2$  gas were generated?

#### SOLUTION

**Analyze:** We are given the volume (250 mL), pressure (1.3 atm), and temperature 31 °C of a sample of  $\text{CO}_2$  gas and asked to calculate the number of moles of  $\text{CO}_2$  in the sample.

**Plan:** Because we are given  $V$ ,  $P$ , and  $T$ , we can solve the ideal-gas equation for the unknown quantity,  $n$ .

**Solve:** In analyzing and solving gas-law problems, it is helpful to tabulate the information given in the problems and then to convert the values to units that are consistent with those for  $R$  (0.0821 L-atm/mol-K). In this case the given values are

$$V = 250 \text{ mL} = 0.250 \text{ L}$$

$$P = 1.3 \text{ atm}$$

$$T = 31 \text{ }^\circ\text{C} = (31 + 273) \text{ K} = 304 \text{ K}$$

Remember: *Absolute temperature must always be used when the ideal-gas equation is solved.*

We now rearrange the ideal-gas equation (Equation 10.5) to solve for  $n$

$$n = \frac{PV}{RT}$$

$$n = \frac{(1.3 \text{ atm})(0.250 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(304 \text{ K})} = 0.013 \text{ mol CO}_2$$

**Check:** Appropriate units cancel, thus ensuring that we have properly rearranged the ideal-gas equation and have converted to the correct units.

### PRACTICE EXERCISE

Tennis balls are usually filled with air or  $\text{N}_2$  gas to a pressure above atmospheric pressure to increase their “bounce.” If a particular tennis ball has a volume of 144  $\text{cm}^3$  and contains 0.33 g of  $\text{N}_2$  gas, what is the pressure inside the ball at 24 °C?

**Answer:** 2.0 atm

In chemistry and throughout your studies of science and math, you may encounter problems that involve several experimentally measured variables as well as several different physical constants. In this chapter we encounter a variety of problems based on the ideal-gas equation, which consists of four experimental quantities— $P$ ,  $V$ ,  $n$ , and  $T$ —and one constant,  $R$ . Depending on the type of problem, we might need to solve for any of the four quantities.

To avoid any difficulty extracting the necessary information from problems when many variables are involved, we suggest you take the following steps as you analyze, plan, and solve such problems:

1. *Tabulate information.* Read the problems carefully to determine which quantity is the unknown and which quantities are given. Every time you encounter a numerical value, jot it down. In many cases, constructing a table of the given information will be useful.
2. *Convert to consistent units.* As you have already seen, we can use several different units to express the same quantity. Make certain that quantities are converted to the proper units by using the correct conversion factors. In using the ideal-gas equation, for example, we usually use the value of  $R$  that has units of L-atm/mol-K. If you are given a pressure in torr, you will need to convert it to atmospheres.
3. *If a single equation relates the variables, rearrange the equation to solve for the unknown.* Make certain that you are comfortable using algebra to solve the equation for the desired variable. In the case of the ideal-gas equation the following algebraic rearrangements will all be used at one time or another:

$$P = \frac{nRT}{V}; \quad V = \frac{nRT}{P}; \quad n = \frac{PV}{RT}; \quad T = \frac{PV}{nR}$$

4. *Use dimensional analysis.* Carry the units through your calculation. Use of dimensional analysis enables you to check that you have solved the equation correctly. If the units of the quantities in the equation cancel properly to give the units of the desired variable, you have probably used the equation correctly.

Sometimes you will not be given values for the necessary variables directly. Rather, you will be given the values of other quantities that can be used to determine the needed variables. For example, suppose you are trying to use the ideal-gas equation to calculate the pressure of a gas. You are given the temperature of the gas, but you are not given explicit values for  $n$  and  $V$ . However, the problem states that “the sample of gas contains 0.15 mol of gas per liter.” We can turn this statement into the expression

$$\frac{n}{V} = 0.15 \text{ mol/L}$$

Solving the ideal-gas equation for pressure yields

$$P = \frac{nRT}{V} = \left(\frac{n}{V}\right)RT$$

Thus, we can solve the equation even though we are not given specific values for  $n$  and  $V$ . We will examine how to use the density and molar mass of a gas in this fashion in Section 10.5.

As we have continuously stressed, the most important thing you can do to become proficient at solving problems is to practice by using practice exercises and assigned exercises at the end of each chapter. By using systematic procedures, such as those described here, you should be able to minimize difficulties in solving problems involving many variables.

### Relating the Ideal-Gas Equation and the Gas Laws

The simple gas laws that we discussed in Section 10.3, such as Boyle’s law, are special cases of the ideal-gas equation. For example, when the quantity of gas and the temperature are held constant,  $n$  and  $T$  have fixed values. Therefore, the product  $nRT$  is the product of three constants and must itself be a constant.

$$PV = nRT = \text{constant} \quad \text{or} \quad PV = \text{constant} \quad [10.6]$$

Thus, we have Boyle’s law. We see that if  $n$  and  $T$  are constant, the individual values of  $P$  and  $V$  can change, but the product  $PV$  must remain constant.

We can use Boyle’s law to determine how the volume of a gas changes when its pressure changes. For example, if a metal cylinder holds 50.0 L of  $O_2$  gas at 18.5 atm and 21 °C, what volume will the gas occupy if the temperature is maintained at 21 °C while the pressure is reduced to 1.00 atm? Because the product  $PV$  is a constant when a gas is held at constant  $n$  and  $T$ , we know that

$$P_1V_1 = P_2V_2 \quad [10.7]$$

where  $P_1$  and  $V_1$  are initial values and  $P_2$  and  $V_2$  are final values. Dividing both sides of this equation by  $P_2$  gives the final volume,  $V_2$ .

$$V_2 = V_1 \times \frac{P_1}{P_2}$$

Substituting the given quantities into this equation gives

$$V_2 = (50.0 \text{ L}) \left( \frac{18.5 \text{ atm}}{1.00 \text{ atm}} \right) = 925 \text{ L}$$

The answer is reasonable because gases expand as their pressures are decreased.

In a similar way we can start with the ideal-gas equation and derive relationships between any other two variables,  $V$  and  $T$  (Charles's law),  $n$  and  $V$  (Avogadro's law), or  $P$  and  $T$ . Sample Exercise 10.5 illustrates how these relationships can be derived and used.

### ■ SAMPLE EXERCISE 10.5 | Calculating the Effect of Temperature Changes on Pressure

The gas pressure in an aerosol can is 1.5 atm at 25 °C. Assuming that the gas inside obeys the ideal-gas equation, what would the pressure be if the can were heated to 450 °C?

#### SOLUTION

**Analyze:** We are given the initial pressure (1.5 atm) and temperature (25 °C) of the gas and asked for the pressure at a higher temperature (450 °C).

**Plan:** The volume and number of moles of gas do not change, so we must use a relationship connecting pressure and temperature. Converting temperature to the Kelvin scale and tabulating the given information, we have

	$P$	$T$
INITIAL	1.5 atm	298 K
FINAL	$P_2$	723 K

**Solve:** To determine how  $P$  and  $T$  are related, we start with the ideal-gas equation and isolate the quantities that do not change ( $n$ ,  $V$ , and  $R$ ) on one side and the variables ( $P$  and  $T$ ) on the other side.

$$\frac{P}{T} = \frac{nR}{V} = \text{constant}$$

Because the quotient  $P/T$  is a constant, we can write

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

(where the subscripts 1 and 2 represent the initial and final states, respectively). Rearranging to solve for  $P_2$  and substituting the given data give

$$P_2 = P_1 \times \frac{T_2}{T_1}$$

$$P_2 = (1.5 \text{ atm}) \left( \frac{723 \text{ K}}{298 \text{ K}} \right) = 3.6 \text{ atm}$$

**Check:** This answer is intuitively reasonable—increasing the temperature of a gas increases its pressure.

**Comment:** It is evident from this example why aerosol cans carry a warning not to incinerate.

#### ■ PRACTICE EXERCISE

A large natural-gas storage tank is arranged so that the pressure is maintained at 2.20 atm. On a cold day in December when the temperature is  $-15$  °C ( $4$  °F), the volume of gas in the tank is  $3.25 \times 10^3 \text{ m}^3$ . What is the volume of the same quantity of gas on a warm July day when the temperature is  $31$  °C ( $88$  °F)?

**Answer:**  $3.83 \times 10^3 \text{ m}^3$

We are often faced with the situation in which  $P$ ,  $V$ , and  $T$  all change for a fixed number of moles of gas. Because  $n$  is constant under these circumstances, the ideal-gas equation gives

$$\frac{PV}{T} = nR = \text{constant}$$

If we represent the initial and final conditions of pressure, temperature, and volume by subscripts 1 and 2, respectively, we can write

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2} \quad [10.8]$$

This equation is often called the *combined gas law*.

**SAMPLE EXERCISE 10.6** Calculating the Effect of Changing  $P$  and  $T$  on the Volume of a Gas

An inflated balloon has a volume of 6.0 L at sea level (1.0 atm) and is allowed to ascend in altitude until the pressure is 0.45 atm. During ascent the temperature of the gas falls from 22 °C to -21 °C. Calculate the volume of the balloon at its final altitude.

**SOLUTION**

**Analyze:** We need to determine a new volume for a gas sample in a situation where both pressure and temperature change.

**Plan:** Let's again proceed by converting temperature to the Kelvin scale and tabulating the given information.

	$P$	$V$	$T$
INITIAL	1.0 atm	6.0 L	295 K
FINAL	0.45 atm	$V_2$	252 K

Because  $n$  is constant, we can use Equation 10.8.

**Solve:** Rearranging Equation 10.8 to solve for  $V_2$  gives

$$V_2 = V_1 \times \frac{P_1}{P_2} \times \frac{T_2}{T_1} = (6.0 \text{ L}) \left( \frac{1.0 \text{ atm}}{0.45 \text{ atm}} \right) \left( \frac{252 \text{ K}}{295 \text{ K}} \right) = 11 \text{ L}$$

**Check:** The result appears reasonable. Notice that the calculation involves multiplying the initial volume by a ratio of pressures and a ratio of temperatures. Intuitively, we expect that decreasing pressure will cause the volume to increase. Similarly, decreasing temperature should cause the volume to decrease. Note that the difference in pressures is more dramatic than the difference in temperatures. Thus, we should expect the effect of the pressure change to predominate in determining the final volume, as it does.

**PRACTICE EXERCISE**

A 0.50-mol sample of oxygen gas is confined at 0 °C in a cylinder with a movable piston, such as that shown in Figure 10.12. The gas has an initial pressure of 1.0 atm. The piston then compresses the gas so that its final volume is half the initial volume. The final pressure of the gas is 2.2 atm. What is the final temperature of the gas in degrees Celsius?

*Answer:* 27 °C

## 10.5 FURTHER APPLICATIONS OF THE IDEAL-GAS EQUATION

The ideal-gas equation can be used to determine many relationships involving the physical properties of gases. In this section we use it first to define the relationship between the density of a gas and its molar mass, and then to calculate the volumes of gases formed or consumed in chemical reactions.

### Gas Densities and Molar Mass

The ideal-gas equation allows us to calculate gas density from the molar mass, pressure, and temperature of the gas. Recall that density has the units of mass per unit volume ( $d = m/V$ ). (Section 1.4) We can arrange the gas equation to obtain similar units, moles per unit volume,  $n/V$ :

$$\frac{n}{V} = \frac{P}{RT}$$

If we multiply both sides of this equation by the molar mass,  $\mathcal{M}$ , which is the number of grams in one mole of a substance, we obtain the following relationship:

$$\frac{n\mathcal{M}}{V} = \frac{P\mathcal{M}}{RT} \quad [10.9]$$

The product of the quantities  $n/V$  and  $\mathcal{M}$  equals the density in g/L, as seen from their units:

$$\frac{\text{moles}}{\text{liter}} \times \frac{\text{grams}}{\text{mole}} = \frac{\text{grams}}{\text{liter}}$$

Thus, the density,  $d$ , of the gas is given by the expression on the right in Equation 10.9:

$$d = \frac{P\mathcal{M}}{RT} \quad [10.10]$$

From Equation 10.10 we see that the density of a gas depends on its pressure, molar mass, and temperature. The higher the molar mass and pressure, the more dense the gas. The higher the temperature, the less dense the gas. Although gases form homogeneous mixtures regardless of their identities, a less dense gas will lie above a more dense gas in the absence of mixing. For example,  $\text{CO}_2$  has a higher molar mass than  $\text{N}_2$  or  $\text{O}_2$  and is therefore more dense than air. When  $\text{CO}_2$  is released from a  $\text{CO}_2$  fire extinguisher, as shown in Figure 10.14, it blankets a fire, preventing  $\text{O}_2$  from reaching the combustible material. The fact that a hotter gas is less dense than a cooler one explains why hot air rises. The difference between the densities of hot and cold air is responsible for the lift of hot-air balloons. It is also responsible for many phenomena in weather, such as the formation of large thunderhead clouds during thunderstorms.

▲ **Figure 10.14 A  $\text{CO}_2$  fire extinguisher.** The  $\text{CO}_2$  gas from a fire extinguisher is denser than air. The  $\text{CO}_2$  cools significantly as it emerges from the tank. Water vapor in the air is condensed by the cool  $\text{CO}_2$  gas and forms a white fog accompanying the colorless  $\text{CO}_2$ .

### GIVE IT SOME THOUGHT

Is water vapor more or less dense than  $\text{N}_2$  under the same conditions of temperature and pressure?

#### SAMPLE EXERCISE 10.7 | Calculating Gas Density

What is the density of carbon tetrachloride vapor at 714 torr and 125 °C?

#### SOLUTION

**Analyze:** We are asked to calculate the density of a gas given its name, its pressure, and its temperature. From the name we can write the chemical formula of the substance and determine its molar mass.

**Plan:** We can use Equation 10.10 to calculate the density. Before we can use that equation, however, we need to convert the given quantities to the appropriate units. We must convert temperature to the Kelvin scale and pressure to atmospheres. We must also calculate the molar mass of  $\text{CCl}_4$ .

**Solve:** The temperature on the Kelvin scale is  $125 + 273 = 398 \text{ K}$ . The pressure in atmospheres is  $(714 \text{ torr})(1 \text{ atm}/760 \text{ torr}) = 0.939 \text{ atm}$ . The molar mass of  $\text{CCl}_4$  is  $12.0 + (4)(35.5) = 154.0 \text{ g/mol}$ . Using these quantities along with Equation 10.10, we have

$$d = \frac{(0.939 \text{ atm})(154.0 \text{ g/mol})}{(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(398 \text{ K})} = 4.43 \text{ g/L}$$

**Check:** If we divide the molar mass (g/mol) by the density (g/L), we end up with L/mol. The numerical value is roughly  $154/4.4 = 35$ . That is in the right ballpark for the molar volume of a gas heated to 125 °C at near atmospheric pressure, so our answer is reasonable.

#### PRACTICE EXERCISE

The mean molar mass of the atmosphere at the surface of Titan, Saturn's largest moon, is 28.6 g/mol. The surface temperature is 95 K, and the pressure is 1.6 atm. Assuming ideal behavior, calculate the density of Titan's atmosphere.

**Answer:** 5.9 g/L

Equation 10.10 can be rearranged to solve for the molar mass of a gas:

$$\mathcal{M} = \frac{dRT}{P} \quad [10.11]$$

Thus, we can use the experimentally measured density of a gas to determine the molar mass of the gas molecules, as shown in Sample Exercise 10.8.

### SAMPLE EXERCISE 10.8 | Calculating the Molar Mass of a Gas

A series of measurements are made to determine the molar mass of an unknown gas. First, a large flask is evacuated and found to weigh 134.567 g. It is then filled with the gas to a pressure of 735 torr at 31 °C and reweighed. Its mass is now 137.456 g. Finally, the flask is filled with water at 31 °C and found to weigh 1067.9 g. (The density of the water at this temperature is 0.997 g/mL.) Assume that the ideal-gas equation applies, and calculate the molar mass of the unknown gas.

#### SOLUTION

**Analyze:** We are given the temperature (31 °C) and pressure (735 torr) for a gas, together with information to determine its volume and mass, and we are asked to calculate its molar mass.

**Plan:** We need to use the mass information given to calculate the volume of the container and the mass of the gas within it. From this we calculate the gas density and then apply Equation 10.11 to calculate the molar mass of the gas.

**Solve:** The mass of the gas is the difference between the mass of the flask filled with gas and that of the empty (evacuated) flask:

$$137.456 \text{ g} - 134.567 \text{ g} = 2.889 \text{ g}$$

The volume of the gas equals the volume of water that the flask can hold. The volume of water is calculated from its mass and density. The mass of the water is the difference between the masses of the full and empty flask:

$$1067.9 \text{ g} - 134.567 \text{ g} = 933.3 \text{ g}$$

By rearranging the equation for density ( $d = m/V$ ), we have

$$V = \frac{m}{d} = \frac{(933.3 \text{ g})}{(0.997 \text{ g/mL})} = 936 \text{ mL} = 0.936 \text{ L}$$

Knowing the mass of the gas (2.889 g) and its volume (936 mL), we can calculate the density of the gas:

$$2.889 \text{ g}/0.936 \text{ L} = 3.09 \text{ g/L}$$

After converting pressure to atmospheres and temperature to kelvins, we can use Equation 10.11 to calculate the molar mass:

$$\begin{aligned} \mathcal{M} &= \frac{dRT}{P} \\ &= \frac{(3.09 \text{ g/L})(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(304 \text{ K})}{(735/760) \text{ atm}} \\ &= 79.7 \text{ g/mol} \end{aligned}$$

**Check:** The units work out appropriately, and the value of molar mass obtained is reasonable for a substance that is gaseous near room temperature.

### PRACTICE EXERCISE

Calculate the average molar mass of dry air if it has a density of 1.17 g/L at 21 °C and 740.0 torr.

**Answer:** 29.0 g/mol

## Volumes of Gases in Chemical Reactions

We are often concerned with knowing the identity of a gas involved as a reactant or product in a chemical reaction, as well as its quantity. Thus, it is useful to be able to calculate the volumes of gases consumed or produced in reactions. Such calculations are based on the use of the mole concept together with balanced chemical equations.  $\infty$  (Section 3.6) We have seen that the coefficients in balanced chemical equations tell us the relative amounts (in moles) of reactants and products in a reaction. The ideal gas equation relates the number of moles of a gas, to  $P$ ,  $V$ , and  $T$ .

## Chemistry Put to Work

### GAS PIPELINES

Most people are quite unaware of the vast network of underground pipelines that undergirds the developed world. Pipelines are used to move massive quantities of liquids and gases over considerable distances. For example, pipelines move natural gas (methane) from huge natural-gas fields in Siberia to Western Europe. Natural gas from Algeria is moved to Italy through a pipeline 120 cm in diameter and 2500 km in length that stretches across the Mediterranean Sea at depths up to 600 m. In the United States the pipeline systems consist of trunk lines, large-diameter pipes for long-distance transport, with branch lines of lower diameter and lower pressure for local transport to and from the trunk lines.

Essentially all substances that are gases at STP are transported commercially by pipeline, including ammonia, carbon dioxide, carbon monoxide, chlorine, ethane, helium, hydrogen, and methane. The largest volume transport by far, though, is natural gas. (Figure 10.15▶) The methane-rich gas from oil and gas wells is processed to remove particulates, water, and various gaseous impurities such as hydrogen sulfide and carbon dioxide. The gas is then compressed to pressures ranging from 3.5 MPa (35 atm) to 10 MPa (100 atm), depending on the age and diameter of the pipe. The long-distance pipelines are about 40 cm in diameter and made of steel. Large compressor stations along the pipeline, spaced at 50- to 100-mile intervals, maintain pressure.

Recall from Figure 5.24 that natural gas is a major source of energy for the United States. To meet this demand, methane must be transported from source wells throughout the United

▲ **Figure 10.15** A natural gas pipeline junction.

States and Canada to all parts of the nation. The total length of pipeline for natural-gas transport in the United States is about  $6 \times 10^5$  km, and growing. The United States is divided into seven regions. The total deliverability of natural gas to the seven regions exceeds  $2.7 \times 10^{12}$  L (measured at STP), which is almost 100 billion cubic feet per day! The volume of the pipelines themselves would be entirely inadequate for managing the enormous quantities of natural gas that are placed into and taken out of the system on a continuing basis. For this reason, underground storage facilities, such as salt caverns and other natural formations, are employed to hold large quantities of gas.

*Related Exercise: 10.117*

#### SAMPLE EXERCISE 10.9 | Relating the Volume of a Gas to the Amount of Another Substance in a Reaction

The safety air bags in automobiles are inflated by nitrogen gas generated by the rapid decomposition of sodium azide,  $\text{NaN}_3$ :

If an air bag has a volume of 36 L and is to be filled with nitrogen gas at a pressure of 1.15 atm at a temperature of 26.0 °C, how many grams of  $\text{NaN}_3$  must be decomposed?

#### SOLUTION

**Analyze:** This is a multistep problem. We are given the volume, pressure, and temperature of the  $\text{N}_2$  gas and the chemical equation for the reaction by which the  $\text{N}_2$  is generated. We must use this information to calculate the number of grams of  $\text{NaN}_3$  needed to obtain the necessary  $\text{N}_2$ .

**Plan:** We need to use the gas data ( $P$ ,  $V$ , and  $T$ ) and the ideal-gas equation to calculate the number of moles of  $\text{N}_2$  gas that should be formed for the air bag to operate correctly. We can then use the balanced equation to determine the number of moles of  $\text{NaN}_3$ . Finally, we can convert the moles of  $\text{NaN}_3$  to grams.

**Solve:** The number of moles of  $\text{N}_2$  is determined using the ideal-gas equation:

$$n = \frac{PV}{RT} = \frac{(1.15 \text{ atm})(36 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(299 \text{ K})} = 1.7 \text{ mol N}_2$$

From here we use the coefficients in the balanced equation to calculate the number of moles of  $\text{NaN}_3$ .

$$(1.7 \text{ mol N}_2) \left( \frac{2 \text{ mol NaN}_3}{3 \text{ mol N}_2} \right) = 1.1 \text{ mol NaN}_3$$

Finally, using the molar mass of  $\text{NaN}_3$ , we convert moles of  $\text{NaN}_3$  to grams:

$$(1.1 \text{ mol NaN}_3) \left( \frac{65.0 \text{ g NaN}_3}{1 \text{ mol NaN}_3} \right) = 72 \text{ g NaN}_3$$

**Check:** The best way to check our approach is to make sure the units cancel properly at each step in the calculation, leaving us with the correct units in the answer, g NaN<sub>3</sub>.

### ■ PRACTICE EXERCISE

In the first step in the industrial process for making nitric acid, ammonia reacts with oxygen in the presence of a suitable catalyst to form nitric oxide and water vapor:

How many liters of NH<sub>3</sub>(g) at 850 °C and 5.00 atm are required to react with 1.00 mol of O<sub>2</sub>(g) in this reaction?

**Answer:** 14.8 L

## 10.6 GAS MIXTURES AND PARTIAL PRESSURES

Thus far we have considered mainly the behavior of pure gases—those that consist of only one substance in the gaseous state. How do we deal with gases composed of a mixture of two or more different substances? While studying the properties of air, John Dalton (Section 2.1) made an important observation: *The total pressure of a mixture of gases equals the sum of the pressures that each would exert if it were present alone.* The pressure exerted by a particular component of a mixture of gases is called the **partial pressure** of that gas. Dalton's observation is known as **Dalton's law of partial pressures**.

### GIVE IT SOME THOUGHT

How is the pressure exerted by N<sub>2</sub> gas affected when some O<sub>2</sub> is introduced into a container if the temperature and volume remain constant?

If we let  $P_t$  be the total pressure of a mixture of gases and  $P_1, P_2, P_3,$  and so forth be the partial pressures of the individual gases, we can write Dalton's law as follows:

$$P_t = P_1 + P_2 + P_3 + \cdots \quad [10.12]$$

This equation implies that each gas in the mixture behaves independently of the others, as we can see by the following analysis. Let  $n_1, n_2, n_3,$  and so forth be the number of moles of each of the gases in the mixture and  $n_t$  be the total number of moles of gas ( $n_t = n_1 + n_2 + n_3 + \cdots$ ).

If each of the gases obeys the ideal-gas equation, we can write

$$P_1 = n_1 \left( \frac{RT}{V} \right); \quad P_2 = n_2 \left( \frac{RT}{V} \right); \quad P_3 = n_3 \left( \frac{RT}{V} \right); \quad \text{and so forth}$$

All the gases in the mixture are at the same temperature and occupy the same volume. Therefore, by substituting into Equation 10.12, we obtain

$$P_t = (n_1 + n_2 + n_3 + \cdots) \frac{RT}{V} = n_t \left( \frac{RT}{V} \right) \quad [10.13]$$

That is, at constant temperature and constant volume the total pressure is determined by the total number of moles of gas present, whether that total represents just one substance or a mixture.

**SAMPLE EXERCISE 10.10** | Applying Dalton's Law of Partial Pressures

A gaseous mixture made from 6.00 g O<sub>2</sub> and 9.00 g CH<sub>4</sub> is placed in a 15.0-L vessel at 0 °C. What is the partial pressure of each gas, and what is the total pressure in the vessel?

**SOLUTION**

**Analyze:** We need to calculate the pressure for two different gases in the same volume and at the same temperature.

**Plan:** Because each gas behaves independently, we can use the ideal-gas equation to calculate the pressure that each would exert if the other were not present. The total pressure is the sum of these two partial pressures.

**Solve:** We must first convert the mass of each gas to moles:

$$n_{\text{O}_2} = (6.00 \text{ g O}_2) \left( \frac{1 \text{ mol O}_2}{32.0 \text{ g O}_2} \right) = 0.188 \text{ mol O}_2$$

$$n_{\text{CH}_4} = (9.00 \text{ g CH}_4) \left( \frac{1 \text{ mol CH}_4}{16.0 \text{ g CH}_4} \right) = 0.563 \text{ mol CH}_4$$

We can now use the ideal-gas equation to calculate the partial pressure of each gas:

$$P_{\text{O}_2} = \frac{n_{\text{O}_2} RT}{V} = \frac{(0.188 \text{ mol})(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(273 \text{ K})}{15.0 \text{ L}} = 0.281 \text{ atm}$$

$$P_{\text{CH}_4} = \frac{n_{\text{CH}_4} RT}{V} = \frac{(0.563 \text{ mol})(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(273 \text{ K})}{15.0 \text{ L}} = 0.841 \text{ atm}$$

According to Dalton's law (Equation 10.12), the total pressure in the vessel is the sum of the partial pressures:

$$P_t = P_{\text{O}_2} + P_{\text{CH}_4} = 0.281 \text{ atm} + 0.841 \text{ atm} = 1.122 \text{ atm}$$

**Check:** Performing rough estimates is good practice, even when you may not feel that you need to do it to check an answer. In this case a pressure of roughly 1 atm seems right for a mixture of about 0.2 mol O<sub>2</sub> (that is, 6/32) and a bit more than 0.5 mol CH<sub>4</sub> (that is, 9/16), together in a 15-L volume, because one mole of an ideal gas at 1 atm pressure and 0 °C occupies about 22 L.

**PRACTICE EXERCISE**

What is the total pressure exerted by a mixture of 2.00 g of H<sub>2</sub> and 8.00 g of N<sub>2</sub> at 273 K in a 10.0-L vessel?

*Answer:* 2.86 atm

**Partial Pressures and Mole Fractions**

Because each gas in a mixture behaves independently, we can relate the amount of a given gas in a mixture to its partial pressure. For an ideal gas,  $P = nRT/V$  and so we can write

$$\frac{P_1}{P_t} = \frac{n_1 RT/V}{n_t RT/V} = \frac{n_1}{n_t} \quad [10.14]$$

The ratio  $n_1/n_t$  is called the mole fraction of gas 1, which we denote  $X_1$ . The **mole fraction**,  $X$ , is a dimensionless number that expresses the ratio of the number of moles of one component to the total number of moles in the mixture. We can rearrange Equation 10.14 to give

$$P_1 = \left( \frac{n_1}{n_t} \right) P_t = X_1 P_t \quad [10.15]$$

Thus, the partial pressure of a gas in a mixture is its mole fraction times the total pressure.

The mole fraction of N<sub>2</sub> in air is 0.78 (that is, 78% of the molecules in air are N<sub>2</sub>). If the total barometric pressure is 760 torr, then the partial pressure of N<sub>2</sub> is

$$P_{\text{N}_2} = (0.78) (760 \text{ torr}) = 590 \text{ torr}$$

This result makes intuitive sense: Because N<sub>2</sub> makes up 78% of the mixture, it contributes 78% of the total pressure.

**SAMPLE EXERCISE 10.11** | Relating Mole Fractions and Partial Pressures

A study of the effects of certain gases on plant growth requires a synthetic atmosphere composed of 1.5 mol percent CO<sub>2</sub>, 18.0 mol percent O<sub>2</sub>, and 80.5 mol percent Ar. (a) Calculate the partial pressure of O<sub>2</sub> in the mixture if the total pressure of the atmosphere is to be 745 torr. (b) If this atmosphere is to be held in a 121-L space at 295 K, how many moles of O<sub>2</sub> are needed?

**SOLUTION**

**Analyze:** (a) We first need to calculate the partial pressure of O<sub>2</sub> given its mole percentage and the total pressure of the mixture. (b) We need to calculate the number of moles of O<sub>2</sub> in the mixture given its volume (121 L), temperature (745 torr), and partial pressure (from part (a)).

**Plan:** (a) We will calculate the partial pressures using Equation 10.15. (b) We will then use  $P_{O_2}$ ,  $V$ , and  $T$  together with the ideal-gas equation to calculate the number of moles of O<sub>2</sub>,  $n_{O_2}$ .

**Solve:** (a) The mole percent is just the mole fraction times 100. Therefore, the mole fraction of O<sub>2</sub> is 0.180. Using Equation 10.15, we have

$$P_{O_2} = (0.180)(745 \text{ torr}) = 134 \text{ torr}$$

(b) Tabulating the given variables and changing them to appropriate units, we have

$$P_{O_2} = (134 \text{ torr}) \left( \frac{1 \text{ atm}}{760 \text{ torr}} \right) = 0.176 \text{ atm}$$

$$V = 121 \text{ L}$$

$$n_{O_2} = ?$$

$$R = 0.0821 \frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}$$

$$T = 295 \text{ K}$$

Solving the ideal-gas equation for  $n_{O_2}$ , we have

$$\begin{aligned} n_{O_2} &= P_{O_2} \left( \frac{V}{RT} \right) \\ &= (0.176 \text{ atm}) \frac{121 \text{ L}}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(295 \text{ K})} = 0.879 \text{ mol} \end{aligned}$$

**Check:** The units check out satisfactorily, and the answer seems to be the right order of magnitude.

**PRACTICE EXERCISE**

From data gathered by *Voyager 1*, scientists have estimated the composition of the atmosphere of Titan, Saturn's largest moon. The total pressure on the surface of Titan is 1220 torr. The atmosphere consists of 82 mol percent N<sub>2</sub>, 12 mol percent Ar, and 6.0 mol percent CH<sub>4</sub>. Calculate the partial pressure of each of these gases in Titan's atmosphere.

**Answer:**  $1.0 \times 10^3$  torr N<sub>2</sub>,  $1.5 \times 10^2$  torr Ar, and 73 torr CH<sub>4</sub>

## Collecting Gases over Water

An experiment that is often encountered in general chemistry laboratories involves determining the number of moles of gas collected from a chemical reaction. Sometimes this gas is collected over water. For example, solid potassium chlorate, KClO<sub>3</sub>, can be decomposed by heating it in a test tube in an arrangement such as that shown in Figure 10.16. The balanced equation for the reaction is

The oxygen gas is collected in a bottle that is initially filled with water and then inverted in a water pan.

The volume of gas collected is measured by raising or lowering the bottle as necessary until the water levels inside and outside the bottle are the same. When this condition is met, the pressure inside the bottle is equal to the atmospheric pressure outside. The total pressure inside is the sum of the pressure of gas collected and the pressure of water vapor in equilibrium with liquid water.

$$P_{\text{total}} = P_{\text{gas}} + P_{\text{H}_2\text{O}} \quad [10.17]$$

The pressure exerted by water vapor,  $P_{\text{H}_2\text{O}}$ , at various temperatures is listed in Appendix B.

◀ **Figure 10.16 Collecting a water-insoluble gas over water.** (a) A solid is heated, releasing a gas, which is bubbled through water into a collection bottle. (b) When the gas has been collected, the bottle is raised or lowered so that the water levels inside and outside the bottle are equal. The total pressure of the gases inside the bottle is then equal to the atmospheric pressure.

### ■ SAMPLE EXERCISE 10.12 Calculating the Amount of Gas Collected over Water

A sample of  $\text{KClO}_3$  is partially decomposed (Equation 10.16), producing  $\text{O}_2$  gas that is collected over water as in Figure 10.16. The volume of gas collected is 0.250 L at  $26^\circ\text{C}$  and 765 torr total pressure. (a) How many moles of  $\text{O}_2$  are collected? (b) How many grams of  $\text{KClO}_3$  were decomposed?

#### SOLUTION

**(a) Analyze:** We need to calculate the number of moles of  $\text{O}_2$  gas in a container that also contains water vapor.

**Plan:** If we tabulate the information presented, we will see that values are given for  $V$  and  $T$ . To use the ideal-gas equation to calculate the unknown,  $n_{\text{O}_2}$ , we also must know the partial pressure of  $\text{O}_2$  in the system. We can calculate the partial pressure of  $\text{O}_2$  from the total pressure (765 torr) and the vapor pressure of water.

**Solve:** The partial pressure of the  $\text{O}_2$  gas is the difference between the total pressure, 765 torr, and the pressure of the water vapor at  $26^\circ\text{C}$ , 25 torr (Appendix B):

$$P_{\text{O}_2} = 765 \text{ torr} - 25 \text{ torr} = 740 \text{ torr}$$

We can use the ideal-gas equation to calculate the number of moles of  $\text{O}_2$ :

$$n_{\text{O}_2} = \frac{P_{\text{O}_2} V}{RT} = \frac{(740 \text{ torr})(1 \text{ atm}/760 \text{ torr})(0.250 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(299 \text{ K})} = 9.92 \times 10^{-3} \text{ mol O}_2$$

**(b) Analyze:** We now need to calculate the number of moles of reactant  $\text{KClO}_3$  decomposed.

**Plan:** We can use the number of moles of  $\text{O}_2$  formed and the balanced chemical equation to determine the number of moles of  $\text{KClO}_3$  decomposed, which we can then convert to grams of  $\text{KClO}_3$ .

**Solve:** From Equation 10.16, we have  $2 \text{ mol KClO}_3 \approx 3 \text{ mol O}_2$ . The molar mass of  $\text{KClO}_3$  is 122.6 g/mol. Thus, we can convert the moles of  $\text{O}_2$  that we found in part (a) to moles of  $\text{KClO}_3$  and then to grams of  $\text{KClO}_3$ :

$$(9.92 \times 10^{-3} \text{ mol O}_2) \left( \frac{2 \text{ mol KClO}_3}{3 \text{ mol O}_2} \right) \left( \frac{122.6 \text{ g KClO}_3}{1 \text{ mol KClO}_3} \right) = 0.811 \text{ g KClO}_3$$

**Check:** As always, we make sure that the units cancel appropriately in the calculations. In addition, the numbers of moles of  $\text{O}_2$  and  $\text{KClO}_3$  seem reasonable, given the small volume of gas collected.

**Comment:** Many chemical compounds that react with water and water vapor would be degraded by exposure to wet gas. Thus, in research laboratories gases are often dried by passing wet gas over a substance that absorbs water (a *desiccant*), such as calcium sulfate,  $\text{CaSO}_4$ . Calcium sulfate crystals are sold as a desiccant under the trade name Drierite™.

#### ■ PRACTICE EXERCISE

Ammonium nitrite,  $\text{NH}_4\text{NO}_2$ , decomposes upon heating to form  $\text{N}_2$  gas:

When a sample of  $\text{NH}_4\text{NO}_2$  is decomposed in a test tube, as in Figure 10.16, 511 mL of  $\text{N}_2$  gas is collected over water at  $26^\circ\text{C}$  and 745 torr total pressure. How many grams of  $\text{NH}_4\text{NO}_2$  were decomposed?

**Answer:** 1.26 g

## 10.7 KINETIC-MOLECULAR THEORY

The ideal-gas equation describes *how* gases behave, but it does not explain *why* they behave as they do. Why does a gas expand when heated at constant pressure? Or, why does its pressure increase when the gas is compressed at constant temperature? To understand the physical properties of gases, we need a model that helps us picture what happens to gas particles as experimental conditions such as pressure or temperature change. Such a model, known as the **kinetic-molecular theory**, was developed over a period of about 100 years, culminating in 1857 when Rudolf Clausius (1822–1888) published a complete and satisfactory form of the theory.

The kinetic-molecular theory (the theory of moving molecules) is summarized by the following statements:

1. Gases consist of large numbers of molecules that are in continuous, random motion. (The word *molecule* is used here to designate the smallest particle of any gas; some gases, such as the noble gases, consist of individual atoms.)
2. The combined volume of all the molecules of the gas is negligible relative to the total volume in which the gas is contained.
3. Attractive and repulsive forces between gas molecules are negligible.
4. Energy can be transferred between molecules during collisions, but the *average* kinetic energy of the molecules does not change with time, as long as the temperature of the gas remains constant. In other words, the collisions are perfectly elastic.
5. The average kinetic energy of the molecules is proportional to the absolute temperature. At any given temperature the molecules of all gases have the same average kinetic energy.

▲ **Figure 10.17 The molecular origin of gas pressure.** The pressure exerted by a gas is caused by collisions of the gas molecules with the walls of their container.

The kinetic-molecular theory explains both pressure and temperature at the molecular level. The pressure of a gas is caused by collisions of the molecules with the walls of the container, as shown in Figure 10.17 ◀. The magnitude of the pressure is determined by both how often and how forcefully the molecules strike the walls.

The absolute temperature of a gas is a measure of the *average* kinetic energy of its molecules. If two different gases are at the same temperature, their molecules have the same average kinetic energy (statement 5 of the kinetic-molecular theory). If the absolute temperature of a gas is doubled, the average kinetic energy of its molecules doubles. Thus, molecular motion increases with increasing temperature.

### GIVE IT SOME THOUGHT

Consider three samples of gas: HCl at 298 K, H<sub>2</sub> at 298 K, and O<sub>2</sub> at 350 K. Compare the average kinetic energies of the molecules in the three samples.

### Distributions of Molecular Speed

Although the molecules in a sample of gas have an *average* kinetic energy and hence an average speed, the individual molecules move at varying speeds. The moving molecules collide frequently with other molecules. Momentum is conserved in each collision, but one of the colliding molecules might be deflected off at high speed while the other is nearly stopped. The result is that the molecules at any instant have a wide range of speeds. Figure 10.18 ► illustrates the distribution of molecular speeds for nitrogen gas at 0 °C (blue line) and at 100 °C (red line). The curve shows us the fraction of molecules moving at each

speed. At higher temperatures, a larger fraction of molecules moves at greater speeds; the distribution curve has shifted to the right toward higher speeds and hence toward higher average kinetic energy. The peak of each curve represents the most probable speed (the speed of the largest number of molecules). Notice that the blue curve (0 °C) has a peak at about  $4 \times 10^2$  m/s, whereas the red curve (100 °C) has a peak at a higherspeed, about  $5 \times 10^2$  m/s.

Figure 10.18 also shows the value of the **root-mean-square (rms) speed**,  $u$ , of the molecules at each temperature. This quantity is the speed of a molecule possessing average kinetic energy. The rms speed is not quite the same as the average (mean) speed. The difference between the two, however, is small.\* Notice that the rms speed is higher at 100 °C than at 0 °C. Notice also that the distribution curve broadens as we go to a higher temperature.

The rms speed is important because the average kinetic energy of the gas molecules in a sample,  $\epsilon$ , is related directly to  $u^2$ :

$$\epsilon = \frac{1}{2} mu^2 \quad [10.18]$$

where  $m$  is the mass of an individual molecule. Mass does not change with temperature. Thus, the increase in the average kinetic energy as the temperature increases implies that the rms speed (and also the average speed) of molecules likewise increases as temperature increases.

### GIVE IT SOME THOUGHT

Consider three samples of gas all at 298 K: HCl, H<sub>2</sub>, and O<sub>2</sub>. List the molecules in order of increasing average speed.

### Application to the Gas Laws

The empirical observations of gas properties as expressed by the various gas laws are readily understood in terms of the kinetic-molecular theory. The following examples illustrate this point:

1. *Effect of a volume increase at constant temperature:* A constant temperature means that the average kinetic energy of the gas molecules remains unchanged. This in turn means that the rms speed of the molecules,  $u$ , is unchanged. If the volume is increased, however, the molecules must move a longer distance between collisions. Consequently, there are fewer collisions per unit time with the container walls, and pressure decreases. Thus, the model accounts in a simple way for Boyle's law.
2. *Effect of a temperature increase at constant volume:* An increase in temperature means an increase in the average kinetic energy of the molecules and thus an increase in  $u$ . If there is no change in volume, there will be more collisions with the walls per unit time. Furthermore, the change in momentum in each collision increases (the molecules strike the walls more forcefully). Hence, the model explains the observed pressure increase.

\*To illustrate the difference between rms speed and average speed, suppose that we have four objects with speeds of 4.0, 6.0, 10.0, and 12.0 m/s. Their average speed is  $\frac{1}{4}(4.0 + 6.0 + 10.0 + 12.0) = 8.0$  m/s. The rms speed,  $u$ , however, is the square root of the average squared speeds of the molecules:

$$\sqrt{\frac{1}{4}(4.0^2 + 6.0^2 + 10.0^2 + 12.0^2)} = \sqrt{74.0} = 8.6 \text{ m/s}$$

For an ideal gas the average speed equals  $0.921 \times u$ . Thus, the average speed is directly proportional to the rms speed, and the two are in fact nearly equal.

▲ **Figure 10.18 The effect of temperature on molecular speeds.** Distribution of molecular speeds for nitrogen at 0 °C (blue line) and 100 °C (red line). Increasing temperature increases both the most probable speed (curve maximum) and the rms speed,  $u$ , which is indicated by the vertical dashed line.

## A Closer Look

### THE IDEAL-GAS EQUATION

Beginning with the five statements given in the text for the kinetic-molecular theory, it is possible to derive the ideal-gas equation. Rather than proceed through a derivation, let's consider in somewhat qualitative terms how the ideal-gas equation might follow. As we have seen, pressure is force per unit area. [\(Section 10.2\)](#) The total force of the molecular collisions on the walls and hence the pressure produced by these collisions depend both on how strongly the molecules strike the walls (impulse imparted per collision) and on the rate at which these collisions occur:

$$P \propto \text{impulse imparted per collision} \times \text{rate of collisions}$$

For a molecule traveling at the rms speed,  $u$ , the impulse imparted by a collision with a wall depends on the momentum of the molecule; that is, it depends on the product of its mass and speed,  $mu$ . The rate of collisions is proportional to both the number of molecules per unit volume,  $n/V$ , and their speed,  $u$ . If there are more molecules in a container, there will be more frequent collisions with the container walls. As the molecular speed increases or the volume of the container decreases, the time required for molecules to traverse the distance from one wall to another is reduced, and the molecules collide more frequently with the walls. Thus, we have

$$P \propto mu \times \frac{n}{V} \times u \propto \frac{nm u^2}{V} \quad [10.19]$$

Because the average kinetic energy,  $\frac{1}{2} m u^2$ , is proportional to temperature, we have  $nm u^2 \propto T$ . Making this substitution into Equation 10.19 gives

$$P \propto \frac{n(mu^2)}{V} \propto \frac{nT}{V} \quad [10.20]$$

Let's now convert the proportionality sign to an equal sign by expressing  $n$  as the number of moles of gas. We then insert a proportionality constant,  $R$ , the gas constant:

$$P = \frac{nRT}{V} \quad [10.21]$$

This expression is the ideal-gas equation.

An eminent Swiss mathematician, Daniel Bernoulli (1700–1782), conceived of a model for gases that was, for all practical purposes, the same as the kinetic theory model. From this model, Bernoulli derived Boyle's law and the ideal-gas equation. His was one of the first examples in science of developing a mathematical model from a set of assumptions, or hypothetical statements. However, Bernoulli's work on this subject was completely ignored, only to be rediscovered a hundred years later by Clausius and others. It was ignored because it conflicted with popular beliefs and was in conflict with Isaac Newton's incorrect model for gases. Those idols of the times had to fall before the way was clear for the kinetic-molecular theory. As this story illustrates, science is not a straight road running from here to the "truth." The road is built by humans, so it zigs and zags.

**Related Exercises:** 10.71, 10.72, 10.73, and 10.74

#### SAMPLE EXERCISE 10.13 | Applying the Kinetic-Molecular Theory

A sample of  $O_2$  gas initially at STP is compressed to a smaller volume at constant temperature. What effect does this change have on (a) the average kinetic energy of  $O_2$  molecules, (b) the average speed of  $O_2$  molecules, (c) the total number of collisions of  $O_2$  molecules with the container walls in a unit time, (d) the number of collisions of  $O_2$  molecules with a unit area of container wall per unit time?

#### SOLUTION

**Analyze:** We need to apply the concepts of the kinetic-molecular theory to a situation in which a gas is compressed at constant temperature.

**Plan:** We will determine how each of the quantities in (a)–(d) is affected by the change in volume at constant temperature.

**Solve:** (a) The average kinetic energy of the  $O_2$  molecules is determined only by temperature. Thus the average kinetic energy is unchanged by the compression of  $O_2$  at constant temperature. (b) If the average kinetic energy of  $O_2$  molecules does not change, the average speed remains constant. (c) The total number of collisions with the container walls per unit time must increase because the molecules are moving within a smaller volume but with the same average speed as before. Under these conditions they must encounter a wall more frequently. (d) The number of collisions with a unit area of wall per unit time increases because the total number of collisions with the walls per unit time increases and the area of the walls decreases.

**Check:** In a conceptual exercise of this kind, there is no numerical answer to check. All we can check in such cases is our reasoning in the course of solving the problem.

#### PRACTICE EXERCISE

How is the rms speed of  $N_2$  molecules in a gas sample changed by (a) an increase in temperature, (b) an increase in volume, (c) mixing with a sample of Ar at the same temperature?

**Answers:** (a) increases, (b) no effect, (c) no effect

## 10.8 MOLECULAR EFFUSION AND DIFFUSION

According to the kinetic-molecular theory, the average kinetic energy of any collection of gas molecules,  $\frac{1}{2}mu^2$ , has a specific value at a given temperature. Thus, a gas composed of lightweight particles, such as He, will have the same average kinetic energy as one composed of much heavier particles, such as Xe, provided the two gases are at the same temperature. The mass,  $m$ , of the particles in the lighter gas is smaller than that in the heavier gas. Consequently, the particles of the lighter gas must have a higher rms speed,  $u$ , than the particles of the heavier one. The following equation, which expresses this fact quantitatively, can be derived from kinetic-molecular theory:

$$u = \sqrt{\frac{3RT}{\mathcal{M}}} \quad [10.22]$$

Because the molar mass,  $\mathcal{M}$ , appears in the denominator, the less massive the gas molecules, the higher the rms speed,  $u$ .

Figure 10.19 shows the distribution of molecular speeds for several gases at 25 °C. Notice how the distributions are shifted toward higher speeds for gases of lower molar masses.

▲ **Figure 10.19** The effect of molecular mass on molecular speeds. The distributions of molecular speeds for different gases are compared at 25 °C. The molecules with lower molecular masses have higher rms speeds.

### ■ SAMPLE EXERCISE 10.14 | Calculating a Root-Mean-Square Speed

Calculate the rms speed,  $u$ , of an  $N_2$  molecule at 25 °C.

#### SOLUTION

**Analyze:** We are given the identity of the gas and the temperature, the two quantities we need to calculate the rms speed.

**Plan:** We will calculate the rms speed using Equation 10.22.

**Solve:** In using Equation 10.22, we should convert each quantity to SI units so that all the units are compatible. We will also use  $R$  in units of J/mol·K (Table 10.2) to make the units cancel correctly.

$$T = 25 + 273 = 298 \text{ K}$$

$$\mathcal{M} = 28.0 \text{ g/mol} = 28.0 \times 10^{-3} \text{ kg/mol}$$

$$R = 8.314 \text{ J/mol}\cdot\text{K} = 8.314 \text{ kg}\cdot\text{m}^2/\text{s}^2\cdot\text{mol}\cdot\text{K} \quad (\text{These units follow from the fact that } 1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2)$$

$$u = \sqrt{\frac{3(8.314 \text{ kg}\cdot\text{m}^2/\text{s}^2\cdot\text{mol}\cdot\text{K})(298 \text{ K})}{28.0 \times 10^{-3} \text{ kg/mol}}} = 5.15 \times 10^2 \text{ m/s}$$

**Comment:** This corresponds to a speed of 1150 mi/hr. Because the average molecular weight of air molecules is slightly greater than that of  $N_2$ , the rms speed of air molecules is a little slower than that for  $N_2$ . The speed at which sound propagates through air is about 350 m/s, a value about two-thirds the average rms speed for air molecules.

#### ■ PRACTICE EXERCISE

What is the rms speed of an He atom at 25 °C?

**Answer:**  $1.36 \times 10^3 \text{ m/s}$

▲ **Figure 10.20 Effusion.** The top half of this cylinder is filled with a gas, and the bottom half is an evacuated space. Gas molecules effuse through a pinhole in the partitioning wall only when they happen to hit the hole.

The dependence of molecular speeds on mass has several interesting consequences. The first phenomenon is **effusion**, which is the escape of gas molecules through a tiny hole into an evacuated space, as shown in Figure 10.20 ◀. The second is **diffusion**, which is the spread of one substance throughout a space or throughout a second substance. For example, the molecules of a perfume diffuse throughout a room.

### Graham's Law of Effusion

In 1846 Thomas Graham (1805–1869) discovered that the effusion rate of a gas is inversely proportional to the square root of its molar mass. Assume that we have two gases at the same temperature and pressure in containers with identical pinholes. If the rates of effusion of the two substances are  $r_1$  and  $r_2$  and their respective molar masses are  $M_1$  and  $M_2$ , **Graham's law** states

$$\frac{r_1}{r_2} = \sqrt{\frac{M_2}{M_1}} \quad [10.23]$$

Equation 10.23 compares the *rates* of effusion of two different gases under identical conditions, and it indicates that the lighter gas effuses more rapidly.

▲ **Figure 10.21 An illustration of Graham's law.**

Figure 10.20 illustrates the basis of Graham's law. The only way for a molecule to escape from its container is for it to "hit" the hole in the partitioning wall. The faster the molecules are moving, the greater is the likelihood that a molecule will hit the hole and effuse. This implies that the rate of effusion is directly proportional to the rms speed of the molecules. Because  $R$  and  $T$  are constant, we have, from Equation 10.22

$$\frac{r_1}{r_2} = \frac{u_1}{u_2} = \sqrt{\frac{3RT/M_1}{3RT/M_2}} = \sqrt{\frac{M_2}{M_1}} \quad [10.24]$$

As expected from Graham's law, helium escapes from containers through tiny pinhole leaks more rapidly than other gases of higher molecular weight (Figure 10.21 ◀).

### ■ SAMPLE EXERCISE 10.15 | Applying Graham's Law

An unknown gas composed of homonuclear diatomic molecules effuses at a rate that is only 0.355 times that of  $O_2$  at the same temperature. Calculate the molar mass of the unknown, and identify it.

#### SOLUTION

**Analyze:** We are given the rate of effusion of an unknown gas relative to that of  $O_2$ , and we are asked to find the molar mass and identity of the unknown. Thus, we need to connect relative rates of effusion to relative molar masses.

**Plan:** We can use Graham's law of effusion, Equation 10.23, to determine the molar mass of the unknown gas. If we let  $r_x$  and  $M_x$  represent the rate of effusion and molar mass of the unknown gas, Equation 10.23 can be written as follows:

$$\frac{r_x}{r_{O_2}} = \sqrt{\frac{M_{O_2}}{M_x}}$$

**Solve:** From the information given,

$$r_x = 0.355 \times r_{O_2}$$

Thus,

$$\frac{r_x}{r_{O_2}} = 0.355 = \sqrt{\frac{32.0 \text{ g/mol}}{M_x}}$$

We now solve for the unknown molar mass,  $M_x$

$$\frac{32.0 \text{ g/mol}}{M_x} = (0.355)^2 = 0.126$$

$$M_x = \frac{32.0 \text{ g/mol}}{0.126} = 254 \text{ g/mol}$$

Because we are told that the unknown gas is composed of homonuclear diatomic molecules, it must be an element. The molar mass must represent twice the atomic weight of the atoms in the unknown gas. We conclude that the unknown gas is  $I_2$ .

### ■ PRACTICE EXERCISE

Calculate the ratio of the effusion rates of  $N_2$  and  $O_2$ ,  $r_{N_2}/r_{O_2}$ .

**Answer:**  $r_{N_2}/r_{O_2} = 1.07$

## Diffusion and Mean Free Path

Diffusion, like effusion, is faster for lower mass molecules than for higher mass ones. In fact, Graham's law, Equation 10.23, approximates the ratio of rates of diffusion of two gases under identical experimental conditions. Nevertheless, molecular collisions make diffusion more complicated than effusion.

We can see from the horizontal scale in Figure 10.19 that the speeds of molecules are quite high. For example, the average speed of  $N_2$  at room temperature is 515 m/s (1150 mi/hr). In spite of this high speed, if someone opens a vial of perfume at one end of a room, some time elapses—perhaps a few minutes—before the scent is detected at the other end of the room. The diffusion of gases is much slower than molecular speeds because of molecular collisions.\* These

\*The rate at which the perfume moves across the room also depends on how well stirred the air is from temperature gradients and the movement of people. Nevertheless, even with the aid of these factors, it still takes much longer for the molecules to traverse the room than one would expect from the rms speed alone.

The fact that lighter molecules move at higher average speeds than more massive ones has many interesting consequences and applications. For example, the effort to develop the atomic bomb during World War II required scientists to separate the relatively low-abundance uranium isotope  $^{235}\text{U}$  (0.7%) from the much more abundant  $^{238}\text{U}$  (99.3%). This separation was accomplished by converting the uranium into a volatile compound,  $\text{UF}_6$ , that was then allowed to pass through porous barriers. Because of the diameters of the pores, this process is not a simple effusion. Nevertheless, the dependence on molar mass is essentially the same. The slight difference in molar mass between the two hexafluorides,  $^{235}\text{UF}_6$  and  $^{238}\text{UF}_6$ , caused the molecules to move at slightly different rates:

$$\frac{r_{235}}{r_{238}} = \sqrt{\frac{352.04}{349.03}} = 1.0043$$

Thus, the gas initially appearing on the opposite side of the barrier was very slightly enriched in the lighter molecule. The effusion process was repeated thousands of times, leading to a nearly complete separation of the two isotopes of uranium.

Separation of uranium isotopes by effusion has been largely replaced by a technique that uses centrifuges. In this procedure, cylindrical rotors containing  $\text{UF}_6$  vapor spin at high speed inside an evacuated casing. Molecules containing the heavier  $^{238}\text{U}$  isotope move closer to the spinning walls, whereas the molecules containing the lighter  $^{235}\text{U}$  isotope remain in the middle of the cylinders. A stream of gas moves the  $\text{UF}_6$  from the center of one centrifuge into another. Plants that use centrifuges consume less energy and can be constructed in a more compact, modular fashion than those that rely on effusion. Such plants are frequently in the news as countries such as Iran and North Korea enrich uranium in the  $^{235}\text{U}$  isotope for both nuclear power and nuclear weaponry.

*Related Exercises: 10.79 and 10.80*

▲ **Figure 10.22 Diffusion of a gas molecule.** For clarity, no other gas molecules in the container are shown. The path of the molecule of interest begins at the dot. Each short segment of line represents travel between collisions. The blue arrow indicates the net distance traveled by the molecule.

collisions occur quite frequently for a gas at atmospheric pressure—about  $10^{10}$  times per second for each molecule. Collisions occur because real gas molecules have finite volumes.

Because of molecular collisions, the direction of motion of a gas molecule is constantly changing. Therefore, the diffusion of a molecule from one point to another consists of many short, straight-line segments as collisions buffet it around in random directions, as depicted in Figure 10.22. First the molecule moves in one direction, then in another; one instant at high speed, the next at low speed.

The average distance traveled by a molecule between collisions is called the **mean free path** of the molecule. The mean free path varies with pressure as the following analogy illustrates. Imagine walking through a shopping mall. When the mall is very crowded (high pressure), the average distance you can walk before bumping into someone is short (short mean free path). When the mall is empty (low pressure), you can walk a long way (long mean free path) before bumping into someone. The mean free path for air molecules at sea level is about 60 nm ( $6 \times 10^{-8}$  m). At about 100 km in altitude, where the air density is much lower, the mean free path is about 10 cm, over 1 million times longer than at Earth's surface.

### GIVE IT SOME THOUGHT

Will the following changes increase, decrease, or have no effect on the mean free path of the gas molecules in a sample of gas? (a) Increasing pressure, (b) increasing temperature?

## 10.9 REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR

Although the ideal-gas equation is a very useful description of gases, all real gases fail to obey the relationship to some degree. The extent to which a real gas departs from ideal behavior can be seen by rearranging the ideal-gas equation to solve for  $n$ :

$$\frac{PV}{RT} = n \quad [10.25]$$

▲ **Figure 10.23** The effect of pressure on the behavior of several gases. The ratios of  $PV/RT$  versus pressure are compared for one mole of several gases at 300 K. The data for  $\text{CO}_2$  are at 313 K because under high pressure  $\text{CO}_2$  liquefies at 300 K. The dashed horizontal line shows the behavior of an ideal gas.

For one mole of ideal gas ( $n = 1$ ) the quantity  $PV/RT$  equals 1 at all pressures. In Figure 10.23 ▲  $PV/RT$  is plotted as a function of  $P$  for one mole of several different gases. At high pressures the deviation from ideal behavior ( $PV/RT = 1$ ) is large and is different for each gas. *Real gases, therefore, do not behave ideally at high pressure.* At lower pressures (usually below 10 atm), however, the deviation from ideal behavior is small, and we can use the ideal-gas equation without generating serious error.

The deviation from ideal behavior also depends on temperature. Figure 10.24 ▲ shows graphs of  $PV/RT$  versus  $P$  for 1 mol of  $\text{N}_2$  at three temperatures. As temperature increases, the behavior of the gas more nearly approaches that of the ideal gas. In general, *the deviations from ideal behavior increase as temperature decreases*, becoming significant near the temperature at which the gas is converted into a liquid.

### GIVE IT SOME THOUGHT

Would you expect helium gas to deviate from ideal behavior more at (a) 100 K and 1 atm, (b) 100 K and 5 atm, or (c) 300 K and 2 atm?

The basic assumptions of the kinetic-molecular theory give us insight into why real gases deviate from ideal behavior. The molecules of an ideal gas are assumed to occupy no space and have no attractions for one another. *Real molecules, however, do have finite volumes, and they do attract one another.* As shown in Figure 10.25 ►, the free, unoccupied space in which molecules can move is somewhat less than the container volume. At relatively low pressures the volume of the gas molecules is negligible relative to the container volume. Thus, the free volume available to the molecules is essentially the entire volume of the container. As the pressure increases, however, the free space in which the molecules can move becomes a smaller fraction of the container volume. Under these conditions, therefore, gas volumes tend to be slightly greater than those predicted by the ideal-gas equation.

▲ **Figure 10.24** The effect of temperature and pressure on the behavior of nitrogen gas. The ratios of  $PV/RT$  versus pressure are shown for 1 mol of nitrogen gas at three temperatures. As temperature increases, the gas more closely approaches ideal behavior, which is represented by the dashed horizontal line.

### ▼ Figure 10.25 Comparing the volume of gas molecules to the container volume.

In (a), at low pressure, the combined volume of the gas molecules is small relative to the container volume, and we can approximate the empty space between molecules as being equal to the container volume. In (b), at high pressure, the combined volume of the gas molecules is a larger fraction of the total space available. Now we must account for the volume of the molecules themselves in determining the empty space available for the motion of the gas molecules.

▲ **Figure 10.26** The effect of intermolecular forces on gas pressure. The molecule that is about to strike the wall experiences attractive forces from nearby gas molecules, and its impact on the wall is thereby lessened. The lessened impact means the molecule exerts a lower-than-expected pressure on the wall. The attractive forces become significant only under high-pressure conditions, when the average distance between molecules is small.

In addition, the attractive forces between molecules come into play at short distances, as when molecules are crowded together at high pressures. Because of these attractive forces, the impact of a given molecule with the wall of the container is lessened. If we could stop the action in a gas, the positions of the molecules might resemble the illustration in Figure 10.26 ◀. The molecule about to make contact with the wall experiences the attractive forces of nearby molecules. These attractions lessen the force with which the molecule hits the wall. As a result, the pressure is less than that of an ideal gas. This effect serves to decrease  $PV/RT$  below its ideal value, as seen in Figure 10.23. When the pressure is sufficiently high, however, the volume effects dominate and  $PV/RT$  increases to above the ideal value.

Temperature determines how effective attractive forces between gas molecules are. As a gas is cooled, the average kinetic energy of the molecules decreases, but intermolecular attractions remain constant. In a sense, cooling a gas deprives molecules of the energy they need to overcome their mutual attractive influence. The effects of temperature shown in Figure 10.24 illustrate this point very well. As temperature increases, the negative departure of  $PV/RT$  from ideal-gas behavior disappears. The difference that remains at high temperature stems mainly from the effect of the finite volumes of the molecules.

### GIVE IT SOME THOUGHT

List two reasons why gases deviate from ideal behavior.

### The van der Waals Equation

Engineers and scientists who work with gases at high pressures often cannot use the ideal-gas equation to predict the pressure-volume properties of gases because departures from ideal behavior are too large. One useful equation developed to predict the behavior of real gases was proposed by the Dutch scientist Johannes van der Waals (1837–1923).

Van der Waals recognized that the ideal gas equation could be corrected to account for the effects of attractive forces between gas molecules and for molecular volumes. He introduced two constants,  $a$  and  $b$ , to make these corrections. The constant  $a$  is a measure of how strongly the gas molecules attract each other. The constant  $b$  is a measure of the small but finite volume occupied by the gas molecules themselves. His description of gas behavior is known as the **van der Waals equation**:

$$\left(P + \frac{n^2a}{V^2}\right)(V - nb) = nRT \quad [10.26]$$

In this equation the factor  $n^2a/V^2$  accounts for the attractive forces. The van der Waals equation adjusts the pressure,  $P$ , upward by adding  $n^2a/V^2$  because attractive forces between molecules tend to reduce the pressure (Figure 10.26). That is, a correction must be added to give the pressure that an ideal gas would have. The form of the correction factor,  $n^2a/V^2$ , results because the attractive forces between pairs of molecules increase as the square of the number of molecules per unit volume,  $(n/V)^2$ .

The factor  $nb$  accounts for the small but finite volume occupied by the gas molecules themselves (Figure 10.25). The van der Waals equation adjusts volume,  $V$ , downward (subtracting  $nb$ ), to give the free volume available to the gas molecules. That is, the particles of an ideal gas have the full volume,  $V$ , as free space in which to move, whereas in a real gas only the volume  $V - nb$  is available as free space.

The constants  $a$  and  $b$ , which are called *van der Waals constants*, are experimentally determined positive quantities that differ for each gas. Values of these constants for several gases are listed in Table 10.3 ▶. Notice that the values of

TABLE 10.3 ■ van der Waals Constants for Gas Molecules

Substance	$a$ (L <sup>2</sup> ·atm/mol <sup>2</sup> )	$b$ (L/mol)
He	0.0341	0.02370
Ne	0.211	0.0171
Ar	1.34	0.0322
Kr	2.32	0.0398
Xe	4.19	0.0510
H <sub>2</sub>	0.244	0.0266
N <sub>2</sub>	1.39	0.0391
O <sub>2</sub>	1.36	0.0318
Cl <sub>2</sub>	6.49	0.0562
H <sub>2</sub> O	5.46	0.0305
CH <sub>4</sub>	2.25	0.0428
CO <sub>2</sub>	3.59	0.0427
CCl <sub>4</sub>	20.4	0.1383

both  $a$  and  $b$  generally increase with an increase in mass of the molecule and with an increase in the complexity of its structure. Larger, more massive molecules have larger volumes and tend to have greater intermolecular attractive forces. As we will see in the next chapter, substances with large intermolecular attractive forces are relatively easy to liquefy.

#### ■ SAMPLE EXERCISE 10.16 | Using the van der Waals Equation

If 1.000 mol of an ideal gas were confined to 22.41 L at 0.0 °C, it would exert a pressure of 1.000 atm. Use the van der Waals equation and the constants in Table 10.3 to estimate the pressure exerted by 1.000 mol of Cl<sub>2</sub>(g) in 22.41 L at 0.0 °C.

#### SOLUTION

**Analyze:** The quantity we need to solve for is pressure. Because we will use the van der Waals equation, we must identify the appropriate values for the constants that appear there.

**Plan:** Solving Equation 10.26 for  $P$ , we have

$$P = \frac{nRT}{V - nb} - \frac{n^2a}{V^2}$$

**Solve:** Substituting  $n = 1.000$  mol,  $R = 0.08206$  L·atm/mol·K,  $T = 273.2$  K,  $V = 22.41$  L,  $a = 6.49$  L<sup>2</sup>·atm/mol<sup>2</sup>, and  $b = 0.0562$  L/mol:

$$P = \frac{(1.000 \text{ mol})(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(273.2 \text{ K})}{22.41 \text{ L} - (1.000 \text{ mol})(0.0562 \text{ L/mol})} - \frac{(1.000 \text{ mol})^2(6.49 \text{ L}^2\cdot\text{atm/mol}^2)}{(22.41 \text{ L})^2}$$

$$= 1.003 \text{ atm} - 0.013 \text{ atm} = 0.990 \text{ atm}$$

**Check:** We expect a pressure not far from 1.000 atm, which would be the value for an ideal gas, so our answer seems very reasonable.

**Comment:** Notice that the first term, 1.003 atm, is the pressure corrected for molecular volume. This value is higher than the ideal value, 1.000 atm, because the volume in which the molecules are free to move is smaller than the container volume, 22.41 L. Thus, the molecules must collide more frequently with the container walls. The second factor, 0.013 atm, corrects for intermolecular forces. The intermolecular attractions between molecules reduce the pressure to 0.990 atm. We can conclude, therefore, that the intermolecular attractions are the main cause of the slight deviation of Cl<sub>2</sub>(g) from ideal behavior under the stated experimental conditions.

#### ■ PRACTICE EXERCISE

Consider a sample of 1.000 mol of CO<sub>2</sub>(g) confined to a volume of 3.000 L at 0.0 °C. Calculate the pressure of the gas using (a) the ideal-gas equation and (b) the van der Waals equation.

**Answers:** (a) 7.473 atm, (b) 7.182 atm

**SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

Cyanogen, a highly toxic gas, is composed of 46.2% C and 53.8% N by mass. At 25 °C and 751 torr, 1.05 g of cyanogen occupies 0.500 L. (a) What is the molecular formula of cyanogen? (b) Predict its molecular structure. (c) Predict the polarity of the compound.

**SOLUTION**

**Analyze:** First we need to determine the molecular formula of a compound from elemental analysis data and data on the properties of the gaseous substance. Thus, we have two separate calculations to do.

**(a) Plan:** We can use the percentage composition of the compound to calculate its empirical formula. [↔ \(Section 3.5\)](#) Then we can determine the molecular formula by comparing the mass of the empirical formula with the molar mass. [↔ \(Section 3.5\)](#)

**Solve:** To determine the empirical formula, we assume that we have a 100-g sample of the compound and then calculate the number of moles of each element in the sample:

$$\text{Moles C} = (46.2 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.01 \text{ g C}} \right) = 3.85 \text{ mol C}$$

$$\text{Moles N} = (53.8 \text{ g N}) \left( \frac{1 \text{ mol N}}{14.01 \text{ g N}} \right) = 3.84 \text{ mol N}$$

Because the ratio of the moles of the two elements is essentially 1:1, the empirical formula is CN.

To determine the molar mass of the compound, we use Equation 10.11.

$$\mathcal{M} = \frac{dRT}{p} = \frac{(1.05 \text{ g}/0.500 \text{ L})(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(298 \text{ K})}{(751/760) \text{ atm}} = 52.0 \text{ g/mol}$$

The molar mass associated with the empirical formula, CN, is 12.0 + 14.0 = 26.0 g/mol. Dividing the molar mass of the compound by that of its empirical formula gives (52.0 g/mol)/(26.0 g/mol) = 2.00. Thus, the molecule has twice as many atoms of each element as the empirical formula, giving the molecular formula C<sub>2</sub>N<sub>2</sub>.

**(b) Plan:** To determine the molecular structure of the molecule, we must first determine its Lewis structure. [↔ \(Section 8.5\)](#) We can then use the VSEPR model to predict the structure. [↔ \(Section 9.2\)](#)

**Solve:** The molecule has 2(4) + 2(5) = 18 valence-shell electrons. By trial and error, we seek a Lewis structure with 18 valence electrons in which each atom has an octet and in which the formal charges are as low as possible. The following structure meets these criteria:

(This structure has zero formal charge on each atom.)

The Lewis structure shows that each atom has two electron domains. (Each nitrogen has a nonbonding pair of electrons and a triple bond, whereas each carbon has a triple bond and a single bond.) Thus the electron-domain geometry around each atom is linear, causing the overall molecule to be linear.

**(c) Plan:** To determine the polarity of the molecule, we must examine the polarity of the individual bonds and the overall geometry of the molecule.

**Solve:** Because the molecule is linear, we expect the two dipoles created by the polarity in the carbon–nitrogen bond to cancel each other, leaving the molecule with no dipole moment.

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Section 10.1** Substances that are gases at room temperatures tend to be molecular substances with low molar masses. Air, a mixture composed mainly of  $N_2$  and  $O_2$ , is the most common gas we encounter. Some liquids and solids can also exist in the gaseous state, where they are known as vapors. Gases are compressible; they mix in all proportions because their component molecules are far apart.

**Section 10.2** To describe the state, or condition, of a gas, we must specify four variables: pressure ( $P$ ), volume ( $V$ ), temperature ( $T$ ), and quantity ( $n$ ). Volume is usually measured in liters, temperature in kelvins, and quantity of gas in moles. **Pressure** is the force per unit area. It is expressed in SI units as **pascals**, Pa ( $1 \text{ Pa} = 1 \text{ N/m}^2 = 1 \text{ kg/m}\cdot\text{s}^2$ ). A related unit, the **bar**, equals  $10^5$  Pa. In chemistry, **standard atmospheric pressure** is used to define the **atmosphere** (atm) and the **torr** (also called the millimeter of mercury). One atmosphere of pressure equals 101.325 kPa, or 760 torr. A barometer is often used to measure the atmospheric pressure. A manometer can be used to measure the pressure of enclosed gases.

**Sections 10.3 and 10.4** Studies have revealed several simple gas laws: For a constant quantity of gas at constant temperature, the volume of the gas is inversely proportional to the pressure (**Boyle's law**). For a fixed quantity of gas at constant pressure, the volume is directly proportional to its absolute temperature (**Charles's law**). Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules (**Avogadro's hypothesis**). For a gas at constant temperature and pressure, the volume of the gas is directly proportional to the number of moles of gas (**Avogadro's law**). Each of these gas laws is a special case of the ideal-gas equation.

The **ideal-gas equation**,  $PV = nRT$ , is the equation of state for an **ideal gas**. The term  $R$  in this equation is the **gas constant**. We can use the ideal-gas equation to calculate variations in one variable when one or more of the others are changed. Most gases at pressures of about 1 atm and temperatures near 273 K and above obey the ideal-gas equation reasonably well. The conditions of 273 K ( $0^\circ\text{C}$ ) and 1 atm are known as the **standard temperature and pressure (STP)**. In all applications of the ideal-gas equation we must remember to convert temperatures to the absolute-temperature scale (the Kelvin scale).

**Sections 10.5 and 10.6** Using the ideal-gas equation, we can relate the density of a gas to its molar mass:  $\mathcal{M} = dRT/P$ . We can also use the ideal-gas equation to solve problems involving gases as reactants or products in chemical reactions.

In gas mixtures the total pressure is the sum of the **partial pressures** that each gas would exert if it were present alone under the same conditions (**Dalton's law of partial pressures**). The partial pressure of a component of a mixture is equal to its mole fraction times the total pressure:  $P_1 = X_1P_t$ . The **mole fraction** is the ratio of the moles of one component of a mixture to the total moles of all components. In calculating the quantity of a gas collected over water, correction must be made for the partial pressure of water vapor in the gas mixture.

**Section 10.7** The **kinetic-molecular theory** accounts for the properties of an ideal gas in terms of a set of statements about the nature of gases. Briefly, these statements are as follows: Molecules are in continuous chaotic motion. The volume of gas molecules is negligible compared to the volume of their container. The gas molecules have no attractive forces for one another. Their collisions are elastic. The average kinetic energy of the gas molecules is proportional to the absolute temperature.

The molecules of a gas do not all have the same kinetic energy at a given instant. Their speeds are distributed over a wide range; the distribution varies with the molar mass of the gas and with temperature. The **root-mean-square (rms) speed**,  $u$ , varies in proportion to the square root of the absolute temperature and **inversely** with the square root of the molar mass:  $u = \sqrt{3RT/\mathcal{M}}$ .

**Section 10.8** It follows from kinetic-molecular theory that the rate at which a gas undergoes **effusion** (escapes through a tiny hole into a vacuum) is inversely proportional to the square root of its molar mass (**Graham's law**). The **diffusion** of one gas through the space occupied by a second gas is another phenomenon related to the speeds at which molecules move. Because molecules undergo frequent collisions with one another, the **mean free path**—the mean distance traveled between collisions—is short. Collisions between molecules limit the rate at which a gas molecule can diffuse.

**Section 10.9** Departures from ideal behavior increase in magnitude as pressure increases and as temperature decreases. The extent of nonideality of a real gas can be seen by examining the quantity  $PV = RT$  for one mole of the gas as a function of pressure; for an ideal gas, this quantity is exactly 1 at all pressures. Real gases depart from ideal behavior because the molecules possess finite volume and because the molecules experience attractive forces for one another. The **van der Waals equation** is an equation of state for gases that modifies the ideal-gas equation to account for intrinsic molecular volume and intermolecular forces.

## KEY SKILLS

- Convert between pressure units with an emphasis on torr and atmospheres.
- Calculate  $P$ ,  $V$ ,  $n$ , or  $T$  using the ideal gas equation.
- Understand how the gas laws relate to the ideal gas equation and apply the gas laws in calculations.
- Calculate the density or molecular weight of a gas.
- Calculate the volume of gas used or formed in a chemical reaction.
- Calculate the total pressure of a gas mixture given its partial pressures or information for calculating partial pressures.
- Describe the kinetic molecular theory and how it explains the pressure and temperature of a gas, the gas laws, and the rates of effusion and diffusion.
- Explain why intermolecular attractions and molecular volumes cause real gases to deviate from ideal behavior at high pressure or low temperature.

## KEY EQUATIONS

- $PV = nRT$  [10.5] Ideal gas equation
- $\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$  [10.8] The combined gas law, showing how  $P$ ,  $V$ , and  $T$  are related for a constant  $n$
- $d = \frac{P\mathcal{M}}{RT}$  [10.10] Calculating the density or molar mass of a gas
- $P_t = P_1 + P_2 + P_3 + \dots$  [10.12] Relating the total pressure of a gas mixture to the partial pressures of its components (Dalton's law of partial pressures)
- $P_i = \left(\frac{n_i}{n_t}\right) P_t = X_i P_t$  [10.15] Relating partial pressure to mole fraction
- $u = \sqrt{\frac{3RT}{\mathcal{M}}}$  [10.22] Relating the root-mean-square (rms) speed of gas molecules to temperature and molar mass
- $\frac{r_1}{r_2} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}}$  [10.23] Relating the relative rates of effusion of two gases to their molar masses

## VISUALIZING CONCEPTS

**10.1** Mars has an average atmospheric pressure of 0.007 atm. Would it be easier or harder to drink from a straw on Mars than on Earth? Explain. [Section 10.2]

**10.2** Assume that you have a sample of gas in a container with a movable piston, such as the one in the drawing. (a) Redraw the container to show what it might look like if the temperature of the gas is increased from 300 K to 500 K while the pressure is kept constant. (b) Redraw the container to show what it might look like if the pressure on the piston is increased from 1.0 atm to 2.0 atm while the temperature is kept constant. [Section 10.3]

**10.3** Consider the sample of gas depicted below. What would the drawing look like if the volume and temperature remained constant while you removed enough of the gas to decrease the pressure by a factor of 2? [Section 10.3]

**10.4** Consider the following reaction:

Imagine that this reaction occurs in a container that has a piston that moves to allow a constant pressure to be maintained when the reaction occurs at constant temperature. (a) What happens to the volume of the container as a result of the reaction? Explain. (b) If the piston is not allowed to move, what happens to the pressure as a result of the reaction? [Sections 10.3 and 10.5]

- 10.5 Consider the apparatus below, which shows gases in two containers and one empty container. When the stopcocks are opened and the gases are allowed to mix at constant temperature, what is the distribution of atoms in each container? Assume that the containers are of equal volume, and ignore the volume of the tubing connecting them. Which gas has the greater partial pressure after the stopcocks are opened? [Section 10.6]

- 10.6 The drawing below represents a mixture of three different gases. (a) Rank the three components in order of increasing partial pressure. (b) If the total pressure of the mixture is 0.90 atm, calculate the partial pressure of each gas. [Section 10.6]

- 10.7 On a single plot, qualitatively sketch the distribution of molecular speeds for (a) Kr(g) at  $-50^\circ\text{C}$ , (b) Kr(g) at  $0^\circ\text{C}$ , (c) Ar(g) at  $0^\circ\text{C}$ . [Section 10.7]
- 10.8 Consider the following drawing. (a) If the curves A and B refer to two different gases, He and  $\text{O}_2$  at the same

temperature, which is which? Explain. (b) If A and B refer to the same gas at two different temperatures, which represents the higher temperature? [Section 10.7]

- 10.9 Consider the following samples of gases:

If the three samples are all at the same temperature, rank them with respect to (a) total pressure, (b) partial pressure of helium, (c) density, (d) average kinetic energy of particles. [Section 10.6 and 10.7]

- 10.10 Which of the substances listed in Table 10.3 would you expect to deviate the most from ideal-gas behavior at low temperature and high pressure? Which would deviate the least? Explain. [Section 10.9]

## EXERCISES

### Gas Characteristics; Pressure

- 10.11 How does a gas differ from a liquid with respect to each of the following properties: (a) density, (b) compressibility, (c) ability to mix with other substances of the same phase to form homogeneous mixtures?
- 10.12 (a) Both a liquid and a gas are moved to larger containers. How does their behavior differ? Explain the difference in molecular terms. (b) Although water and carbon tetrachloride,  $\text{CCl}_4(l)$ , do not mix, their vapors form homogeneous mixtures. Explain. (c) The densities of gases are generally reported in units of g/L, whereas those for liquids are reported as g/mL. Explain the molecular basis for this difference.
- 10.13 Suppose that a woman weighing 130 lb and wearing high-heeled shoes momentarily places all her weight on the heel of one foot. If the area of the heel is  $0.50\text{ in.}^2$ , calculate the pressure exerted on the underlying surface in kilopascals.
- 10.14 A set of bookshelves rests on a hard floor surface on four legs, each having a cross-sectional dimension of  $3.0 \times 4.1\text{ cm}$  in contact with the floor. The total mass of the shelves plus the books stacked on them is 262 kg. Calculate the pressure in pascals exerted by the shelf footings on the surface.
- 10.15 (a) How high in meters must a column of water be to exert a pressure equal to that of a 760-mm column of mercury? The density of water is  $1.0\text{ g/mL}$ , whereas that of mercury is  $13.6\text{ g/mL}$ . (b) What is the pressure in atmospheres on the body of a diver if he is 39 ft below the surface of the water when atmospheric pressure at the surface is 0.97 atm?
- 10.16 The compound 1-iodododecane is a nonvolatile liquid with a density of  $1.20\text{ g/mL}$ . The density of mercury is  $13.6\text{ g/mL}$ . What do you predict for the height of a barometer column based on 1-iodododecane, when the atmospheric pressure is 752 torr?
- 10.17 Each of the following statements concerns a mercury barometer such as that shown in Figure 10.2. Identify any incorrect statements, and correct them. (a) The tube must be  $1\text{ cm}^2$  in cross-sectional area. (b) At equilibrium the force of gravity per unit area acting on the mercury column at the level of the outside mercury equals the force of gravity per unit area acting on the atmosphere. (c) The column of mercury is held up by the vacuum at the top of the column.

- 10.18** Suppose you make a mercury barometer using a glass tube about 50 cm in length, closed at one end. What would you expect to see if the tube is filled with mercury and inverted in a mercury dish, as in Figure 10.2? Explain.
- 10.19** The typical atmospheric pressure on top of Mt. Everest (29,028 ft) is about 265 torr. Convert this pressure to (a) atm, (b) mm Hg, (c) pascals, (d) bars.
- 10.20** Perform the following conversions: (a) 0.850 atm to torr, (b) 785 torr to kilopascals, (c) 655 mm Hg to atmospheres, (d)  $1.323 \times 10^5$  Pa to atmospheres, (e) 2.50 atm to bars.
- 10.21** In the United States, barometric pressures are generally reported in inches of mercury (in. Hg). On a beautiful summer day in Chicago the barometric pressure is 30.45 in. Hg. (a) Convert this pressure to torr. (b) A meteorologist explains the nice weather by referring to a “high-pressure area.” In light of your answer to part (a), explain why this term makes sense.
- 10.22** (a) On Titan, the largest moon of Saturn, the atmospheric pressure is 1.63105 Pa. What is the atmospheric pressure of Titan in atm? (b) On Venus the surface atmospheric pressure is about 90 Earth atmospheres. What is the Venesian atmospheric pressure in kilopascals?

## The Gas Laws

- 10.25** Assume that you have a cylinder with a movable piston. What would happen to the gas pressure inside the cylinder if you do the following? (a) Decrease the volume to one-fourth the original volume while holding the temperature constant. (b) Reduce the Kelvin temperature to half its original value while holding the volume constant. (c) Reduce the amount of gas to half while keeping the volume and temperature constant.
- 10.26** A fixed quantity of gas at 21 °C exhibits a pressure of 752 torr and occupies a volume of 4.38 L. (a) Use Boyle’s law to calculate the volume the gas will occupy if the pressure is increased to 1.88 atm while the temperature is held constant. (b) Use Charles’s law to calculate the volume the gas will occupy if the temperature is increased to 175 °C while the pressure is held constant.

## The Ideal-Gas Equation

- 10.29** (a) Write the ideal-gas equation, and give the units used for each term in the equation when  $R = 0.0821$  L·atm/mol·K. (b) What is an ideal gas?
- 10.30** (a) What conditions are represented by the abbreviation STP? (b) What is the molar volume of an ideal gas at STP? (c) Room temperature is often assumed to be 25 °C. Calculate the molar volume of an ideal gas at 25 °C and 1 atm pressure.
- 10.31** Suppose you are given two 1-L flasks and told that one contains a gas of molar mass 30, the other a gas of molar mass 60, both at the same temperature. The pressure in

- 10.23** If the atmospheric pressure is 0.985 atm, what is the pressure of the enclosed gas in each of the three cases depicted in the drawing?

- 10.24** An open-end manometer containing mercury is connected to a container of gas, as depicted in Sample Exercise 10.2. What is the pressure of the enclosed gas in torr in each of the following situations? (a) The mercury in the arm attached to the gas is 15.4 mm higher than in the one open to the atmosphere; atmospheric pressure is 0.966 atm. (b) The mercury in the arm attached to the gas is 8.7 mm lower than in the one open to the atmosphere; atmospheric pressure is 0.99 atm.

- 10.27** (a) How is the law of combining volumes explained by Avogadro’s hypothesis? (b) Consider a 1.0-L flask containing neon gas and a 1.5-L flask containing xenon gas. Both gases are at the same pressure and temperature. According to Avogadro’s law, what can be said about the ratio of the number of atoms in the two flasks?
- 10.28** Nitrogen and hydrogen gases react to form ammonia gas as follows:

At a certain temperature and pressure, 1.2 L of  $\text{N}_2$  reacts with 3.6 L of  $\text{H}_2$ . If all the  $\text{N}_2$  and  $\text{H}_2$  are consumed, what volume of  $\text{NH}_3$ , at the same temperature and pressure, will be produced?

- flask A is  $X$  atm, and the mass of gas in the flask is 1.2 g. The pressure in flask B is  $0.5X$  atm, and the mass of gas in that flask is 1.2 g. Which flask contains gas of molar mass 30, and which contains the gas of molar mass 60?
- 10.32** Suppose you are given two flasks at the same temperature, one of volume 2 L and the other of volume 3 L. The 2-L flask contains 4.8 g of gas, and the gas pressure is  $X$  atm. The 3-L flask contains 0.36 g of gas, and the gas pressure is  $0.1X$ . Do the two gases have the same molar mass? If not, which contains the gas of higher molar mass?

**10.33** Complete the following table for an ideal gas:

<i>P</i>	<i>V</i>	<i>n</i>	<i>T</i>
2.00 atm	1.00 L	0.500 mol	? K
0.300 atm	0.250 L	? mol	27°C
650 torr	? L	0.333 mol	350 K
? atm	585 mL	0.250 mol	295 K

**10.34** Calculate each of the following quantities for an ideal gas: (a) the volume of the gas, in liters, if 1.50 mol has a pressure of 0.985 atm at a temperature of  $-6^\circ\text{C}$ ; (b) the absolute temperature of the gas at which  $3.33 \times 10^{-3}$  mol occupies 325 mL at 750 torr; (c) the pressure, in atmospheres, if 0.0467 mol occupies 413 mL at  $138^\circ\text{C}$ ; (d) the quantity of gas, in moles, if 55.7 L at  $54^\circ\text{C}$  has a pressure of 11.25 kPa.

**10.35** The Goodyear blimps, which frequently fly over sporting events, hold approximately  $175,000\text{ ft}^3$  of helium. If the gas is at  $23^\circ\text{C}$  and 1.0 atm, what mass of helium is in the blimp?

**10.36** A neon sign is made of glass tubing whose inside diameter is 2.5 cm and whose length is 5.5 m. If the sign contains neon at a pressure of 1.78 torr at  $35^\circ\text{C}$ , how many grams of neon are in the sign? (The volume of a cylinder is  $\pi r^2 h$ .)

**10.37** Calculate the number of molecules in a deep breath of air whose volume is 2.25 L at body temperature,  $37^\circ\text{C}$ , and a pressure of 735 torr.

**10.38** If the pressure exerted by ozone,  $\text{O}_3$ , in the stratosphere is  $3.0 \times 10^{-3}$  atm and the temperature is 250 K, how many ozone molecules are in a liter?

**10.39** A scuba diver's tank contains 0.29 kg of  $\text{O}_2$  compressed into a volume of 2.3 L. (a) Calculate the gas pressure inside the tank at  $9^\circ\text{C}$ . (b) What volume would this oxygen occupy at  $26^\circ\text{C}$  and 0.95 atm?

**10.40** An aerosol spray can with a volume of 250 mL contains 2.30 g of propane gas ( $\text{C}_3\text{H}_8$ ) as a propellant. (a) If the can is at  $23^\circ\text{C}$ , what is the pressure in the can? (b) What volume would the propane occupy at STP? (c) The can says that exposure to temperatures above  $130^\circ\text{F}$  may cause the can to burst. What is the pressure in the can at this temperature?

**10.41** Chlorine is widely used to purify municipal water supplies and to treat swimming pool waters. Suppose that the volume of a particular sample of  $\text{Cl}_2$  gas is 8.70 L at 895 torr and  $24^\circ\text{C}$ . (a) How many grams of  $\text{Cl}_2$  are in the sample? (b) What volume will the  $\text{Cl}_2$  occupy at STP? (c) At what temperature will the volume be 15.00 L if the pressure is  $8.76 \times 10^2$  torr? (d) At what pressure will the volume equal 6.00 L if the temperature is  $58^\circ\text{C}$ ?

**10.42** Many gases are shipped in high-pressure containers. Consider a steel tank whose volume is 65.0 L and which contains  $\text{O}_2$  gas at a pressure of 16,500 kPa at  $23^\circ\text{C}$ . (a) What mass of  $\text{O}_2$  does the tank contain? (b) What volume would the gas occupy at STP? (c) At what temperature would the pressure in the tank equal 150.0 atm? (d) What would be the pressure of the gas, in kPa, if it were transferred to a container at  $24^\circ\text{C}$  whose volume is 55.0 L?

**10.43** In an experiment reported in the scientific literature, male cockroaches were made to run at different speeds on a miniature treadmill while their oxygen consumption was measured. In one hour the average cockroach running at 0.08 km/hr consumed 0.8 mL of  $\text{O}_2$  at 1 atm pressure and  $24^\circ\text{C}$  per gram of insect weight. (a) How many moles of  $\text{O}_2$  would be consumed in 1 hr by a 5.2-g cockroach moving at this speed? (b) This same cockroach is caught by a child and placed in a 1-qt fruit jar with a tight lid. Assuming the same level of continuous activity as in the research, will the cockroach consume more than 20% of the available  $\text{O}_2$  in a 48-hr period? (Air is 21 mol percent  $\text{O}_2$ .)

**10.44** After the large eruption of Mount St. Helens in 1980, gas samples from the volcano were taken by sampling the downwind gas plume. The unfiltered gas samples were passed over a gold-coated wire coil to absorb mercury (Hg) present in the gas. The mercury was recovered from the coil by heating it, and then analyzed. In one particular set of experiments scientists found a mercury vapor level of 1800 ng of Hg per cubic meter in the plume, at a gas temperature of  $10^\circ\text{C}$ . Calculate (a) the partial pressure of Hg vapor in the plume, (b) the number of Hg atoms per cubic meter in the gas, (c) the total mass of Hg emitted per day by the volcano if the daily plume volume was  $1600\text{ km}^3$ .

## Further Applications of the Ideal-Gas Equation

**10.45** Which gas is most dense at 1.00 atm and 298 K?  $\text{CO}_2$ ,  $\text{N}_2\text{O}$ , or  $\text{Cl}_2$ . Explain.

**10.46** Rank the following gases from least dense at 1.00 atm and 298 K to most dense under these same conditions:  $\text{SO}_2$ ,  $\text{HBr}$ ,  $\text{CO}_2$ . Explain.

**10.47** Which of the following statements best explains why a closed balloon filled with helium gas rises in air?

(a) Helium is a monatomic gas, whereas nearly all the molecules that make up air, such as nitrogen and oxygen, are diatomic.

(b) The average speed of helium atoms is higher than the average speed of air molecules, and the higher speed of collisions with the balloon walls propels the balloon upward.

(c) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The balloon thus weighs less than the air displaced by its volume.

(d) Because helium has a lower molar mass than the average air molecule, the helium atoms are in faster motion. This means that the temperature of the helium is higher than the air temperature. Hot gases tend to rise.

- 10.48 Which of the following statements best explains why nitrogen gas at STP is less dense than Xe gas at STP?
- Because Xe is a noble gas, there is less tendency for the Xe atoms to repel one another, so they pack more densely in the gas state.
  - Xe atoms have a higher mass than N<sub>2</sub> molecules. Because both gases at STP have the same number of molecules per unit volume, the Xe gas must be denser.
  - The Xe atoms are larger than N<sub>2</sub> molecules and thus take up a larger fraction of the space occupied by the gas.
  - Because the Xe atoms are much more massive than the N<sub>2</sub> molecules, they move more slowly and thus exert less upward force on the gas container and make the gas appear denser.
- 10.49 (a) Calculate the density of NO<sub>2</sub> gas at 0.970 atm and 35 °C. (b) Calculate the molar mass of a gas if 2.50 g occupies 0.875 L at 685 torr and 35 °C.
- 10.50 (a) Calculate the density of sulfur hexafluoride gas at 707 torr and 21 °C. (b) Calculate the molar mass of a vapor that has a density of 7.135 g/L at 12 °C and 743 torr.
- 10.51 In the Dumas-bulb technique for determining the molar mass of an unknown liquid, you vaporize the sample of a liquid that boils below 100 °C in a boiling-water bath and determine the mass of vapor required to fill the bulb (see drawing). From the following data, calculate the molar mass of the unknown liquid: mass of unknown vapor, 1.012 g; volume of bulb, 354 cm<sup>3</sup>; pressure, 742 torr; temperature, 99 °C.

- 10.52 The molar mass of a volatile substance was determined by the Dumas-bulb method described in Exercise 10.51. The unknown vapor had a mass of 0.846 g; the volume of the bulb was 354 cm<sup>3</sup>, pressure 752 torr, and temperature 100 °C. Calculate the molar mass of the unknown vapor.

- 10.53 Magnesium can be used as a “getter” in evacuated enclosures, to react with the last traces of oxygen. (The magnesium is usually heated by passing an electric current through a wire or ribbon of the metal.) If an enclosure of 0.382 L has a partial pressure of O<sub>2</sub> of  $3.5 \times 10^{-6}$  torr at 27 °C, what mass of magnesium will react according to the following equation?

- 10.54 Calcium hydride, CaH<sub>2</sub>, reacts with water to form hydrogen gas:

This reaction is sometimes used to inflate life rafts, weather balloons, and the like, where a simple, compact means of generating H<sub>2</sub> is desired. How many grams of CaH<sub>2</sub> are needed to generate 53.5 L of H<sub>2</sub> gas if the pressure of H<sub>2</sub> is 814 torr at 21 °C?

- 10.55 The metabolic oxidation of glucose, C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>, in our bodies produces CO<sub>2</sub>, which is expelled from our lungs as a gas:

Calculate the volume of dry CO<sub>2</sub> produced at body temperature (37 °C) and 0.970 atm when 245 g of glucose is consumed in this reaction.

- 10.56 Both Jacques Charles and Joseph Louis Guy-Lussac were avid balloonists. In his original flight in 1783, Jacques Charles used a balloon that contained approximately 31,150 L of H<sub>2</sub>. He generated the H<sub>2</sub> using the reaction between iron and hydrochloric acid:

How many kilograms of iron were needed to produce this volume of H<sub>2</sub> if the temperature was 22 °C?

- 10.57 Hydrogen gas is produced when zinc reacts with sulfuric acid:

If 159 mL of wet H<sub>2</sub> is collected over water at 24 °C and a barometric pressure of 738 torr, how many grams of Zn have been consumed? (The vapor pressure of water is tabulated in Appendix B.)

- 10.58 Acetylene gas, C<sub>2</sub>H<sub>2</sub>(g), can be prepared by the reaction of calcium carbide with water:

Calculate the volume of C<sub>2</sub>H<sub>2</sub> that is collected over water at 23 °C by reaction of 0.752 g of CaC<sub>2</sub> if the total pressure of the gas is 745 torr. (The vapor pressure of water is tabulated in Appendix B.)

## Partial Pressures

- 10.59 Consider the apparatus shown in the drawing on the next page. (a) When the stopcock between the two containers is opened and the gases allowed to mix, how does the volume occupied by the N<sub>2</sub> gas change? What is

the partial pressure of N<sub>2</sub> after mixing? (b) How does the volume of the O<sub>2</sub> gas change when the gases mix? What is the partial pressure of O<sub>2</sub> in the mixture? (c) What is the total pressure in the container after the gases mix?

- 10.60** Consider a mixture of two gases, A and B, confined in a closed vessel. A quantity of a third gas, C, is added to the same vessel at the same temperature. How does the addition of gas C affect the following: (a) the partial pressure of gas A, (b) the total pressure in the vessel, (c) the mole fraction of gas B?
- 10.61** A mixture containing 0.477 mol He(g), 0.280 mol Ne(g), and 0.110 mol Ar(g) is confined in a 7.00-L vessel at 25 °C. (a) Calculate the partial pressure of each of the gases in the mixture. (b) Calculate the total pressure of the mixture.
- 10.62** A deep-sea diver uses a gas cylinder with a volume of 10.0 L and a content of 51.2 g of  $O_2$  and 32.6 g of He. Calculate the partial pressure of each gas and the total pressure if the temperature of the gas is 19 °C.
- 10.63** A piece of solid carbon dioxide with a mass of 5.50 g is placed in a 10.0-L vessel that already contains air at 705 torr and 24 °C. After the carbon dioxide has totally vaporized, what is the partial pressure of carbon dioxide and the total pressure in the container at 24 °C?
- 10.64** A sample of 4.00 mL of diethylether ( $C_2H_5OC_2H_5$ , density = 0.7134 g/mL) is introduced into a 5.00-L vessel that already contains a mixture of  $N_2$  and  $O_2$ , whose partial pressures are  $P_{N_2} = 0.751$  atm and  $P_{O_2} = 0.208$  atm. The temperature is held at 35.0 °C, and the diethylether

totally evaporates. (a) Calculate the partial pressure of the diethylether. (b) Calculate the total pressure in the container.

- 10.65** A mixture of gases contains 0.75 mol  $N_2$ , 0.30 mol  $O_2$ , and 0.15 mol  $CO_2$ . If the total pressure of the mixture is 1.56 atm, what is the partial pressure of each component?
- 10.66** A mixture of gases contains 10.25 g of  $N_2$ , 1.83 g of  $H_2$ , and 7.95 g of  $NH_3$ . If the total pressure of the mixture is 1.85 atm, what is the partial pressure of each component?
- 10.67** At an underwater depth of 250 ft, the pressure is 8.38 atm. What should the mole percent of oxygen be in the diving gas for the partial pressure of oxygen in the mixture to be 0.21 atm, the same as in air at 1 atm?
- 10.68** (a) What are the mole fractions of each component in a mixture of 5.08 g of  $O_2$ , 7.17 g of  $N_2$ , and 1.32 g of  $H_2$ ? (b) What is the partial pressure in atm of each component of this mixture if it is held in a 12.40-L vessel at 15 °C?
- 10.69** A quantity of  $N_2$  gas originally held at 4.75 atm pressure in a 1.00-L container at 26 °C is transferred to a 10.0-L container at 20 °C. A quantity of  $O_2$  gas originally at 5.25 atm and 26 °C in a 5.00-L container is transferred to this same container. What is the total pressure in the new container?
- 10.70** A sample of 3.00 g of  $SO_2$ (g) originally in a 5.00-L vessel at 21 °C is transferred to a 10.0-L vessel at 26 °C. A sample of 2.35 g  $N_2$ (g) originally in a 2.50-L vessel at 20 °C is transferred to this same 10.0-L vessel. (a) What is the partial pressure of  $SO_2$ (g) in the larger container? (b) What is the partial pressure of  $N_2$ (g) in this vessel? (c) What is the total pressure in the vessel?

## Kinetic-Molecular Theory; Graham's Law

- 10.71** What change or changes in the state of a gas bring about each of the following effects? (a) The number of impacts per unit time on a given container wall increases. (b) The average energy of impact of molecules with the wall of the container decreases. (c) The average distance between gas molecules increases. (d) The average speed of molecules in the gas mixture is increased.
- 10.72** Indicate which of the following statements regarding the kinetic-molecular theory of gases are correct. For those that are false, formulate a correct version of the statement. (a) The average kinetic energy of a collection of gas molecules at a given temperature is proportional to  $m^{1/2}$ . (b) The gas molecules are assumed to exert no forces on each other. (c) All the molecules of a gas at a given temperature have the same kinetic energy. (d) The volume of the gas molecules is negligible in comparison to the total volume in which the gas is contained.
- 10.73** What property or properties of gases can you point to that support the assumption that most of the volume in a gas is empty space?
- 10.74** Newton had an incorrect theory of gases in which he assumed that all gas molecules repel one another and the walls of their container. Thus, the molecules of a gas are statically and uniformly distributed, trying to get as far apart as possible from one another and the vessel walls. This repulsion gives rise to pressure. Explain why Charles's law argues for the kinetic-molecular theory and against Newton's model.
- 10.75** The temperature of a 5.00-L container of  $N_2$  gas is increased from 20 °C to 250 °C. If the volume is held constant, predict qualitatively how this change affects the following: (a) the average kinetic energy of the molecules; (b) the average speed of the molecules; (c) the strength of the impact of an average molecule with the container walls; (d) the total number of collisions of molecules with walls per second.
- 10.76** Suppose you have two 1-L flasks, one containing  $N_2$  at STP, the other containing  $CH_4$  at STP. How do these systems compare with respect to (a) number of molecules, (b) density, (c) average kinetic energy of the molecules, (d) rate of effusion through a pinhole leak?

- 10.77** (a) Place the following gases in order of increasing average molecular speed at 25 °C: Ne, HBr, SO<sub>2</sub>, NF<sub>3</sub>, CO. (b) Calculate the rms speed of NF<sub>3</sub> molecules at 25 °C.
- 10.78** (a) Place the following gases in order of increasing average molecular speed at 300 K: CO, SF<sub>6</sub>, H<sub>2</sub>S, Cl<sub>2</sub>, HBr. (b) Calculate and compare the rms speeds of CO and Cl<sub>2</sub> molecules at 300 K.
- 10.79** Hydrogen has two naturally occurring isotopes, <sup>1</sup>H and <sup>2</sup>H. Chlorine also has two naturally occurring isotopes, <sup>35</sup>Cl and <sup>37</sup>Cl. Thus, hydrogen chloride gas consists of four distinct types of molecules: <sup>1</sup>H<sup>35</sup>Cl, <sup>1</sup>H<sup>37</sup>Cl, <sup>2</sup>H<sup>35</sup>Cl, and <sup>2</sup>H<sup>37</sup>Cl. Place these four molecules in order of increasing rate of effusion.
- 10.80** As discussed in the "Chemistry Put to Work" box in Section 10.8, enriched uranium can be produced by gaseous diffusion of UF<sub>6</sub>. Suppose a process were developed to allow diffusion of gaseous uranium atoms, U(g).

Calculate the ratio of diffusion rates for <sup>235</sup>U and <sup>238</sup>U, and compare it to the ratio for UF<sub>6</sub> given in the essay.

- 10.81** Arsenic(III) sulfide sublimes readily, even below its melting point of 320 °C. The molecules of the vapor phase are found to effuse through a tiny hole at 0.28 times the rate of effusion of Ar atoms under the same conditions of temperature and pressure. What is the molecular formula of arsenic(III) sulfide in the gas phase?
- 10.82** A gas of unknown molecular mass was allowed to effuse through a small opening under constant-pressure conditions. It required 105 s for 1.0 L of the gas to effuse. Under identical experimental conditions it required 31 s for 1.0 L of O<sub>2</sub> gas to effuse. Calculate the molar mass of the unknown gas. (Remember that the faster the rate of effusion, the shorter the time required for effusion of 1.0 L; that is, rate and time are inversely proportional.)

## Nonideal-Gas Behavior

- 10.83** (a) List two experimental conditions under which gases deviate from ideal behavior. (b) List two reasons why the gases deviate from ideal behavior. (c) Explain how the function  $PV/RT$  can be used to show how gases behave nonideally.
- 10.84** The planet Jupiter has a surface temperature of 140 K and a mass 318 times that of Earth. Mercury has a surface temperature between 600 K and 700 K and a mass 0.05 times that of Earth. On which planet is the atmosphere more likely to obey the ideal-gas law? Explain.
- 10.85** Based on their respective van der Waals constants (Table 10.3), is Ar or CO<sub>2</sub> expected to behave more nearly like an ideal gas at high pressures? Explain.
- 10.86** Briefly explain the significance of the constants  $a$  and  $b$  in the van der Waals equation.

- 10.87** In Sample Exercise 10.16, we found that one mole of Cl<sub>2</sub> confined to 22.41 L at 0 °C deviated slightly from ideal behavior. Calculate the pressure exerted by 1.00 mol Cl<sub>2</sub> confined to a smaller volume, 5.00 L, at 25 °C. (a) First use the ideal gas equation and (b) then use van der Waals equation for your calculation. (Values for the van der Waals constants are given in Table 10.3.) (c) Why is the difference between the result for an ideal gas and that calculated using van der Waals equation greater when the gas is confined to 5.00 L compared to 22.4 L?
- 10.88** Calculate the pressure that CCl<sub>4</sub> will exert at 40 °C if 1.00 mol occupies 28.0 L, assuming that (a) CCl<sub>4</sub> obeys the ideal-gas equation; (b) CCl<sub>4</sub> obeys the van der Waals equation. (Values for the van der Waals constants are given in Table 10.3.) (c) Which would you expect to deviate more from ideal behavior under these conditions, Cl<sub>2</sub> or CCl<sub>4</sub>? Explain.

## ADDITIONAL EXERCISES

- 10.89** Suppose the mercury used to make a barometer has a few small droplets of water trapped in it that rise to the top of the mercury in the tube. Will the barometer show the correct atmospheric pressure? Explain.
- 10.90** Suppose that when Torricelli had his great idea for constructing a mercury manometer, he had rushed into the laboratory and found the following items of glass:

Which of these would have been satisfactory for his use in forming the first manometer? Explain why the unsatisfactory ones would not have worked.

- 10.91** A gas bubble with a volume of 1.0 mm<sup>3</sup> originates at the bottom of a lake where the pressure is 3.0 atm. Calculate its volume when the bubble reaches the surface of the lake where the pressure is 695 torr, assuming that the temperature doesn't change.
- 10.92** A 15.0-L tank is filled with helium gas at a pressure of  $1.00 \times 10^2$ . How many balloons (each 2.00 L) can be inflated to a pressure of 1.00 atm, assuming that the temperature remains constant and that the tank cannot be emptied below 1.00 atm?
- 10.93** To minimize the rate of evaporation of the tungsten filament,  $1.4 \times 10^{-5}$  mol of argon is placed in a 600-cm<sup>3</sup> lightbulb. What is the pressure of argon in the lightbulb at 23 °C?

- 10.94** Carbon dioxide, which is recognized as the major contributor to global warming as a "greenhouse gas," is formed when fossil fuels are combusted, as in electrical power plants fueled by coal, oil, or natural gas. One potential way to reduce the amount of  $\text{CO}_2$  added to the atmosphere is to store it as a compressed gas in underground formations. Consider a 1000-megawatt coal-fired power plant that produces about  $6 \times 10^6$  tons of  $\text{CO}_2$  per year. (a) Assuming ideal gas behavior, 1.00 atm, and  $27^\circ\text{C}$ , calculate the volume of  $\text{CO}_2$  produced by this power plant. (b) If the  $\text{CO}_2$  is stored underground as a liquid at  $10^\circ\text{C}$  and 120 atm and a density of  $1.2\text{ g/cm}^3$ , what volume does it possess? (c) If it is stored underground as a gas at  $36^\circ\text{C}$  and 90 atm, what volume does it occupy?
- 10.95** Propane,  $\text{C}_3\text{H}_8$ , liquefies under modest pressure, allowing a large amount to be stored in a container. (a) Calculate the number of moles of propane gas in a 110-L container at 3.00 atm and  $27^\circ\text{C}$ . (b) Calculate the number of moles of liquid propane that can be stored in the same volume if the density of the liquid is  $0.590\text{ g/mL}$ . (c) Calculate the ratio of the number of moles of liquid to moles of gas. Discuss this ratio in light of the kinetic-molecular theory of gases.
- 10.96** Nickel carbonyl,  $\text{Ni}(\text{CO})_4$ , is one of the most toxic substances known. The present maximum allowable concentration in laboratory air during an 8-hr workday is 1 part in  $10^9$  parts by volume, which means that there is one mole of  $\text{Ni}(\text{CO})_4$  for every  $10^9$  moles of gas. Assume  $24^\circ\text{C}$  and 1.00 atm pressure. What mass of  $\text{Ni}(\text{CO})_4$  is allowable in a laboratory that is  $54\text{ m}^2$  in area, with a ceiling height of  $3.1\text{ m}$ ?
- 10.97** A large flask is evacuated and weighed, filled with argon gas, and then reweighed. When reweighed, the flask is found to have gained  $3.224\text{ g}$ . It is again evacuated and then filled with a gas of unknown molar mass. When reweighed, the flask is found to have gained  $8.102\text{ g}$ . (a) Based on the molar mass of argon, estimate the molar mass of the unknown gas. (b) What assumptions did you make in arriving at your answer?
- 10.98** Consider the arrangement of bulbs shown in the drawing. Each of the bulbs contains a gas at the pressure shown. What is the pressure of the system when all the stopcocks are opened, assuming that the temperature remains constant? (We can neglect the volume of the capillary tubing connecting the bulbs.)

- 10.99** Assume that a single cylinder of an automobile engine has a volume of  $524\text{ cm}^3$ . (a) If the cylinder is full of air at  $74^\circ\text{C}$  and 0.980 atm, how many moles of  $\text{O}_2$  are present? (The mole fraction of  $\text{O}_2$  in dry air is 0.2095.)

(b) How many grams of  $\text{C}_8\text{H}_{18}$  could be combusted by this quantity of  $\text{O}_2$ , assuming complete combustion with formation of  $\text{CO}_2$  and  $\text{H}_2\text{O}$ ?

- 10.100** Assume that an exhaled breath of air consists of 74.8%  $\text{N}_2$ , 15.3%  $\text{O}_2$ , 3.7%  $\text{CO}_2$ , and 6.2% water vapor. (a) If the total pressure of the gases is 0.980 atm, calculate the partial pressure of each component of the mixture. (b) If the volume of the exhaled gas is 455 mL and its temperature is  $37^\circ\text{C}$ , calculate the number of moles of  $\text{CO}_2$  exhaled. (c) How many grams of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) would need to be metabolized to produce this quantity of  $\text{CO}_2$ ? (The chemical reaction is the same as that for combustion of  $\text{C}_6\text{H}_{12}\text{O}_6$ . See Section 3.2.)
- 10.101** A sample of 1.42 g of helium and an unweighed quantity of  $\text{O}_2$  are mixed in a flask at room temperature. The partial pressure of helium in the flask is 42.5 torr, and the partial pressure of oxygen is 158 torr. What is the mass of the oxygen in the container?
- 10.102** A gaseous mixture of  $\text{O}_2$  and Kr has a density of  $1.104\text{ g/L}$  at 435 torr and 300 K. What is the mole percent  $\text{O}_2$  in the mixture?
- 10.103** The density of a gas of unknown molar mass was measured as a function of pressure at  $0^\circ\text{C}$ , as in the table below. (a) Determine a precise molar mass for the gas. *Hint:* Graph  $d/P$  versus  $P$ . (b) Why is  $d/P$  not a constant as a function of pressure?

Pressure (atm)	1.00	0.666	0.500	0.333	0.250
Density (g/L)	2.3074	1.5263	1.1401	0.7571	0.5660

- 10.104** A glass vessel fitted with a stopcock has a mass of 337.428 g when evacuated. When filled with Ar, it has a mass of 339.854 g. When evacuated and refilled with a mixture of Ne and Ar, under the same conditions of temperature and pressure, it weighs 339.076 g. What is the mole percent of Ne in the gas mixture?
- 10.105** You have a sample of gas at  $-33^\circ\text{C}$ . You wish to increase the rms speed by 10.0%. To what temperature should the gas be heated?
- 10.106** Consider the following gases, all at STP: Ne,  $\text{SF}_6$ ,  $\text{N}_2$ ,  $\text{CH}_4$ . (a) Which gas is most likely to depart from assumption 3 of the kinetic molecular theory (Section 10.7)? (b) Which one is closest to an ideal gas in its behavior? (c) Which one has the highest root-mean-square molecular speed? (d) Which one has the highest total molecular volume relative to the space occupied by the gas? (e) Which has the highest average kinetic molecular energy? (f) Which one would effuse more rapidly than  $\text{N}_2$ ?
- 10.107** Does the effect of intermolecular attraction on the properties of a gas become more significant or less significant if (a) the gas is compressed to a smaller volume at constant temperature; (b) the temperature of the gas is increased at constant volume?
- 10.108** For nearly all real gases, the quantity  $PV/RT$  decreases below the value of 1, which characterizes an ideal gas, as pressure on the gas increases. At much higher

pressures, however,  $PV/RT$  increases and rises above the value of 1. (a) Explain the initial drop in value of  $PV/RT$  below 1 and the fact that it rises above 1 for still higher pressures. (b) The effects we have just noted are smaller for gases at higher temperature. Why is this so?

- 10.109** Which of the noble gases other than radon would you expect to depart most readily from ideal behavior? Use the density data in Table 7.8 to show evidence in support of your answer.
- 10.110** It turns out that the van der Waals constant  $b$  equals four times the total volume actually occupied by the molecules of a mole of gas. Using this figure, calculate the fraction of the volume in a container actually occupied

by Ar atoms (a) at STP, (b) at 100 atm pressure and 0 °C. (Assume for simplicity that the ideal-gas equation still holds.)

- [10.111]** Large amounts of nitrogen gas are used in the manufacture of ammonia, principally for use in fertilizers. Suppose 120.00 kg of  $N_2(g)$  is stored in a 1100.0-L metal cylinder at 280 °C. (a) Calculate the pressure of the gas, assuming ideal-gas behavior. (b) By using data in Table 10.3, calculate the pressure of the gas according to the van der Waals equation. (c) Under the conditions of this problem, which correction dominates, the one for finite volume of gas molecules or the one for attractive interactions?

## INTEGRATIVE EXERCISES

- 10.112** Cyclopropane, a gas used with oxygen as a general anesthetic, is composed of 85.7% C and 14.3% H by mass. (a) If 1.56 g of cyclopropane has a volume of 1.00 L at 0.984 atm and 50.0 °C, what is the molecular formula of cyclopropane? (b) Judging from its molecular formula, would you expect cyclopropane to deviate more or less than Ar from ideal-gas behavior at moderately high pressures and room temperature? Explain.

- 10.113** Consider the combustion reaction between 25.0 mL of liquid methanol (density = 0.850 g/mL) and 12.5 L of oxygen gas measured at STP. The products of the reaction are  $CO_2(g)$  and  $H_2O(g)$ . Calculate the number of moles of  $H_2O$  formed if the reaction goes to completion.

- 10.114** An herbicide is found to contain only C, H, N, and Cl. The complete combustion of a 100.0-mg sample of the herbicide in excess oxygen produces 83.16 mL of  $CO_2$  and 73.30 mL of  $H_2O$  vapor at STP. A separate analysis shows that the sample also contains 16.44 mg of Cl. (a) Determine the percent composition of the substance. (b) Calculate its empirical formula.

- [10.115]** A 4.00-g sample of a mixture of CaO and BaO is placed in a 1.00-L vessel containing  $CO_2$  gas at a pressure of 730 torr and a temperature of 25 °C. The  $CO_2$  reacts with the CaO and BaO, forming  $CaCO_3$  and  $BaCO_3$ . When the reaction is complete, the pressure of the remaining  $CO_2$  is 150 torr. (a) Calculate the number of moles of  $CO_2$  that have reacted. (b) Calculate the mass percentage of CaO in the mixture.

- [10.116]** Ammonia,  $NH_3(g)$ , and hydrogen chloride,  $HCl(g)$ , react to form solid ammonium chloride,  $NH_4Cl(s)$ :

Two 2.00-L flasks at 25 °C are connected by a stopcock, as shown in the drawing. One flask contains 5.00 g  $NH_3(g)$ , and the other contains 5.00 g  $HCl(g)$ . When the stopcock is opened, the gases react until one is completely consumed. (a) Which gas will remain in the sys-

tem after the reaction is complete? (b) What will be the final pressure of the system after the reaction is complete? (Neglect the volume of the ammonium chloride formed.)

- 10.117** The “Chemistry Put to Work” box on pipelines in Section 10.5 mentions that the total deliverability of natural gas (methane,  $CH_4$ ) to the various regions of the United States is on the order of  $2.7 \times 10^{12}$  L per day, measured at STP. Calculate the total enthalpy change for combustion of this quantity of methane. (Note: Less than this amount of methane is actually combusted daily. Some of the delivered gas is passed through to other regions.)

- [10.118]** A gas forms when elemental sulfur is heated carefully with AgF. The initial product boils at 15 °C. Experiments on several samples yielded a gas density of  $0.803 \pm 0.010$  g/L for the gas at 150 mm pressure and 32 °C. When the gas reacts with water, all the fluorine is converted to aqueous HF. Other products are elemental sulfur,  $S_8$ , and other sulfur-containing compounds. A 480-mL sample of the dry gas at 126 mm pressure and 28 °C, when reacted with 80 mL of water, yielded a 0.081 M solution of HF. The initial gaseous product undergoes a transformation over a period of time to a second compound with the same empirical and molecular formula, which boils at -10 °C. (a) Determine the empirical and molecular formulas of the first compound formed. (b) Draw at least two reasonable Lewis structures that represent the initial compound and the one into which it is transformed over time. (c) Describe the likely geometries of these compounds, and estimate the single bond distances, given that the S—S bond distance in  $S_8$  is 2.04 Å and the F—F distance in  $F_2$  is 1.43 Å.

- 10.119** Chlorine dioxide gas ( $\text{ClO}_2$ ) is used as a commercial bleaching agent. It bleaches materials by oxidizing them. In the course of these reactions, the  $\text{ClO}_2$  is itself reduced. (a) What is the Lewis structure for  $\text{ClO}_2$ ? (b) Why do you think that  $\text{ClO}_2$  is reduced so readily? (c) When a  $\text{ClO}_2$  molecule gains an electron, the chlorite ion,  $\text{ClO}_2^-$ , forms. Draw the Lewis structure for  $\text{ClO}_2^-$ . (d) Predict the  $\text{O}-\text{Cl}-\text{O}$  bond angle in the  $\text{ClO}_2^-$  ion. (e) One method of preparing  $\text{ClO}_2$  is by the reaction of chlorine and sodium chlorite:

If you allow 10.0 g of  $\text{NaClO}_2$  to react with 2.00 L of chlorine gas at a pressure of 1.50 atm at 21 °C, how many grams of  $\text{ClO}_2$  can be prepared?

- 10.120** Natural gas is very abundant in many Middle Eastern oil fields. However, the costs of shipping the gas to markets in other parts of the world are high because it is necessary to liquefy the gas, which is mainly methane and thus has a boiling point at atmospheric pressure of -164 °C. One possible strategy is to oxidize the methane to methanol,  $\text{CH}_3\text{OH}$ , which has a boiling point of 65 °C and can therefore be shipped more readily. Suppose that  $10.7 \times 10^9 \text{ ft}^3$  of methane at atmospheric pressure and 25 °C are oxidized to methanol. (a) What volume of methanol is formed if the density of  $\text{CH}_3\text{OH}$  is 0.791 g/mL? (b) Write balanced chemical equations for the oxidations of methane and methanol to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ . Calculate the total enthalpy change for complete combustion of the  $10.7 \times 10^9 \text{ ft}^3$  of methane described

above and for complete combustion of the equivalent amount of methanol, as calculated in part (a). (c) Methane, when liquefied, has a density of 0.466 g/mL; the density of methanol at 25 °C is 0.791 g/mL. Compare the enthalpy change upon combustion of a unit volume of liquid methane and liquid methanol. From the standpoint of energy production, which substance has the higher enthalpy of combustion per unit volume?

- [10.121]** Gaseous iodine pentafluoride,  $\text{IF}_5$ , can be prepared by the reaction of solid iodine and gaseous fluorine:

A 5.00-L flask containing 10.0 g  $\text{I}_2$  is charged with 10.0 g  $\text{F}_2$ , and the reaction proceeds until one of the reagents is completely consumed. After the reaction is complete, the temperature in the flask is 125 °C. (a) What is the partial pressure of  $\text{IF}_5$  in the flask? (b) What is the mole fraction of  $\text{IF}_5$  in the flask?

- [10.122]** A 6.53-g sample of a mixture of magnesium carbonate and calcium carbonate is treated with excess hydrochloric acid. The resulting reaction produces 1.72 L of carbon dioxide gas at 28 °C and 743 torr pressure. (a) Write balanced chemical equations for the reactions that occur between hydrochloric acid and each component of the mixture. (b) Calculate the total number of moles of carbon dioxide that forms from these reactions. (c) Assuming that the reactions are complete, calculate the percentage by mass of magnesium carbonate in the mixture.

CHAPTER  
11

# INTERMOLECULAR FORCES, LIQUIDS, AND SOLIDS

THE WATER IN HOT SPRINGS is at least 5–10 °C warmer than the mean annual air temperature where they are located. There are over 1000 hot springs in the United States, the majority in the West. Some hot springs are popular for bathing, while others are far too hot for people to enter them safely.

### 11.1 A Molecular Comparison of Gases, Liquids, and Solids

We begin with a brief comparison of solids, liquids, and gases from a molecular perspective. This comparison reveals the important roles that temperature and *intermolecular forces* play in determining the physical state of a substance.

### 11.2 Intermolecular Forces

We then examine the main kinds of intermolecular forces that occur within and between substances: *ion-dipole forces*, *dipole-dipole forces*, *London dispersion forces*, and *hydrogen bonds*.

### 11.3 Some Properties of Liquids

We will learn that the nature and strength of the intermolecular forces between molecules are largely responsible for many properties of liquids, including their *viscosity*, which is a measure of a liquid's resistance to flow, and *surface tension*, which is a measure of a liquid's resistance to increasing its surface area.

### 11.4 Phase Changes

We will explore *phase changes*—the transitions of matter between the gaseous, liquid, and solid states—and their associated energies.

### 11.5 Vapor Pressure

We will examine the *dynamic equilibrium* that exists between a liquid and its gaseous state and introduce the idea of *vapor pressure*. A liquid boils when its vapor pressure equals the pressure acting on the surface of the liquid.

### 11.6 Phase Diagrams

We will recognize that in a *phase diagram* the equilibria among the gaseous, liquid, and solid phases are displayed graphically.

### 11.7 Structures of Solids

We then observe that the orderly arrangements of molecules or ions in three dimensions characterize *crystalline solids*. We also examine how the structure of a crystalline solid can be conveyed in terms of its *unit cell* and how simple molecules and ions are most efficiently arranged in three dimensions.

### 11.8 Bonding in Solids

We learn that solids can be characterized and classified according to the attractive forces between their component atoms, molecules, or ions. We examine four such classes: *molecular solids*, *covalent-network solids*, *ionic solids*, and *metallic solids*.

**SITTING IN A HOT SPRING ON A SNOWY** day is not something many of us have experienced. If we were in the hot spring shown in the chapter-opening photo, however, we would be surrounded simultaneously by all three phases of water—gas, liquid, and solid. The water vapor—

or humidity—in the air, the water in the hot spring, and the surrounding snow are all forms of the same substance,  $\text{H}_2\text{O}$ . They all have the same chemical properties. Their physical properties differ greatly, however, because the physical properties of a substance depend on its physical state. In Chapter 10 we discussed the gaseous state in some detail. In this chapter we turn our attention to the physical properties of liquids and solids and to the phase changes that occur between the three states of matter.

Many of the substances that we will consider in this chapter are molecular. In fact, virtually all substances that are liquids at room temperature are molecular substances. The intramolecular forces *within* molecules that give rise to covalent bonding influence molecular shape, bond energies, and many aspects of chemical behavior. The physical properties of molecular liquids and solids, however, are due largely to **intermolecular forces**, the forces that exist *between* molecules. We learned in Section 10.9 that attractions between gas molecules lead to deviations from ideal-gas behavior. But how do these intermolecular attractions arise? By understanding the nature and strength of intermolecular forces, we can begin to relate the composition and structure of molecules to their physical properties.

**TABLE 11.1** ■ Some Characteristic Properties of the States of Matter

Gas	Assumes both the volume and shape of its container Is compressible Flows readily Diffusion within a gas occurs rapidly
Liquid	Assumes the shape of the portion of the container it occupies Does not expand to fill container Is virtually incompressible Flows readily Diffusion within a liquid occurs slowly
Solid	Retains its own shape and volume Is virtually incompressible Does not flow Diffusion within a solid occurs extremely slowly

## 11.1 A MOLECULAR COMPARISON OF GASES, LIQUIDS, AND SOLIDS

Some of the characteristic properties of gases, liquids, and solids are listed in Table 11.1▲. These properties can be understood in terms of the energy of motion (kinetic energy) of the particles (atoms, molecules, or ions) of each state, compared to the energy of the intermolecular interactions between those particles. As we learned from the kinetic-molecular theory of gases in Chapter 10, the average kinetic energy, which is related to the particle's average speed, is proportional to the absolute temperature.

Gases consist of a collection of widely separated particles in constant, chaotic motion. The average energy of the attractions between the particles is much smaller than their average kinetic energy. The lack of strong attractive forces between particles allows a gas to expand to fill its container.

In liquids the intermolecular attractive forces are stronger than in gases and are strong enough to hold particles close together. Thus, liquids are much denser and far less compressible than gases. Unlike gases, liquids have a definite volume, independent of the size and shape of their container. The attractive forces in liquids are not strong enough, however, to keep the particles from moving past one another. Thus, any liquid can be poured, and it assumes the shape of whatever portion of its container it occupies.

In solids the intermolecular attractive forces are strong enough to hold particles close together and to lock them virtually in place. Solids, like liquids, are not very compressible because the particles have little free space between them. Because the particles in a solid or liquid are fairly close together compared with those of a gas, we often refer to solids and liquids as *condensed phases*. Often the particles of a solid take up positions in a highly regular three-dimensional pattern. Solids that possess highly ordered three-dimensional structures are said to be *crystalline*. Because the particles of a solid are not free to undergo long-range movement, solids are rigid. Keep in mind, however, that the units that form the solid, whether ions or molecules, possess thermal energy and vibrate in place. This vibrational motion increases in amplitude as a solid is heated. In fact, the energy may increase to the point that the solid either melts or sublimes.

Figure 11.1▶ compares the three states of matter. The particles that compose the substance can be individual atoms, as in Ar; molecules, as in H<sub>2</sub>O; or ions, as in NaCl. *The state of a substance depends largely on the balance between the kinetic energies of the particles and the interparticle energies of attraction.* The kinetic energies, which depend on temperature, tend to keep the particles apart and moving. The interparticle attractions tend to draw the particles together.

◀ **Figure 11.1 Molecular-level comparison of gases, liquids, and solids.** The particles can be atoms, ions, or molecules. The density of particles in the gas phase is exaggerated compared with most real situations.

Substances that are gases at room temperature have weaker interparticle attractions than those that are liquids; substances that are liquids have weaker interparticle attractions than those that are solids.

We can change a substance from one state to another by heating or cooling, which changes the average kinetic energy of the particles. NaCl, for example, which is a solid at room temperature, melts at 801 °C and boils at 1413 °C under 1 atm pressure. N<sub>2</sub>O, on the other hand, which is a gas at room temperature, liquefies at -88.5 °C and solidifies at -90.8 °C under 1 atm pressure. As the temperature of a gas decreases, the average kinetic energy of its particles decreases, allowing the attractions between the particles to first draw the particles close together, forming a liquid, and then virtually locking them in place, forming a solid.

Increasing the pressure on a gas forces the molecules closer together, which in turn increases the strength of the intermolecular forces of attraction. Propane (C<sub>3</sub>H<sub>8</sub>) is a gas at room temperature and 1 atm pressure, whereas liquefied propane (LP) gas is a liquid at room temperature because it is stored under much higher pressure.

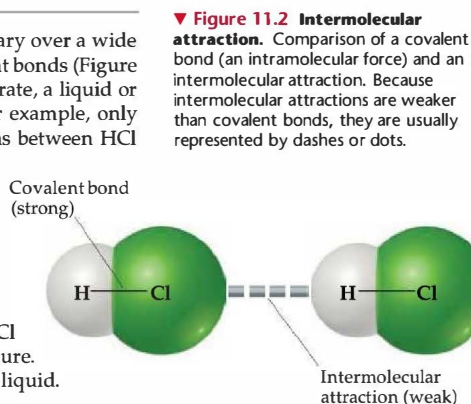

### GIVE IT SOME THOUGHT

How does the energy of attraction between particles compare with their kinetic energies in (a) a gas, (b) a solid?

## 11.2 INTERMOLECULAR FORCES

The strengths of intermolecular forces of different substances vary over a wide range, but they are generally much weaker than ionic or covalent bonds (Figure 11.2▶). Less energy, therefore, is required to vaporize, or evaporate, a liquid or to melt a solid than to break covalent bonds in molecules. For example, only 16 kJ/mol is required to overcome the intermolecular attractions between HCl molecules in liquid HCl to vaporize it. In contrast, the energy required to break the covalent bond to dissociate HCl into H and Cl atoms is 431 kJ/mol. Thus, when a molecular substance such as HCl changes from solid to liquid to gas, the molecules themselves remain intact.

Many properties of liquids, including their *boiling points*, reflect the strengths of the intermolecular forces. For example, because the forces between HCl molecules are so weak, HCl boils at a very low temperature, -85 °C at atmospheric pressure. A liquid boils when bubbles of its vapor form within the liquid.

▼ **Figure 11.2 Intermolecular attraction.** Comparison of a covalent bond (an intramolecular force) and an intermolecular attraction. Because intermolecular attractions are weaker than covalent bonds, they are usually represented by dashes or dots.

▲ **Figure 11.3 Ion-dipole attractions.** Illustration of the preferred orientations of polar molecules toward ions. The negative end of the dipoles is oriented toward a cation (a), and the positive end of the dipoles is oriented toward an anion (b).

The molecules of a liquid must overcome their attractive forces to separate and form a vapor. The stronger the attractive forces are, the higher the temperature at which the liquid boils. Similarly, the *melting points* of solids increase as the strengths of the intermolecular forces increase.

Three types of intermolecular attractions exist between neutral molecules: dipole-dipole attractions, London dispersion forces, and hydrogen bonding. The first two forms of attraction are collectively called *van der Waals forces* after Johannes van der Waals, who developed the equation for predicting the deviation of gases from ideal behavior. ∞ (Section 10.9) Another kind of attractive force, the ion-dipole force, is important in solutions. All of these intermolecular interactions are electrostatic in nature, involving attractions between positive and negative species. Even at their strongest, these interactions are much weaker than covalent or ionic bonds (<15% as strong).

### Ion-Dipole Forces

An **ion-dipole force** exists between an ion and the partial charge on the end of a polar molecule. Polar molecules are dipoles; they have a positive end and a negative end. ∞ (Section 9.3) HCl is a polar molecule, for example, because the electronegativities of the H and Cl atoms differ.

Positive ions are attracted to the negative end of a dipole, whereas negative ions are attracted to the positive end, as shown in Figure 11.3 ▲. The magnitude of the attraction increases as either the charge of the ion or the magnitude of the dipole moment increases. Ion-dipole forces are especially important for solutions of ionic substances in polar liquids, such as a solution of NaCl in water. ∞ (Section 4.1) We will discuss these solutions in more detail in Section 13.1.

### GIVE IT SOME THOUGHT

In which of the following mixtures do you encounter ion-dipole forces:  $\text{CH}_3\text{OH}$  in water or  $\text{Ca}(\text{NO}_3)_2$  in water?

▼ **Figure 11.4 Dipole-dipole attractions.** The interaction of many dipoles in a condensed state. There are both repulsive interactions between like charges and attractive interactions between unlike charges, but the attractive interactions predominate.

### Dipole-Dipole Forces

Neutral polar molecules attract each other when the positive end of one molecule is near the negative end of another, as shown in Figure 11.4 ◀. These **dipole-dipole forces** are effective only when polar molecules are very close together. Dipole-dipole forces are generally weaker than ion-dipole forces.

In liquids polar molecules are free to move with respect to one another. As shown in Figure 11.4, the polar molecules will sometimes be in an orientation that is attractive (red solid lines) and sometimes in an orientation that is repulsive (blue dashed lines). Two molecules that are attracting each other spend more time near each other than do two that are repelling each other. Thus, the overall effect is a net attraction. When we examine various liquids, we find that *for molecules of approximately equal mass and size, the strengths of intermolecular attractions increase with increasing polarity.* We can see this trend in Table 11.2 ▶, which lists several substances with similar molecular weights but different dipole moments. Notice that the boiling point increases as the dipole moment increases. For dipole-dipole forces to operate, the molecules must be able to get close together in the correct orientation.

**TABLE 11.2** Molecular Weight, Dipole Moment, and Boiling Points of Several Simple Organic Substances

Substance	Molecular Weight (amu)	Dipole Moment $\mu$ (D)	Boiling Point (K)
Propane, $\text{CH}_3\text{CH}_2\text{CH}_3$	44	0.1	231
Dimethyl ether, $\text{CH}_3\text{OCH}_3$	46	1.3	248
Methyl chloride, $\text{CH}_3\text{Cl}$	50	1.9	249
Acetaldehyde, $\text{CH}_3\text{CHO}$	44	2.7	294
Acetonitrile, $\text{CH}_3\text{CN}$	41	3.9	355

For molecules of comparable polarity, therefore, those with smaller molecular volumes generally experience higher dipole–dipole attractive forces.

### GIVE IT SOME THOUGHT

For which of the substances in Table 11.2 are the dipole–dipole attractive forces greatest?

## London Dispersion Forces

No dipole–dipole forces exist between nonpolar atoms and molecules, because nonpolar molecules (and atoms) do not have a dipole moment. Some kind of attractive interactions exist, however, because nonpolar gases such as helium and argon can be liquefied. Fritz London, a German-American physicist, first proposed the origin of this attraction in 1930. London recognized that the motion of electrons in an atom or molecule can create an *instantaneous*, or momentary, dipole moment.

In a collection of helium atoms, for example, the *average* distribution of the electrons about each nucleus is spherically symmetrical. The atoms are nonpolar and possess no permanent dipole moment. The *instantaneous* distribution of the electrons, however, can be different from the average distribution. If we could freeze the motion of the electrons in a helium atom at any given instant, both electrons could be on one side of the nucleus. At just that instant, then, the atom would have an instantaneous dipole moment.

The motions of electrons on one atom influence the motions of electrons on its neighbors. The temporary dipole on one atom can induce a similar temporary dipole on an adjacent atom, causing the atoms to be attracted to each other as shown in Figure 11.5. This attractive interaction is called the **London dispersion force** (or merely the *dispersion force*). The dispersion force, like dipole–dipole forces, is significant only when molecules are very close together.

The strength of the dispersion force depends on the ease with which the charge distribution in a molecule can be distorted to induce a momentary dipole. The ease with which the electron distribution in a molecule is distorted is called its **polarizability**. We can think of the polarizability of a molecule as a measure of the “squashiness” of its electron cloud; the greater the polarizability of the molecule, the more easily its electron cloud can be distorted to give a momentary dipole. Therefore, more polarizable molecules have larger dispersion forces.

◀ **Figure 11.5 Dispersion forces.** On the average, the charge distribution in the helium atoms is spherical, as represented by the spheres in (a). At a particular instant, however, there can be a nonspherical arrangement of the electrons, as indicated by the location of the electrons ( $e^-$ ) in (a) and by the nonspherical shape of the electron cloud in (b). The nonspherical electron distributions produce momentary dipoles and allow momentary electrostatic attractions between atoms that are called London dispersion forces or merely dispersion forces.

TABLE 11.3 ■ Boiling Points of the Halogens and the Noble Gases

Halogen	Molecular Weight (amu)	Boiling Point (K)	Noble Gas	Molecular Weight (amu)	Boiling Point (K)
F <sub>2</sub>	38.0	85.1	He	4.0	4.6
Cl <sub>2</sub>	71.0	238.6	Ne	20.2	27.3
Br <sub>2</sub>	159.8	332.0	Ar	39.9	87.5
I <sub>2</sub>	253.8	457.6	Kr	83.8	120.9
			Xe	131.3	166.1

In general, larger molecules tend to have greater polarizabilities because they have a greater number of electrons, and their electrons are farther from the nuclei. The strength of the dispersion forces, therefore, tends to increase with increasing atomic or molecular size. Because molecular size and mass generally parallel each other, *dispersion forces tend to increase in strength with increasing molecular weight*. Thus, the boiling points of the halogens and the noble gases increase with increasing molecular weight (Table 11.3 ▲).

### GIVE IT SOME THOUGHT

List the substances CCl<sub>4</sub>, CBr<sub>4</sub>, and CH<sub>4</sub> in order of increasing (a) polarizability, (b) strength of dispersion forces, and (c) boiling point.

The shapes of molecules also influence the magnitudes of dispersion forces. For example, *n*-pentane\* and neopentane, illustrated in Figure 11.6 ◀, have the same molecular formula (C<sub>5</sub>H<sub>12</sub>), yet the boiling point of *n*-pentane is 27 K higher than that of neopentane. The difference can be traced to the different shapes of the two molecules. The overall attraction between molecules is greater for *n*-pentane because the molecules can come in contact over the entire length of the long, somewhat cylindrically shaped molecule. Less contact is possible between the more compact and nearly spherical molecules of neopentane.

*Dispersion forces operate between all molecules*, whether they are polar or non-polar. Polar molecules experience dipole–dipole interactions, but they also experience dispersion forces at the same time. In fact, dispersion forces between polar molecules commonly contribute more to intermolecular attractions than do dipole–dipole forces. In liquid HCl, for example, dispersion forces are estimated to account for more than 80% of the total attraction between molecules; dipole–dipole attractions account for the rest.

When comparing the relative strengths of intermolecular attractions in two substances, consider the following generalizations:

1. When the molecules of two substances have comparable molecular weights and shapes, dispersion forces are approximately equal in the two substances. In this case, differences in the magnitudes of the attractive forces are due to differences in the strengths of dipole–dipole attractions, with the more polar molecules having the stronger attractions.
2. When the molecules of two substances differ widely in molecular weights, dispersion forces tend to be decisive in determining which substance has the stronger intermolecular attractions. In this case differences in the magnitudes of the attractive forces can usually be associated with differences in molecular weights, with the substance made up of the more massive molecule having the strongest attractions (assuming similar dipole moments).

\*The *n* in *n*-pentane is an abbreviation for the word *normal*. A *normal hydrocarbon* is one in which the carbon atoms are arranged in a straight chain. ↔ (Section 2.9)

*n*-Pentane  
(bp = 309.4 K)

Neopentane  
(bp = 282.7 K)

▲ **Figure 11.6 Molecular shape affects intermolecular attraction.** The *n*-pentane molecules make more contact with each other than do the neopentane molecules. Thus, *n*-pentane has the greater intermolecular attractive forces and therefore has the higher boiling point (bp).

The hydrogen bond, which we consider after Sample Exercise 11.1, is a special type of dipole–dipole attraction that is typically stronger than dispersion forces.

### SAMPLE EXERCISE 11.1 | Comparing Intermolecular Forces

The dipole moments of acetonitrile,  $\text{CH}_3\text{CN}$ , and methyl iodide,  $\text{CH}_3\text{I}$ , are 3.9 D and 1.62 D, respectively. (a) Which of these substances has greater dipole–dipole attractions among its molecules? (b) Which of these substances has greater London dispersion attractions? (c) The boiling points of  $\text{CH}_3\text{CN}$  and  $\text{CH}_3\text{I}$  are 354.8 K and 315.6 K, respectively. Which substance has the greater overall attractive forces?

#### SOLUTION

(a) Dipole–dipole attractions increase in magnitude as the dipole moment of the molecule increases. Thus,  $\text{CH}_3\text{CN}$  molecules attract each other by stronger dipole–dipole forces than  $\text{CH}_3\text{I}$  molecules do. (b) When molecules differ in their molecular weights, the more massive molecule generally has the stronger dispersion attractions. In this case  $\text{CH}_3\text{I}$  (142.0 g/mol) is much more massive than  $\text{CH}_3\text{CN}$  (41.0 g/mol), so the dispersion forces will be stronger for  $\text{CH}_3\text{I}$ . (c) Because  $\text{CH}_3\text{CN}$  has the higher boiling point, we can conclude that more energy is required to overcome attractive interactions between  $\text{CH}_3\text{CN}$  molecules. Thus, the total intermolecular attractions are stronger for  $\text{CH}_3\text{CN}$ , suggesting that the energies resulting from dipole–dipole forces are decisive when comparing these two substances. Nevertheless, the attractive interactions due to dispersion forces play an important role in determining the properties of  $\text{CH}_3\text{I}$ .

#### PRACTICE EXERCISE

Of  $\text{Br}_2$ , Ne, HCl, HBr, and  $\text{N}_2$ , which is likely to have (a) the largest intermolecular dispersion forces, (b) the largest dipole–dipole attractive forces?

Answers: (a)  $\text{Br}_2$  (largest molecular weight), (b) HCl (largest polarity)

## Hydrogen Bonding

Figure 11.7 shows the boiling points of the simple hydrogen compounds of group 4A and 6A elements. In general, the boiling point increases with increasing molecular weight, owing to increased dispersion forces. The notable exception to this trend is  $\text{H}_2\text{O}$ , whose boiling point is much higher than we would expect because of its molecular weight. This observation indicates that there are stronger intermolecular attractions between  $\text{H}_2\text{O}$  molecules than there are between other molecules in the same group. The compounds  $\text{NH}_3$  and  $\text{HF}$  likewise have abnormally high boiling points. In fact, these compounds have many characteristics that distinguish them from other substances of similar molecular weight and polarity. For example, water has a high melting point, a high specific heat, and a high heat of vaporization. Each of these properties indicates that the intermolecular forces between  $\text{H}_2\text{O}$  molecules are abnormally strong.

The strong intermolecular attractions in  $\text{H}_2\text{O}$  result from hydrogen bonding. **Hydrogen bonding** is a special type of intermolecular attraction between the hydrogen atom in a polar bond (particularly an  $\text{H}-\text{F}$ ,  $\text{H}-\text{O}$ , or  $\text{H}-\text{N}$  bond) and nonbonding electron pair on a nearby small electronegative ion or atom (usually an  $\text{F}$ ,  $\text{O}$ , or  $\text{N}$  atom in another molecule). For example, a hydrogen bond exists between the H atom in an HF molecule and the F atom of an adjacent HF molecule,  $\text{F}-\text{H}\cdots\text{F}-\text{H}$  (where the

▼ **Figure 11.7** Boiling point as a function of molecular weight. The boiling points of the group 4A (bottom) and 6A (top) hydrides are shown as a function of molecular weight. In general, the boiling points increase with increasing molecular weight, because of the increasing strength of dispersion forces. The very strong hydrogen-bonding forces between  $\text{H}_2\text{O}$  molecules, however, cause water to have an unusually high boiling point.

**▲ Figure 11.8** Examples of hydrogen bonding. The solid lines represent covalent bonds; the red dotted lines represent hydrogen bonds.

dots represent the hydrogen bond between the molecules). Several additional examples are shown in Figure 11.8 ◀.

Hydrogen bonds can be considered unique dipole–dipole attractions. Because F, N, and O are so electronegative, a bond between hydrogen and any of these three elements is quite polar, with hydrogen at the positive end:

The hydrogen atom has no inner core of electrons. Thus, the positive side of the bond dipole has the concentrated charge of the partially exposed, nearly bare proton of the hydrogen nucleus. This positive charge is attracted to the negative charge of an electronegative atom in a nearby molecule. Because the electron-poor hydrogen is so small, it can approach an electronegative atom very closely and thus interact strongly with it.

### SAMPLE EXERCISE 11.2 Identifying Substances that Can Form Hydrogen Bonds

In which of the following substances is hydrogen bonding likely to play an important role in determining physical properties: methane ( $\text{CH}_4$ ), hydrazine ( $\text{H}_2\text{NNH}_2$ ), methyl fluoride ( $\text{CH}_3\text{F}$ ), or hydrogen sulfide ( $\text{H}_2\text{S}$ )?

#### SOLUTION

**Analyze:** We are given the chemical formulas of four substances and asked to predict whether they can participate in hydrogen bonding. All of these compounds contain H, but hydrogen bonding usually occurs only when the hydrogen is covalently bonded to N, O, or F.

**Plan:** We can analyze each formula to see if it contains N, O, or F directly bonded to H. There also needs to be a nonbonding pair of electrons on an electronegative atom (usually N, O, or F) in a nearby molecule, which can be revealed by drawing the Lewis structure for the molecule.

**Solve:** The criteria listed above eliminate  $\text{CH}_4$  and  $\text{H}_2\text{S}$ , which do not contain H bonded to N, O, or F. They also eliminate  $\text{CH}_3\text{F}$ , whose Lewis structure shows a central C atom surrounded by three H atoms and an F atom. (Carbon always forms four bonds, whereas hydrogen and fluorine form one each.) Because the molecule contains a C–F bond and not a H–F bond, it does not form hydrogen bonds. In  $\text{H}_2\text{NNH}_2$ , however, we find N–H bonds. If we draw the Lewis structure for the molecule, we see that there is a nonbonding pair of electrons on each N atom. Therefore, hydrogen bonds can exist between the molecules as depicted below.

**Check:** While we can generally identify substances that participate in hydrogen bonding based on their containing N, O, or F covalently bonded to H, drawing the Lewis structure for the interaction, as shown above, provides a way to check the prediction.

#### PRACTICE EXERCISE

In which of the following substances is significant hydrogen bonding possible: methylene chloride ( $\text{CH}_2\text{Cl}_2$ ), phosphine ( $\text{PH}_3$ ), hydrogen peroxide ( $\text{HOOH}$ ), or acetone ( $\text{CH}_3\text{COCH}_3$ )?

**Answer:** HOOH

The energies of hydrogen bonds vary from about 5 kJ/mol to 25 kJ/mol or so, although there are isolated examples of hydrogen bond energies that are close to 100 kJ/mol. Thus, hydrogen bonds are typically much weaker than ordinary chemical bonds, which have bond energies of 200–1100 kJ/mol (see Table 8.4). Nevertheless, because hydrogen bonds are generally stronger than dipole–dipole or dispersion forces, they play important roles in many chemical systems, including those of biological significance. For example, hydrogen bonds help stabilize the structures of proteins, which are key parts of skin, muscles, and other structural components of animal tissues.  $\leftarrow$  (Section 25.9) They are also responsible for the way that DNA is able to carry genetic information.  $\leftarrow$  (Section 25.11)

One of the remarkable consequences of hydrogen bonding is found when the densities of ice and liquid water are compared. In most substances the molecules in the solid are more densely packed than in the liquid. Thus, the solid phase is denser than the liquid phase (Figure 11.9). By contrast, the density of ice at 0 °C (0.917 g/mL) is less than that of liquid water at 0 °C (1.00 g/mL), so ice floats on liquid water (Figure 11.9).

The lower density of ice compared to that of water can be understood in terms of hydrogen-bonding interactions between  $\text{H}_2\text{O}$  molecules. In ice, the  $\text{H}_2\text{O}$  molecules assume an ordered, open arrangement as shown in Figure 11.10. This arrangement optimizes the hydrogen bonding interactions between molecules, with each  $\text{H}_2\text{O}$  molecule forming hydrogen bonds to four other  $\text{H}_2\text{O}$  molecules. These hydrogen bonds, however, create the open cavities shown in the structure. When the ice melts, the motions of the molecules cause the structure to collapse. The hydrogen bonding in the liquid is more random than in ice, but it is strong enough to hold the molecules close together. Consequently, liquid water has a more dense structure than ice, meaning that a given mass of water occupies a smaller volume than the same mass of ice.

▲ **Figure 11.9 Comparing densities of liquid and solid phases.** As with most other substances, the solid phase of paraffin is denser than the liquid phase, and the solid therefore sinks below the surface of the liquid paraffin in the beaker on the left. In contrast, the solid phase of water, ice, is less dense than its liquid phase (right beaker), causing the ice to float on the water.

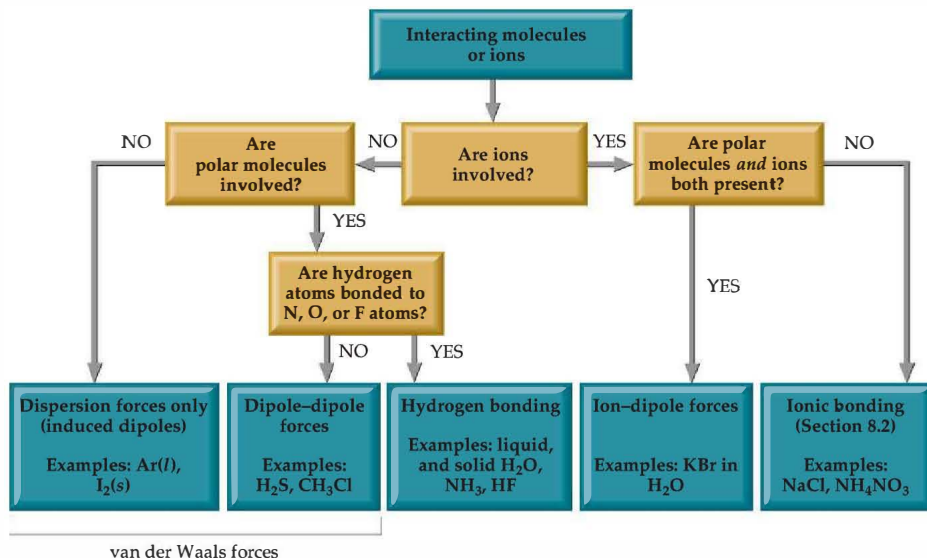

▲ **Figure 11.10 Hydrogen bonding in ice.** (a) The hexagonal shape is characteristic of snowflakes. (b) The arrangement of  $\text{H}_2\text{O}$  molecules in ice. Each hydrogen atom on one  $\text{H}_2\text{O}$  molecule is oriented toward a nonbonding pair of electrons on an adjacent  $\text{H}_2\text{O}$  molecule. As a result, ice has an open, hexagonal arrangement of  $\text{H}_2\text{O}$  molecules. (c) Hydrogen bonding between two water molecules. The distances shown are those found in ice.

▲ **Figure 11.11 Expansion of water upon freezing.** Water is one of the few substances that expand upon freezing. The expansion is due to the open structure of ice relative to that of liquid water.

▼ **Figure 11.12 Flowchart for determining intermolecular forces.** London dispersion forces occur in all instances. The strengths of the other forces generally increase proceeding from left to right across the chart.

The lower density of ice compared to liquid water profoundly affects life on Earth. Because ice floats (Figure 11.9), it covers the top of the water when a lake freezes in cold weather, thereby insulating the water below. If ice were more dense than water, ice forming at the top of a lake would sink to the bottom, and the lake could freeze solid. Most aquatic life could not survive under these conditions. The expansion of water upon freezing (Figure 11.11) is also what causes water pipes to break in freezing weather.

### GIVE IT SOME THOUGHT

What is unusual about the relative densities of liquid water and ice?

### Comparing Intermolecular Forces

We can identify the intermolecular forces that are operative in a substance by considering its composition and structure. *Dispersion forces are found in all substances.* The strengths of these attractions increase with increasing molecular weight and depend on molecular shapes. Dipole-dipole forces add to the effect of dispersion forces and are found in polar molecules. Hydrogen bonds, which require H atoms bonded to F, O, or N, also add to the effect of dispersion forces. Hydrogen bonds tend to be the strongest type of intermolecular attraction. None of these intermolecular attractions, however, is as strong as ordinary ionic or covalent bonds. In general, the energies associated with the dispersion forces and dipole-dipole forces are in the range of 2–10 kJ/mol, while the energies of hydrogen bonds are in the range 5–25 kJ/mol. Ion-dipole attractions lead to energies of approximately 15 kJ/mol.

It is important to realize that the effects of all these attractions are additive. For example, if a pair of molecules can make one hydrogen bond between them but a second pair can make three equivalent hydrogen bonds between them, the second pair of molecules will be held together with triple the energy of the first pair. Likewise, very large polar molecules such as proteins, which have multiple dipoles over their surfaces, can be held together in solution to a surprisingly high degree by multiple dipole-dipole attractions. Figure 11.12 presents a systematic way of identifying the kinds of intermolecular forces in a particular system, including ion-dipole and ion-ion forces.

**SAMPLE EXERCISE 11.3** Predicting the Types and Relative Strengths of Intermolecular Attractions

List the substances  $\text{BaCl}_2$ ,  $\text{H}_2$ ,  $\text{CO}$ ,  $\text{HF}$ , and  $\text{Ne}$  in order of increasing boiling points.

**SOLUTION**

**Analyze:** We need to relate the properties of the listed substances to boiling point.

**Plan:** The boiling point depends in part on the attractive forces in the liquid. We need to order these according to the relative strengths of the different kinds of intermolecular attractions.

**Solve:** The attractive forces are stronger for ionic substances than for molecular ones, so  $\text{BaCl}_2$  should have the highest boiling point. The intermolecular forces of the remaining substances depend on molecular weight, polarity, and hydrogen bonding. The molecular weights are  $\text{H}_2$  (2),  $\text{CO}$  (28),  $\text{HF}$  (20), and  $\text{Ne}$  (20). The boiling point of  $\text{H}_2$  should be the lowest because it is nonpolar and has the lowest molecular weight. The molecular weights of  $\text{CO}$ ,  $\text{HF}$ , and  $\text{Ne}$  are roughly the same. Because  $\text{HF}$  can hydrogen bond, however, it should have the highest boiling point of the three. Next is  $\text{CO}$ , which is slightly polar and has the highest molecular weight. Finally,  $\text{Ne}$ , which is nonpolar, should have the lowest boiling point of these three. The predicted order of boiling points is therefore

**Check:** The actual normal boiling points are  $\text{H}_2$  (20 K),  $\text{Ne}$  (27 K),  $\text{CO}$  (83 K),  $\text{HF}$  (293 K), and  $\text{BaCl}_2$  (1813 K)—in agreement with our predictions.

**PRACTICE EXERCISE**

(a) Identify the intermolecular attractions present in the following substances, and (b) select the substance with the highest boiling point:  $\text{CH}_3\text{CH}_3$ ,  $\text{CH}_3\text{OH}$ , and  $\text{CH}_3\text{CH}_2\text{OH}$ .

**Answers:** (a)  $\text{CH}_3\text{CH}_3$  has only dispersion forces, whereas the other two substances have both dispersion forces and hydrogen bonds; (b)  $\text{CH}_3\text{CH}_2\text{OH}$

## 11.3 SOME PROPERTIES OF LIQUIDS

The intermolecular attractions we have just discussed can help us understand many familiar properties of liquids and solids. In this section we examine two important properties of liquids: viscosity and surface tension.

### Viscosity

Some liquids, such as molasses and motor oil, flow very slowly; others, such as water and gasoline, flow easily. The resistance of a liquid to flow is called its **viscosity**. The greater a liquid's viscosity, the more slowly it flows. Viscosity can be measured by timing how long it takes a certain amount of the liquid to flow through a thin tube under gravitational force. More viscous liquids take longer (Figure 11.13 ▶). Viscosity can also be determined by measuring the rate at which steel balls fall through the liquid. The balls fall more slowly as the viscosity increases.

Viscosity is related to the ease with which individual molecules of the liquid can move with respect to one another. It thus depends on the attractive forces between molecules, and on whether structural features exist that cause the molecules to become entangled (for example, long molecules might become tangled like spaghetti). For a series of related compounds, therefore, viscosity increases with molecular weight, as illustrated in Table 11.4 ▼. The SI units for viscosity are  $\text{kg/m}\cdot\text{s}$ . For any given substance, viscosity decreases with increasing temperature. Octane, for example, has a viscosity of  $7.06 \times 10^{-4} \text{ kg/m}\cdot\text{s}$  at  $0^\circ\text{C}$ , and of  $4.33 \times 10^{-4} \text{ kg/m}\cdot\text{s}$  at  $40^\circ\text{C}$ . At higher temperatures the greater average kinetic energy of the molecules more easily overcomes the attractive forces between molecules.

▲ **Figure 11.13 Comparing viscosities.** The Society of Automotive Engineers (SAE) has established numbers to indicate the viscosity of motor oils. The higher the number, the greater the viscosity is at any given temperature. The SAE 40 motor oil on the left is more viscous and flows more slowly than the less viscous SAE 10 oil on the right.

▲ **Figure 11.14 Surface tension.** Surface tension permits an insect such as the water strider to “walk” on water.

▲ **Figure 11.15 Molecular-level view of surface and interior intermolecular forces in a liquid.** Molecules at the surface are attracted only by other surface molecules and by molecules below the surface. The result is a net downward attraction into the interior of the liquid. Molecules in the interior experience attractions in all directions, resulting in no net attraction in any direction.

▲ **Figure 11.16 Two meniscus shapes.** The water meniscus in a glass tube compared with the mercury meniscus in a similar tube. Water wets the glass, and the bottom of the meniscus is below the level of the water–glass contact line, giving a U-shape to the water surface. Mercury does not wet glass and the meniscus is above the mercury–glass contact line, giving an inverted U-shape to the mercury surface.

**TABLE 11.4** ■ Viscosities of a Series of Hydrocarbons at 20 °C

Substance	Formula	Viscosity (kg/m·s)
Hexane	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	$3.26 \times 10^{-4}$
Heptane	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	$4.09 \times 10^{-4}$
Octane	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	$5.42 \times 10^{-4}$
Nonane	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	$7.11 \times 10^{-4}$
Decane	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	$1.42 \times 10^{-3}$

## Surface Tension

The surface of water behaves almost as if it had an elastic skin, as evidenced by the ability of certain insects to “walk” on water (Figure 11.14 ◀). This behavior is due to an imbalance of intermolecular forces at the surface of the liquid, as shown in Figure 11.15 ◀. Notice that molecules in the interior are attracted equally in all directions, whereas those at the surface experience a net inward force. The resultant inward force pulls molecules from the surface into the interior, thereby reducing the surface area and making the molecules at the surface pack closely together. Because spheres have the smallest surface area for their volume, water droplets assume an almost spherical shape. Similarly, water tends to “bead up” on a newly waxed car because there is little or no attraction between the polar water molecules and the nonpolar wax molecules.

A measure of the inward forces that must be overcome to expand the surface area of a liquid is given by its surface tension. **Surface tension** is the energy required to increase the surface area of a liquid by a unit amount. For example, the surface tension of water at 20 °C is  $7.29 \times 10^{-2} \text{ J/m}^2$ , which means that an energy of  $7.29 \times 10^{-2} \text{ J}$  must be supplied to increase the surface area of a given amount of water by  $1 \text{ m}^2$ . Water has a high surface tension because of its strong hydrogen bonds. The surface tension of mercury is even higher ( $4.6 \times 10^{-1} \text{ J/m}^2$ ) because of even stronger metallic bonds between the atoms of mercury. ⇌ (Section 11.8)

### GIVE IT SOME THOUGHT

How do viscosity and surface tension change (a) as temperature increases, (b) as intermolecular forces of attraction become stronger?

Intermolecular forces that bind similar molecules to one another, such as the hydrogen bonding in water, are also called *cohesive forces*. Intermolecular forces that bind a substance to a surface are called *adhesive forces*. Water placed in a glass tube adheres to the glass because the adhesive forces between the water and glass are even greater than the cohesive forces between water molecules. The curved upper surface, or *meniscus*, of the water is therefore U-shaped (Figure 11.16 ◀). For mercury, however, the meniscus is curved downward where the mercury contacts the glass. In this case the cohesive forces between the mercury atoms are much greater than the adhesive forces between the mercury atoms and the glass.

When a small-diameter glass tube, or capillary, is placed in water, water rises in the tube. The rise of liquids up very narrow tubes is called **capillary action**. The adhesive forces between the liquid and the walls of the tube tend to increase the surface area of the liquid. The surface tension of the liquid tends to reduce the area, thereby pulling the liquid up the tube. The liquid climbs until the force of gravity on the liquid balances the adhesive and cohesive forces. Capillary action helps water and dissolved nutrients move upward through plants.

### GIVE IT SOME THOUGHT

If a liquid in a thin tube has no meniscus (in other words, the top of the liquid looks completely flat), what does that imply about the relative strengths of cohesive and adhesive forces?

## 11.4 PHASE CHANGES

Water left uncovered in a glass for several days evaporates. An ice cube left in a warm room quickly melts. Solid  $\text{CO}_2$  (sold as dry ice) *sublimes* at room temperature; that is, it changes directly from the solid to the vapor state. In general, each state of matter can change into either of the other two states. Figure 11.17 shows the name associated with each of these transformations. These transformations are called either **phase changes** or changes of state.

### Energy Changes Accompanying Phase Changes

Every phase change is accompanied by a change in the energy of the system. In a solid, for example, the molecules or ions are in more or less fixed positions with respect to one another and closely arranged to minimize the energy of the system. As the temperature of the solid increases, the units of the solid vibrate about their equilibrium positions with increasingly energetic motion. When the solid melts, the units that made up the solid are freed to move with respect to one another, which ordinarily means that their average separations increase. This melting process is called (somewhat confusingly) *fusion*. The increased freedom of motion of the molecules or ions comes at a price, measured by the **heat of fusion**, or enthalpy of fusion, denoted  $\Delta H_{\text{fus}}$ . The heat of fusion of ice, for example, is 6.01 kJ/mol.

As the temperature of the liquid phase increases, the molecules of the liquid move about with increasing energy. One measure of this increasing energy is that the concentration of gas-phase molecules over the liquid increases with temperature. These molecules exert a pressure called the vapor pressure. We will explore vapor pressure in Section 11.5. For now we just need to understand that the vapor pressure increases with increasing temperature until it equals the external pressure over the liquid, typically atmospheric pressure. At this point the liquid boils—the molecules of the liquid move into the gaseous state, where they are widely separated. The energy required to cause this transition is called the **heat of vaporization**, or enthalpy of vaporization, denoted  $\Delta H_{\text{vap}}$ . For water, the heat of vaporization is 40.7 kJ/mol.

Figure 11.18 shows the comparative values of  $\Delta H_{\text{fus}}$  and  $\Delta H_{\text{vap}}$  for four substances.  $\Delta H_{\text{vap}}$  values tend to be larger than  $\Delta H_{\text{fus}}$  because in the transition from the liquid to the vapor state, the molecules must essentially sever all their intermolecular attractive interactions; whereas in melting, many of these attractive interactions remain.

**▲ Figure 11.18 Comparing enthalpy changes for fusion and vaporization.** Heats of fusion (violet bars) and heats of vaporization (blue bars) for several substances. Notice that the heat of vaporization for a substance is always larger than its heat of fusion. The heat of sublimation is the sum of the heats of vaporization and fusion.

**▲ Figure 11.17 Phase changes and the names associated with them.**

Those changes indicated by red arrows and names are endothermic, whereas those in green are exothermic.

The molecules of a solid can be transformed directly into the gaseous state. The enthalpy change required for this transition is called the **heat of sublimation**, denoted  $\Delta H_{\text{sub}}$ . For the substances shown in Figure 11.18,  $\Delta H_{\text{sub}}$  is the sum of  $\Delta H_{\text{fus}}$  and  $\Delta H_{\text{vap}}$ . Thus,  $\Delta H_{\text{sub}}$  for water is approximately 47 kJ/mol.

Phase changes of matter show up in important ways in our everyday experiences. We use ice cubes to cool our liquid drinks; the heat of fusion of ice cools the liquid in which the ice is immersed. We feel cool when we step out of a swimming pool or a warm shower because the heat of vaporization is drawn from our bodies as the water evaporates from our skin. Our bodies use the evaporation of water from skin to regulate body temperature, especially when we exercise vigorously in warm weather. A refrigerator also relies on the cooling effects of vaporization. Its mechanism contains an enclosed gas that can be liquefied under pressure. The liquid absorbs heat as it subsequently evaporates, thereby cooling the interior of the refrigerator. The vapor is then recycled through a compressor.

What happens to the heat absorbed when the liquid refrigerant vaporizes? According to the first law of thermodynamics (see Section 5.2), the heat absorbed by the liquid in vaporizing must be released when the reverse process, condensation of the vapor to form the liquid, occurs. As the refrigerator compresses the vapor to form a liquid, the heat released by the condensation process is dissipated through cooling coils in the back of the refrigerator. Just as the heat of condensation is equal in magnitude to the heat of vaporization and has the opposite sign, so also the *heat of deposition* is exothermic to the same degree that the heat of sublimation is endothermic; and the *heat of freezing* is exothermic to the same degree that the heat of fusion is endothermic. These relationships, shown in Figure 11.17, are consequences of the first law of thermodynamics.

### GIVE IT SOME THOUGHT

What is the name of the phase change that occurs when ice left at room temperature changes to liquid water? Is this change exothermic or endothermic?

**▲ Figure 11.19 Heating curve for water.** This graph indicates the changes that occur when 1.00 mol of water is heated from 25 °C to 125 °C at a constant pressure of 1 atm. Blue lines show the heating of one phase from a lower temperature to a higher one. Red lines show the conversion of one phase to another at constant temperature.

### Heating Curves

What happens when we heat an ice cube that is initially at  $-25\text{ °C}$  and 1 atm pressure? The addition of heat causes the temperature of the ice to increase. As long as the temperature is below  $0\text{ °C}$ , the ice cube remains frozen. When the temperature reaches  $0\text{ °C}$ , the ice begins to melt. Because melting is an endothermic process, the heat we add at  $0\text{ °C}$  is used to convert ice to water; the temperature remains constant until all the ice has melted. Once we reach this point, the further addition of heat causes the temperature of the liquid water to increase.

A graph of the temperature of the system versus the amount of heat added is called a *heating curve*. Figure 11.19 ◀ shows a heating curve for transforming ice at  $-25\text{ °C}$  to steam at  $125\text{ °C}$  under a constant pressure of 1 atm. Heating the ice from  $-25\text{ °C}$  to  $0\text{ °C}$  is represented by the line segment AB in Figure 11.19, while converting the ice at  $0\text{ °C}$  to water at  $0\text{ °C}$  is the horizontal segment BC. Additional heat increases the temperature of the water until the temperature reaches  $100\text{ °C}$  (segment CD). The heat is then used to convert water to steam at a constant temperature of  $100\text{ °C}$  (segment DE). Once all the water has been converted to steam, the steam is heated to its final temperature of  $125\text{ °C}$  (segment EF).

We can calculate the enthalpy change of the system for each of the segments of the heating curve. In segments *AB*, *CD*, and *EF* we are heating a single phase from one temperature to another. As we saw in Section 5.5, the amount of heat needed to raise the temperature of a substance is given by the product of the specific heat, mass, and temperature change (Equation 5.22). The greater the specific heat of a substance, the more heat we must add to accomplish a certain temperature increase. Because the specific heat of water is greater than that of ice, the slope of segment *CD* is less than that of segment *AB*; we must add more heat to water to achieve a 1 °C temperature change than is needed to warm the same quantity of ice by 1 °C.

In segments *BC* and *DE* we are converting one phase to another at a constant temperature. The temperature remains constant during these phase changes because the added energy is used to overcome the attractive forces between molecules rather than to increase their average kinetic energy. For segment *BC*, in which ice is converted to water, the enthalpy change can be calculated by using  $\Delta H_{\text{fus}}$ , while for segment *DE* we can use  $\Delta H_{\text{vap}}$ . In Sample Exercise 11.4 we calculate the total enthalpy change for the heating curve in Figure 11.19.

### SAMPLE EXERCISE 11.4 | Calculating $\Delta H$ for Temperature and Phase Changes

Calculate the enthalpy change upon converting 1.00 mol of ice at  $-25\text{ }^{\circ}\text{C}$  to water vapor (steam) at  $125\text{ }^{\circ}\text{C}$  under a constant pressure of 1 atm. The specific heats of ice, water, and steam are  $2.03\text{ J/g}\cdot\text{K}$ ,  $4.18\text{ J/g}\cdot\text{K}$ , and  $1.84\text{ J/g}\cdot\text{K}$ , respectively. For  $\text{H}_2\text{O}$ ,  $\Delta H_{\text{fus}} = 6.01\text{ kJ/mol}$  and  $\Delta H_{\text{vap}} = 40.67\text{ kJ/mol}$ .

#### SOLUTION

**Analyze:** Our goal is to calculate the total heat required to convert 1 mol of ice at  $-25\text{ }^{\circ}\text{C}$  to steam at  $125\text{ }^{\circ}\text{C}$ .

**Plan:** We can calculate the enthalpy change for each segment and then sum them to get the total enthalpy change (Hess's law, Section 5.6).

**Solve:** For segment *AB* in Figure 11.19, we are adding enough heat to ice to increase its temperature by  $25\text{ }^{\circ}\text{C}$ . A temperature change of  $25\text{ }^{\circ}\text{C}$  is the same as a temperature change of 25 K, so we can use the specific heat of ice to calculate the enthalpy change during this process:

$$AB: \Delta H = (1.00\text{ mol})(18.0\text{ g/mol})(2.03\text{ J/g}\cdot\text{K})(25\text{ K}) = 914\text{ J} = 0.91\text{ kJ}$$

For segment *BC* in Figure 11.19, in which we convert ice to water at  $0\text{ }^{\circ}\text{C}$ , we can use the molar enthalpy of fusion directly:

$$BC: \Delta H = (1.00\text{ mol})(6.01\text{ kJ/mol}) = 6.01\text{ kJ}$$

The enthalpy changes for segments *CD*, *DE*, and *EF* can be calculated in similar fashion:

$$CD: \Delta H = (1.00\text{ mol})(18.0\text{ g/mol})(4.18\text{ J/g}\cdot\text{K})(100\text{ K}) = 7520\text{ J} = 7.52\text{ kJ}$$

$$DE: \Delta H = (1.00\text{ mol})(40.67\text{ kJ/mol}) = 40.7\text{ kJ}$$

$$EF: \Delta H = (1.00\text{ mol})(18.0\text{ g/mol})(1.84\text{ J/g}\cdot\text{K})(25\text{ K}) = 830\text{ J} = 0.83\text{ kJ}$$

The total enthalpy change is the sum of the changes of the individual steps:

$$\Delta H = 0.91\text{ kJ} + 6.01\text{ kJ} + 7.52\text{ kJ} + 40.7\text{ kJ} + 0.83\text{ kJ} = 56.0\text{ kJ}$$

**Check:** The components of the total energy change are reasonable in comparison with the lengths of the horizontal segments of the lines in Figure 11.19. Notice that the largest component is the heat of vaporization.

#### PRACTICE EXERCISE

What is the enthalpy change during the process in which 100.0 g of water at  $50.0\text{ }^{\circ}\text{C}$  is cooled to ice at  $-30.0\text{ }^{\circ}\text{C}$ ? (Use the specific heats and enthalpies for phase changes given in Sample Exercise 11.4.)

**Answer:**  $-20.9\text{ kJ} - 33.4\text{ kJ} - 6.09\text{ kJ} = -60.4\text{ kJ}$

Cooling a substance has the opposite effect of heating it. Thus, if we start with water vapor and begin to cool it, we would move right to left through the events shown in Figure 11.19. We would first lower the temperature of the

vapor ( $F \rightarrow E$ ), then condense it ( $E \rightarrow D$ ), and so forth. Sometimes as we remove heat from a liquid, we can temporarily cool it below its freezing point without forming a solid. This phenomenon is called *supercooling*. Supercooling occurs when heat is removed from a liquid so rapidly that the molecules literally have no time to assume the ordered structure of a solid. A supercooled liquid is unstable; particles of dust entering the solution or gentle stirring is often sufficient to cause the substance to solidify quickly.

### Critical Temperature and Pressure

A gas normally liquefies at some point when pressure is applied to it. Suppose we have a cylinder with a piston, containing water vapor at 100 °C. If we increase the pressure on the water vapor, liquid water will form when the pressure is 760 torr. On the other hand, if the temperature is 110 °C, the liquid phase does not form until the pressure is 1075 torr. At 374 °C the liquid phase forms only at  $1.655 \times 10^5$  torr (217.7 atm). Above this temperature no amount of pressure will cause a distinct liquid phase to form. Instead, as pressure increases, the gas merely becomes steadily more compressed. The highest temperature at which a distinct liquid phase can form is referred to as the **critical temperature**. The **critical pressure** is the pressure required to bring about liquefaction at this critical temperature.

The critical temperature is the highest temperature at which a liquid can exist. Above the critical temperature, the motional energies of the molecules are greater than the attractive forces that lead to the liquid state regardless of how much the substance is compressed to bring the molecules closer together. The greater the intermolecular forces, the greater the critical temperature of a substance.

The critical temperatures and pressures are listed for several substances in Table 11.5 ▼. Notice that nonpolar, low molecular weight substances, which have weak intermolecular attractions, have lower critical temperatures and pressures than those that are polar or of higher molecular weight. Notice also that water and ammonia have exceptionally high critical temperatures and pressures as a consequence of strong intermolecular hydrogen-bonding forces.

The critical temperatures and pressures of substances are often of considerable importance to engineers and other people working with gases, because they provide information about the conditions under which gases liquefy. Sometimes we want to liquefy a gas; other times we want to avoid liquefying it. It is useless to try to liquefy a gas by applying pressure if the gas is above its critical temperature. For example,  $O_2$  has a critical temperature of 154.4 K. It must be cooled below this temperature before it can be liquefied by pressure. In contrast, ammonia has a critical temperature of 405.6 K. Thus, it can be liquefied at room temperature (approximately 295 K) by compressing the gas to a sufficient pressure.

**TABLE 11.5** ■ Critical Temperatures and Pressures of Selected Substances

Substance	Critical Temperature (K)	Critical Pressure (atm)
Ammonia, $NH_3$	405.6	111.5
Argon, Ar	150.9	48
Carbon dioxide, $CO_2$	304.3	73.0
Hydrogen sulfide, $H_2S$	373.5	88.9
Nitrogen, $N_2$	126.1	33.5
Oxygen, $O_2$	154.4	49.7
Phosphine, $PH_3$	324.4	64.5
Propane, $CH_3CH_2CH_3$	370.0	42.0
Water, $H_2O$	647.6	217.7

## Chemistry Put to Work

### SUPERCRITICAL FLUID EXTRACTION

At ordinary pressures, a substance above its critical temperature behaves as an ordinary gas. However, as pressure increases up to several hundred atmospheres, its character changes. Like a gas, the substance still expands to fill the confines of its container, but its density approaches that of a liquid. (For example, the critical temperature of water is 647.6 K, and its critical pressure is 217.7 atm. At this temperature and pressure, the density of water is 0.4 g/mL.) A substance at temperatures and pressures higher than its critical temperature and pressure is better considered a *supercritical fluid* rather than a gas.

Like liquids, supercritical fluids can behave as solvents, dissolving a wide range of substances. Using *supercritical fluid extraction*, the components of mixtures can be separated. The solvent power of a supercritical fluid increases as its density increases. Conversely, lowering its density (by either decreasing pressure or increasing temperature) causes the supercritical fluid and the dissolved material to separate. By appropriate manipulation of pressure, supercritical fluid extraction has been used successfully to separate complex mixtures in the chemical, food, pharmaceutical, and energy industries. Supercritical carbon dioxide, for example, is environmentally benign

▲ **Figure 11.20** Photograph of carbon dioxide under temperature and pressure conditions so that it is a supercritical fluid.

because there are no problems disposing of solvent and there are no toxic residues resulting from the process. In addition, supercritical CO<sub>2</sub> is inexpensive compared to solvents other than water. Figure 11.20 shows what supercritical CO<sub>2</sub> looks like through a window in a high-pressure vessel.

A process for removing caffeine from green coffee beans by extraction with supercritical CO<sub>2</sub>, diagrammed in Figure 11.21, has been in commercial operation for several years. At the proper temperature and pressure the supercritical CO<sub>2</sub> removes caffeine from the beans by dissolution, but leaves the flavor and aroma components, producing decaffeinated coffee. Supercritical CO<sub>2</sub> is also now used as a solvent in dry cleaning. In 2007, the state of California banned the most common dry-cleaning solvent, perchloroethylene (Cl<sub>2</sub>C=CCl<sub>2</sub>), which is an environmental hazard and a suspected human carcinogen. Supercritical CO<sub>2</sub> is a more sustainable alternative.

*Related Exercises:* 11.41, 11.42, 11.87

▲ **Figure 11.21** Diagram of a supercritical fluid extraction process. The material to be processed is placed in the extractor. The desired material dissolves in supercritical CO<sub>2</sub> at high pressure, then is precipitated in the separator when the CO<sub>2</sub> pressure is reduced. The carbon dioxide is then recycled through the compressor with a fresh batch of material in the extractor.

## 11.5 VAPOR PRESSURE

Molecules can escape from the surface of a liquid into the gas phase by evaporation. Suppose we conduct an experiment in which we place a quantity of ethanol (CH<sub>3</sub>CH<sub>2</sub>OH) in an evacuated, closed container such as that in Figure 11.22. The ethanol will quickly begin to evaporate. As a result, the pressure exerted by the vapor in the space above the liquid will begin to increase. After a short time the pressure of the vapor will attain a constant value, which we call the **vapor pressure** of the substance.

► **Figure 11.22 Illustration of the equilibrium vapor pressure over a liquid.** In (a) we imagine that no molecules of the liquid are in the gas phase initially; there is zero vapor pressure in the vessel. In (b), after equilibrium is reached, the rate at which molecules leave the surface equals the rate at which gas molecules return to the liquid phase. These equal rates produce a stable vapor pressure that does not change as long as the temperature remains constant.

▲ **Figure 11.23 The effect of temperature on the distribution of kinetic energies in a liquid.** The distribution of kinetic energies of surface molecules of a hypothetical liquid are shown at two temperatures. Only the fastest molecules have sufficient kinetic energy to escape the liquid and enter the vapor, as shown by the shaded areas. The higher the temperature, the larger is the fraction of molecules with enough energy to escape from the liquid into the vapor phase.

### Explaining Vapor Pressure on the Molecular Level

The molecules of a liquid move at various speeds. Figure 11.23 ◀ shows the distribution of kinetic energies of the particles at the surface of a liquid at two temperatures. The distribution curves are like those shown earlier for gases. ◀ (Section 10.7) At any instant some of the molecules on the surface of the liquid possess sufficient kinetic energy to overcome the attractive forces of their neighbors and escape into the gas phase. The weaker the attractive forces, the larger is the number of molecules that are able to escape and therefore the higher the vapor pressure.

At any particular temperature the movement of molecules from the liquid to the gas phase goes on continuously. As the number of gas-phase molecules increases, however, the probability increases that a molecule in the gas phase will strike the liquid surface and be recaptured by the liquid, as shown in Figure 11.22(b). Eventually, the rate at which molecules return to the liquid exactly equals the rate at which they escape. The number of molecules in the gas phase then reaches a steady value, and the pressure of the vapor at this stage becomes constant.

The condition in which two opposing processes are occurring simultaneously at equal rates is called a **dynamic equilibrium**, but is usually referred to merely as *equilibrium*. A liquid and its vapor are in dynamic equilibrium when evaporation and condensation occur at equal rates. It may appear that nothing is occurring at equilibrium because there is no net change in the system. In fact, a great deal is happening: molecules continuously pass from the liquid state to the gas state and from the gas state to the liquid state. All equilibria between different states of matter possess this dynamic character. *The vapor pressure of a liquid is the pressure exerted by its vapor when the liquid and vapor states are in dynamic equilibrium.*

### Volatility, Vapor Pressure, and Temperature

When vaporization occurs in an open container, as when water evaporates from a bowl, the vapor spreads away from the liquid. Little, if any, is recaptured at the surface of the liquid. Equilibrium never occurs, and the vapor continues to form until the liquid evaporates to dryness. Substances with high vapor pressure (such as gasoline) evaporate more quickly than substances with low vapor pressure (such as motor oil). Liquids that evaporate readily are said to be **volatile**.

Hot water evaporates more quickly than cold water because vapor pressure increases with increasing temperature. We see this effect in Figure 11.23: As the temperature of a liquid is increased, the molecules move more energetically and a greater fraction can therefore escape more readily from their neighbors. Figure 11.24 depicts the variation in vapor pressure with temperature for four common substances that differ greatly in volatility. Note that the vapor pressure in all cases increases nonlinearly with increasing temperature.

### GIVE IT SOME THOUGHT

Which compound do you think would be more volatile at 25 °C,  $\text{CCl}_4$  or  $\text{CBr}_4$ ?

### Vapor Pressure and Boiling Point

A liquid boils when its vapor pressure equals the external pressure acting on the surface of the liquid. At this point bubbles of vapor form within the liquid. The temperature at which a given liquid boils increases with increasing external pressure. The boiling point of a liquid at 1 atm (or 760 torr) pressure is called its **normal boiling point**. From Figure 11.24 we see that the normal boiling point of water is 100 °C.

The boiling point is important to many processes that involve heating liquids, including cooking. The time required to cook food depends on the temperature. As long as water is present, the maximum temperature of the food being cooked is the boiling point of water. Pressure cookers work by allowing steam to escape only when it exceeds a predetermined pressure; the pressure above the water can therefore increase above atmospheric pressure. The higher pressure causes the water to boil at a higher temperature, thereby allowing the food to get hotter and to cook more rapidly. The effect of pressure on boiling point also explains why it takes longer to cook food at higher elevations than at sea level. The atmospheric pressure is lower at higher altitudes, so water boils at a lower temperature and foods generally take longer to cook.

▲ **Figure 11.24** Vapor pressure for four common liquids as a function of temperature. The temperature at which the vapor pressure is 760 torr is the normal boiling point of each liquid.

#### SAMPLE EXERCISE 11.5 | Relating Boiling Point to Vapor Pressure

Use Figure 11.24 to estimate the boiling point of diethyl ether under an external pressure of 0.80 atm.

#### SOLUTION

**Analyze:** We are asked to read a graph of vapor pressure versus temperature to determine the boiling point of a substance at a particular pressure. The boiling point is the temperature at which the vapor pressure is equal to the external pressure.

**Plan:** We need to convert 0.80 atm to torr because that is the pressure scale on the graph. We estimate the location of that pressure on the graph, move horizontally to the vapor pressure curve, and then drop vertically from the curve to estimate the temperature.

**Solve:** The pressure equals  $(0.80 \text{ atm})(760 \text{ torr/atm}) = 610 \text{ torr}$ . From Figure 11.24 we see that the boiling point at this pressure is about 27 °C, which is close to room temperature.

**Comment:** We can make a flask of diethyl ether boil at room temperature by using a vacuum pump to lower the pressure above the liquid to about 0.8 atm.

#### PRACTICE EXERCISE

At what external pressure will ethanol have a boiling point of 60 °C?  
*Answer:* about 340 torr (0.45 atm)

## A Closer Look THE CLAUSIUS–CLAPEYRON EQUATION

You might have noticed that the plots of the variation of vapor pressure with temperature shown in Figure 11.24 have a distinct shape: Each curves sharply upward to a higher vapor pressure with increasing temperature. The relationship between vapor pressure and temperature is given by an equation called the *Clausius–Clapeyron equation*:

$$\ln P = \frac{-\Delta H_{\text{vap}}}{RT} + C \quad [11.1]$$

In this equation  $P$  is the vapor pressure,  $T$  is the absolute temperature,  $R$  is the gas constant (8.314 J/mol·K),  $\Delta H_{\text{vap}}$  is the molar enthalpy of vaporization, and  $C$  is a constant. The Clausius–Clapeyron equation predicts that a graph of  $\ln P$  versus  $1/T$  should give a straight line with a slope equal to  $-\Delta H_{\text{vap}}/R$ . Thus, we can use such a plot to determine the enthalpy of vaporization of a substance as follows:

$$\Delta H_{\text{vap}} = -\text{slope} \times R$$

As an example of the application of the Clausius–Clapeyron equation, the vapor-pressure data for ethanol shown in Figure 11.24 are graphed as  $\ln P$  versus  $1/T$  in Figure 11.25. The data lie on a straight line with a negative slope. We can use the slope of the line to determine  $\Delta H_{\text{vap}}$  for ethanol. We can also extrapolate the line to obtain values for the vapor pressure of ethanol at temperatures above and below the temperature range for which we have data.

*Related Exercises: 11.89, 11.90, 11.91*

▲ **Figure 11.25** Linear graph of vapor pressure data for ethanol. The Clausius–Clapeyron equation, Equation 11.1, indicates that a graph of  $\ln P$  versus  $1/T$  gives a straight line whose slope equals  $-\Delta H_{\text{vap}}/R$ . The slope of this line gives  $\Delta H_{\text{vap}} = 38.56$  kJ/mol.

## 11.6 PHASE DIAGRAMS

The equilibrium between a liquid and its vapor is not the only dynamic equilibrium that can exist between states of matter. Under appropriate conditions of temperature and pressure, a solid can be in equilibrium with its liquid state or even with its vapor state. A **phase diagram** is a graphic way to summarize the conditions under which equilibria exist between the different states of matter. Such a diagram also allows us to predict the phase of a substance that is stable at any given temperature and pressure.

The general form of a phase diagram for a substance that can exist in any one of the three phases of matter is shown in Figure 11.26. The diagram is a two-dimensional graph, with pressure and temperature as the axes. It contains three important curves, each of which represents the conditions of temperature and pressure at which the various phases can coexist at equilibrium. The only substance present in the system is the one whose phase diagram is under consideration. The pressure shown in the diagram is either the pressure applied to the system or the pressure generated by the substance itself. The curves may be described as follows:

1. The line from  $T$  to  $C$  is the vapor-pressure curve of the liquid. It represents the equilibrium between the liquid and gas phases. The point on this curve where the vapor pressure is 1 atm is the normal boiling point of the substance. The vapor-pressure curve ends at the *critical point* ( $C$ ), which is at the critical temperature and critical pressure of the substance. Beyond the critical point the liquid and gas phases become indistinguishable from each other, and the state of the substance is a *supercritical fluid*.

▲ **Figure 11.26 Phase diagram for a three-phase system.** In this generic diagram, the substance being investigated can exist as a solid, a liquid, or a gas, depending on pressure and temperature. Beyond the critical point (C), the distinction between liquid and gas is lost, and the substance is a supercritical fluid.

- The line that separates the solid phase from the gas phase represents the change in the vapor pressure of the solid as it sublimates at different temperatures.
- The line that separates the solid phase from the liquid phase corresponds to the change in melting point of the solid with increasing pressure. This line usually slopes slightly to the right as pressure increases, because for most substances the solid form is denser than the liquid form. An increase in pressure usually favors the more compact solid phase; thus, higher temperatures are required to melt the solid at higher pressures. The *melting point* of a substance is identical to its *freezing point*. The two differ only in the direction from which the phase change is approached. The melting point at 1 atm is the **normal melting point**.

Point *T*, where the three curves intersect, is known as the **triple point**. All three phases are in equilibrium at this temperature and pressure. Any other point on the three curves represents equilibrium between two phases. Any point on the diagram that does not fall on a line corresponds to conditions under which only one phase is present. The gas phase, for example, is stable at low pressures and high temperatures, whereas the solid phase is stable at low temperatures and high pressures. Liquids are stable in the region between the other two.

### GIVE IT SOME THOUGHT

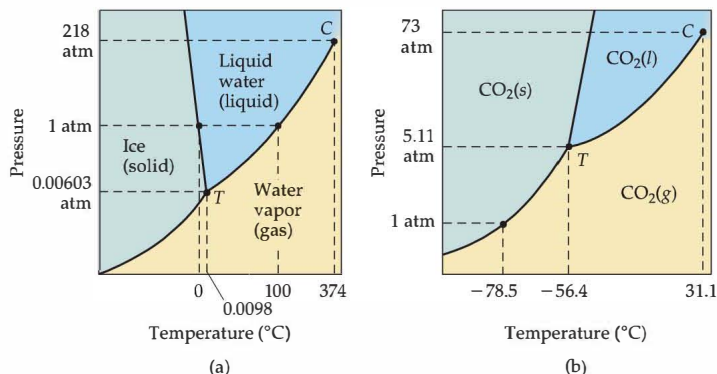

On a phase diagram, which way does the line representing boiling usually slope, and why?

### The Phase Diagrams of H<sub>2</sub>O and CO<sub>2</sub>

Figure 11.27 ▼ shows the phase diagrams of H<sub>2</sub>O and CO<sub>2</sub>. The solid–liquid equilibrium (melting point) line of CO<sub>2</sub> follows the typical behavior, slanting to the right with increasing pressure, telling you that its melting point increases with increasing pressure. In contrast, the melting point line of H<sub>2</sub>O is atypical, slanting to the left with increasing pressure, indicating that for water the melting point *decreases* with increasing pressure. As seen in Figure 11.11, water is among the very few substances whose liquid form is more compact than its solid form. ∞ (Section 11.2)

The triple point of H<sub>2</sub>O (0.0098 °C and 0.00603 atm) is at much lower pressure than that of CO<sub>2</sub> (−56.4 °C and 5.11 atm). For CO<sub>2</sub> to exist as a liquid, the pressure must exceed 5.11 atm. Consequently, solid CO<sub>2</sub> does not melt but

► **Figure 11.27 Phase diagrams of H<sub>2</sub>O and CO<sub>2</sub>.** The axes are not drawn to scale in either case. In (a), for water, note the triple point *T* at 0.0098 °C and 0.00603 atm, the normal melting (or freezing) point of 0 °C at 1 atm, the normal boiling point of 100 °C at 1 atm, and the critical point *C* (374.4 °C and 217.7 atm). In (b), for carbon dioxide, note the triple point *T* at −56.4 °C and 5.11 atm, the normal sublimation point of −78.5 °C at 1 atm, and the critical point *C* (31.1 °C and 73.0 atm).

sublimes when heated at 1 atm. Thus, CO<sub>2</sub> does not have a normal melting point; instead, it has a normal sublimation point, −78.5 °C. Because CO<sub>2</sub> sublimates rather than melts as it absorbs energy at ordinary pressures, solid CO<sub>2</sub> (dry ice) is a convenient coolant. For water (ice) to sublime, however, its vapor pressure must be below 0.00603 atm. Food is “freeze-dried” by placing frozen food in a low-pressure chamber (below 0.00603 atm) so that the ice in it sublimates.

▲ **Figure 11.28 Phase diagram of H<sub>2</sub>O.**

### ■ SAMPLE EXERCISE 11.6 | Interpreting a Phase Diagram

Referring to Figure 11.28 ◀, describe any changes in the phases present when H<sub>2</sub>O is (a) kept at 0 °C while the pressure is increased from that at point 1 to that at point 5 (vertical line), (b) kept at 1.00 atm while the temperature is increased from that at point 6 to that at point 9 (horizontal line).

#### SOLUTION

**Analyze:** We are asked to use the phase diagram provided to deduce what phase changes might occur when specific pressure and temperature changes are brought about.

**Plan:** Trace the path indicated on the phase diagram, and note what phases and phase changes occur.

**Solve:**

(a) At point 1, H<sub>2</sub>O exists totally as a vapor. At point 2 a solid–vapor equilibrium exists. Above that pressure, at point 3, all the H<sub>2</sub>O is converted to a solid. At point 4 some of the solid melts and equilibrium between solid and liquid is achieved. At still higher pressures all the H<sub>2</sub>O melts, so only the liquid phase is present at point 5.

(b) At point 6 the H<sub>2</sub>O exists entirely as a solid. When the temperature reaches point 4, the solid begins to melt and equilibrium exists between the solid and liquid phases. At an even higher temperature, point 7, the solid has been converted entirely to a liquid. A liquid–vapor equilibrium exists at point 8. Upon further heating to point 9, the H<sub>2</sub>O is converted entirely to the vapor phase.

**Check:** The indicated phases and phase changes are consistent with our knowledge of the properties of water.

#### ■ PRACTICE EXERCISE

Using Figure 11.27(b), describe what happens when the following changes are made to a CO<sub>2</sub> sample: (a) Pressure increases from 1 atm to 60 atm at a constant temperature of −60 °C. (b) Temperature increases from −60 °C to −20 °C at a constant pressure of 60 atm.

**Answers:** (a) CO<sub>2</sub>(g) → CO<sub>2</sub>(s); (b) CO<sub>2</sub>(s) → CO<sub>2</sub>(l)

## 11.7 STRUCTURES OF SOLIDS

Throughout the remainder of this chapter we will focus on how the properties of solids relate to their structures and bonding. Solids can be either crystalline or amorphous (noncrystalline). In a **crystalline solid** the atoms, ions, or molecules are ordered in well-defined three-dimensional arrangements.

(a) Pyrite (fool's gold)

(b) Fluorite

(c) Amethyst

These solids usually have flat surfaces, or *faces*, that make definite angles with one another. The orderly stacks of particles that produce these faces also cause the solids to have highly regular shapes (Figure 11.29 ▲). Quartz and diamond are crystalline solids.

An **amorphous solid** (from the Greek words for “without form”) is a solid in which particles have no orderly structure. These solids lack well-defined faces and shapes. Many amorphous solids are mixtures of particles that do not stack together well. Most others are composed of large, complicated molecules. Familiar amorphous solids include rubber and glass.

Quartz ( $\text{SiO}_2$ ) is a crystalline solid with a three-dimensional structure like that shown in Figure 11.30(a) ▼. When quartz melts (at about  $1600^\circ\text{C}$ ), it becomes a viscous, tacky liquid. Although the silicon–oxygen network remains largely intact, many  $\text{Si}-\text{O}$  bonds are broken, and the rigid order of the quartz is lost. If the melt is rapidly cooled, the atoms are unable to return to an orderly arrangement. As a result, an amorphous solid known either as quartz glass or as silica glass results [Figure 11.30(b)].

▲ **Figure 11.29 Crystalline solids.** Crystalline solids come in a variety of forms and colors: (a) pyrite (fool's gold), (b) fluorite, (c) amethyst.

▼ **Figure 11.30 Schematic comparisons of (a) crystalline  $\text{SiO}_2$  (quartz) and (b) amorphous  $\text{SiO}_2$  (quartz glass).** The structures are actually three-dimensional and not planar as drawn. The two-dimensional unit shown as the basic building block of the structure (silicon and three oxygens) actually has four oxygens, the fourth coming out of the plane of the paper and capable of bonding to other silicon atoms. The actual three-dimensional building block is shown.

(a) Crystalline  $\text{SiO}_2$ (b) Amorphous  $\text{SiO}_2$ 

Two-dimensional unit

Actual three-dimensional unit

▲ **Figure 11.31** A two-dimensional analog of a lattice and its unit cell. The wallpaper design shows a characteristic repeat pattern. Each dashed blue square denotes a unit cell of the pattern. The unit cell could equally well be selected with red figures at the corners.

▲ **Figure 11.32** Part of a simple crystal lattice and its associated unit cell. A lattice is an array of points that define the positions of particles in a crystalline solid. Each lattice point represents an identical environment in the solid. The points here are shown connected by lines to help convey the three-dimensional character of the lattice and to help us see the unit cell.

Because the particles of an amorphous solid lack any long-range order, intermolecular forces vary in strength throughout a sample. Thus, amorphous solids do not melt at specific temperatures. Instead, they soften over a temperature range as intermolecular forces of various strengths are overcome. A crystalline solid, in contrast, melts at a specific temperature.

### GIVE IT SOME THOUGHT

What is the general difference in the melting behaviors of crystalline and amorphous solids?

### Unit Cells

The characteristic order of crystalline solids allows us to convey a picture of an entire crystal by looking at only a small part of it. We can think of the solid as being built by stacking together identical building blocks, much as stacking rows of individual “identical” bricks forms a brick wall. The repeating unit of a solid, the crystalline “brick,” is known as the **unit cell**. A simple two-dimensional example appears in the sheet of wallpaper shown in Figure 11.31 ◀. There are several ways of choosing a unit cell, but the choice is usually the smallest unit cell that shows clearly the symmetry characteristic of the entire pattern.

A crystalline solid can be represented by a three-dimensional array of points called a **crystal lattice**. Each point in the lattice is called a *lattice point*, and it represents an identical environment within the solid. The crystal lattice is, in effect, an abstract scaffolding for the crystal structure. We can imagine forming the entire crystal structure by arranging the contents of the unit cell repeatedly on the crystal lattice. In the simplest case the crystal structure would consist of identical atoms, and each atom would be centered on a lattice point. This is the case for most metals.

Figure 11.32 ◀ shows a crystal lattice and its associated unit cell. In general, unit cells are parallelepipeds (six-sided figures whose faces are parallelograms). Each unit cell can be described by the lengths of the edges of the cell and by the angles between these edges. Seven basic types of unit cells can describe the lattices of all crystalline compounds. The simplest of these is the cubic unit cell, in which all the sides are equal in length and all the angles are  $90^\circ$ .

Three kinds of cubic unit cells are illustrated in Figure 11.33 ▼. When lattice points are at the corners only, the unit cell is called **primitive cubic** (or *simple cubic*). When a lattice point also occurs at the center of the unit cell, the cell is **body-centered cubic**. When the cell has lattice points at the center of each face, as well as at each corner, it is **face-centered cubic**.

The simplest crystal structures are cubic unit cells with only one atom centered at each lattice point. Most metals have such structures. Nickel, for example, has a face-centered cubic unit cell, whereas sodium has a body-centered cubic one. Figure 11.34 ► shows how atoms fill the cubic unit cells. Notice that

▲ **Figure 11.33** The three types of unit cells found in cubic lattices. For clarity, the corner spheres are red and the body-centered and face-centered ones are yellow. Each sphere represents a lattice point (an identical environment in the solid).

▲ **Figure 11.34** Space-filling view of cubic unit cells. Only the portion of each atom that belongs to the unit cell is shown.

the atoms on the corners and faces do not lie wholly within the unit cell. Instead, these atoms are shared between unit cells. As an example, let's look at the primitive cubic structure in Figure 11.34. In an actual solid, this primitive cubic structure has other primitive cubic unit cells next to it in all directions, on top of it, and underneath it. If you look at any one corner of the primitive cubic unit cell, you will see that is shared by 8 unit cells. Therefore, in an individual primitive cubic unit cell, each corner contains only one-eighth of an atom. Because a cube has eight corners, each primitive cubic unit cell has a total of  $1/8 \times 8 = 1$  atom. Similarly, each body-centered cubic unit cell shown in Figure 11.34 contains two atoms ( $1/8 \times 8 = 1$  from the corners, and 1 totally inside the cube). Two unit cells share equally atoms that are on the faces of a face-centered cubic unit cell so that only one-half of the atom belongs to each unit cell. Therefore, the total number of atoms in the face-centered cubic unit cell shown in Figure 11.34 is four (that is,  $1/8 \times 8 = 1$  from the corners and  $1/2 \times 6 = 3$  from the faces). Table 11.6 summarizes the fraction of an atom that occupies a unit cell when atoms are shared between unit cells.

**TABLE 11.6** Fraction of an Atom That Occupies a Unit Cell for Various Positions in the Unit Cell

Position in Unit Cell	Fraction in Unit Cell
Center	1
Face	$\frac{1}{2}$
Edge	$\frac{1}{4}$
Corner	$\frac{1}{8}$

### GIVE IT SOME THOUGHT

If you know the unit cell dimensions for a solid, the number of atoms per unit cell, and the mass of the atoms, show how you can calculate the density of the solid.

## The Crystal Structure of Sodium Chloride

In the crystal structure of NaCl (Figure 11.35) we can center either the  $\text{Na}^+$  ions or the  $\text{Cl}^-$  ions on the lattice points of a face-centered cubic unit cell. Thus, we can describe the structure as being face-centered cubic.

▼ **Figure 11.35** Two ways of defining the unit cell of NaCl. A representation of an NaCl crystal lattice can show either (a)  $\text{Cl}^-$  ions (green spheres) or (b)  $\text{Na}^+$  ions (purple spheres) at the lattice points of the unit cell. In both cases, the red lines define the unit cell. In both cases, the red lines define the unit cell. Both of these choices for the unit cell are acceptable; both have the same volume, and in both cases identical points are arranged in a face-centered cubic fashion.

► **Figure 11.36**  
**Relative size of ions in an NaCl unit cell.**  
 As in Figure 11.35, purple represents  $\text{Na}^+$  ions and green represents  $\text{Cl}^-$  ions. Only portions of most of the ions lie within the boundaries of the single unit cell.

In Figure 11.35 the  $\text{Na}^+$  and  $\text{Cl}^-$  ions have been moved apart so the symmetry of the structure can be seen more clearly. In this representation no attention is paid to the relative sizes of the ions. The representation in Figure 11.36 ◀, on the other hand, shows the relative sizes of the ions and how they fill the unit cell. Notice that other unit cells share the particles at corners, edges, and faces.

The total cation-to-anion ratio of a unit cell must be the same as that for the entire crystal. Therefore, within the unit cell of NaCl there must be an equal number of  $\text{Na}^+$  and  $\text{Cl}^-$  ions. Similarly, the unit cell for  $\text{CaCl}_2$  would have one  $\text{Ca}^{2+}$  for every two  $\text{Cl}^-$ , and so forth.

### SAMPLE EXERCISE 11.7 | Determining the Contents of a Unit Cell

Determine the net number of  $\text{Na}^+$  and  $\text{Cl}^-$  ions in the NaCl unit cell (Figure 11.36).

#### SOLUTION

**Analyze:** We must sum the various contributing elements to determine the number of  $\text{Na}^+$  and  $\text{Cl}^-$  ions within the unit cell.

**Plan:** To find the total number of ions of each type, we must identify the different locations within the unit cell and determine the fraction of the ion that lies within the unit cell boundaries.

**Solve:** There is one-fourth of an  $\text{Na}^+$  on each edge, a whole  $\text{Na}^+$  in the center of the cube (refer also to Figure 11.35), one-eighth of a  $\text{Cl}^-$  on each corner, and one-half of a  $\text{Cl}^-$  on each face. Thus, we have the following:

$$\text{Na}^+: \left(\frac{1}{4} \text{Na}^+ \text{ per edge}\right)(12 \text{ edges}) = 3 \text{Na}^+$$

$$(1 \text{Na}^+ \text{ per center})(1 \text{ center}) = 1 \text{Na}^+$$

$$\text{Cl}^-: \left(\frac{1}{8} \text{Cl}^- \text{ per corner}\right)(8 \text{ corners}) = 1 \text{Cl}^-$$

$$\left(\frac{1}{2} \text{Cl}^- \text{ per face}\right)(6 \text{ faces}) = 3 \text{Cl}^-$$

Thus, the unit cell contains

$$4 \text{Na}^+ \text{ and } 4 \text{Cl}^-$$

**Check:** Since individually the  $\text{Cl}^-$  ions form a face-centered cubic lattice [see Figure 11.35(a)], as do the  $\text{Na}^+$  ions [see Figure 11.35(b)], we would expect there to be four ions of each type in the unit cell. More important, the presence of equal amounts of the two ions agree with the compound's stoichiometry:

$$1 \text{Na}^+ \text{ for each } \text{Cl}^-$$

### PRACTICE EXERCISE

The element iron crystallizes in a form called  $\alpha$ -iron, which has a body-centered cubic unit cell. How many iron atoms are in the unit cell?

**Answer:** two

### SAMPLE EXERCISE 11.8 | Using the Contents and Dimensions of a Unit Cell to Calculate Density

The geometric arrangement of ions in crystals of LiF is the same as that in NaCl. The unit cell of LiF is  $4.02 \text{ \AA}$  on an edge. Calculate the density of LiF.

#### SOLUTION

**Analyze:** We are asked to calculate the density of LiF from the size of the unit cell.

**Plan:** Density is mass per volume, and this is true at the unit cell level as well as the bulk level. We need to determine the number of formula units of LiF within the unit cell. From that, we can calculate the total mass within the unit cell. Because we know the mass and can calculate the volume of the unit cell, we can then calculate density.

**Solve:** The arrangement of ions in LiF is the same as that in NaCl (Sample Exercise 11.7), so a unit cell of LiF contains

$$4 \text{Li}^+ \text{ ions and } 4 \text{F}^- \text{ ions}$$

Density is mass per unit volume. Thus, we can calculate the density of LiF from the mass contained in a unit cell and the volume of the unit cell. The mass contained in one unit cell is

$$4(6.94 \text{ amu}) + 4(19.0 \text{ amu}) = 103.8 \text{ amu}$$

The volume of a cube of length  $a$  on an edge is  $a^3$ , so the volume of the unit cell is  $(4.02 \text{ \AA})^3$ . We can now calculate the density, converting to the common units of  $\text{g}/\text{cm}^3$ :

$$\text{Density} = \frac{(103.8 \text{ amu})}{(4.02 \text{ \AA})^3} \left( \frac{1 \text{ g}}{6.02 \times 10^{23} \text{ amu}} \right) \left( \frac{1 \text{ \AA}}{10^{-8} \text{ cm}} \right)^3 = 2.65 \text{ g}/\text{cm}^3$$

**Check:** This value agrees with that found by simple density measurements,  $2.640 \text{ g}/\text{cm}^3$  at  $20^\circ\text{C}$ . The size and contents of the unit cell are therefore consistent with the macroscopic density of the substance.

### ■ PRACTICE EXERCISE

The body-centered cubic unit cell of a particular crystalline form of iron is  $2.8664 \text{ \AA}$  on each side. Calculate the density of this form of iron.

**Answer:**  $7.8753 \text{ g}/\text{cm}^3$

## Close Packing of Spheres

The structures adopted by crystalline solids are those that bring particles in closest contact to maximize the attractive forces between them. In many cases the particles that make up the solids are spherical or approximately so. Such is the case for atoms in metallic solids. It is therefore instructive to consider how equal-sized spheres can pack most efficiently (that is, with the minimum amount of empty space).

The most efficient arrangement of a layer of equal-sized spheres is shown in Figure 11.37(a) ▼. Each sphere is surrounded by six others in the layer. A second layer of spheres can be placed in the depressions on top of the first layer. A third layer can then be added above the second with the spheres sitting in the depressions of the second layer. However, there are two types of depressions for this third layer, and they result in different structures, as shown in Figure 11.37(b) and (c).

If the spheres of the third layer are placed in line with those of the first layer, as shown in Figure 11.37(b), the structure is known as **hexagonal close packing**. The third layer repeats the first layer, the fourth layer repeats the second layer, and so forth, giving a layer sequence that we denote ABAB.

The spheres of the third layer, however, can be placed so they do not sit above the spheres in the first layer. The resulting structure, shown in Figure 11.37(c), is known as **cubic close packing**. In this case it is the fourth layer that repeats the first layer, and the layer sequence is ABCA. Although it cannot be seen in Figure 11.37(c), the unit cell of the cubic close-packed structure is face-centered cubic.

▲ **Figure 11.37 Close packing of equal-sized spheres.** (a) Close packing of a single layer of equal-sized spheres. (b) In the hexagonal close-packed structure the atoms in the third layer lie directly over those in the first layer. The order of layers is ABAB. (c) In the cubic close-packed structure the atoms in the third layer are not over those in the first layer. Instead, they are offset a bit, and it is the fourth layer that lies directly over the first. Thus, the order of layers is ABCA.

In both of the close-packed structures, each sphere has 12 equidistant nearest neighbors: six in one plane, three above that plane, and three below. We say that each sphere has a **coordination number** of 12. The coordination number is the number of particles immediately surrounding a particle in the crystal structure. In both types of close packing, spheres occupy 74% of the total volume of the structure; 26% is empty space between the spheres. By comparison, each sphere in the body-centered cubic structure has a coordination number of 8, and only 68% of the space is occupied. In the primitive cubic structure the coordination number is 6, and only 52% of the space is occupied.

When unequal-sized spheres are packed in a lattice, the larger particles sometimes assume one of the close-packed arrangements, with smaller particles occupying the holes between the large spheres. In  $\text{Li}_2\text{O}$ , for example, the larger oxide ions assume a cubic close-packed structure, and the smaller  $\text{Li}^+$  ions occupy small cavities that exist between oxide ions.

### GIVE IT SOME THOUGHT

Based on the information given above for close-packed structures and structures with cubic unit cells, what qualitative relationship exists between coordination numbers and packing efficiencies?

## 11.8 BONDING IN SOLIDS

The physical properties of crystalline solids, such as melting point and hardness, depend both on the arrangements of particles (atoms, ions, or molecules) and on the attractive forces between them. Table 11.7 ▼ classifies solids according to the types of forces between particles in solids.

### Molecular Solids

**Molecular solids** consist of atoms or molecules held together by intermolecular forces (dipole–dipole forces, London dispersion forces, and hydrogen bonds). Because these forces are weak, molecular solids are soft. Furthermore, they normally have relatively low melting points (usually below 200 °C). Most substances that are gases or liquids at room temperature form molecular solids at low temperature. Examples include Ar,  $\text{H}_2\text{O}$ , and  $\text{CO}_2$ .

TABLE 11.7 ■ Types of Crystalline Solids

Type of Solid	Form of Unit Particles	Forces Between Particles	Properties	Examples
Molecular	Atoms or molecules	London dispersion forces, dipole–dipole forces, hydrogen bonds	Fairly soft, low to moderately high melting point, poor thermal and electrical conduction	Argon, Ar; methane, $\text{CH}_4$ ; sucrose, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ; Dry Ice, $\text{CO}_2$
Covalent-network	Atoms connected in a network of covalent bonds	Covalent bonds	Very hard, very high melting point, variable thermal and electrical conduction	Diamond, C; quartz, $\text{SiO}_2$
Ionic	Positive and negative ions	Electrostatic attractions	Hard and brittle, high melting point, poor thermal and electrical conduction	Typical salts—for example, $\text{NaCl}$ , $\text{Ca}(\text{NO}_3)_2$
Metallic	Atoms	Metallic bonds	Soft to very hard, low to very high melting point, excellent thermal and electrical conduction, malleable and ductile	All metallic elements—for example, Cu, Fe, Al, Pt

## A Closer Look

## X-RAY DIFFRACTION BY CRYSTALS

When light waves pass through a narrow slit, they are scattered in such a way that the wave seems to spread out. This physical phenomenon is called *diffraction*. When light passes through many evenly spaced narrow slits (a *diffraction grating*), the scattered waves interact to form a series of bright and dark bands, known as a diffraction pattern. The bright bands correspond to constructive overlapping of the light waves, and the dark bands correspond to destructive overlapping of the light waves (see Section 9.8, “A Closer Look: Phases in Atomic and Molecular Orbitals”). The most effective diffraction of light occurs when the wavelength of the light and the width of the slits are similar in magnitude.

The spacing of the layers of atoms in solid crystals is usually about 2–20 Å. The wavelengths of X-rays are also in this range. Thus, a crystal can serve as an effective diffraction grating for X-rays. X-ray diffraction results from the scattering of X-rays by a regular arrangement of atoms, molecules, or ions. Much of what we know about crystal structures has been obtained from studies of X-ray diffraction by crystals, a technique known as *X-ray crystallography*. Figure 11.38 depicts the diffraction of a beam of X-rays as it passes through a crystal. The diffracted X-rays were formerly detected by photographic film. Today, crystallographers use an *array detector*, a device analogous to that used in digital cameras, to capture and measure the intensities of the diffracted rays. The diffraction pattern of spots on the detector in Figure 11.38 depends on the particular arrangement of atoms in the crystal. Thus, different types of crystals give rise to different diffraction

patterns. In 1913 the English scientists William and Lawrence Bragg (father and son) determined for the first time how the spacing of layers in crystals leads to different X-ray diffraction patterns. By measuring the intensities of the diffracted beams and the angles at which they are diffracted, it is possible to reason backward to the structure that must have given rise to the pattern. One of the most famous X-ray diffraction patterns is the one for crystals of the genetic material DNA (Figure 11.39), first obtained in the early 1950s. Working from X-ray diffraction data obtained by Rosalind Franklin, Franklin, Maurice Wilkins, James Watson, and Francis Crick determined the double-helix structure of DNA, one of the most important discoveries in molecular biology. For this achievement, Watson, Crick, and Wilkins were awarded the Nobel Prize in Physiology or Medicine in 1962. Franklin died in 1958, at age 37, from cancer; Nobel Prizes are awarded only to the living (and can be shared by three people at the most).

Today X-ray crystallography is used extensively to determine the structures of molecules in crystals. The instruments used to measure X-ray diffraction, known as *X-ray diffractometers*, are now computer-controlled, making the collection of diffraction data highly automated. The diffraction pattern of a crystal can be determined very accurately and quickly (sometimes in a matter of hours), even though thousands of diffraction points are measured. Computer programs are then used to analyze the diffraction data and determine the arrangement and structure of the molecules in the crystal.

*Related Exercises: 11.95, 11.96*

◀ **Figure 11.38** Diffraction of X-rays by a crystal.

In X-ray crystallography, an X-ray beam is diffracted by a crystal. The diffraction pattern can be recorded as spots where the diffracted X-rays strike a detector, which records the positions and intensities of the spots.

▶ **Figure 11.39** The X-ray diffraction photograph of one form of crystalline DNA. This photograph was taken in the early 1950s. From the pattern of dark spots, the double-helical shape of the DNA molecule was deduced.

			
	Benzene	Toluene	Phenol
Melting point (°C)	5	-95	43
Boiling point (°C)	80	111	182

▲ **Figure 11.40** Comparative melting and boiling points for benzene, toluene, and phenol.

The properties of molecular solids depend on the strengths of the forces that exist between molecules and on the abilities of the molecules to pack efficiently in three dimensions. Benzene ( $C_6H_6$ ), for example, is a highly symmetrical planar molecule. [∞ \(Section 8.6\)](#) It has a higher melting point than toluene, a compound in which one of the hydrogen atoms of benzene has been replaced by a  $CH_3$  group (Figure 11.40 ◀). The lower symmetry of toluene molecules prevents them from packing as efficiently as benzene molecules. As a result, the intermolecular forces that depend on close contact are not as effective and the melting point is lower. In contrast, the boiling point of toluene is higher than that of benzene, indicating that the intermolecular attractive forces are larger in liquid toluene than in liquid benzene. Both the melting and boiling points of phenol, another substituted benzene shown in Figure 11.40, are higher than those of benzene because the OH group of phenol can form hydrogen bonds.

### GIVE IT SOME THOUGHT

Which of the following substances would you expect to form molecular solids: Co,  $C_6H_6$ , or  $K_2O$ ?

## Covalent-Network Solids

**Covalent-network solids** consist of atoms held together, throughout the entire sample of material, in large networks or chains by covalent bonds. Because covalent bonds are much stronger than intermolecular forces, these solids are much harder and have higher melting points than molecular solids. Diamond and graphite, two allotropes of carbon, are covalent-network solids. Other examples include silicon and germanium; quartz,  $SiO_2$ ; silicon carbide, SiC; and boron nitride, BN.

In diamond, each carbon atom is bonded tetrahedrally to four other carbon atoms, as shown in Figure 11.41(a) ▼. This interconnected three-dimensional array of strong carbon-carbon single bonds that are  $sp^3$  hybridized contributes to diamond's unusual hardness. Industrial-grade diamonds are employed in the blades of saws for the most demanding cutting jobs. Diamond also has a high melting point, 3550 °C.

In graphite, the carbon atoms are bonded in trigonal planar geometries to three other carbons to form interconnected hexagonal rings, as shown in Figure 11.41(b). The distance between adjacent carbon atoms in the plane, 1.42 Å, is very close to the C—C distance in benzene, 1.395 Å. In fact, the bonding resembles that of benzene, with delocalized  $\pi$  bonds extending over the layers. [∞ \(Section 9.6\)](#) Electrons move freely through the delocalized orbitals,

► **Figure 11.41** Structures of (a) diamond and (b) graphite. The blue color in (b) is added to emphasize the planarity of the carbon layers.

▲ **Figure 11.42 Unit cells of some common ionic structures.** The ZnS shown in (b) is called zinc blende, and the  $\text{CaF}_2$  of (c) is known as fluorite.

making graphite a good conductor of electricity along the layers. (In fact, graphite is used as a conducting electrode in batteries.) These  $sp^2$ -hybridized sheets of carbon atoms are separated by  $3.35 \text{ \AA}$  from one another, and the sheets are held together only by weak dispersion forces. Thus, the layers readily slide past one another when rubbed, giving graphite a greasy feel. Graphite is used as a lubricant and in the “lead” in pencils. The enormous differences in physical properties of graphite and diamond—both of which are pure carbon—arise from their differences in their three-dimensional structure and bonding.

## Ionic Solids

**Ionic solids** consist of ions held together by ionic bonds. ⇔ (Section 8.2) The strength of an ionic bond depends greatly on the charges of the ions. Thus, NaCl, in which the ions have charges of  $1+$  and  $1-$ , has a melting point of  $801 \text{ }^\circ\text{C}$ , whereas MgO, in which the charges are  $2+$  and  $2-$ , melts at  $2852 \text{ }^\circ\text{C}$ .

The structures of simple ionic solids can be classified as a few basic types. The NaCl structure is a representative example of one type. Other compounds that possess this same structure include LiF, KCl, AgCl, and CaO. Three other common types of crystal structures are shown in Figure 11.42▲.

The structure adopted by an ionic solid depends largely on the charges and relative sizes of the ions. In the NaCl structure, for example, the  $\text{Na}^+$  ions have a coordination number of 6 because each  $\text{Na}^+$  ion is surrounded by six nearest neighbor  $\text{Cl}^-$  ions. In the CsCl structure [Figure 11.42(a)], by comparison, the  $\text{Cl}^-$  ions adopt a primitive cubic arrangement with each  $\text{Cs}^+$  ion surrounded by eight  $\text{Cl}^-$  ions. The increase in the coordination number as the alkali metal ion changes from  $\text{Na}^+$  to  $\text{Cs}^+$  is a consequence of the larger size of  $\text{Cs}^+$  compared to  $\text{Na}^+$ .

In the zinc blende (ZnS) structure [Figure 11.42(b)], the  $\text{S}^{2-}$  ions adopt a face-centered cubic arrangement, with the smaller  $\text{Zn}^{2+}$  ions arranged so they are each surrounded tetrahedrally by four  $\text{S}^{2-}$  ions (compare with Figure 11.33). CuCl also adopts this structure.

In the fluorite ( $\text{CaF}_2$ ) structure [Figure 11.42(c)], the  $\text{Ca}^{2+}$  ions are shown in a face-centered cubic arrangement. As required by the chemical formula of the substance, there are twice as many  $\text{F}^-$  ions (blue) in the unit cell as there are  $\text{Ca}^{2+}$  ions. Other compounds that have the fluorite structure include  $\text{BaCl}_2$  and  $\text{PbF}_2$ .

## Metallic Solids

**Metallic solids**, also simply called metals, consist entirely of metal atoms. Metallic solids usually have hexagonal close-packed, cubic close-packed (face-centered cubic), or body-centered cubic structures. Thus, each atom typically is surrounded by eight or 12 adjacent atoms.

## A Closer Look

### THE THIRD FORM OF CARBON

Until the mid-1980s pure solid carbon was thought to exist in only two forms: diamond and graphite, both of which are covalent-network solids. In 1985 a group of researchers led by Richard Smalley and Robert Curl of Rice University in Houston and Harry Kroto of the University of Sussex in England made a startling discovery. They vaporized a sample of graphite with an intense pulse of laser light and used a stream of helium gas to carry the vaporized carbon into a mass spectrometer (see Section 2.4, “A Closer Look: The Mass Spectrometer”). The mass spectrum showed peaks corresponding to clusters of carbon atoms, with a particularly strong peak corresponding to molecules composed of 60 carbon atoms,  $C_{60}$ .

Because  $C_{60}$  clusters were so preferentially formed, the group proposed a radically different form of carbon, namely,  $C_{60}$  molecules that were nearly spherical in shape. They proposed that the carbon atoms of  $C_{60}$  form a “ball” with 32 faces, 12 of which are pentagons and 20 are hexagons (Figure 11.43 ▼), exactly like a soccer ball. The shape of this molecule is reminiscent of the geodesic dome invented by the U.S. engineer and philosopher R. Buckminster Fuller, so  $C_{60}$  was whimsically named “buckminsterfullerene,” or “buckyball” for short. Since the discovery of  $C_{60}$ , other related molecules of carbon atoms have been discovered. These molecules are now known as fullerenes.

Appreciable amounts of buckyball can be prepared by electrically evaporating graphite in an atmosphere of helium gas. About 14% of the resulting soot consists of  $C_{60}$  and a related molecule,  $C_{70}$ , which has a more elongated structure.

▲ **Figure 11.43** The buckminsterfullerene molecule,  $C_{60}$ . The molecule has a highly symmetric structure in which the 60 carbon atoms sit at the vertices of a truncated icosahedron—the same geometry as a soccer ball.

The carbon-rich gases from which  $C_{60}$  and  $C_{70}$  condense also contain other fullerenes, mostly with more carbon atoms such as  $C_{76}$  and  $C_{84}$ . The smallest possible fullerene,  $C_{20}$ , was first detected in 2000. This small, ball-shaped molecule is much more reactive than the larger fullerenes.

Because the fullerenes are composed of individual molecules, they dissolve in various organic solvents, whereas diamond and graphite do not (Figure 11.44 ▼). This solubility permits the fullerenes to be separated from the other components of soot and even from each other. It also allows the study of their reactions in solution. Study of these substances has led to the discovery of some very interesting chemistry. For example, it is possible to place a metal atom inside a buckyball, generating a molecule in which a metal atom is completely enclosed by the carbon sphere. The  $C_{60}$  molecules also react with potassium to give  $K_3C_{60}$ , which contains a face-centered cubic array of buckyballs with  $K^+$  ions in the cavities between them. This compound is a superconductor at 18 K (to see Section 12.1), suggesting the possibility that other fullerenes may also have interesting electrical, magnetic, or optical properties. For their discovery and pioneering work with fullerenes, Professors Smalley, Curl, and Kroto were awarded the 1996 Nobel Prize in Chemistry.

**Related Exercise:** 11.97

▲ **Figure 11.44** Solutions of fullerenes. Unlike diamond and graphite, the new molecular forms of carbon can be dissolved in organic solvents. The orange solution on the left is a solution of  $C_{70}$  in *n*-hexane, which is a colorless liquid. The magenta solution on the right is a solution of buckyball,  $C_{60}$ , in *n*-hexane.

The bonding in metals is too strong to be due to London dispersion forces, and yet there are not enough valence electrons for ordinary covalent bonds between atoms. The bonding is due to valence electrons that are delocalized throughout the entire solid. In fact, we can visualize the metal as an array of positive ions immersed in a sea of delocalized valence electrons, as shown in Figure 11.45 ▶. This type of bonding is called *metallic bonding* and will be discussed in more detail in Section 23.5.

Metals vary greatly in the strength of their bonding, as shown by their wide range of physical properties such as hardness and melting point. In general, however, the strength of the bonding increases as the number of electrons available for bonding increases. Thus, sodium, which has only one valence electron per atom, melts at 97.5 °C, whereas chromium, with six electrons beyond the noble-gas core, melts at 1890 °C. The mobility of the electrons explains why metals are good conductors of heat and electricity. The bonding and properties of metals will be examined more closely in Chapter 23.

### SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

The substance CS<sub>2</sub> has a melting point of -110.8 °C and a boiling point of 46.3 °C. Its density at 20 °C is 1.26 g/cm<sup>3</sup>. It is highly flammable. (a) What is the name of this compound? (b) List the intermolecular forces that CS<sub>2</sub> molecules would have with each other. (c) Predict what type of crystalline solid CS<sub>2</sub>(s) would form. (d) Write a balanced equation for the combustion of this compound in air. (You will have to decide on the most likely oxidation products.) (e) The critical temperature and pressure for CS<sub>2</sub> are 552 K and 78 atm, respectively. Compare these values with those for CO<sub>2</sub> (Table 11.5), and discuss the possible origins of the differences. (f) Would you expect the density of CS<sub>2</sub> at 40 °C to be greater or less than at 20 °C? What accounts for the difference?

### SOLUTION

(a) The compound is named carbon disulfide, in analogy with the naming of other binary molecular compounds such as carbon dioxide. [☞ \(Section 2.8\)](#)  
 (b) Only London dispersion forces affect CS<sub>2</sub>; it does not have a dipole moment, based upon its molecular shape, and obviously cannot undergo hydrogen bonding.  
 (c) Because CS<sub>2</sub>(s) consists of individual CS<sub>2</sub> molecules, it will be a molecular solid.  
 (d) The most likely products of the combustion will be CO<sub>2</sub> and SO<sub>2</sub>. [☞ \(Sections 3.2 and 7.8\)](#) Under some conditions SO<sub>3</sub> might be formed, but this would be the less likely outcome. Thus, we have the following equation for combustion:

(e) The critical temperature and pressure of CS<sub>2</sub> (552 K and 78 atm) are both higher than those given for CO<sub>2</sub> in Table 11.5 (304 K and 73 atm). The difference in critical temperatures is especially notable. The higher values for CS<sub>2</sub> arise from the greater London dispersion attractions between the CS<sub>2</sub> molecules compared with CO<sub>2</sub>. These greater attractions are due to the larger size of the sulfur compared to oxygen and therefore its greater polarizability.

(f) The density would be lower at the higher temperature. Density decreases with increasing temperature because the molecules possess higher kinetic energies. Their more energetic movements result in larger average distances between molecules, which translate into lower densities.

▲ **Figure 11.45** Representation of a cross section of a metal. Each sphere represents the nucleus and inner-core electrons of a metal atom. The surrounding blue “fog” represents the mobile sea of electrons that binds the atoms together.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 11.1** Substances that are gases or liquids at room temperature are usually composed of molecules. In gases the intermolecular attractive forces are negligible compared to the kinetic energies of the molecules; thus, the molecules are widely separated and undergo constant, chaotic motion. In liquids the **intermolecular forces** are strong enough to keep the molecules in close proximity; nevertheless, the molecules are free to move with respect to one another. In solids the interparticle attractive forces are strong enough to restrain

molecular motion and to force the particles to occupy specific locations in a three-dimensional arrangement

**Section 11.2** Three types of intermolecular forces exist between neutral molecules: **dipole-dipole forces**, **London dispersion forces**, and **hydrogen bonding**. **Ion-dipole forces** are important in solutions in which ionic compounds are dissolved in polar solvents. London dispersion forces operate between all molecules (and atoms, for atomic substances such as He, Ne, Ar, and so forth). The relative

strengths of the dipole–dipole and dispersion forces depend on the polarity, **polarizability**, size, and shape of the molecule. Dipole–dipole forces increase in strength with increasing polarity. Dispersion forces increase in strength with increasing molecular weight, although molecular shape is also an important factor. Hydrogen bonding occurs in compounds containing O—H, N—H, and F—H bonds. Hydrogen bonds are generally stronger than dipole–dipole or dispersion forces.

**Section 11.3** The stronger the intermolecular forces, the greater is the **viscosity**, or resistance to flow, of a liquid. The surface tension of a liquid also increases as intermolecular forces increase in strength. **Surface tension** is a measure of the tendency of a liquid to maintain a minimum surface area. The adhesion of a liquid to the walls of a narrow tube and the cohesion of the liquid account for **capillary action** and the formation of a meniscus at the surface of a liquid.

**Section 11.4** A substance may exist in more than one state of matter, or phase. **Phase changes** are transformations from one phase to another. Changes of a solid to liquid (melting), solid to gas (sublimation), and liquid to gas (vaporization) are all endothermic processes. Thus, the **heat of fusion** (melting), the **heat of sublimation**, and the **heat of vaporization** are all positive quantities. The reverse processes are exothermic. A gas cannot be liquefied by application of pressure if the temperature is above its **critical temperature**. The pressure required to liquefy a gas at its critical temperature is called the **critical pressure**.

**Section 11.5** The **vapor pressure** of a liquid indicates the tendency of the liquid to evaporate. The vapor pressure is the partial pressure of the vapor when it is in **dynamic equilibrium** with the liquid. At equilibrium the rate of transfer of molecules from the liquid to the vapor equals the rate of transfer from the vapor to the liquid. The higher the vapor pressure of a liquid, the more readily it evaporates and the more **volatile** it is. Vapor pressure increases nonlinearly with temperature. Boiling occurs when the vapor pressure equals the external pressure.

The **normal boiling point** is the temperature at which the vapor pressure equals 1 atm.

**Section 11.6** The equilibria between the solid, liquid, and gas phases of a substance as a function of temperature and pressure are displayed on a **phase diagram**. A line indicates equilibria between any two phases. The line through the **melting point** usually slopes slightly to the right as pressure increases, because the solid is usually more dense than the liquid. The melting point at 1 atm is the **normal melting point**. The point on the diagram at which all three phases coexist in equilibrium is called the **triple point**.

**Section 11.7** In a **crystalline solid**, particles are arranged in a regularly repeating pattern. An **amorphous solid** is one whose particles show no such order. The essential structural features of a crystalline solid can be represented by its **unit cell**, the smallest part of the crystal that can, by simple displacement, reproduce the three-dimensional structure. The three-dimensional structures of a crystal can also be represented by its **crystal lattice**. The points in a crystal lattice represent positions in the structure where there are identical environments. The simplest unit cells are cubic. There are three kinds of cubic unit cells: **primitive cubic**, **body-centered cubic**, and **face-centered cubic**. Many solids have a close-packed structure in which spherical particles are arranged so as to leave the minimal amount of empty space. Two closely related forms of close packing, **cubic close packing** and **hexagonal close packing**, are possible. In both, each sphere has a **coordination number** of 12.

**Section 11.8** The properties of solids depend both on the arrangements of particles and on the attractive forces between them. **Molecular solids**, which consist of atoms or molecules held together by intermolecular forces, are soft and low melting. **Covalent-network solids**, which consist of atoms held together by covalent bonds that extend throughout the solid, are hard and high melting. **Ionic solids** are hard and brittle and have high melting points. **Metallic solids**, which consist of metal cations held together by a sea of electrons, exhibit a wide range of properties.

## KEY SKILLS

- Understand and be able to describe the intermolecular attractive interactions (ion–dipole, dipole–dipole, London dispersion, hydrogen bonding) that exist between molecules or ions, and be able to compare the relative strengths of intermolecular attractions in substances based on their molecular structure, or physical properties.
- Understand the concept of polarizability.
- Understand the concepts of viscosity and surface tension in liquids.
- Know the names of the various phase changes for a pure substance.
- Interpret heating curves and be able to calculate quantities related to temperature and enthalpies of phase changes.
- Define critical pressure, critical temperature, vapor pressure, normal boiling point, normal melting point, critical point, triple point.
- Be able to interpret and sketch phase diagrams; know how water’s phase diagram differs from most other substances, and why.

- Know the difference between crystalline and amorphous solids, and be able to explain the differences between primitive cubic, body-centered cubic, and face-centered cubic unit cells.
- Classify solids based on their bonding/intermolecular forces and understand how difference in bonding relates to physical properties.

## VISUALIZING CONCEPTS

- 11.1 Does the following diagram best describe a crystalline solid, liquid, or gas? Explain. [Section 11.1]

- 11.2 (a) What kind of intermolecular attractive force is shown in each of the following cases? (b) Predict which two interactions are stronger than the other two. [Section 11.2]

- 11.3 The molecular models of glycerol and 1-propanol are given here.

Do you expect the viscosity of glycerol to be larger or smaller than that of 1-propanol? Explain. [Section 11.3]

- 11.4 Using the following graph of  $\text{CS}_2$  data, determine (a) the approximate vapor pressure of  $\text{CS}_2$  at  $30^\circ\text{C}$ , (b) the temperature at which the vapor pressure equals 300 torr, (c) the normal boiling point of  $\text{CS}_2$ . [Section 11.5]

- 11.5 The following molecules have the same molecular formula ( $\text{C}_3\text{H}_8\text{O}$ ), yet they have different normal boiling points, as shown. Rationalize the difference in boiling points. [Sections 11.2 and 11.5]

- 11.6 The phase diagram of a hypothetical substance is shown below.

- (a) Estimate the normal boiling point and freezing point of the substance.  
 (b) What is the physical state of the substance under the following conditions?  
 (i)  $T = 150\text{ K}$ ,  $P = 0.2\text{ atm}$   
 (ii)  $T = 100\text{ K}$ ,  $P = 0.8\text{ atm}$   
 (iii)  $T = 300\text{ K}$ ,  $P = 1.0\text{ atm}$   
 (c) What is the triple point of the substance? [Section 11.6]

- 11.7 Niobium(II) oxide crystallizes in the following cubic unit cell.

- (a) How many niobium atoms and how many oxygen atoms are within the unit cell?  
 (b) What is the empirical formula of niobium oxide?  
 (c) Is this a molecular, covalent-network, or ionic solid? [Sections 11.7 and 11.8]

- 11.8 (a) What kind of packing arrangement is seen in the accompanying photo? (b) What is the coordination number of each orange in the interior of the stack? (c) If each orange represents an argon atom, what category of solid is represented? [Sections 11.7 and 11.8]

## EXERCISES

### Molecular Comparisons of Gases, Liquids, and Solids

- 11.9 List the three states of matter in order of (a) increasing molecular disorder and (b) increasing intermolecular attractions. (c) Which state of matter is most easily compressed?
- 11.10 (a) How does the average kinetic energy of molecules compare with the average energy of attraction between molecules in solids, liquids, and gases? (b) Why does increasing the temperature cause a solid substance to change in succession from a solid to a liquid to a gas? (c) What happens to a gas if you put it under extremely high pressure?
- 11.11 If you mix olive oil with water, the olive oil will float on top of the water. The density of water is  $1.00 \text{ g/cm}^3$  at

room temperature. (a) Is the density of olive oil more or less than  $1.00 \text{ g/cm}^3$ ? (b) The density of olive oil in its liquid phase does vary with temperature. Do you think olive oil would be more dense or less dense at higher temperatures? Explain.

- 11.12 Benzoic acid,  $\text{C}_6\text{H}_5\text{COOH}$ , melts at  $122^\circ\text{C}$ . The density in the liquid state at  $130^\circ\text{C}$  is  $1.08 \text{ g/cm}^3$ . The density of solid benzoic acid at  $15^\circ\text{C}$  is  $1.266 \text{ g/cm}^3$ . (a) In which of these two states is the average distance between molecules greater? (b) Explain the difference in densities at the two temperatures in terms of the relative kinetic energies of the molecules.

### Intermolecular Forces

- 11.13 Which type of intermolecular attractive force operates between (a) all molecules, (b) polar molecules, (c) the hydrogen atom of a polar bond and a nearby small electronegative atom?
- 11.14 Based on what you have learned about intermolecular forces, would you say that matter is fundamentally attracted or repulsed by other matter?
- 11.15 Describe the intermolecular forces that must be overcome to convert each of the following from a liquid or solid to a gas: (a)  $\text{I}_2$ , (b)  $\text{CH}_3\text{CH}_2\text{OH}$ , (c)  $\text{H}_2\text{Se}$ .
- 11.16 What type of intermolecular force accounts for the following differences in each case? (a)  $\text{CH}_3\text{OH}$  boils at  $65^\circ\text{C}$ ,  $\text{CH}_3\text{SH}$  boils at  $6^\circ\text{C}$ . (b) Xe is liquid at atmospheric pressure and  $120 \text{ K}$ , whereas Ar is a gas. (c) Kr,

atomic weight 84, boils at  $120.9 \text{ K}$ , whereas  $\text{Cl}_2$ , molecular weight about 71, boils at  $238 \text{ K}$ . (d) Acetone boils at  $56^\circ\text{C}$ , whereas 2-methylpropane boils at  $-12^\circ\text{C}$ .

- 11.17 (a) What is meant by the term *polarizability*? (b) Which of the following atoms would you expect to be most polarizable: N, P, As, Sb? Explain. (c) Put the following molecules in order of increasing polarizability:  $\text{GeCl}_4$ ,  $\text{CH}_4$ ,  $\text{SiCl}_4$ ,  $\text{SiH}_4$ , and  $\text{GeBr}_4$ . (d) Predict the order of boiling points of the substances in part (c).

- 11.18 True or false:
- The more polarizable the molecules, the stronger the dispersion forces between them.
  - The boiling points of the noble gases decrease as you go down the column in the periodic table.
  - In general, the smaller the molecule, the stronger the dispersion forces.
  - All other factors being the same, dispersion forces between molecules increase with the number of electrons in the molecules.
- 11.19 Which member of the following pairs has the larger London dispersion forces: (a)  $\text{H}_2\text{O}$  or  $\text{H}_2\text{S}$ , (b)  $\text{CO}_2$  or  $\text{CO}$ , (c)  $\text{SiH}_4$  or  $\text{GeH}_4$ ?
- 11.20 Which member of the following pairs has the stronger intermolecular dispersion forces: (a)  $\text{Br}_2$  or  $\text{O}_2$ , (b)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{SH}$  or  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{SH}$ , (c)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{Cl}$  or  $(\text{CH}_3)_2\text{CHCl}$ ?
- 11.21 Butane and 2-methylpropane, whose space-filling models are shown, are both nonpolar and have the same molecular formula, yet butane has the higher boiling point ( $-0.5^\circ\text{C}$  compared to  $-11.7^\circ\text{C}$ ). Explain.

(a) Butane (b) 2-Methylpropane

- 11.22 Propyl alcohol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ ) and isopropyl alcohol [ $(\text{CH}_3)_2\text{CHOH}$ ], whose space-filling models are shown, have boiling points of  $97.2^\circ\text{C}$  and  $82.5^\circ\text{C}$ , respectively. Explain why the boiling point of propyl alcohol is higher, even though both have the molecular formula of  $\text{C}_3\text{H}_8\text{O}$ .

(a) Propyl alcohol (b) Isopropyl alcohol

- 11.23 (a) What atoms must a molecule contain to participate in hydrogen bonding with other molecules of the same kind? (b) Which of the following molecules can form hydrogen bonds with other molecules of the same kind:  $\text{CH}_3\text{F}$ ,  $\text{CH}_3\text{NH}_2$ ,  $\text{CH}_3\text{OH}$ ,  $\text{CH}_3\text{Br}$ ?
- 11.24 Rationalize the difference in boiling points between the members of the following pairs of substances: (a)  $\text{HF}$  ( $20^\circ\text{C}$ ) and  $\text{HCl}$  ( $-85^\circ\text{C}$ ), (b)  $\text{CHCl}_3$  ( $61^\circ\text{C}$ ) and  $\text{CHBr}_3$  ( $150^\circ\text{C}$ ), (c)  $\text{Br}_2$  ( $59^\circ\text{C}$ ) and  $\text{ICl}$  ( $97^\circ\text{C}$ ).
- 11.25 Ethylene glycol ( $\text{HOCH}_2\text{CH}_2\text{OH}$ ), the major substance in antifreeze, has a normal boiling point of  $198^\circ\text{C}$ . By comparison, ethyl alcohol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) boils at  $78^\circ\text{C}$  at atmospheric pressure. Ethylene glycol dimethyl ether ( $\text{CH}_3\text{OCH}_2\text{CH}_2\text{OCH}_3$ ) has a normal boiling point of  $83^\circ\text{C}$ , and ethyl methyl ether ( $\text{CH}_3\text{CH}_2\text{OCH}_3$ ) has a normal boiling point of  $11^\circ\text{C}$ . (a) Explain why replacement of a hydrogen on the oxygen by  $\text{CH}_3$  generally results in a lower boiling point. (b) What are the major factors responsible for the difference in boiling points of the two ethers?
- 11.26 Identify the types of intermolecular forces present in each of the following substances, and select the substance in each pair that has the higher boiling point: (a)  $\text{C}_6\text{H}_{14}$  or  $\text{C}_8\text{H}_{18}$ , (b)  $\text{C}_3\text{H}_8$  or  $\text{CH}_3\text{OCH}_3$ , (c)  $\text{HOOH}$  or  $\text{HSSH}$ , (d)  $\text{NH}_2\text{NH}_2$  or  $\text{CH}_3\text{CH}_3$ .

- 11.27 Look up and compare the normal boiling points and normal melting points of  $\text{H}_2\text{O}$  and  $\text{H}_2\text{S}$ . (a) Based on these physical properties, which substance has stronger intermolecular forces? What kind of intermolecular forces exist for each molecule? (b) Predict whether solid  $\text{H}_2\text{S}$  is more or less dense than liquid  $\text{H}_2\text{S}$ . How does this compare to  $\text{H}_2\text{O}$ ? Explain. (c) Water has an unusually high specific heat. Is this related to its intermolecular forces? Explain.
- 11.28 The following quote about ammonia ( $\text{NH}_3$ ) is from a textbook of inorganic chemistry: "It is estimated that 26% of the hydrogen bonding in  $\text{NH}_3$  breaks down on melting, 7% on warming from the melting to the boiling point, and the final 67% on transfer to the gas phase at the boiling point." From the standpoint of the kinetic energy of the molecules, explain (a) why there is a decrease of hydrogen-bonding energy on melting and (b) why most of the loss in hydrogen bonding occurs in the transition from the liquid to the vapor state.

## Viscosity and Surface Tension

- 11.29 (a) Explain why surface tension and viscosity decrease with increasing temperature. (b) Why do substances with high surface tensions also tend to have high viscosities?
- 11.30 (a) Distinguish between adhesive forces and cohesive forces. (b) What adhesive and cohesive forces are involved when a paper towel absorbs water? (c) Explain the cause for the U-shaped meniscus formed when water is in a glass tube.
- 11.31 Explain the following observations: (a) The surface tension of  $\text{CHBr}_3$  is greater than that of  $\text{CHCl}_3$ . (b) As tem-

perature increases, oil flows faster through a narrow tube. (c) Raindrops that collect on a waxed automobile hood take on a nearly spherical shape. (d) Oil droplets that collect on a waxed automobile hood take on a flat shape.

- 11.32 Hydrazine ( $\text{H}_2\text{NNH}_2$ ), hydrogen peroxide ( $\text{HOOH}$ ), and water ( $\text{H}_2\text{O}$ ) all have exceptionally high surface tensions compared with other substances of comparable molecular weights. (a) Draw the Lewis structures for these three compounds. (b) What structural property do these substances have in common, and how might that account for the high surface tensions?

## Phase Changes

- 11.33** Name the phase transition in each of the following situations, and indicate whether it is exothermic or endothermic: (a) When ice is heated, it turns to water. (b) Wet clothes dry on a warm summer day. (c) Frost appears on a window on a cold winter day. (d) Droplets of water appear on a cold glass of beer.
- 11.34** Name the phase transition in each of the following situations, and indicate whether it is exothermic or endothermic: (a) Bromine vapor turns to bromine liquid as it is cooled. (b) Crystals of iodine disappear from an evaporating dish as they stand in a fume hood. (c) Rubbing alcohol in an open container slowly disappears. (d) Molten lava from a volcano turns into solid rock.
- 11.35** Explain why the heat of fusion of any substance is generally lower than its heat of vaporization.
- 11.36** Ethyl chloride ( $C_2H_5Cl$ ) boils at  $12^\circ C$ . When liquid  $C_2H_5Cl$  under pressure is sprayed on a room-temperature ( $25^\circ C$ ) surface in air, the surface is cooled considerably. (a) What does this observation tell us about the specific heat of  $C_2H_5Cl(g)$  as compared with  $C_2H_5Cl(l)$ ? (b) Assume that the heat lost by the surface is gained by ethyl chloride. What enthalpies must you consider if you were to calculate the final temperature of the surface?
- 11.37** For many years drinking water has been cooled in hot climates by evaporating it from the surfaces of canvas bags or porous clay pots. How many grams of water can be cooled from  $35^\circ C$  to  $20^\circ C$  by the evaporation of 60 g of water? (The heat of vaporization of water in this temperature range is 2.4 kJ/g. The specific heat of water is 4.18 J/g-K.)
- 11.38** Compounds like  $CCl_2F_2$  are known as chlorofluorocarbons, or CFCs. These compounds were once widely used as refrigerants but are now being replaced by compounds that are believed to be less harmful to the environment. The heat of vaporization of  $CCl_2F_2$  is 289 J/g. What mass of this substance must evaporate to freeze 200 g of water initially at  $15^\circ C$ ? (The heat of fusion of water is 334 J/g; the specific heat of water is 4.18 J/g-K.)
- 11.39** Ethanol ( $C_2H_5OH$ ) melts at  $-114^\circ C$  and boils at  $78^\circ C$ . Its density is 0.789 g/mL. The enthalpy of fusion of ethanol is 5.02 kJ/mol, and its enthalpy of vaporization is 38.56 kJ/mol. The specific heats of solid and liquid ethanol are 0.97 J/g-K and 2.3 J/g-K, respectively. (a) How much heat is required to convert 25.0 g of ethanol at  $25^\circ C$  to the vapor phase at  $78^\circ C$ ? (b) How much heat is required to convert 5.00 L of ethanol at  $-140^\circ C$  to the vapor phase at  $78^\circ C$ ?
- 11.40** The fluorocarbon compound  $C_2Cl_3F_3$  has a normal boiling point of  $47.6^\circ C$ . The specific heats of  $C_2Cl_3F_3(l)$  and  $C_2Cl_3F_3(g)$  are 0.91 J/g-K and 0.67 J/g-K, respectively. The heat of vaporization for the compound is 27.49 kJ/mol. Calculate the heat required to convert 50.0 g of  $C_2Cl_3F_3$  from a liquid at  $10.00^\circ C$  to a gas at  $85.00^\circ C$ .
- 11.41** (a) What is the significance of the critical pressure of a substance? (b) What happens to the critical temperature of a series of compounds as the force of attraction between molecules increases? (c) Which of the substances listed in Table 11.5 can be liquefied at the temperature of liquid nitrogen ( $-196^\circ C$ )?
- 11.42** The critical temperatures (K) and pressures (atm) of a series of halogenated methanes are as follows:

Compound	$CCl_3F$	$CCl_2F_2$	$CClF_3$	$CF_4$
Critical Temperature	471	385	302	227
Critical Pressure	43.5	40.6	38.2	37.0

(a) List the intermolecular forces that occur for each compound. (b) Predict the order of increasing intermolecular attraction, from least to most, for this series of compounds. (c) Predict the critical temperature and pressure for  $CCl_4$  based on the trends in this table. Look up the experimentally determined critical temperatures and pressures for  $CCl_4$ , using a source such as the *CRC Handbook of Chemistry and Physics*, and suggest a reason for any discrepancies.

## Vapor Pressure and Boiling Point

- 11.43** Explain how each of the following affects the vapor pressure of a liquid: (a) volume of the liquid, (b) surface area, (c) intermolecular attractive forces, (d) temperature, (e) density of the liquid.
- 11.44** A liquid that has an equilibrium vapor pressure of 130 torr at  $25^\circ C$  is placed into a 1-L vessel like that shown in Figure 11.22. What is the pressure difference shown on the manometer, and what is the composition of the gas in the vessel, under each of the following conditions: (a) Two hundred mL of the liquid is introduced into the vessel and frozen at the bottom. The vessel is evacuated and sealed, and the liquid is allowed to warm to  $25^\circ C$ . (b) Two hundred milliliters of the liquid is added to the vessel at  $25^\circ C$  under atmospheric pressure, and after a few minutes the vessel is closed off. (c) A few mL of the liquid is introduced into the vessel at  $25^\circ C$  while it has a pressure of 1 atm of air in it, without allowing any of the air to escape. After a few minutes a few drops of liquid remain in the vessel.
- 11.45** (a) Place the following substances in order of increasing volatility:  $CH_4$ ,  $CBr_4$ ,  $CH_2Cl_2$ ,  $CH_3Cl$ ,  $CHBr_3$ , and  $CH_2Br_2$ . Explain. (b) How do the boiling points vary through this series?
- 11.46** True or false: (a)  $CBr_4$  is more volatile than  $CCl_4$ . (b)  $CBr_4$  has a higher boiling point than  $CCl_4$ . (c)  $CBr_4$  has weaker intermolecular forces than  $CCl_4$ . (d)  $CBr_4$  has a higher vapor pressure at the same temperature than  $CCl_4$ .

- 11.47** (a) Two pans of water are on different burners of a stove. One pan of water is boiling vigorously, while the other is boiling gently. What can be said about the temperature of the water in the two pans? (b) A large container of water and a small one are at the same temperature. What can be said about the relative vapor pressures of the water in the two containers?
- 11.48** Explain the following observations: (a) Water evaporates more quickly on a hot, dry day than on a hot, humid day. (b) It takes longer to boil water for tea at high altitudes than at lower altitudes.
- 11.49** Using the vapor-pressure curves in Figure 11.24, (a) estimate the boiling point of ethanol at an external pressure of 200 torr; (b) estimate the external pressure at which ethanol will boil at 60 °C; (c) estimate the boiling point of diethyl ether at 400 torr; (d) estimate the external pressure at which diethyl ether will boil at 40 °C.
- 11.50** Appendix B lists the vapor pressure of water at various external pressures.
- (a) Plot the data in Appendix B, vapor pressure (torr) vs. temperature (°C). From your plot, estimate the vapor pressure of water at body temperature, 37 °C.
- (b) Explain the significance of the data point at 760.0 torr, 100 °C.
- (c) A city at an altitude of 5000 ft above sea level has a barometric pressure of 633 torr. To what temperature would you have to heat water to boil it in this city?
- (d) A city at an altitude of 500 ft below sea level would have a barometric pressure of 774 torr. To what temperature would you have to heat water to boil it in this city?
- (e) For the two cities in parts (c) and (d), compare the average kinetic energies of the water molecules at their boiling points. Are the kinetic energies the same or different? Explain.

## Phase Diagrams

- 11.51** (a) What is the significance of the critical point in a phase diagram? (b) Why does the line that separates the gas and liquid phases end at the critical point?
- 11.52** (a) What is the significance of the triple point in a phase diagram? (b) Could you measure the triple point of water by measuring the temperature in a vessel in which water vapor, liquid water, and ice are in equilibrium under one atmosphere of air? Explain.
- 11.53** Refer to Figure 11.27(a), and describe all the phase changes that would occur in each of the following cases: (a) Water vapor originally at 0.005 atm and -0.5 °C is slowly compressed at constant temperature until the final pressure is 20 atm. (b) Water originally at 100.0 °C and 0.50 atm is cooled at constant pressure until the temperature is -10 °C.
- 11.54** Refer to Figure 11.27(b), and describe the phase changes (and the temperatures at which they occur) when CO<sub>2</sub> is heated from -80 °C to -20 °C at (a) a constant pressure of 3 atm, (b) a constant pressure of 6 atm.
- 11.55** Sketch a generic phase diagram for a substance that has a more dense solid phase than a liquid phase. Label all regions, lines, and points.
- 11.56** The normal melting and boiling points of O<sub>2</sub> are -218 °C and -183 °C respectively. Its triple point is at -219 °C and 1.14 torr, and its critical point is at -119 °C and 49.8 atm. (a) Sketch the phase diagram for O<sub>2</sub>, showing the four points given and indicating the area in which each phase is stable. (b) Will O<sub>2</sub>(s) float on O<sub>2</sub>(l)? Explain. (c) As it is heated, will solid O<sub>2</sub> sublime or melt under a pressure of 1 atm?

## Structures of Solids

- 11.57** (a) Draw a picture that represents a crystalline solid at the atomic level. (b) Now draw a picture that represents an amorphous solid at the atomic level.
- 11.58** Amorphous silica has a density of about 2.2 g/cm<sup>3</sup>, whereas the density of crystalline quartz is 2.65 g/cm<sup>3</sup>. Account for this difference in densities.
- 11.59** Tausonite, a mineral composed of Sr, O, and Ti, has the cubic unit cell shown in the drawing. (a) What is the chemical formula of this mineral? (b) It is easy to see that Ti is coordinated by six oxygen atoms, because the Ti atom is located at the center of the unit cell. To see the full coordination environment of the other ions, we have to consider neighboring unit cells. How many oxygens are coordinated to strontium?

- 11.60** Rutile is a mineral composed of Ti and O. Its unit cell, shown in the drawing, contains Ti atoms at each corner and a Ti atom at the center of the cell. Four O atoms are

on the opposite faces of the cell, and two are entirely within the cell. (a) What is the chemical formula of this mineral? (b) What is the nature of the bonding that holds the solid together? (c) What is the coordination number of each atom?

- 11.61** Iridium crystallizes in a face-centered cubic unit cell that has an edge length of  $3.833 \text{ \AA}$ . The atom in the center of the face is in contact with the corner atoms, as shown in the drawing. (a) Calculate the atomic radius of an iridium atom. (b) Calculate the density of iridium metal.

- 11.62** Aluminum metal crystallizes in a cubic close-packed structure (face-centered cubic cell, Figure 11.34). (a) How many aluminum atoms are in a unit cell? (b) What is the coordination number of each aluminum atom? (c) Assume that the aluminum atoms can be represented as spheres, as shown in the drawing for

Exercise 11.61. If each Al atom has a radius of  $1.43 \text{ \AA}$ , what is the length of a side of the unit cell? (d) Calculate the density of aluminum metal.

- 11.63** An element crystallizes in a body-centered cubic lattice. The edge of the unit cell is  $2.86 \text{ \AA}$ , and the density of the crystal is  $792 \text{ g/cm}^3$ . Calculate the atomic weight of the element.
- 11.64** KCl has the same structure as NaCl. The length of the unit cell is  $628 \text{ pm}$ . The density of KCl is  $1.984 \text{ g/cm}^3$ , and its formula mass is  $74.55 \text{ amu}$ . Using this information, calculate Avogadro's number.
- 11.65** NaF has the same structure as NaCl. (a) Use ionic radii from Chapter 7 to estimate the length of the unit cell edge for NaF. (b) Use the unit cell size calculated in part (a) to estimate the density of NaF.
- 11.66** What is the coordination number of (a)  $\text{Na}^+$  in the NaCl structure, Figure 11.35; (b)  $\text{Zn}^{2+}$  in the ZnS unit cell, Figure 11.42(b); (c)  $\text{Ca}^{2+}$  in the  $\text{CaF}_2$  unit cell, Figure 11.42(c)?
- 11.67** Clausthalite is a mineral composed of lead selenide ( $\text{PbSe}$ ). The mineral adopts a NaCl-type structure. The density of  $\text{PbSe}$  at  $25^\circ\text{C}$  is  $8.27 \text{ g/cm}^3$ . Calculate the length of an edge of the  $\text{PbSe}$  unit cell.
- 11.68** A particular form of cinnabar ( $\text{HgS}$ ) adopts the zinc blende structure, Figure 11.42(b). The length of the unit cell side is  $5.852 \text{ \AA}$ . (a) Calculate the density of  $\text{HgS}$  in this form. (b) The mineral tiemannite ( $\text{HgSe}$ ) also forms a solid phase with the zinc blende structure. The length of the unit cell side in this mineral is  $6.085 \text{ \AA}$ . What accounts for the larger unit cell length in tiemannite? (c) Which of the two substances has the higher density? How do you account for the difference in densities?

## Bonding in Solids

- 11.69** It is possible to change the temperature and pressure of a vessel containing argon gas so that the gas solidifies. (a) What intermolecular forces exist between argon atoms? (b) Is the solid argon a "covalent network solid"? Why or why not?
- 11.70** (a) Silicon is the fundamental component of integrated circuits. Si has the same structure as diamond. Is Si a molecular, metallic, ionic, or covalent-network solid? (b) Silica is  $\text{SiO}_2$ . What type of solid would you expect silica to form?
- 11.71** What kinds of attractive forces exist between particles in (a) molecular crystals, (b) covalent-network crystals, (c) ionic crystals, (d) metallic crystals?
- 11.72** Indicate the type of crystal (molecular, metallic, covalent-network, or ionic) each of the following would form upon solidification: (a)  $\text{CaCO}_3$ , (b) Pt, (c)  $\text{ZrO}_2$  (melting point,  $2677^\circ\text{C}$ ), (d) table sugar ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ), (e) benzene, (f)  $\text{I}_2$ .
- 11.73** Covalent bonding occurs in both molecular and covalent-network solids. Why do these two kinds of solids differ so greatly in their hardness and melting points?
- 11.74** Which type (or types) of crystalline solid is characterized by each of the following: (a) high mobility of electrons throughout the solid; (b) softness, relatively low melting point; (c) high melting point and poor electrical conductivity; (d) network of covalent bonds; (e) charged particles throughout the solid.
- 11.75** A white substance melts with some decomposition at  $730^\circ\text{C}$ . As a solid, it does not conduct electricity, but it dissolves in water to form a conducting solution. Which type of solid (Table 11.7) might the substance be?
- 11.76** You are given a white substance that sublimates at  $3000^\circ\text{C}$ ; the solid is a nonconductor of electricity and is insoluble in water. Which type of solid (Table 11.7) might this substance be?
- 11.77** For each of the following pairs of substances, predict which will have the higher melting point and indicate why: (a) Ar, Xe; (b)  $\text{SiO}_2$ ,  $\text{CO}_2$ ; (c) KBr,  $\text{Br}_2$ ; (d)  $\text{C}_6\text{Cl}_6$ ,  $\text{C}_6\text{H}_6$ .
- 11.78** For each of the following pairs of substances, predict which will have the higher melting point, and indicate why: (a) HF, HCl; (b) C (graphite),  $\text{CH}_4$ ; (c) KCl,  $\text{Cl}_2$ ; (d) LiF,  $\text{MgF}_2$ .

## ADDITIONAL EXERCISES

- 11.79** As the intermolecular attractive forces between molecules increase in magnitude, do you expect each of the following to increase or decrease in magnitude? (a) vapor pressure, (b) heat of vaporization, (c) boiling point, (d) freezing point, (e) viscosity, (f) surface tension, (g) critical temperature.
- 11.80** Suppose you have two colorless molecular liquids, one boiling at  $-84^\circ\text{C}$ , the other at  $34^\circ\text{C}$ , and both at atmospheric pressure. Which of the following statements is correct? For those that are not correct, modify the statement so that it is correct. (a) The higher-boiling liquid has greater total intermolecular forces than the other. (b) The lower boiling liquid must consist of nonpolar molecules. (c) The lower-boiling liquid has a lower molecular weight than the higher-boiling liquid. (d) The two liquids have identical vapor pressures at their normal boiling points. (e) At  $34^\circ\text{C}$  both liquids have vapor pressures of 760 mm Hg.
- 11.81** Two isomers of the planar compound 1,2-dichloroethylene are shown here, along with their melting and boiling points.

Melting point ( $^\circ\text{C}$ )	-80.5	-49.8
Boiling point ( $^\circ\text{C}$ )	60.3	47.5

- (a) Which of the two isomers will have the stronger dipole-dipole forces? Is this prediction borne out by the data presented here? (b) Based on the data presented here, which isomer packs more efficiently in the solid phase?
- 11.82** In dichloromethane,  $\text{CH}_2\text{Cl}_2$  ( $\mu = 1.60\text{ D}$ ), the dispersion force contribution to the intermolecular attractive forces is about five times larger than the dipole-dipole contribution. Would you expect the relative importance of the two kinds of intermolecular attractive forces to differ (a) in dibromomethane ( $\mu = 1.43\text{ D}$ ), (b) in difluoromethane ( $\mu = 1.93\text{ D}$ )? Explain.
- 11.83** When an atom or group of atoms is substituted for an H atom in benzene ( $\text{C}_6\text{H}_6$ ), the boiling point changes. Explain the order of the following boiling points:  $\text{C}_6\text{H}_6$  ( $80^\circ\text{C}$ ),  $\text{C}_6\text{H}_5\text{Cl}$  ( $132^\circ\text{C}$ ),  $\text{C}_6\text{H}_5\text{Br}$  ( $156^\circ\text{C}$ ),  $\text{C}_6\text{H}_5\text{OH}$  ( $182^\circ\text{C}$ ).
- 11.84** The DNA double helix (Figure 25.40) at the atomic level looks like a twisted ladder, where the “rungs” of the ladder consist of molecules that are hydrogen-bonded together. Sugar and phosphate groups make up the sides of the ladder. Shown are the structures of the adenine-thymine (AT) “base pair” and the guanine-cytosine (GC) base pair:

You can see that AT base pairs are held together by two hydrogen bonds, and the GC base pairs are held together by three hydrogen bonds. Which base pair is more stable to heating?

- 11.85** Ethylene glycol [ $\text{CH}_2(\text{OH})\text{CH}_2(\text{OH})$ ] is the major component of antifreeze. It is a slightly viscous liquid, not very volatile at room temperature, with a boiling point of  $198^\circ\text{C}$ . Pentane ( $\text{C}_5\text{H}_{12}$ ), which has about the same molecular weight, is a nonviscous liquid that is highly volatile at room temperature and whose boiling point is  $36.1^\circ\text{C}$ . Explain the differences in the physical properties of the two substances.
- 11.86** Using the following list of normal boiling points for a series of hydrocarbons, estimate the normal boiling point for octane,  $\text{C}_8\text{H}_{18}$ : propane ( $\text{C}_3\text{H}_8$ ,  $-42.1^\circ\text{C}$ ), butane ( $\text{C}_4\text{H}_{10}$ ,  $-0.5^\circ\text{C}$ ), pentane ( $\text{C}_5\text{H}_{12}$ ,  $36.1^\circ\text{C}$ ), hexane ( $\text{C}_6\text{H}_{14}$ ,  $68.7^\circ\text{C}$ ), heptane ( $\text{C}_7\text{H}_{16}$ ,  $98.4^\circ\text{C}$ ). Explain the trend in the boiling points.
- [11.87]** Notice in Figure 11.21 that there is a pressure-reduction valve in the line just before the supercritical  $\text{CO}_2$  and dissolved caffeine enter the separator. Suggest an explanation for the function of this valve in the overall process.
- 11.88** (a) When you exercise vigorously, you sweat. How does this help your body cool? (b) A flask of water is connected to a vacuum pump. A few moments after the pump is turned on, the water begins to boil. After a few minutes, the water begins to freeze. Explain why these processes occur.
- [11.89]** The following table gives the vapor pressure of hexafluorobenzene ( $\text{C}_6\text{F}_6$ ) as a function of temperature:

Temperature (K)	Vapor Pressure (torr)
280.0	32.42
300.0	92.47
320.0	225.1
330.0	334.4
340.0	482.9

- (a) By plotting these data in a suitable fashion, determine whether the Clausius–Clapeyron equation is obeyed. If it is obeyed, use your plot to determine  $\Delta H_{\text{vap}}$  for  $\text{C}_6\text{F}_6$ . (b) Use these data to determine the boiling point of the compound.
- [11.90]** Suppose the vapor pressure of a substance is measured at two different temperatures. (a) By using the Clausius–Clapeyron equation, Equation 11.1, derive the following relationship between the vapor pressures,  $P_1$  and  $P_2$ , and the absolute temperatures at which they were measured,  $T_1$  and  $T_2$ :

$$\ln \frac{P_1}{P_2} = -\frac{\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

(b) Gasoline is a mixture of hydrocarbons, a major component of which is octane,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ . Octane has a vapor pressure of 13.95 torr at 25 °C and a vapor pressure of 144.78 torr at 75 °C. Use these data and the equation in part (a) to calculate the heat of vaporization of octane. (c) By using the equation in part (a) and the data given in part (b), calculate the normal boiling point of octane. Compare your answer to the one you obtained from Exercise 11.86. (d) Calculate the vapor pressure of octane at  $-30^\circ\text{C}$ .

- [11.91] The following data present the temperatures at which certain vapor pressures are achieved for dichloromethane ( $\text{CH}_2\text{Cl}_2$ ) and methyl iodide ( $\text{CH}_3\text{I}$ ):

Vapor Pressure (torr):	10.0	40.0	100.0	400.0
$T$ for $\text{CH}_2\text{Cl}_2$ (°C):	-43.3	-22.3	-6.3	24.1
$T$ for $\text{CH}_3\text{I}$ (°C):	-45.8	-24.2	-7.0	25.3

- (a) Which of the two substances is expected to have the greater dipole-dipole forces? Which is expected to have the greater London dispersion forces? Based on your answers, explain why it is difficult to predict which compound would be more volatile. (b) Which compound would you expect to have the higher boiling point? Check your answer in a reference book such as the *CRC Handbook of Chemistry and Physics*. (c) The order of volatility of these two substances changes as the temperature is increased. What quantity must be different for the two substances in order for this phenomenon to occur? (d) Substantiate your answer for part (c) by drawing an appropriate graph.
- 11.92 The elements xenon and gold both have solid-state structures with face-centered cubic unit cells, yet Xe melts at  $-112^\circ\text{C}$  and gold melts at  $1064^\circ\text{C}$ . Account for these greatly different melting points.
- 11.93 In Chapter 7 we saw that Li reacts with oxygen to form lithium oxide,  $\text{Li}_2\text{O}$ , while the larger alkali metals react with oxygen to form peroxides (such as  $\text{Na}_2\text{O}_2$ ,  $\text{K}_2\text{O}_2$ , etc.). The origin of this curious pattern of reactivity is

related to the relative sizes of the cation and anion and the overall stoichiometry.  $\text{Li}_2\text{O}$  crystallizes with a structure called the antifluorite structure. This structure is identical to the fluorite structure shown in Figure 11.42(c), but the cations and anions have been switched. (a) In  $\text{Li}_2\text{O}$ , what are the coordination numbers for each ion? (b) As the cation radius increases, would you expect the coordination number to increase or decrease (assuming the anion size does not change)? (c) Why do you think the antifluorite structure becomes unstable for  $\text{A}_2\text{O}$  ( $\text{A} = \text{Li}, \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ ) compounds of the heavier alkali metal ions?

- 11.94 Gold crystallizes in a face-centered cubic unit cell that has an edge length of  $4.078 \text{ \AA}$ . The atom in the center of the face is in contact with the corner atoms, as shown in the drawing for Exercise 11.61. (a) Calculate the apparent radius of a gold atom in this structure. (b) Calculate the density of gold metal.
- 11.95 (a) Explain why X-rays can be used to measure atomic distances in crystals but visible light cannot. (b) Why can't  $\text{CaCl}_2$  have the same crystal structure as  $\text{NaCl}$ ?
- 11.96 In their study of X-ray diffraction, William and Lawrence Bragg determined that the relationship among the wavelength of the radiation ( $\lambda$ ), the angle at which the radiation is diffracted ( $\theta$ ), and the distance between the layers of atoms in the crystal that cause the diffraction ( $d$ ) is given by  $n\lambda = 2d \sin \theta$ . (a) X-rays from a copper X-ray tube that have a wavelength of  $1.54 \text{ \AA}$  are diffracted at an angle of  $14.22$  degrees by crystalline silicon. Using the Bragg equation, calculate the interplanar spacing in the crystal, assuming  $n = 1$  (first-order diffraction). (b) Repeat the calculation of part (a) but for the  $n = 2$  case (second-order diffraction).
- [11.97] (a) The density of diamond [Figure 11.41(a)] is  $3.5 \text{ g/cm}^3$ , and that of graphite [Figure 11.41(b)] is  $2.3 \text{ g/cm}^3$ . Based on the structure of buckminsterfullerene (Figure 11.43), what would you expect its density to be relative to these other forms of carbon? (b) X-ray diffraction studies of buckminsterfullerene show that it has a face-centered cubic lattice of  $\text{C}_{60}$  molecules. The length of a side of the unit cell is  $14.2 \text{ \AA}$ . Calculate the density of buckminsterfullerene.

## INTEGRATIVE EXERCISES

- 11.98 Spinel is a mineral that contains 37.9% Al, 17.1% Mg, and 45.0% O, by mass, and has a density of  $3.57 \text{ g/cm}^3$ . The unit cell is cubic, with an edge length of  $809 \text{ pm}$ . How many atoms of each type are in the unit cell?
- 11.99 (a) At the molecular level, what factor is responsible for the steady increase in viscosity with increasing molecular weight in the hydrocarbon series shown in Table 11.4? (b) Although the viscosity varies over a factor of more than two in the series from hexane to nonane, the surface tension at  $25^\circ\text{C}$  increases by only about 20% in the same series. How do you account for this? (c) *n*-Octyl alcohol,  $\text{CH}_3(\text{CH}_2)_7\text{OH}$ , has a viscosity of  $1.01 \times 10^{-2} \text{ kg m}^{-1}\text{s}^{-1}$ , much higher than nonane, which has about the same molecular weight. What accounts for this difference? How does your answer relate to the difference in normal boiling points for these two substances?
- 11.100 Acetone,  $(\text{CH}_3)_2\text{CO}$ , is widely used as an industrial solvent. (a) Draw the Lewis structure for the acetone molecule, and predict the geometry around each carbon atom. (b) Is the acetone molecule polar or nonpolar? (c) What kinds of intermolecular attractive forces exist between acetone molecules? (d) 1-Propanol,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ , has a molecular weight that is very similar to that of acetone, yet acetone boils at  $56.5^\circ\text{C}$  and 1-propanol boils at  $97.2^\circ\text{C}$ . Explain the difference.

- 11.101** The table shown here lists the molar heats of vaporization for several organic compounds. Use specific examples from this list to illustrate how the heat of vaporization varies with (a) molar mass, (b) molecular shape, (c) molecular polarity, (d) hydrogen-bonding interactions. Explain these comparisons in terms of the nature of the intermolecular forces at work. (You may find it helpful to draw out the structural formula for each compound.)

Compound	Heat of Vaporization (kJ/mol)
CH <sub>3</sub> CH <sub>2</sub> CH <sub>3</sub>	19.0
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	27.6
CH <sub>3</sub> CHBrCH <sub>3</sub>	31.8
CH <sub>3</sub> COCH <sub>3</sub>	32.0
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> Br	33.6
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> OH	47.3

- 11.102** Liquid butane, C<sub>4</sub>H<sub>10</sub>, is stored in cylinders, to be used as a fuel. The normal boiling point of butane is listed as -0.5 °C. (a) Suppose the tank is standing in the sun and reaches a temperature of 35 °C. Would you expect the pressure in the tank to be greater or less than atmospheric pressure? How does the pressure within the tank depend on how much liquid butane is in it? (b) Suppose the valve to the tank is opened and a few liters of butane are allowed to escape rapidly. What do you expect would happen to the temperature of the remaining liquid butane in the tank? Explain. (c) How much heat must be added to vaporize 250 g of butane if its heat of vaporization is 21.3 kJ/mol? What volume does this much butane occupy at 755 torr and 35 °C?
- [11.103]** Using information in Appendices B and C, calculate the minimum number of grams of propane, C<sub>3</sub>H<sub>8</sub>(g), that must be combusted to provide the energy necessary to convert 5.50 kg of ice at -20 °C to liquid water at 75 °C.

- 11.104** In a certain type of nuclear reactor, liquid sodium metal is employed as a circulating coolant in a closed system, protected from contact with air or water. Much like the coolant that circulates in an automobile engine, the liquid sodium carries heat from the hot reactor core to heat exchangers. (a) What properties of the liquid sodium are of special importance in this application? (b) The viscosity of liquid sodium varies with temperature as follows:

Temperature (°C)	Viscosity (kg m <sup>-1</sup> s <sup>-1</sup> )
100	7.05 × 10 <sup>-4</sup>
200	4.50 × 10 <sup>-4</sup>
300	3.45 × 10 <sup>-4</sup>
600	2.10 × 10 <sup>-4</sup>

What forces within the liquid sodium are likely to be the major contributors to the viscosity? Why does viscosity decrease with increasing temperature?

- 11.105** The vapor pressure of a volatile liquid can be determined by slowly bubbling a known volume of gas through it at a known temperature and pressure. In an experiment, 500 L of N<sub>2</sub> gas is passed through 7.2146 g of liquid benzene, C<sub>6</sub>H<sub>6</sub>, at 26.0 °C. The liquid remaining after the experiment weighs 5.1493 g. Assuming that the gas becomes saturated with benzene vapor and that the total gas volume and temperature remain constant, what is the vapor pressure of the benzene in torr?
- 11.106** The relative humidity of air equals the ratio of the partial pressure of water in the air to the equilibrium vapor pressure of water at the same temperature, times 100%. If the relative humidity of the air is 58% and its temperature is 68 °F, how many molecules of water are present in a room measuring 12 ft × 10 ft × 8 ft?
- 11.107** Use a reference source such as the *CRC Handbook of Chemistry and Physics* to compare the melting and boiling points of the following pairs of inorganic substances: (a) W and WF<sub>6</sub>, (b) SO<sub>2</sub> and SF<sub>4</sub>, (c) SiO<sub>2</sub> and SiCl<sub>4</sub>. Account for the major differences observed in terms of likely structures and bonding.

CHAPTER  
12 MODERN  
MATERIALS

HERE, THERE, AND EVERYWHERE. The element silicon is the primary component of computer processor chips and commercial solar panels.

## WHAT'S AHEAD

---

### 12.1 Classes of Materials

We will characterize materials according to their predominant bonding interactions and their ability to conduct electricity. Ionic solids have localized electrons and are *insulators*. Covalent-network solids also have localized electrons, but in some cases conductivity can result when electrons are excited or impurities are added. Hence they are called *semiconductors*. The valence electrons in metallic solids are collectively shared, resulting in high electrical conductivity.

### 12.2 Electronic Structure of Materials

We see that the behavior of electrons in bulk solids can be explained by the rules of molecular orbital theory. The large number of atoms in a solid leads to *bands* of allowed energy instead of discrete molecular orbitals. The electrical and optical properties of materials depend upon the filling of these bands.

### 12.3 Semiconductors

We next study semiconductors, where there is an energy gap between the filled and empty bands called the *band gap*. The size of the band gap can be controlled by manipulating the orbital overlap and bond polarity. The conductivity of semiconductors can be controlled by intentionally adding controlled amounts of impurities called *dopants*. A variety of important technological devices can be built from semiconductors, including computer chips, solar cells, and light-emitting diodes (LEDs).

### 12.4 Ceramics

We investigate a class of materials called *ceramics*, which are inorganic solids, such as oxides, nitrides, carbides, and silicates, that are highly resistant to heat, corrosion, and wear. Many ceramics are stronger and lighter than metals, but their applications are somewhat limited by their brittle nature.

### 12.5 Superconductors

We examine materials with the remarkable ability to conduct electricity with no resistance when they are cooled to low temperature. Another unusual property of *superconductors* is that they expel magnetic fields.

### 12.6 Polymers and Plastics

Next we investigate *polymers*—long chainlike molecules where the motif of a small molecule is repeated many times over. We will see how the shapes, interactions, and bonding between polymer chains affect the physical properties.

### 12.7 Biomaterials

We recognize that materials used in biomedical applications must meet special requirements to be compatible with living organisms. We will see several examples of *biomaterials* and how they work in such applications as heart valves, artificial tissues, and vascular grafts.

### 12.8 Liquid Crystals

We will learn that instead of passing directly from the solid to the liquid phase when heated, some substances pass through an intermediate liquid crystalline phase that has some of the structural order of a solid and some of the freedom of motion possessed by liquids. *Liquid crystals* are widely used in electronic displays.

### 12.9 Nanomaterials

We will discuss how physical and chemical properties of bulk materials change when their crystals become very small. These effects begin to occur when materials have sizes on the order of 1–100 nm. Materials that take advantage of these effects are collectively called *nanomaterials*.

**THE MODERN WORLD IS FULL OF “STUFF”**—materials that are used to make computers, compact discs, cell phones, contact lenses, skis, furniture, and a host of other things.

Chemists have contributed to the discovery and development of new materials by inventing entirely new substances and

by developing the means for processing naturally occurring materials to form fibers, films, coatings, adhesives, and substances with special electrical, magnetic, or optical properties. In this chapter we will discuss classes of materials, their properties, and their applications in modern society. Our aim is to show how we can understand the physical or chemical properties of materials by applying the principles discussed in earlier chapters.

This chapter demonstrates the important point that *the observable, macroscopic properties of materials are the result of atomic- and molecular-level structures and processes.*

## 12.1 CLASSES OF MATERIALS

When we say “material,” we generally mean a substance or mixture of substances that is held together by strong chemical bonds throughout the whole sample—in other words, covalent-network solids, ionic solids, and metallic solids. [↔ \(Section 11.8\)](#) The electrical, mechanical, optical, and magnetic properties of these substances find numerous technological uses. Because the types of materials and their applications are so diverse, we need a system for classifying them. One possibility is to classify materials according to the type of bonding that holds the atoms together: ionic, covalent, or metallic. Another possible organization would be to classify materials according to their electrical conductivity: **insulators**, **semiconductors**, or **conductors**. Because bonding and conductivity both depend upon the behavior of the electrons, these two classification schemes are related.

In ionic solids the valence electrons are localized predominantly on the anions. The localized nature of the electrons leads to insulating behavior. In metallic solids the valence electrons are delocalized and shared collectively. The delocalized nature of the valence electrons makes it possible for the electrons to move freely throughout the sample and is responsible for the high electrical and thermal conductivity of metals. In covalent network solids the electrons are localized in covalent bonds. This localization limits the conductivity, but in many such materials conductivity can result if light, heat, or an electrical field excites some of the electrons. Therefore, many covalent-network solids are classified as semiconductors because they have conductivities that are intermediate between metals and insulators. In this chapter we will discuss semiconductors and their applications in some detail. We will also consider ceramics, which are an important class of materials that are normally insulators. We will defer a detailed discussion of the largest class of conductors, metals, to Chapter 23.

Examples of functional and structural materials also exist among molecular solids. In these materials the intermolecular forces we learned about in Chapter 11—London dispersion forces, dipole-dipole interactions, and hydrogen bonds—play an important role. Because intermolecular forces are relatively weak, molecular materials are often softer than materials with extended networks of chemical bonds. Hence, molecular materials are often referred to as “soft” materials, while extended solids are referred to as “hard” materials. Two important types of soft materials are investigated in this chapter: polymers and liquid crystals. Both are examples of molecular solids in which the intermolecular forces give rise to unusual properties that are the basis of important technological applications.

## 12.2 ELECTRONIC STRUCTURE OF MATERIALS

To understand the relationship between conductivity and bonding, let’s consider how the atomic orbitals interact in a crystalline solid. In a crystal there are numerous atoms, each with its own atomic orbitals. These atomic orbitals overlap and combine to give numerous molecular orbitals. Nevertheless, the bonding concepts that apply to a simple diatomic molecule also apply to a crystal with a gigantic number of atoms. Let’s briefly review some of the basic rules of molecular orbital theory. [↔ \(Section 9.7\)](#) First, the atomic orbitals combine in a molecule to make molecular orbitals that can extend over the entire molecule. Second, a given molecular orbital can contain up to two electrons, depending on the energy level of the molecular orbital and how many electrons the molecule possesses.

◀ **Figure 12.1 Discrete energy levels in molecules become continuous bands in solids.** A schematic illustration of the energies and filling of molecular orbitals for a linear chain of hydrogen atoms as the number of atoms increases. The molecular orbitals holding electrons are shaded in blue, while the empty ones are shaded in pink. When the chain becomes very long, essentially no separation exists between energy levels, and the chain possesses a continuous band of energy levels.

Finally, the number of molecular orbitals in a molecule is equal to the number of atomic orbitals that combine to make the molecular orbitals.

The electronic structures of bulk solids and small molecules have many similarities as well as some important differences. To illustrate this point, consider the following thought experiment. How does the molecular orbital diagram for a chain of hydrogen atoms change as we increase the length of the chain (Figure 12.1 ▲)? For one hydrogen atom there is only a single half-filled  $1s$  orbital. For two atoms the molecular orbital diagram corresponds to the molecular orbital diagram of an  $H_2$  molecule that we considered in detail in Chapter 9. ∞ (Section 9.7) For a four-atom chain there are now four molecular orbitals. These range from the lowest energy orbital, where the orbital interactions are completely bonding (0 nodal planes), to the highest energy orbital, where all of the orbital interactions are antibonding (a nodal plane between each pair of atoms).

As the length of the chain increases, the number of molecular orbitals also increases. Fortunately, we can apply a few general concepts regardless of the length of the chain. First, the lowest energy molecular orbitals are always the most bonding, while the highest energy molecular orbitals are the most antibonding. In the middle, the bonding and antibonding interactions tend to balance out. Second, because each hydrogen atom has only one atomic orbital, the number of molecular orbitals is equal to the number of hydrogen atoms in the chain. Given the fact that each hydrogen atom has one electron, this means that half of the molecular orbitals will be fully occupied while the other half will be empty, regardless of chain length.\*

If the length of the chain becomes very large, there are so many molecular orbitals that the energy separation between them becomes vanishingly small, which leads to the formation of a continuous **band** of energy states (Figure 12.1). For the bulk solids we will discuss later in this chapter, the number of atoms is very large. Consequently, their electronic structures will consist of bands, as shown for the very long chain of hydrogen atoms, rather than discrete molecular orbitals. The electronic structures of most materials are more complicated because we have to consider more than one type of atomic orbital on each atom. As each type of orbital can give rise to its own band, the electronic structure of a solid will consist of a series of bands. Consequently, the electronic structure of a bulk solid is referred to as a **band structure**.

\*This is only strictly true for chains with an even number of atoms.

TABLE 12.1 ■ Electronic Properties of Common Materials\*

Material	Type	Band Gap Energy, kJ/mol	Band Gap Energy, eV	Conductivity, $\text{ohm}^{-1} \text{cm}^{-1}$
SiO <sub>2</sub>	Insulator	~870	~9	$<10^{-18}$
Al <sub>2</sub> O <sub>3</sub>	Insulator	~850	~8.8	$<10^{-14}$
C (diamond)	Insulator	~530	~5.5	$<10^{-18}$
Si	Semiconductor	110	1.1	$5 \times 10^{-6}$
Ge	Semiconductor	65	0.67	0.02
Al	Metal	—	—	$3.8 \times 10^5$
Cu	Metal	—	—	$5.9 \times 10^5$
Ag	Metal	—	—	$6.3 \times 10^5$
Au	Metal	—	—	$4.3 \times 10^5$

\*Band gap energies and conductivities are room temperature values. Electron volts (eV) are a commonly used energy unit in the semiconductor industry;  $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$ .

▲ **Figure 12.2 Energy bands in metals, semiconductors, and insulators.** Metals are characterized by the highest-energy electrons occupying a partially filled band. Semiconductors and insulators have an energy gap that separates the completely filled band (shaded in blue) and the empty band (unshaded), known as the band gap and represented by the symbol  $E_g$ . The filled band is called the valence band (VB), and the empty band is called the conduction band (CB). Semiconductors have a smaller band gap than insulators.

The band structures of metals, semiconductors, and insulators differ from each other (Figure 12.2 ◀). The electron count for metals is such that the highest energy band is only partially filled. To conduct electricity, the electrons need to be able to move easily from filled orbitals to empty orbitals. For metals there is almost no energy cost for electrons to jump from the lower, occupied part of the partially filled band to the upper, empty part of the same band. This is the reason why metals conduct electricity so easily, as illustrated by the dramatic differences in conductivity between metals, semiconductors, and insulators (Table 12.1 ▲). Based on this classification the semi-infinite chain of hydrogen atoms discussed above would behave as a metal. Under normal conditions this does not happen because hydrogen forms diatomic

molecules instead of long chains (or three-dimensional crystals). However, theoretical studies suggest that hydrogen becomes metallic under very high pressures. The hydrogen that surrounds the rocky planetary cores of the gas giant planets, such as Jupiter and Saturn, is thought to be metallic.

In semiconductors and insulators an energy gap, known as the **band gap**, separates a completely filled band from an empty band. The electrons in these materials do not move so easily because they must be excited across the gap before they can become delocalized and move through the solid. The situation is analogous to the energy gap that exists between the highest-occupied molecular orbital and the lowest-unoccupied molecular orbital in a molecule. ∞ (Section 9.8: “Chemistry Put to Work: Orbitals and Energy”) Semiconductors are measurably conductive, but far less so than metals because the presence of a band gap lowers the probability that an electron will have enough energy at any given temperature to jump the gap. The distinction between semiconductors and insulators lies in the size of the band gap. If the band gap is much larger than approximately 3 eV, a material is generally classified as an insulator.

## 12.3 SEMICONDUCTORS

Semiconductors can be divided into two classes, **elemental semiconductors**, which contain only one type of atom, and **compound semiconductors**, which are made up of two or more elements. At room temperature the only elemental semiconductors are silicon, germanium, gray tin, and carbon in its graphite form.\* What special feature makes these elements semiconductors, whereas their neighbors are either metals or insulators? First, notice that each of these elements belongs to group 4A. Second, with the exception of graphite, all of these elements adopt the same crystal structure as diamond. ∞ (Section 11.8) In this structure four atoms in a tetrahedral coordination geometry surround each atom (Figure 12.3 ▶).

\*Graphite is unusual. Within the layers graphite is nearly metallic, but it is a semiconductor between the layers. ∞ (Section 11.8)

When the atomic  $s$  and  $p$  orbitals overlap, they form bonding molecular orbitals and antibonding molecular orbitals. Each pair of  $s$  orbitals overlaps to give one bonding and one antibonding molecular orbital, while at the same time the  $p$  orbitals overlap to give three bonding and three antibonding molecular orbitals. The large numbers of atoms in a bulk crystal lead to the formation of bands (Figure 12.4). The band that forms from the bonding molecular orbitals is called the **valence band**, while the band that forms from the antibonding orbitals is called the **conduction band**. In a semiconductor the valence band is filled with electrons and the conduction band is empty. These two bands are separated by the band gap,  $E_g$ .

As described in the preceding paragraph every pair of atoms in the solid generates four bonding molecular orbitals and four antibonding molecular orbitals. As each molecular orbital can accommodate two electrons this means that the bonding molecular orbitals can hold eight electrons for every pair of atoms, or four electrons per atom. For the group 4A elements this is equal to the number of valence electrons, which explains why the elemental semiconductors belong to group 4A.

Compound semiconductors maintain the same average valence electron count as elemental semiconductors—four per atom. For example, gallium, Ga, is in column 3A of the periodic table, and arsenic, As, is in column 5A. In gallium arsenide, GaAs, each Ga atom contributes three electrons and each As atom contributes five, which averages out to four per atom—the same number as in silicon or germanium. GaAs is indeed a semiconductor, as are silicon and germanium. Similarly, InP, where indium provides three valence electrons and phosphorus contributes five, and CdTe, where cadmium provides two valence electrons and tellurium contributes six, are also semiconductors because they maintain an average of four valence electrons per atom.

GaAs, InP, and CdTe all crystallize with a zinc blende structure. (Section 11.8) While the zinc blende structure can be described as a face-centered cubic lattice of anions, with cations in the tetrahedral voids, as was done in Chapter 11, it also can be described (perhaps more simply) starting from the diamond structure. The zinc blende structure can be generated from the diamond structure if we change half of the carbon atoms into zinc (or gallium) and the other half into sulfur (or arsenic) (Figure 12.3). In this structure each atom is surrounded by a tetrahedron of atoms of the opposite type. That is, in gallium arsenide each gallium atom is surrounded by four arsenic atoms, and vice versa. This structure is commonly observed among compound semiconductors.

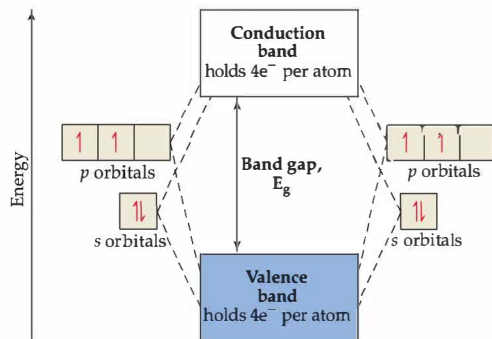

Si

GaAs

▲ **Figure 12.3** The structures of silicon and gallium arsenide. The crystal structure of silicon (above) is the same as the structure of diamond. In this structure, each atom is tetrahedrally coordinated. The crystal structure of gallium arsenide (below) is similar to diamond and silicon, but now gallium (shown in blue) replaces half of the silicon atoms and arsenic (shown in red) replaces the other half.

▲ **Figure 12.4** The electronic band structure of semiconductors with the diamond structure. In semiconductors with the diamond structure each atom is surrounded by a tetrahedron of like atoms. The atomic  $s$  and  $p$  orbitals form bonding molecular orbitals that make up the valence band and antibonding molecular orbitals that make up the conduction band. The completely filled valence band is separated from the empty conduction band by the band gap,  $E_g$ .

TABLE 12.2 • Band Gaps of Elemental and Compound Semiconductors\*

Material	Structure Type	Band Gap Energy, kJ/mol	Band Gap Energy, eV
Si	Diamond	107	1.11
AlP	Zinc Blende	234	2.43
GaP	Zinc Blende	218	2.26
Ge	Diamond	65	0.67
GaAs	Zinc Blende	138	1.43
ZnSe	Zinc Blende	249	2.58
CuBr	Zinc Blende	294	3.05
Sn**	Diamond	8	0.08
InSb	Zinc Blende	17	0.18
CdTe	Zinc Blende	145	1.50

\*Band gap energies and conductivities are room temperature values. Electron volts (eV) are a commonly used energy unit in the semiconductor industry;  $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$ .

\*\*These data are for gray tin, the semiconducting allotrope of tin. The other allotrope, white tin, is a metal.

▼ **Figure 12.5 The relationship between orbital overlap and band gap.**

(a) In diamond the C–C distance is relatively short (1.55 Å). This distance leads to effective overlap of orbitals on neighboring atoms, which in turn leads to a large splitting between the valence and conduction bands ( $E_g = 5.5 \text{ eV}$ ). (b) In silicon the Si–Si distance is much longer (2.35 Å), which diminishes the orbital overlap leading to small splitting between the valence and conduction bands ( $E_g = 1.11 \text{ eV}$ ).

The band gaps of semiconductors range from a few tenths of an electron volt to approximately 3 eV (Table 12.2 ◀). A close look at the values of the band gaps reveals some interesting periodic trends. Upon moving down a group (for example,  $\text{C} \rightarrow \text{Si} \rightarrow \text{Ge} \rightarrow \text{Sn}$ ), the band gap decreases. This trend stems from the fact that as the interatomic distance increases the orbital overlap decreases. The decrease in orbital overlap reduces both the energetic stabilization of the bonding molecular orbitals that make up the valence band and the energetic destabilization of the anti-bonding molecular orbitals that make up the conduction band. The net result is a decrease in the band gap (Figure 12.5 ▼).

By the time we reach tin the band gap is almost gone, which explains why tin has two allotropes: gray tin, which is a semiconductor with a very small band gap, and white tin, which is a metal. Going one element further down the group we come to lead, where the orbital overlap is not sufficient to separate the valence and conduction bands. Consequently, lead has a crystal structure and physical properties that are characteristic of a metal rather than a semiconductor.

The second periodic trend that can be deduced from Table 12.2 is a tendency for the band gap to increase as the difference in group numbers of the elements increases. For example, upon moving from the elemental semiconductor germanium with a band gap of 0.67 eV to the compound semiconductor GaAs, where gallium is from group 3A and arsenic from group 5A, the band gap effectively doubles to 1.43 eV. If we further increase the difference in group number to four, as is the case for ZnSe, the band gap increases to 2.70 eV. Increasing the horizontal separation of the elements even more leads to a band gap of 3.05 eV in CuBr. This progression is a result of the transition from pure covalent bonding in the elemental semiconductors to polar covalent bonding in compound semiconductors. As the difference in electronegativity of the elements increases, the bonding becomes more polar and the band gap increases (Figure 12.6 ▶). Electrical engineers manipulate both the orbital overlap and the bond polarity to control the band gaps of compound semiconductors for use in a wide range of electrical and optical devices.

▲ **Figure 12.6** The relationship between bond polarity and band gap.

In germanium the bonding is purely covalent. In gallium arsenide the difference in electronegativity introduces bond polarity into the bonds. The gallium atoms are less electronegative than germanium, which is reflected in an upward shift of the energies of the gallium atomic orbitals. The arsenic atoms are more electronegative than germanium, which is reflected in a downward shift of the energies of the arsenic atomic orbitals. The introduction of bond polarity increases the band gap from 0.67 eV for Ge to 1.43 eV for GaAs.

### SAMPLE EXERCISE 12.1 | Qualitative Comparison of Semiconductor Band Gaps

Will GaP have a larger or smaller band gap than ZnS? Will it have a larger or smaller band gap than GaN?

#### SOLUTION

**Analyze:** The size of the band gap depends upon the vertical and horizontal positions of the elements in the periodic table. The band gap will increase when either of the following conditions is met: (1) The elements are located higher up in the periodic table, where enhanced orbital overlap leads to a larger splitting between bonding and antibonding orbitals; or (2) The horizontal separation between the elements increases, which leads to an increase in the electronegativity difference and the bond polarity.

**Plan:** We must look at the periodic table and compare the relative positions of the elements in each case.

**Solve:** Gallium is in the fourth period and group 3A. Its electron configuration is  $[\text{Ar}]3d^{10}4s^24p^1$ . Phosphorus is in the third period and group 5A. Its electron configuration is  $[\text{Ne}]3s^23p^3$ . Zinc and sulfur are in the same periods as gallium and phosphorus, respectively. However, zinc, in group 2B, is one element to the left of gallium and sulfur in group 5A, is one element to the right of phosphorus. Thus we would expect the electronegativity difference to be larger for ZnS, which should result in ZnS having a larger band gap than GaP.

For both GaP and GaN the more electropositive element is gallium. So we need only compare the positions of the more electronegative elements, P and N. Nitrogen is located above phosphorus in group 5A. Therefore, based on increased orbital overlap, we would expect GaN to have a larger band gap than GaP. Additionally, nitrogen is more electronegative than phosphorus, which also should result in a larger band gap for GaP.

**Check:** Looking in Table 12.2 we see that the band gap of GaP is 2.26 eV. ZnS and GaN are not listed in the table, but external references show the band gaps for these compounds to be 3.6 eV for ZnS and 3.4 eV for GaN.

### PRACTICE EXERCISE

Will ZnSe have a larger or smaller band gap than ZnS?

**Answer:** Because zinc is common to both compounds and selenium is below sulfur in the periodic table, the band gap of ZnSe will be smaller than ZnS.

**▲ Figure 12.7** The addition of controlled small amounts of impurities (doping) to a semiconductor changes the electronic properties of the material. Left:

A pure, intrinsic semiconductor has a filled valence band and an empty conduction band (ideally). Middle: The addition of a dopant atom that has more valence electrons than the host atom adds electrons to the conduction band (i.e., phosphorus doped into silicon). The resulting material is an *n-type semiconductor*. Right: The addition of a dopant atom that has fewer valence electrons than the host atom leads to fewer electrons in the valence band or more holes in the valence band (i.e., aluminum doped into silicon). The resulting material is a *p-type semiconductor*.

## Semiconductor Doping

The electrical conductivity of a semiconductor is influenced by the presence of small amounts of impurity atoms. The process of adding controlled amounts of impurity atoms to a material is known as **doping**. Consider what happens when a few phosphorus atoms (known as dopants) replace silicon atoms in a silicon crystal. Phosphorus has five valence electrons; silicon has only four. Therefore, the extra electrons that come with the phosphorus atoms are forced to occupy the conduction band because the valence band is already completely filled (Figure 12.7 ◀, middle). The resulting material is called an *n-type semiconductor*, “n” signifying that the number of negatively charged electrons in the conduction band has increased. These extra electrons can move very easily in the conduction band. Thus, just a few parts per million (ppm) of phosphorus in silicon can increase silicon’s intrinsic conductivity by a factor of a million! The dramatic change in conductivity in response to the addition of a trace amount of a dopant means that extreme care must be taken to control the impurities in semiconductors. We will return to this point later.

It is also possible to dope semiconductors with atoms that have fewer valence electrons than the host material. Consider what happens when a few aluminum atoms, in group 3A, replace silicon atoms in a silicon crystal. Aluminum has only three valence electrons compared to silicon’s four. Thus, there are electron vacancies, known as *holes*, in the valence band when silicon is doped with aluminum. Since the negatively charged electron is not there, the hole can be thought of as having a positive charge. When an adjacent electron jumps into the hole, the electron leaves behind a new hole. Thus, the positive hole moves about in the lattice like a particle itself. This movement is analogous to watching people changing seats in a classroom; you can watch the people (electrons) move about the seats (atoms), or you can watch the empty seats (holes) “move.” Thus, holes can conduct, too, and a material like this is called a *p-type semiconductor*, “p” signifying that the number of positive holes in the material has increased. Like n-type conductivity, only parts-per-million levels of a p-type dopant can lead to a millionfold increase in the conductivity of the semiconductor—but in this case, the holes in the valence band are doing the conduction (Figure 12.7, right). The junction of an n-type semiconductor with a p-type semiconductor forms the basis for diodes, transistors, solar cells, and other devices.

### ■ SAMPLE EXERCISE 12.2 | Identifying Types of Semiconductors

Which of the following elements, if doped into silicon, would yield an n-type semiconductor? Ga; As; C.

#### SOLUTION

**Analyze:** An n-type semiconductor means that the dopant atoms must have more valence electrons than the host material. Silicon is the host material in this case.

**Plan:** We must look at the periodic table and determine the number of valence electrons associated with Si, Ga, As, and C. The elements with more valence electrons than silicon are the ones that will produce an n-type material upon doping.

**Solve:** Si is in column 4A, and so has four valence electrons. Ga is in column 3A, and so has three valence electrons. As is in column 5A, and so has five valence electrons; C is in column 4A, and so has four valence electrons. Therefore, As, if doped into silicon, would yield an n-type semiconductor.

#### ■ PRACTICE EXERCISE

Suggest an element that could be used to dope silicon to yield a p-type material. **Answer:** Because Si is in group 4A, we need to pick an element in group 3A. Boron and aluminum are both good choices—both are in group 3A. In the semiconductor industry boron and aluminum are commonly used dopants for silicon.

▲ **Figure 12.8 Photograph of a Pentium 4 processor computer chip.** On this scale, mostly what you can see is the connections between transistors.

## The Silicon Chip

Silicon is the most important commercial semiconductor. It is also one of the most abundant elements on Earth. ∞(Section 1.2) The semiconductor industry that is responsible for the circuitry in computers, cell phones, and a host of other devices relies on silicon wafers called “chips,” on which complex patterns of semiconductors, insulators, and metal wires are assembled (Figure 12.8▲). Although the details of integrated circuit design are beyond the scope of this book, we can say that the process of making chips relies mostly on chemistry.

Silicon is the semiconductor of choice because it is abundant and cheap in its raw form (obtained from sand), it can be made 99.999999999% pure in highly specialized facilities called “clean rooms” (Figure 12.9▲), and it can be grown into enormous crystals that are nearly atomically perfect. If you recall that as little as parts-per-million level of impurities can change the conductivity of silicon by a millionfold, it becomes clear why clean rooms are necessary. In addition, the individual units that make up integrated circuits are about 50 nm wide, which makes them similar in size to an individual virus particle and quite a bit smaller than ordinary dust particles. Thus, to an integrated circuit, a dust particle looks like a boulder.

Silicon has some other important advantages over competing semiconductors. It is nontoxic (compared to GaAs, its closest competitor), and its surface can be chemically protected by  $\text{SiO}_2$ , the natural product of its reaction with air.  $\text{SiO}_2$  is an excellent insulator, and its atoms are in excellent registry with the underlying silicon substrate, which means it is easy to grow crystalline layers of  $\text{SiO}_2$  on top of Si. The basic unit of the integrated circuit, the **transistor**, requires a metal/insulator “gate” between a semiconductor “source” and a semiconductor “drain.” Electrons move from the source to the drain when voltage is applied to the gate. That silicon’s naturally occurring oxide is a very chemically stable insulator provides a huge benefit to silicon technology.

## Solar Energy Conversion

The magnitude of the band gap for semiconductors is  $\sim 50$  kJ/mol to  $\sim 300$  kJ/mol (Table 12.2)—just into the range of the bond-dissociation energies for single chemical bonds—and corresponds to photon energies of infrared, visible, and low-energy ultraviolet light. ∞(Section 6.2) Thus, if you shine light of the appropriate wavelength on a semiconductor, you will promote electrons from bonding molecular orbitals in the valence band to antibonding molecular orbitals in the conduction band. The promotion of an electron into the empty conduction band allows it to move freely through the crystal.

## A Closer Look

THE TRANSISTOR

The transistor is the heart of integrated circuits. By applying a small electric charge, a transistor controls the flow of a substantially larger current. Therefore, the transistor controls information flow in the form of electrons; it also amplifies the signal.

One common type of transistor is the MOSFET, which stands for *metal-oxide-semiconductor field-effect transistor*. The design of a MOSFET is shown in Figure 12.10. A piece of silicon is p-doped to form the substrate, and then patches of n-type doping are created and connected to metal wires. The back of the substrate is also connected to a metal wire. The n-type regions are the *source* and *drain*. They are separated by a p-type *channel*, which is about 65 nm long in a Pentium 4 processor. Deposited on top of the channel is the *gate*, an insulating oxide—traditionally  $\text{SiO}_2$ , but it can also be silicon nitride,  $\text{Si}_3\text{N}_4$ , or a mixture of these two. In the Pentium 4 chip, the oxide layer is only about 2 nm, or 20 atoms, thick. A metal contact is made to this oxide gate.

When a tiny positive charge is applied to the gate, electrons from the n-type source are drawn into the channel and flow to the drain. The larger the charge applied, the more the channel is “opened” and the greater the number of electrons that flow. The reverse situation, in which the source and drain are p-type and the channel is n-type, can also be made. There are many other transistor designs.

The size of a MOSFET is defined by the gate channel length, which defines the distance electrons must travel to get from the source to the drain. Using  $\text{SiO}_2$  as the gate oxide, the smallest circuit elements in commercial use are 65 nm wide. This means that a typical integrated circuit board holds in excess of 65 million transistors over an area the size of your fingernail. The electrical properties of  $\text{SiO}_2$  prevent further reduction in the size of the gate channel. To continue shrinking the size of transistors scientists have turned to hafnium oxide,  $\text{HfO}_2$ , as the gate oxide of choice. This materials advance has enabled chip designers to reduce the gate channel length to 45 nm, resulting

▲ **Figure 12.10** Design of a basic MOSFET. The substrate is greenish blue, the source and drain are pale gray, the channel is blue, and the gate oxide is pale brown. The blue lines and gray cylinders represent metallic contacts. A small positive voltage applied to the gate creates a positive channel through which electrons (red arrows) from the source are drawn, and go into the drain.

in a twofold increase in the number of transistors that can be manufactured per unit area.

The patterning of 300-mm commercial silicon wafers, which are about the size of a medium pizza, results from a series of chemical reactions that put down layers of thin films of semiconductor, insulator, and metal in patterns that are defined by a series of masks. Figure 12.11 shows that the thickness of the layers varies from about 100 nm to 3000 nm. In the research laboratory, film thicknesses have been made as thin as several atoms.

### The First Steps in Making a Transistor:

1. Wafer is oxidized

2. Oxidized wafer is covered with photoresist

3. Wafer is exposed to UV light through a photomask

4. Exposed photoresist is dissolved in developer solution

5. Oxide now unprotected by photoresist is etched away in hydrofluoric acid

6. The rest of the photoresist is removed; wafer is now ready for doping

◀ **Figure 12.11** Schematic illustration of the process of photolithography. Typical film thicknesses are 200–600  $\mu\text{m}$  for the silicon substrate; 80 nm for the silicon dioxide layer; and 0.3–2.5  $\mu\text{m}$  for the photoresist, which is a polymer that degrades when irradiated with ultraviolet light so it will be chemically dissolved by organic solvents in the “developer” solution. The mask protects parts of the photoresist from light and provides patterning to the surface on the ~100-nm scale. Commercial silicon chips can have as many as 30 layers. Other forms of lithography utilize means other than light to pattern the surface (for example, ion-beam lithography and electron-beam lithography use beams of ions or electrons to “write” on the surface).

The same can be said for the hole that is left behind in the valence band. Hence, the material becomes more conductive when irradiated by photons whose energy is greater than the band gap. This property, known as *photoconductivity*, is essential for many solar energy conversion applications.

A **solar cell** is a semiconductor device that converts photons from the sun into electricity. The heart of a solar cell is a junction between an n-type semiconductor and a p-type semiconductor (Figure 12.12). When a photon is absorbed in the region near the junction, an electron is excited from the valence band to the conduction band, creating a hole at the same time. The photoexcited electron moves toward the n-type semiconductor and the hole moves toward the p-type semiconductor. In this way the energy of the photon is partially converted into an electrical current (Figure 12.13).

The efficiency of a solar cell depends upon a number of factors including the band gap. If the energy of the photon is smaller than the band gap, the photon will not be absorbed and its energy cannot be harvested. On the other hand, if the energy of the photon is larger than the band gap energy, the excess energy of the photon is converted into thermal energy rather than electrical energy. Therefore, a tradeoff in the size of the band gap is necessary. For a solar cell made out of a single material, the maximum efficiency occurs for a material with a band gap of approximately 1.3 eV, where the conversion of optical energy into electrical energy is theoretically predicted to be as high as 31%. In the laboratory single crystal silicon solar cells have been produced with efficiencies of approximately 24%, while the efficiencies of commercial silicon solar cells tend to fall closer to 15%.

Power generation using solar cells has many attractive aspects. Sunlight is renewable, abundant, free, and widely distributed. There are no greenhouse gas emissions. The fundamental limitation is the cost of producing solar cells. Assuming a 20-year system lifetime, the present cost of electricity generated from solar cells is in the range of \$0.25–\$0.65 per kilowatt hour (kWh). In comparison, electricity generated from a coal-based power plant is closer to \$0.04–\$0.06 per kWh. This cost comparison does not take into account the long-term environmental costs of burning coal, which are significant. Burning coal releases a number of undesirable pollutants into the atmosphere including sulfur dioxide and nitrogen oxides, which are responsible for acid rain (Section 18.4), as well as fly ash and other particulates. The sheer volume of coal that is burned means that even elements that are present in only trace amounts, such as mercury, arsenic, and uranium, are released in fairly large quantities over time.

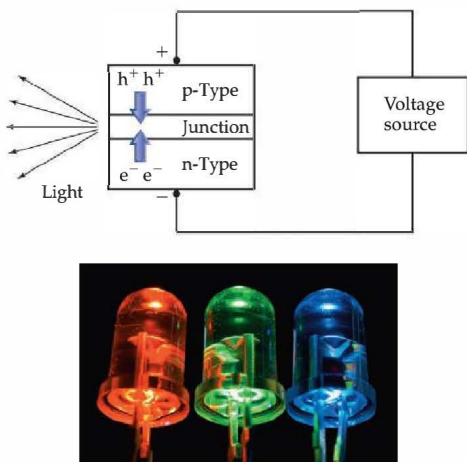

In the most advanced coal-fired power plants, modern technologies are employed that significantly reduce the emission of many pollutants. However, it is not possible to remove carbon dioxide, the main product of coal burning. It is estimated that a 500 MW coal-fired power plant, which is large enough to power a city of 140,000, releases 3.7 million tons of CO<sub>2</sub> every year. Given the concerns about global warming and climate change (Section 18.4), this release of CO<sub>2</sub> will continue to be a major concern associated with generating electricity from coal. Driven in large part by environmental concerns, many governments have initiated programs to encourage development of solar power, which has led to an almost exponential growth in the market for solar cells. In 2005 the market exceeded \$10 billion.

▲ **Figure 12.12 Absorption of light at a p-n junction.** This figure illustrates the process by which light is absorbed at the junction between a p-type and an n-type semiconductor. First, a photon is absorbed in the junction exciting an electron from the valence band into the conduction band creating an electron-hole pair (this process is marked with a 1). Next the electron (e<sup>-</sup>) is attracted to the n-type semiconductor and the hole (h<sup>+</sup>) toward the p-type semiconductor (this process is marked with a 2). In this way the energy of the photon can be converted into electrical energy.

▲ **Figure 12.13 Electricity from sunlight.** Solar panels, made of silicon, are used both as an energy source and as architectural elements in this apartment building in southern California.

▲ **Figure 12.14 Light emitting diodes.** Top: The heart of a light emitting diode is a p-n junction where an applied voltage drives electrons and holes to meet. Bottom: The color of light emitted depends upon the band gap of the semiconductor used to form the p-n junction. For display technology red, green, and blue are the most important colors because all other colors can be made by mixing these colors.

## Semiconductor Light-Emitting Diodes

Light-emitting diodes (LEDs) are used as displays in clocks; brake lights, turn signals, and dashboards of some cars; as traffic lights; and in many other places. There is a growing interest to replace incandescent and fluorescent lights with white LEDs because of their efficiency and long lifetimes, which are approximately 25 times longer than incandescent lights and roughly twice as long as fluorescent lights. Their efficiency is currently 2–3 times greater than incandescent lights and competitive with fluorescent lights.

The mechanism by which LEDs work is the opposite of the mechanism operating in solar energy conversion devices. In an LED, a small voltage is applied to a semiconductor device that, like a solar cell, has a junction between an n-type semiconductor and a p-type semiconductor. The junction forms a p-n *diode*, in which electrons can flow only one way. When a voltage is applied, electrons in the conduction band from the n-side are forced to the junction where they meet holes from the p-side. The electron falls into the empty hole, and its energy is converted into light whose photons have energy equal to the band gap (Figure 12.14 ◀). In this way electrical energy is converted into optical energy.

Because the wavelength of light that is emitted is inversely proportional to the band gap of the semiconductor, the color of light produced by the LED can be controlled by appropriate choice of semiconductor. Most red LEDs are made of a mixture of GaP and GaAs. The band gap of GaP is 2.26 eV ( $3.62 \times 10^{-19}$  J), which corresponds to a green photon with a wavelength of 549 nm. (Section 6.1) On the other hand, GaAs has a band gap of 1.43 eV ( $2.29 \times 10^{-19}$  J), which corresponds to an infrared photon with a wavelength of 867 nm. By forming solid solutions of these two compounds, with stoichiometries of  $\text{GaP}_{1-x}\text{As}_x$ , the band gap can be adjusted to any intermediate value. Thus,  $\text{GaP}_{1-x}\text{As}_x$  is the solid solution of choice for red, orange, and yellow LEDs. Green LEDs are made from mixtures of GaP and AlP ( $E_g = 2.43$  eV). Blue LEDs, made from GaN ( $E_g = 3.4$  eV) and InN ( $E_g = 2.4$  eV), are beginning to appear in consumer products as well. White light can be produced from LEDs using different approaches. In some cases, light is combined from blue, green, and red LEDs. More commonly a blue LED is coated with a material that converts some of the blue light into yellow light. In either case the combined colors appear white to the eye.

### SAMPLE EXERCISE 12.3 Designing an LED

Green light-emitting diodes can be made from a solid solution of GaP and AlP. These two compounds have band gaps that are 2.26 eV and 2.43 eV, respectively. If we assume that the band gap of a  $\text{Ga}_{1-x}\text{Al}_x\text{P}$  solid solution varies linearly from GaP to AlP, what composition would be needed for the emitted light to have a wavelength of 520 nm?

#### SOLUTION

**Analyze:** The wavelength of the emitted light has an energy that is nearly equal to the band gap of the semiconductor. The band gap depends upon the composition.

**Plan:** First we must convert the desired wavelength of emitted light, 520 nm, to an energy in eV. Next we must estimate the value of  $x$  that gives a band gap of this size.

**Solve:** The wavelength of light can be determined from Equation 6.3:

$$E = \frac{hc}{\lambda} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m/s})}{520 \times 10^{-9} \text{ m}}$$

$$E = (3.82 \times 10^{-19} \text{ J}) \times \frac{1 \text{ eV}}{1.602 \times 10^{-19} \text{ J}} = 2.38 \text{ eV}$$

The band gap changes linearly from 2.26 eV for GaP to 2.43 for AlP. Therefore, we can estimate the band gap of any composition in the  $\text{Ga}_{1-x}\text{Al}_x\text{P}$  solid solution from the following expression:

$$E = 2.26 \text{ eV} + x(2.43 \text{ eV} - 2.26 \text{ eV}) = (2.26 + 0.17x) \text{ eV}$$

We can solve for  $x$  by rearranging the equation and inserting the desired value of the band gap:

$$x = \frac{E - 2.26}{0.17} = \frac{2.38 - 2.26}{0.17} = 0.71$$

Thus, the desired composition would be  $\text{Ga}_{0.29}\text{Al}_{0.71}\text{P}$ .

### PRACTICE EXERCISE

If we assume that the band gap of an  $\text{In}_{1-x}\text{Ga}_x\text{N}$  solid solution varies linearly from  $\text{InN}$  (2.4 eV) to  $\text{GaN}$  (3.4 eV), what composition would be needed for the emitted light to have a wavelength of 410 nm?

**Answer:** The emitted light has an energy of 3.02 eV ( $485 \times 10^{-19}$  J). Therefore, the composition of the semiconductor should be  $\text{In}_{0.37}\text{Ga}_{0.63}\text{N}$ .

## 12.4 CERAMICS

**Ceramics** are inorganic solids that are normally hard, brittle, and stable at high temperatures. They are generally electrical insulators. Ceramic materials include such familiar objects as pottery, china, cement, roof tiles, and spark-plug insulators. Ceramic materials (Table 12.3 ▼) come in a variety of chemical forms, including *oxides* (oxygen and metals), *carbides* (carbon and metals), *nitrides* (nitrogen and metals), *silicates* (silica,  $\text{SiO}_2$ , mixed with metal oxides), and *aluminates* (alumina,  $\text{Al}_2\text{O}_3$ , mixed with metal oxides).

Ceramics are highly resistant to heat, corrosion, and wear; do not readily deform under stress; and are less dense than the metals used for high-temperature applications. Some ceramics used in aircraft, missiles, and spacecraft weigh only 40% as much as the metal components they replace. In spite of these advantages, the use of ceramics as engineering materials has been limited because ceramics are extremely brittle. Whereas a metal component might suffer a dent when struck, a ceramic part typically shatters.

The important differences in the mechanical properties of metals and ceramics arise from bonding interactions at the atomic scale. In a metal, a sea of delocalized electrons holds the atoms together. Metallic bonding tends to be very similar in strength in all directions. This characteristic allows the metal atoms to slip past one another under force, giving rise to the important properties of malleability and ductility. In a ceramic the atoms are held together by ionic or polar covalent bonds. These bonds are typically strong, but they are also highly directional, which prevents the atoms from sliding over one another and is responsible for the brittle nature of ceramics.

TABLE 12.3 ■ Properties of Some Ceramic and Metallic Materials

Material	Melting Point (°C)	Density (g/cm <sup>3</sup> )	Hardness (Mohs) <sup>†</sup>	Modulus of Elasticity <sup>**</sup>	Coefficient of Thermal Expansion <sup>***</sup>
<b>Ceramic materials</b>					
Alumina, $\text{Al}_2\text{O}_3$	2050	3.8	9	34	8.1
Silicon carbide, $\text{SiC}$	2800	3.2	9	65	4.3
Silicon nitride, $\text{Si}_3\text{N}_4$	1900	3.2	9	31	3.3
Zirconia, $\text{ZrO}_2$	2660	5.6	8	24	6.6
Beryllia, $\text{BeO}$	2550	3.0	9	40	10.4
<b>Metallic materials</b>					
Mild steel	1370	7.9	5	17	15
Aluminum	660	2.7	3	7	24

<sup>†</sup>The Mohs scale is a logarithmic scale based on the relative ability of a material to scratch another softer material. Diamond, the hardest material, is assigned a value of 10.

<sup>\*\*</sup>A measure of the stiffness of a material when subjected to a load ( $\text{MPa} \times 10^8$ ). The larger the number, the stiffer the material.

<sup>\*\*\*</sup>In units of ( $\text{K}^{-1} \times 10^{-6}$ ). The larger the number, the greater is the size change upon heating or cooling.

## Applications of Ceramics

Ceramics are used in structural applications such as bricks and concrete, where the major components are  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ , and  $\text{CaO}$ . For more specialized applications synthetic ceramics such as silicon carbide and silicon nitride are used.  $\text{SiC}$  and  $\text{Si}_3\text{N}_4$ , expand more slowly with increasing temperature (Table 12.3) because the bonding is three dimensional and more covalent than most ceramics. Thermal expansion can be an important criterion for high temperature applications.

At high temperatures the oxide ions in zirconia can move through the crystal, a property known as **ionic conductivity**. The ionic conductivity increases when some of the oxygen atoms are missing because the empty sites are used by the oxygen ions as they hop through the crystal. To create oxygen vacancies  $\text{Zr}^{4+}$  ions are substituted by  $\text{Y}^{3+}$  ions. Because the charge of the yttrium cation is one less than zirconium, an oxygen vacancy is created for every two  $\text{Y}^{3+}$  ions that substitute for  $\text{Zr}^{4+}$ , as reflected in the empirical formula,  $\text{Zr}_{1-2x}\text{Y}_{2x}\text{O}_{2-x}$ . This compound is used in many important applications such as gas sensors and fuel cells because of its ability to conduct oxide ions.

Ceramic components are difficult to manufacture free of defects. Ceramic parts often develop random, undetectable microcracks and voids (hollow spaces) during processing. These defects are more susceptible to stress than the rest of the ceramic; thus, they are generally the origin of cracking and fractures. To “toughen” a ceramic—to increase its resistance to fracture—scientists produce very pure, uniform particles of the ceramic material that are less than  $1\ \mu\text{m}$  ( $10^{-6}\ \text{m}$ ) in diameter. These are then *sintered* (heated at high temperature under pressure so that the individual particles bond together) to form the desired object.

## Making Ceramics

Many ceramics are naturally occurring and can be mined. However, there are inorganic counterparts of the polymerization reactions that we will discuss later in this chapter that are useful for making ceramic materials with increased purity and controlled particle size. The **sol-gel process** is an important method of forming extremely fine particles of uniform size. A typical sol-gel procedure begins with a *metal alkoxide*, which contains organic groups (for example,  $-\text{CH}_3$ ,  $-\text{C}_2\text{H}_5$ ,  $-\text{C}_3\text{H}_7$ , etc.) bonded to a metal atom through oxygen atoms. Metal alkoxides are produced when the metal reacts with an alcohol, which is an organic compound containing an OH group bonded to carbon.  $\rightleftharpoons$  (Section 2.9) To illustrate this process, we will use titanium as the metal and ethanol,  $\text{CH}_3\text{CH}_2\text{OH}$ , as the alcohol.

The alkoxide product,  $\text{Ti}(\text{OCH}_2\text{CH}_3)_4$ , is dissolved in an appropriate alcohol solvent. Water is then added, and it reacts with the alkoxide to form  $\text{Ti}-\text{OH}$  groups and regenerate ethanol.

Even though the ethanol is simply regenerated, the initial reaction with ethanol is important because the direct reaction of  $\text{Ti}(s)$  with  $\text{H}_2\text{O}(l)$  leads to a complex mixture of titanium oxides and titanium hydroxides. The intermediate formation of  $\text{Ti}(\text{OC}_2\text{H}_5)_4(s)$  ensures that a uniform suspension of  $\text{Ti}(\text{OH})_4$  will be formed. The  $\text{Ti}(\text{OH})_4$  is present at this stage as a *sol*, a suspension of extremely small particles. The acidity or basicity of the sol is adjusted to split out water from between two of the  $\text{Ti}-\text{OH}$  bonds.

This is an example of a *condensation reaction*. We will learn more about condensation reactions when discussing polymers. Condensation also occurs at some of the other OH groups bonded to the central titanium atom, producing a

three-dimensional network. The resultant material, called a *gel*, is a porous, interconnected network of extremely small particles with the consistency of gelatin. When this material is heated carefully at 200 °C to 500 °C, all the liquid is removed, and the gel is converted to a finely divided metal oxide powder with particles in the range of 3 to 100 nm in diameter. These particles might be used in an application where small, uniform particle size is required, such as the TiO<sub>2</sub> solar cells discussed in Chapter 9 (Section 9.8: “Chemistry Put to Work: Orbitals and Energy”), or they might be used as the starting point in the sintering process. Figure 12.15► shows SiO<sub>2</sub> particles, formed into remarkably uniform spheres by a precipitation process similar to the sol-gel process.

## 12.5 SUPERCONDUCTORS

Even metals are not infinitely conductive; there is some resistance to electron flow due to the vibrations of atoms and the presence of impurities and defects. However, in 1911 the Dutch physicist H. Kamerlingh Onnes discovered that when mercury is cooled below 4.2 K, it loses all resistance to the flow of an electrical current. Since that discovery, scientists have found that many substances exhibit this “frictionless” flow of electrons, known as **superconductivity**. Substances that exhibit superconductivity do so only when cooled below a particular temperature called the **superconducting transition temperature**,  $T_c$ . The observed values of  $T_c$  are generally very low. Table 12.4► lists numerous superconducting materials, the year of their discovery, and their transition temperature. Some are notable for their relatively high  $T_c$ , and others for the mere fact that a material of that composition would superconduct at all. It is surprising to see that the materials with the highest transition temperatures are ceramics rather than metals. Until a few decades ago most scientists working in the area of superconductivity concentrated their studies on metallic elements and compounds.

Superconductivity has tremendous economic potential. If electrical power lines or the conductors in a variety of electrical devices were capable of conducting current without resistance, enormous amounts of energy could be saved. Unfortunately, this advantage is offset by the need to cool the superconducting wires to a temperature below  $T_c$  (Figure 12.16▼). However, superconducting power lines have the advantage that they can carry 2–5 times more current than a conventional power

▲ **Figure 12.15 Uniformly sized spheres of amorphous silica, SiO<sub>2</sub>.** These are formed by precipitation from a methanol solution of Si(OCH<sub>3</sub>)<sub>4</sub> upon addition of water and ammonia. The average diameter is 550 nm.

◀ **Figure 12.16 Superconducting power transmission cable.** The superconducting wires surround a hollow core through which liquid nitrogen flows, cooling the superconductor to the zero resistance state. An electrical insulator surrounds the superconducting wires.

▲ **Figure 12.17 Magnetic levitation.** A small permanent magnet is levitated by its interaction with a ceramic superconductor that is cooled to liquid nitrogen temperature, 77 K. The magnet floats in space because the superconductor excludes magnetic field lines, a property known as the Meissner effect.

▲ **Figure 12.18 Superconduction in action.** High speed superconductive magnetic levitation (maglev) train. Shown is the ML002 experimental train being tested in Japan.

transmission cable in the same volume of space. This characteristic makes them attractive alternatives in crowded urban areas where power distribution demands are pushing the capacity of the system, but the population density makes it very expensive to dig up the streets to install new lines. Prototype underground superconducting transmission lines installed in the United States and Japan have demonstrated the potential of this technology.

In addition to their remarkable electrical properties, superconducting materials exhibit a property called the *Meissner effect* (Figure 12.17 ▲), in which they exclude all magnetic fields from their volume. The Meissner effect is being explored for high-speed trains that are magnetically levitated “maglev” (Figure 12.18 ▲). Because superconductivity appears in most materials only at very low temperatures, applications of this phenomenon to date have been limited. One important use of superconductors is in the windings of the large magnets that form the magnetic fields needed in magnetic resonance imaging (MRI) instruments, used in medical imaging (Figure 12.19 ▼). The magnet

▶ **Figure 12.19 A magnetic resonance imaging (MRI) machine used in medical diagnosis.** The magnetic field needed for the procedure is generated by current flowing in superconducting wires, which must be kept below their superconducting transition temperature,  $T_c$ , of 18 K. This low temperature requires liquid helium as a coolant.

windings, typically formed from  $\text{Nb}_3\text{Sn}$ , must be kept cooled with liquid helium, which boils at about 4 K. The cost of liquid helium is a significant factor in the cost of using an MRI instrument.

## Ceramic Superconductors

Before 1986 the highest value observed for  $T_c$  was about 22 K for the compound  $\text{Nb}_3\text{Ge}$  (Table 12.4). While most of the known superconductors at that time were elements and compounds containing only metals, superconductivity at a respectable  $T_c$  of 13 K had been found a decade earlier in an oxide material,  $\text{BaBi}_{1-x}\text{Pb}_x\text{O}_3$  by A. W. Sleight and coworkers at DuPont in Wilmington, Delaware. In 1986, working on a structurally related oxide system, J. G. Bednorz and K. A. Müller, at the IBM research laboratories in Zürich, Switzerland, discovered superconductivity above 30 K in a ceramic oxide containing lanthanum, barium, and copper. That discovery, for which Bednorz and Müller received the Nobel Prize in Physics in 1987, set off a flurry of research activity all over the world. Before the end of 1987 scientists had verified the onset of superconductivity at 95 K in yttrium-barium-copper oxide,  $\text{YBa}_2\text{Cu}_3\text{O}_7$ . The highest temperature observed to date for onset of zero resistance at 1 atm pressure is 138 K, which was achieved in another complex copper oxide,  $\text{Hg}_{0.8}\text{Tl}_{0.2}\text{Ba}_2\text{Ca}_2\text{Cu}_3\text{O}_{8.33}$ .

The discovery of so-called **high-temperature** (high- $T_c$ ) **superconductivity** is of great significance. Because maintaining extremely low temperatures is costly, many applications of superconductivity will become feasible only with the development of usable high-temperature superconductors. Liquid nitrogen is the favored coolant because of its low cost (it is cheaper than milk), but it can cool objects to only 77 K. The only readily available safe coolant at temperatures below 77 K is liquid helium, which costs as much as fine wine. Thus, many practical applications of superconductors, such as the power transmission cables discussed in the previous section, will become commercially viable only if  $T_c$  is well above 77 K.

What is the mechanism of superconductivity in the materials with unexpectedly high values of  $T_c$ ? The answer to this question is still being vigorously debated. One of the most widely studied ceramic superconductors is  $\text{YBa}_2\text{Cu}_3\text{O}_7$ , whose structure is shown in Figure 12.20. The copper-oxygen planes present in  $\text{YBaCu}_3\text{O}_7$  (marked in transparent blue) are present in all of the high- $T_c$  oxide superconductors containing copper and oxygen in Table 12.4, as well as many others. Extensive work has gone into studying these materials. This work indicates that the copper-oxygen planes are responsible for the superconductivity, as well as the relatively high metallic-type conductivity observed at temperatures above  $T_c$ , where the electrical conductivity parallel to the copper-oxygen planes is  $10^4$  times greater than in the perpendicular direction. The  $\text{Cu}^{2+}$  ions have an  $[\text{Ar}]3d^9$  electron configuration with a single electron in the  $3d_{x^2-y^2}$  orbital.  $\infty$  (Section 6.6) The copper  $3d_{x^2-y^2}$  orbital forms strong covalent bonds with the  $2p_x$  and  $2p_y$  orbitals on the neighboring oxygen atoms. In this way the copper and oxygen atoms form a partially filled band that is responsible for the metallic conductivity of  $\text{YBaCu}_3\text{O}_7$  and related cuprate superconductors.

Our understanding of superconductivity is much better in metals and metal alloys, such as  $\text{Nb}_3\text{Sn}$ , where the mechanism of superconductivity is reasonably well accounted for by *BCS theory*, named after its inventors John Bardeen, Leon Cooper, and Robert Schrieffer, who shared the 1972 Nobel Prize in Physics for their work.\* However, after years of research there is still no satisfactory theory of superconductivity in the newer ceramic materials. Because it seems that superconductivity might arise in many different kinds of materials, much empirical research is devoted to discovering new classes of superconductors.

▲ **Figure 12.20** The structure of  $\text{YBa}_2\text{Cu}_3\text{O}_7$ . The copper-oxygen planes responsible for the superconductivity are highlighted in blue. The unit cell is defined by the black lines that outline the large rectangular box.

\*Bardeen had previously received the 1956 Nobel Prize in Physics, together with Walter H. Brattain and William Shockley, for the discovery of the transistor (Section 12.3: "A Closer Look: The Transistor").

As noted in Table 12.4, it was discovered in 1995 that when  $C_{60}$  (Section 11.8: “A Closer Look: Buckyball”) reacts with an alkali metal, it becomes an electrically conducting material that becomes superconducting at about 40 K. Even more recently, the simple binary compound magnesium diboride,  $MgB_2$ , was found to become superconducting at 39 K. This observation is surprising and potentially quite important, since  $MgB_2$ , which is a semiconductor somewhat like graphite\*, is a relatively cheap material. This material is also easier to machine than the copper containing superconductors. The field of superconductivity has a great deal of promise, and the appearance of superconductors in major commercial products is just beginning (see “Chemistry Put to Work: Cell Phone Tower Range”).

## Chemistry Put to Work

### CELL PHONE TOWER RANGE

Cell phone towers increasingly dot both rural and urban landscapes (Figure 12.21 ▼), yet it can be difficult to maintain contact with a tower in the midst of a telephone conversation. A cell phone communicates with the system by receiving a signal from the tower’s transmitter and transmitting signals back to it. Although the tower’s transmitter may be quite powerful, the cell phone has very limited power. As the distance from the tower increases or intervening structures interfere, the cell phone signal becomes too weak to be distinguished from general electronic noise.

The amplifiers in the tower’s receiver have electronic filters that discriminate between the desired incoming signal and
