other electronic signals. The sharper the filter, the higher is the discrimination between one channel and another, and therefore, the higher is the capability of detecting the desired signal with clarity. Filters can be made from a high-temperature superconducting oxide that when cooled below its  $T_c$  provides much sharper filtering capabilities than conventional filters. By incorporating such filters in the tower receivers, communications companies can extend the range of the tower by up to a factor of two, which saves construction costs and improves the reliability of communication.

Superconducting technology is now being deployed in personal-computer-sized boxes located in cell phone base stations (the little building at the foot of the tower). The filters are formed from a ceramic oxide, typically  $YBa_2Cu_3O_7$  or  $Tl_2Ba_2CaCu_2O_8$ . The requisite cooling is provided by a mechanical cooling device, which is a small refrigeration unit capable of cooling the filter below its  $T_c$  (Figure 12.22 ▼).

▲ **Figure 12.21** Wireless communications tower. Towers like this (here, disguised as a tree) enable cell phone communication.

▲ **Figure 12.22** Cryogenic receiver system employing a cryo-cooled superconducting filter and a low-noise amplifier (LNA). The cylindrical object to the left is the cryogenic refrigerator used to keep the filter and LNA at a temperature below its  $T_c$  value.

\*The boron atoms in  $MgB_2$  form hexagonal layers identical to the layers of carbon atoms in graphite.

## 12.6 POLYMERS AND PLASTICS

In nature we find many substances of very high molecular mass, running into millions of amu, that make up much of the structure of living organisms and tissues. Some examples include starch and cellulose, which abound in plants, as well as proteins, which are found in both plants and animals. In 1827 Jons Jakob Berzelius coined the word **polymer** (from the Greek *polys*, “many,” and *meros*, “parts”) to denote molecular substances of high molecular mass formed by the *polymerization* (joining together) of **monomers**, molecules with low molecular mass.

For a long time humans processed naturally occurring polymers, such as wool, leather, silk, and natural rubber, into usable materials. During the past 70 years or so, chemists have learned to form synthetic polymers by polymerizing monomers through controlled chemical reactions. A great many of these synthetic polymers have a backbone of carbon–carbon bonds because carbon atoms have an exceptional ability to form strong stable bonds with one another.

**Plastics** are materials that can be formed into various shapes, usually by the application of heat and pressure. **Thermoplastic** materials can be reshaped. For example, plastic milk containers are made from a polymer known as *polyethylene* that has a high molecular mass. These containers can be melted down and the polymer recycled for some other use. In contrast, a **thermosetting plastic** is shaped through irreversible chemical processes and therefore cannot be reshaped readily.

An **elastomer** is a material that exhibits rubbery or elastic behavior. When subjected to stretching or bending, it regains its original shape upon removal of the distorting force, if it has not been distorted beyond some elastic limit. Some polymers, such as nylon and polyesters, can also be formed into fibers that, like hair, are very long relative to their cross-sectional area and are not elastic. These fibers can be woven into fabrics and cords and fashioned into clothing, tire cord, and other useful objects.

### Making Polymers

The simplest example of a polymerization reaction is the formation of polyethylene from ethylene molecules. In this reaction the double bond in each ethylene molecule “opens up,” and two of the electrons originally in this bond are used to form new C–C single bonds with two other ethylene molecules:

Polymerization that occurs by the coupling of monomers through their multiple bonds is called **addition polymerization**.

We can write the equation for the polymerization reaction as follows:

Here  $n$  represents the large number—ranging from hundreds to many thousands—of monomer molecules (ethylene in this case) that react to form one large polymer molecule. Within the polymer a repeat unit (the unit shown in brackets in Equation 12.4) appears along the entire chain. The ends of the chain are capped by carbon–hydrogen bonds or by some other bond, so that the end carbons have four bonds.

Polyethylene is a very important material; the demand in North America is approximately 40 billion pounds each year. Although its composition is simple, the polymer is not easy to make. The right conditions for manufacturing this commercially useful polymer were identified only after many years of research. Today many different forms of polyethylene, varying widely in physical properties, are known. Polymers of other chemical compositions provide still greater variety in physical and chemical properties. Table 12.5 ▼ lists several other common polymers obtained by addition polymerization.

**TABLE 12.5** ■ Polymers of Commercial Importance

Polymer	Structure	Uses
<b>Addition Polymers</b>		
Polyethylene	$\left( \text{CH}_2-\text{CH}_2 \right)_n$	Films, packaging, bottles
Polypropylene	$\left[ \begin{array}{c} \text{CH}_2-\text{CH} \\   \\ \text{CH}_3 \end{array} \right]_n$	Kitchenware, fibers, appliances
Polystyrene	$\left[ \begin{array}{c} \text{CH}_2-\text{CH} \\   \\ \text{C}_6\text{H}_5 \end{array} \right]_n$	Packaging, disposable food containers, insulation
Polyvinyl chloride (PVC)	$\left[ \begin{array}{c} \text{CH}_2-\text{CH} \\   \\ \text{Cl} \end{array} \right]_n$	Pipe fittings, clear film for meat packaging
<b>Condensation polymers</b>		
Polyurethane	$\left[ \begin{array}{c} \text{C}=\text{O} \\   \\ \text{NH}-\text{R}-\text{NH}-\text{C}=\text{O}-\text{O}-\text{R}'-\text{O} \\   \\ \text{O} \end{array} \right]_n$ R, R' = $-\text{CH}_2-\text{CH}_2-$ (for example)	"Foam" furniture stuffing, spray-on insulation, automotive parts, footwear, water-protective coatings
Polyethylene terephthalate (a polyester)	$\left[ \text{O}-\text{CH}_2-\text{CH}_2-\text{O}-\text{C}(=\text{O})-\text{C}_6\text{H}_4-\text{C}(=\text{O}) \right]_n$	Tire cord, magnetic tape, apparel, soft-drink bottles
Nylon 6,6	$\left[ \text{NH}-(\text{CH}_2)_6-\text{NH}-\text{C}(=\text{O})-(\text{CH}_2)_4-\text{C}(=\text{O}) \right]_n$	Home furnishings, apparel, carpet, fishing line, toothbrush bristles
Polycarbonate	$\left[ \begin{array}{c} \text{O} \\   \\ \text{C}_6\text{H}_4-\text{C}(\text{CH}_3)_2-\text{C}_6\text{H}_4-\text{O}-\text{C}(=\text{O}) \\   \\ \text{O} \end{array} \right]_n$	Shatterproof eyeglass lenses, CDs, DVDs, bulletproof windows, greenhouses

▲ **Figure 12.24** A segment of a polyethylene chain. The segment shown here consists of 28 carbon atoms. In commercial polyethylenes the chain lengths range from about  $10^3$  to  $10^5$   $\text{CH}_2$  units. As this illustration implies, the chains are flexible and can coil and twist in random fashion, which makes it difficult to see all 28 carbons in this illustration.

▲ **Figure 12.25** Interactions between polymer chains. In the circled regions, the forces that operate between adjacent polymer-chain segments lead to ordering analogous to the ordering in crystals, though less regular.

A condensation reaction occurs on each end of the diamine and the acid. The components of  $\text{H}_2\text{O}$  are split out, and  $\text{N}-\text{C}$  bonds are formed between molecules. Table 12.5 lists nylon 6,6 and some other common polymers obtained by condensation polymerization. Notice that these polymers have backbones containing N or O atoms as well as C atoms. In Chapter 25 we will see that proteins, DNA, and RNA are also condensation polymers.

### GIVE IT SOME THOUGHT

Would it be possible to make a condensation polymer out of this molecule alone?

### Structure and Physical Properties of Polymers

The simple structural formulas given for polyethylene and other polymers are deceptive. Because four bonds surround each carbon atom in polyethylene, the atoms are arranged in a tetrahedral fashion, so that the chain is not straight as we have depicted it. Furthermore, the atoms are relatively free to rotate around the  $\text{C}-\text{C}$  single bonds. Rather than being straight and rigid, therefore, the chains are very flexible, folding readily (Figure 12.24 ◀). The flexibility in the molecular chains causes the entire polymer material to be very flexible.

Both synthetic and naturally occurring polymers commonly consist of a collection of *macromolecules* (large molecules) of different molecular weights. Depending on the conditions of formation, the molecular weights may be distributed over a wide range or be closely clustered around an average value. In part because of this distribution in molecular weights, polymers are largely amorphous (noncrystalline) materials. Rather than exhibiting a well-defined crystalline phase with a sharp melting point, polymers soften over a range of temperatures. They may, however, possess short-range order in some regions of the solid, with chains lined up in regular arrays as shown in Figure 12.25 ◀. The extent of such ordering is indicated by the degree of **crystallinity** of the polymer. Mechanical stretching or pulling to align the chains as the molten polymer is drawn through small holes can frequently enhance the crystallinity of a polymer. Intermolecular forces between the polymer chains hold the chains together in the ordered crystalline regions, making the polymer denser, harder, less soluble, and more resistant to heat. Table 12.7 ▼ shows how the properties of polyethylene change as the degree of crystallinity increases.

The simple linear structure of polyethylene is conducive to intermolecular interactions that lead to crystallinity. However, the degree of crystallinity in polyethylene strongly depends on the average molecular mass. Polymerization

**TABLE 12.7** ■ Properties of Polyethylene as a Function of Crystallinity

	Crystallinity				
	55%	62%	70%	77%	85%
Melting point ( $^{\circ}\text{C}$ )	109	116	125	130	133
Density ( $\text{g}/\text{cm}^3$ )	0.92	0.93	0.94	0.95	0.96
Stiffness*	25	47	75	120	165
Yield stress*	1700	2500	3300	4200	5100

\*These test results show that the mechanical strength of the polymer increases with increased crystallinity. The physical units for the stiffness test are  $\text{psi} \times 10^{-3}$  (psi = pounds per square inch), those for the yield stress test are psi. Discussion of the exact meaning and significance of these tests is beyond the scope of this text.

▲ **Figure 12.26 Two types of polyethylene.** (a) Schematic illustration of the structure of low-density polyethylene (LDPE) and food-storage bags made of LDPE film. (b) Schematic illustration of the structure of high-density polyethylene (HDPE) and containers formed from HDPE.

results in a mixture of macromolecules with varying values of  $n$  and hence varying molecular masses. So-called low-density polyethylene (LDPE) used in forming films and sheets has an average molecular mass in the range of  $10^4$  amu and has substantial chain branching. That is, there are side chains off the main chain of the polymer, much like spur lines that branch from a main railway line. These branches inhibit the formation of crystalline regions, reducing the density of the material. High-density polyethylene (HDPE), used to form bottles, drums, and pipes, has an average molecular mass in the range of  $10^6$  amu. This form has less branching and thus a higher degree of crystallinity. Low-density and high-density polyethylene are illustrated in Figure 12.26▲, where the higher degree of branching of the low-density form can clearly be seen. Thus, the properties of polyethylene can be “tuned” by varying the average length, crystallinity, and branching of the chains, making it a very versatile material.

### GIVE IT SOME THOUGHT

Both the melting point and the degree of crystallinity decrease in copolymers made of ethylene and vinyl acetate monomers as the percentage of vinyl acetate increases. Suggest an explanation.

▲ **Figure 12.27 Cross-linking of polymer chains.** The cross-linking groups (red) constrain the relative motions of the polymer chains, making the material harder and less flexible than when the cross-links are not present.

Various substances may be added to polymers to provide protection against the effects of sunlight or against degradation by oxidation. For example, manganese(II) salts and copper(I) salts, in concentrations as low as  $5 \times 10^{-4}$  mol%, are added to nylons to provide protection from light and oxidation and to help maintain whiteness. In addition, the physical properties of polymeric materials can be modified extensively by adding substances with lower molecular mass, called *plasticizers*, to reduce the extent of interactions between chains and thus to make the polymer more pliable. Polyvinyl chloride (PVC) (Table 12.5), for example, is a hard, rigid material of high molecular mass that is used to manufacture home drainpipes. When blended with a suitable substance of lower molecular mass, however, it forms a flexible polymer that can be used to make rain boots and doll parts. In some applications the plasticizer in a plastic object may be lost over time because of evaporation. As this happens, the plastic loses its flexibility and becomes subject to cracking.

Polymers can be made stiffer by introducing chemical bonds between the polymer chains, as illustrated in Figure 12.27 ◀. Forming bonds between chains is called **cross-linking**. The greater the number of cross-links in a polymer, the more rigid the material. Whereas thermoplastic materials consist of independent polymer chains, thermosetting ones become cross-linked when heated; the cross-links allow them to hold their shapes.

An important example of cross-linking is the **vulcanization** of natural rubber, a process discovered by Charles Goodyear in 1839. Natural rubber is formed from a liquid resin derived from the inner bark of the *Hevea brasiliensis* tree. Chemically, it is a polymer of isoprene,  $C_5H_8$ .

[12.7]

Because rotation about the carbon-carbon double bond does not readily occur, the orientation of the groups bound to the carbons is rigid. In naturally occurring rubber, the chain extensions are on the same side of the double bond, as shown in Equation 12.7. This form is called *cis*-polyisoprene; the prefix *cis*- is derived from a Latin phrase meaning “on this side.”

Natural rubber is not a useful polymer because it is too soft and too chemically reactive. Goodyear accidentally discovered that adding sulfur to rubber and then heating the mixture makes the rubber harder and reduces its susceptibility to oxidation or other chemical attack. The sulfur changes rubber into a thermosetting polymer by cross-linking the polymer chains through reactions at some of the double bonds, as shown schematically in Figure 12.28 ▶. Cross-linking of about 5% of the double bonds creates a flexible, resilient rubber. When the rubber is stretched, the cross-links help prevent the chains from slipping, so that the rubber retains its elasticity.

▲ **Figure 12.28 Vulcanization of rubber.** (a) In polymeric natural rubber, there are carbon-carbon double bonds at regular intervals along the chain, as shown in Equation 12.7. (b) Chains of four sulfur atoms have been added across two polymer chains, by the opening of a carbon-carbon double bond on each chain.

### ■ SAMPLE EXERCISE 12.4 | The Stoichiometry of Cross-Linking

If we assume four sulfur atoms per cross-link connection, what mass of sulfur per gram of isoprene,  $C_5H_8$ , is required to establish a cross-link as illustrated in Figure 12.28 with 5% of the isoprene units in rubber?

#### SOLUTION

**Analyze:** We are asked to calculate the mass of sulfur required per gram of isoprene.

**Plan:** We need to evaluate the ratio of sulfur atoms to isoprene units based on Figure 12.15, then scale the required mass of sulfur to take account of the 5% cross-linking.

**Solve:** We can see from the figure that each cross-link involves eight sulfur atoms for every two isoprene units; this means that the ratio of S to  $C_5H_8$  is four. Thus, with 5% (0.05) of the isoprene units cross-linked, we have

$$(1.0 \text{ g } C_5H_8) \left( \frac{1 \text{ mol } C_5H_8}{68.1 \text{ g } C_5H_8} \right) \left( \frac{4 \text{ mol S}}{1 \text{ mol } C_5H_8} \right) \left( \frac{32.1 \text{ g S}}{1 \text{ mol S}} \right) (0.05) = 0.09 \text{ g S}$$

#### ■ PRACTICE EXERCISE

How would you expect the properties of vulcanized rubber to vary as the percentage of sulfur increases? Explain.

**Answer:** The rubber would be harder and less flexible as the percentage of sulfur increases because of an increased degree of cross-linking, which covalently bonds the polymer chains together.

## 12.7 BIOMATERIALS

Increasingly, modern synthetic materials are being used in medical and biological applications. For the purposes of our discussion here, a **biomaterial** is any material that has a biomedical application. The material might have a therapeutic use, for example, in the treatment of an injury or a disease. Or it might have a diagnostic use, as part of a system for identifying a disease or for monitoring a quantity such as the glucose level in blood. Whether the use is therapeutic or diagnostic, the biomaterial is in contact with biological fluids, and this material must have properties that meet the demands of that application. For example, a polymer employed to form a disposable contact lens must be soft and have an easily wetted surface, whereas the polymer used to fill a dental cavity must be hard and wear-resistant.

Many polymers can be formulated and processed to have sufficient structural strength, rigidity, and heat stability to replace metals, glass, and other materials in a variety of applications. The housings of electric motors and kitchen appliances such as coffeemakers and can openers, for example, are now commonly formed from specially formulated polymers. *Engineering polymers* are tailored to particular applications through choice of polymers, blending of polymers, and modifications of processing steps. They generally have lower costs or superior performance over the materials they replace. In addition, shaping and coloring of the individual parts and their assembly to form the final product are often much easier.

▲ **Figure 12.29 Plastic engines.** The intake manifold of some Ford V-8 engines is formed from nylon.

▲ **Figure 12.30 Plastic fenders.** The fenders of this Volkswagen Beetle are made of General Electric Noryl GTX, a composite of nylon and polyphenylene ether.

The modern automobile provides many examples of the inroads engineering polymers have made in automobile design and construction. Car interiors have long been formed mainly of plastics. Through development of high-performance materials, significant progress has been made in introducing engineering polymers as engine components and car body parts. Figure 12.29 ◀, for example, shows the manifold in a series of Ford V-8 pickup and van engines. The use of an engineering polymer in this application eliminates machining and several assembly steps. The manifold, which is made of nylon, must be stable at high temperatures.

Car body parts can also be formed from engineering polymers. Components formed from engineering polymers usually weigh less than the components they replace, thus improving fuel economy. The fenders of the Volkswagen Beetle (Figure 12.30 ◀), for example, are made of nylon reinforced with a second polymer, polyphenylene ether (PPE), which has the following structure:

Because the polyphenylene ether polymer is linear and rather rigid, the PPE confers rigidity and shape retention.

A big advantage of most engineering polymers over metals is that they eliminate the need for costly corrosion protection steps in manufacture. In addition, some engineering polymer formulations permit manufacturing with the color built in, thus eliminating painting steps (Figure 12.31 ▼).

▲ **Figure 12.31 A mostly plastic truck.** This truck has door handles and bumper supports made of polycarbonate/polybutylene plastic. Coloring pigments are incorporated into the manufacture of the plastic, eliminating the need for painting.

## Characteristics of Biomaterials

The most important characteristics that influence the choice of a biomaterial are **biocompatibility**, **physical requirements**, and **chemical requirements**, as illustrated in Figure 12.32. Each of these characteristics is examined in turn below.

Living organisms, particularly those in higher animals, have a complex set of protections against invasions by other organisms. Our bodies have an extraordinary ability to determine whether an object is the body's own material or whether it is foreign. Any substance that is foreign to the body has the potential to generate a response from the immune system. Molecular-sized objects are bound by antibodies and rejected, whereas larger objects induce an inflammatory response. Some materials are more **biocompatible** than others; that is, they are more readily integrated into the body without an inflammatory response. The most important determining factors in the biocompatibility of a substance are its chemical nature and the physical texture of its surface.

The physical properties of a biomaterial are often required to meet very exacting demands. Tubing that is to be used to replace a defective blood vessel must be flexible and must not collapse under bending or other distortion. Materials used in joint replacements must be wear-resistant. An artificial heart valve must open and close 70 to 80 times a minute, day after day, for many years. If the valve is to have a life expectancy of 20 years, the valve will have to open and close about 750 million times! Unlike the failure of the valve in a car engine, failure of the heart valve may have fatal consequences for its owner.

The chemical properties of a biomaterial are also critically important. Biomaterials must be *medical grade*, which means that they must be approved for use in any medical application. All ingredients present in a medical-grade biomaterial must remain innocuous over the lifetime of the application. Polymers are important biomaterials, but most commercial polymeric materials contain contaminants such as unreacted monomers, fillers or plasticizers, and antioxidants or other stabilizers. The small amounts of foreign materials present in HDPE used in milk jugs (Figure 12.26) pose no threat in that application, but they might if the same plastic material were implanted in the body.

## Polymeric Biomaterials

Specialized polymers have been developed for a variety of biomedical applications. The degree to which the body accepts or rejects the foreign polymer is determined by the nature of the atomic groups along the chain and the possibilities for interactions with the body's own molecules. Our bodies are composed largely of biopolymers such as proteins, polysaccharides (sugars), and polynucleotides (RNA, DNA). We will learn more about these molecules in Chapter 25. For now, we can simply note that the body's own biopolymers have complex structures, with polar groups along the polymer chain. Proteins, for example, are long strings of amino acids (the monomers) that have formed a condensation polymer. The protein chain has the following structure:

where R represents a small group of atoms [i.e.  $-\text{CH}_3$ ,  $-\text{CH}(\text{CH}_3)_2$ , etc.]

▲ **Figure 12.32 Schematic illustration of a human-made device implanted in a biological system.** To function successfully, the device must be biocompatible with its surroundings and meet the necessary physical and chemical requirements, some of which are listed for illustrative purposes.

which vary along the chain. Twenty different amino acids are used in different combinations to make up proteins in humans. By contrast, synthetic polymers are simpler, being formed from a single repeating unit or perhaps two different repeating units, as described in Section 12.6. This difference in complexity is one of the reasons that the body identifies synthetic polymers as foreign objects. Another reason is that the chain may have few or no polar groups that can interact with the body's aqueous medium. [↔ \(Section 11.2\)](#)

We learned in Section 12.6 that polymers can be characterized by their physical properties. Elastomers are used as biomaterials in flexible tubing over leads for implanted heart pacemakers and as catheters (tubes implanted into the body to administer a drug or to drain fluids). Thermoplastics, such as polyethylene or polyesters, are employed as membranes in blood dialysis machines and as replacements for blood vessels. Thermoset plastics find limited but important uses. Because they are hard, inflexible, and somewhat brittle, they are most often used in dental devices or in orthopedic applications, such as in joint replacements. To fill a cavity, for example, the dentist may pack some material into the cavity, and then shine an ultraviolet lamp on it. The light initiates a photochemical reaction that forms a hard, highly cross-linked thermoset polymer.

### Heart Repair

The term *cardiovascular* pertains to the heart, blood, and blood vessels. The heart is, of course, an absolutely essential organ. A donor organ can replace a heart that fails completely. But, about 60,000 people suffer terminal heart failure each year in the United States while only about 2500 donor hearts become available for transplant. Many attempts have been made—and continue to be made—to produce an artificial heart that can serve over a long time as a replacement for the natural organ. We will not devote attention to these efforts, except to note that recent results are quite promising.

It often happens that only a part of the heart, such as the aortic valve, fails and needs replacement. Repair could be made by using foreign tissue (for example, a pig heart valve) or a mechanical heart valve implant to replace a diseased one. About 250,000 valve replacement procedures are performed annually worldwide. In the United States about 45% of the procedures involve a mechanical valve. The most widely used valve is shown in Figure 12.33 ◀. It has two semicircular discs that move to allow blood to flow in the desired direction as the heart pumps. The discs then fall back together to form a seal against the backflow of blood.

It is vital to minimize fluid disturbance as the blood passes through artificial devices. Surface roughness in a device causes *hemolysis*, the breakdown of red blood cells. Furthermore, surface roughness can serve as a site for invading bacteria to adhere and colonize. Finally, rough surfaces also promote coagulation of the blood, which forms a thrombus, or blood clot. Thus, even though we may have a perfectly fine piece of machinery from a mechanical point of view, the heart valve may not be suitable as a long-term implant. To minimize blood clots, the discs in the heart valve must have a smooth, chemically inert surface.

A second challenge in the use of a heart valve implant is to fix it in place. As shown in Figure 12.33, the retainer ring that forms the body of the valve is covered with a mesh of woven fabric. The material of choice is Dacron®, du Pont's trade name for the fiber formed from polyethylene terephthalate (PET, a polyester; Table 12.5). The mesh acts as a lattice on which the body's tissues can grow, so that the valve becomes incorporated into its surroundings. Tissue grows through the polyester mesh, whereas it does not do so on many other plastics. Apparently the polar, oxygen-containing functional groups along the polyester chain afford attractive interactions to facilitate tissue growth.

▲ **Figure 12.33** A disc heart valve. Known as the St. Jude valve, this device was named for the medical center at which it was developed. The surfaces of the valve are coated with pyrolytic carbon. The valve is secured to the surrounding tissue via a Dacron® sewing ring.

## Vascular Grafts

A vascular graft is a replacement for a segment of diseased blood vessels. Where possible, diseased blood vessels are replaced with vessels taken from the patient's own body. When this procedure is not feasible, artificial materials must be used. Dacron<sup>®</sup> is used as replacement for large-diameter arteries around the heart. For this purpose, it is fabricated into a crimped, woven, tubular form, as shown in Figure 12.34 ▶. The tubing is crimped to enable it to bend without serious decrease in its cross-sectional area. The graft must integrate with surrounding tissue after it has been put in place. It must therefore have an open structure, with pores of approximately 10 μm in diameter. During the healing process blood capillaries grow into the graft and new tissues form throughout it. Similarly, polytetrafluoroethylene [—(CF<sub>2</sub>CF<sub>2</sub>)<sub>n</sub>—] is used for the smaller-diameter vascular grafts in the limbs.

Ideally, the inside surface of the graft would become lined with the same sorts of cells that line the native vessel, but this process does not occur with materials currently available. Instead, the inside surface of the tubing is recognized as being foreign to the blood. Platelets, which are circulating components of the blood, normally serve the function of sealing up wounds in the blood vessel walls. Unfortunately, platelets also attach to foreign surfaces and cause blood coagulation. The search for a more biocompatible lining for grafts is an area of active research, but at present there is a continuing risk of blood clots. Excess tissue growth at the intersection of the graft with the native blood vessel is also a frequent problem. Because of the possibility of blood clot formation, patients who have received artificial heart valves or vascular grafts are generally required to take anticoagulation drugs on a continuing basis.

▲ **Figure 12.34** A Dacron<sup>®</sup> vascular graft. Grafts like this are used in coronary artery surgery.

## Artificial Tissue

The treatment of patients who have lost extensive skin tissue—for example, burn patients or those with skin ulcers—is one of the most difficult problems in therapeutic medicine. Today, laboratory-grown skin can be employed to replace grafts in such patients. Ideally, the “artificial” tissue would be grown from cells taken from the patient. When this procedure is not possible, for example with burn victims, the tissue cells come from another source. When the graft skin is not formed from the patient's own cells, drugs that suppress the body's natural immune defense system must be used, or steps must be taken to modify the new cell line to prevent rejection of the tissue.

The challenge in growing artificial tissue is to get the cells to organize themselves as they would in a living system. The first step in accomplishing this objective is to provide a suitable scaffold on which the cells can grow—one that will keep them in contact with each other and allow them to organize. Such a scaffold must be biocompatible; cells must adhere to the scaffold and differentiate (that is, develop into cells of different types) as the culture grows. The scaffolding must also be mechanically strong and biodegradable over time.

The most successful scaffolds have been lactic acid—glycolic acid copolymers. Formation of the copolymer via a condensation reaction is shown in Equation 12.8.

The copolymer has an abundance of polar carbon–oxygen bonds along the chain, affording many opportunities for hydrogen-bonding interactions. The ester linkages formed in the condensation reaction are susceptible to hydrolysis,

▲ **Figure 12.35 Artificial skin prepared for use as a skin graft.** Burn victims benefit from these biocompatible polymers.

which is just the reverse reaction. When the artificial tissue is deployed in the body, the underlying copolymer scaffold slowly hydrolyzes away as the tissue cells continue to develop and merge with adjacent tissue. An example of a graft skin product is shown in Figure 12.35 ◀.

Until the 1970s, if you had to go to the doctor to get stitches, you later had to go back to get the stitches removed. Stitches that are used to hold living tissue together are called *sutures*. Since the 1970s, biodegradable sutures have been available. After the sutures have been applied to the tissue, they slowly dissolve away and do not release any harmful by-products. Today's biodegradable sutures are made out of lactic acid—glycolic acid copolymers, similar to those just described, which slowly hydrolyze over time.

## 12.8 LIQUID CRYSTALS

(a)

(b)

▲ **Figure 12.36 Liquid and liquid crystal.** (a) Molten cholesteryl benzoate at a temperature above 179 °C. In this temperature region the substance is a clear liquid. Note that the printing on the surface of the beaker in back of the sample test tube is readable. (b) Cholesteryl benzoate at a temperature between 179 °C and its melting point, 145 °C. In this temperature interval cholesteryl benzoate exists as a milky liquid crystalline phase.

Almost all electronic devices, such as laptops, cellular phones, calculators, and portable media players such as iPods, have to display information. Most electronic displays are based on one of two technologies: light-emitting diodes (LEDs) (Section 12.3) and liquid crystal displays (LCDs). In this section we will explore the molecular principles that give liquid crystals their special optical properties.

When a solid is heated to its melting point, the added thermal energy overcomes the intermolecular attractions that provide molecular order to the solid. ⇨ (Section 11.1) The liquid that forms is characterized by random molecular orientations and considerable molecular motion. In a typical liquid the molecules are not ordered at all (zero-dimensional order). Some substances, however, exhibit more complex behavior as their solids are heated. Instead of the three-dimensional order that characterizes a crystalline solid, these substances exhibit phases that have one- or two-dimensional order, meaning that the molecules line up so that they point in one direction (one-dimensional order) or are arranged in layers (two-dimensional order).

In 1888 Frederick Reinitzer, an Austrian botanist, discovered that an organic compound he was studying, cholesteryl benzoate, has interesting and unusual properties. When heated, the substance melts at 145 °C to form a viscous milky liquid; then at 179 °C the milky liquid suddenly becomes clear. When the substance is cooled, the reverse processes occur. The clear liquid turns viscous and milky at 179 °C (Figure 12.36 ◀), and the milky liquid solidifies at 145 °C. Reinitzer's work represents the first systematic report of what we now call a **liquid crystal**.

Instead of passing directly from the solid to the liquid phase when heated, some substances, such as cholesteryl benzoate, pass through an intermediate liquid crystalline phase that has some of the structure of solids and some of the freedom of motion possessed by liquids. Because of the partial ordering, liquid crystals may be very viscous and possess properties intermediate between those of the solid and liquid phases. The region in which they exhibit these properties is marked by sharp transition temperatures, as in Reinitzer's example.

From the time of their discovery in 1888 until about 30 years ago, liquid crystals were largely a laboratory curiosity. They are now widely used as pressure and temperature sensors and in the displays of electrical devices such as digital watches, cellular phones, calculators, and laptop computers (Figure 12.37 ◀). Liquid crystals can be used for these applications because the weak intermolecular forces that hold the molecules together in a liquid crystal are easily affected by changes in temperature, pressure, and electric fields.

▲ **Figure 12.37 A handheld wireless device with liquid crystal display.** LCDs can be made very thin and light.

▲ **Figure 12.38** Ordering in liquid crystalline phases and a normal (non-liquid crystalline) liquid. The ordering arises from intermolecular forces. Smectic A and smectic C phases are both smectic phases; they differ in the angles that the molecules make with respect to the layers.

### Types of Liquid Crystalline Phases

Substances that form liquid crystals are often composed of long, rodlike molecules. In the normal liquid phase these molecules are oriented randomly [Figure 12.38(a)▲]. Liquid crystalline phases, by contrast, exhibit some ordering of the molecules. Depending on the nature of the ordering, liquid crystals can be classified as nematic, smectic, or cholesteric.

In the **nematic liquid crystalline phase** the molecules exhibit one-dimensional ordering. The molecules are aligned along their long axes [Figure 12.38(b)]. The arrangement of the molecules is like that of a handful of pencils whose ends are not aligned. In the **smectic liquid crystalline phases** the molecules exhibit two-dimensional ordering; the molecules are aligned along their long axes and in layers [Figure 12.38(c, d)].

Two molecules that exhibit liquid crystalline phases are shown in Figure 12.39▼. The lengths of these molecules are much greater than their widths. The C=N double bond and the benzene rings add rigidity to the chainlike molecules. The flat benzene rings also help the molecules stack with one another. In addition, many liquid crystalline molecules contain polar groups that give rise to dipole-dipole interactions and promote alignment of the molecules. ∞ (Section 11.2) Thus, the molecules order themselves quite naturally along their long axes. They can, however, rotate around their axes and slide parallel to one another. In smectic phases the intermolecular forces between the molecules (such as London dispersion forces, dipole-dipole attractions, and hydrogen bonding) limit the ability of the molecules to slide past one another.

▲ **Figure 12.39** Structures and liquid crystal temperature intervals of two typical liquid crystalline materials. The temperature interval indicates the temperature range in which the substance exhibits liquid crystalline behavior.

Cholesteric structure

(a)

▲ **Figure 12.40** Ordering in a cholesteric liquid crystal. (a) The molecules in successive layers are oriented at a characteristic angle with respect to those in adjacent layers to avoid repulsive interactions. (b) The result is a screwlike axis.

(b)

Figure 12.40 ◀ shows the ordering of the **cholesteric liquid crystalline phase**. The molecules are aligned along their long axes as in nematic liquid crystals, but they are arranged in layers with the molecules in each plane twisted slightly in relation to the molecules in the planes above and below. These liquid crystals are so named because many derivatives of cholesterol adopt this structure. The spiral nature of the molecular ordering produces unusual coloring patterns with visible light. Changes in temperature and pressure change

the order and hence the color (Figure 12.41 ◀). Cholesteric liquid crystals have been used to monitor temperature changes in situations where conventional methods are not feasible. For example, they can detect hot spots in microelectronic circuits, which may signal the presence of flaws. They can also be fashioned into thermometers for measuring the skin temperature of infants.

▲ **Figure 12.41** Color change in a cholesteric liquid crystalline material as a function of temperature.

### ■ SAMPLE EXERCISE 12.5 | Properties of Liquid Crystals

Which of the following substances is most likely to exhibit liquid crystalline behavior?

(i)

(ii)

(iii)

### SOLUTION

**Analyze:** We have three molecules of differing molecular structure, and we are asked to determine whether any of them is likely to be a liquid crystalline substance.

**Plan:** We need to identify the structural features of each case that might induce liquid crystalline behavior.

**Solve:** Molecule (i) is not likely to be liquid crystalline because it does not have a long axial structure. Molecule (iii) is ionic; the generally high melting points of ionic materials and the absence of a characteristic long axis make it unlikely that this substance will exhibit liquid crystalline behavior. Molecule (ii) possesses the characteristic long axis and the kinds of structural features that are often seen in liquid crystals (Figure 12.39).

### ■ PRACTICE EXERCISE

Suggest a reason why the following molecule, decane, does not exhibit liquid crystalline behavior:

**Answer:** Because rotation can occur about carbon–carbon single bonds, molecules whose backbone consists predominantly of C–C single bonds are too flexible; the molecules tend to coil in random ways and thus are not rodlike.

## Chemistry Put to Work LIQUID CRYSTAL DISPLAYS

Liquid crystals are widely used in electrically controlled LCD devices in watches, calculators, and computer screens, as illustrated in Figure 12.37. These applications are possible because an applied electrical field changes the orientation of liquid crystal molecules and thus affects the optical properties of the device.

LCDs come in a variety of designs, but the structure illustrated in Figure 12.42 is typical. A thin layer (5–20  $\mu\text{m}$ ) of liquid crystalline material is placed between electrically conducting, transparent glass electrodes. Ordinary light passes through a vertical polarizer that permits light in only the vertical plane to pass. Through a special process the liquid crystal molecules are oriented so that the molecules at the front plate are oriented vertically and those at the bottom plate horizontally. The molecules in between vary in orientation in a regular way, as shown in Figure 12.42. Displays of this kind are called “twisted nematic.” The plane of polarization of the light is turned by  $90^\circ$  as it passes through the device and is thus in the correct orientation to pass

through the horizontal polarizer. In a watch display, a mirror reflects the light back, and the light retraces its path, allowing the device to look bright. When a voltage is applied to the plates, the liquid crystalline molecules align with the voltage [Figure 12.42(b)]. The light rays thus are not properly oriented to pass through the horizontal polarizer, and the device appears dark.

Computer screens employ backlighting rather than reflected light, but the principle is the same. The computer screen is divided into a large number of tiny cells, with the voltages at points on the screen surface controlled by transistors made from thin films of amorphous silicon. Red-green-blue color filters are employed to provide full color. The entire display is refreshed at a frequency of about 60 Hz, so the display can change rapidly with respect to the response time of the human eye. Displays of this kind are remarkable technical achievements, based on a combination of basic scientific discovery and creative engineering.

**Related Exercises:** 12.64, 12.74, 12.78

◀ **Figure 12.42** Schematic illustration of the operation of a twisted nematic liquid crystal display (LCD). (a) Ordinary light, which is unpolarized, passes through the vertical polarizer. The vertically polarized light then passes into the liquid crystalline layer, where the plane of polarization is rotated  $90^\circ$ . It passes through the horizontal polarizer, is reflected, and retraces its path to give a bright display. (b) When a voltage is applied to the segment electrode that covers the small area, the liquid crystal molecules align along the direction of the light path. Thus, the vertically polarized light is not turned  $90^\circ$  and is unable to pass through the horizontal polarizer. The area encompassed by the small transparent segment electrode therefore appears dark. Digital watches typically have such displays.

## 12.9 NANOMATERIALS

The prefix “nano” means  $10^{-9}$ . ∞ (Section 1.4) When people speak of “nano-technology,” they usually mean making devices that are on the 1–100 nm scale. It turns out that the properties of semiconductors and metals change in this size range. **Nanomaterials**—materials that have dimensions on the 1–100 nm scale—are under intense investigation in the research laboratories of scientists and engineers. Chemistry plays a central role in nanomaterials research.

### Semiconductors on the Nanoscale

Look back at Figure 12.1 and consider the pictures of electron energy levels for molecules and bulk solids. Electrons are in discrete molecular orbitals for individual molecules and in delocalized bands for solids. At what point does a molecule get so large that it starts behaving as though it has delocalized bands, rather than localized molecular orbitals? For semiconductors, both theory and experiment now tell us that the answer is roughly at 1 to 10 nm (about 10–100 atoms across). The exact number depends on the specific semiconductor material. The equations of quantum mechanics that were used for electrons in atoms can be applied to electrons (and holes) in semiconductors to estimate the size at

▲ **Figure 12.43**  $\text{Cd}_3\text{P}_2$  powders with different particle sizes. The arrows indicate increasing particle size and a corresponding decrease in the band gap energy, so that the material looks white (smallest nanoparticles), yellow, orange, red, brown, and finally black (the largest nanoparticles).

which unusual effects occur because of the crossover from molecular orbitals to bands. Because these effects become important at 1 to 10 nm, semiconductor particles with diameters in this size range are called *quantum dots*.

One of the most spectacular effects is that the band gap of the semiconductor changes substantially with size in the 1–10-nm range. As the particle gets smaller, the band gap gets bigger. This effect is easily seen by the naked eye, as shown in Figure 12.43 ◀. On the macro level, the semiconductor cadmium phosphide looks black because its band gap is small ( $E_g = 0.5$  eV), and it absorbs all wavelengths of visible light. As the crystals are made smaller, the material progressively changes color until it looks white! It looks white because now no visible light is absorbed. The band gap is so large that only high-energy ultraviolet light can excite electrons to the conduction band ( $E_g > 3.0$  eV).

Making quantum dots is most easily accomplished using chemical reactions in solution. For example, to make CdS, you can mix  $\text{Cd}(\text{NO}_3)_2$  and  $\text{Na}_2\text{S}$  in water. If you do not do anything else, you will precipitate large crystals of CdS. However, if you first add a negatively charged polymer to the water (such as polyphosphate,  $-(\text{OPO}_2)_n-$ ), the  $\text{Cd}^{2+}$  will associate with the polymer, like tiny “meatballs” in the polymer “spaghetti.” When sulfide is added, CdS particles grow but are kept from forming large crystals by the polymer. A great deal of fine-tuning of reaction conditions is necessary to produce nanocrystals that are of uniform size and shape.

We saw in Section 12.3 that semiconductors can emit light when a voltage is applied. Some semiconductors can also emit light with a wavelength equal to the band gap energy when illuminated by light with photon energies larger than the band gap. This process is called *photoluminescence*. An electron from the valence band first absorbs a photon and is promoted to the conduction band. If the excited electron then falls back down into the hole it can emit a photon having energy equal to the band gap. In the case of quantum dots, the band gap is tunable with the crystal size, and thus all the colors of the rainbow can be obtained from just one material (Figure 12.44 ◀).

Quantum dots are being explored for applications ranging from electronics to lasers to medical imaging because they are very bright, very stable, and small enough to be taken up by living cells, even after being coated with a biocompatible surface layer. Quantum dots of semiconductors such as InP, CdSe, CdS, and PbS, with sizes in the range of 3–5 nm, have been used in place of conjugated organic dye molecules to absorb light and transfer electrons to somewhat larger  $\text{TiO}_2$  nanoparticles (Figure 12.45 ▶) in a variation on the solar cell described in Chapter 9 (Section 9.8: “Chemistry Put to Work: Orbitals and Energy”).

Semiconductors do not have to be shrunk to the nanoscale in all three dimensions to show new properties. They can be laid down in relatively large two-dimensional areas on a substrate, but be only a few nanometers in thickness, or even thinner, to make *quantum wells*. *Quantum wires*, in which the semiconductor wire diameter is only a few nanometers but its length is very long, have also been made by various chemical routes. In both quantum wells and quantum wires, measurements along the nanoscale dimension(s) show quantum behavior, but in the long dimension, the properties seem to be just like those of the bulk material.

▲ **Figure 12.44** Semiconductor nanoparticles of CdS of different sizes. When illuminated with ultraviolet light, these solutions of semiconductor nanoparticles emit light that corresponds to their respective band gap energies.

◀ **Figure 12.45 Titanium dioxide solar cell sensitized with semiconductor nanoparticles.** In this solar cell CdS nanoparticles absorb visible photons and transfer the electrons from their conduction band into the conduction band of larger TiO<sub>2</sub> nanoparticles. The electrons (e<sup>-</sup>) then move to through the TiO<sub>2</sub> nanoparticles to the transparent electrode and through an external circuit generating electricity. The hole (h<sup>+</sup>) that is created in the CdS nanoparticle is filled through oxidation of iodide ions, I<sup>-</sup>, in the electrolyte. The I<sup>-</sup> ions are regenerated by reduction reactions at the counter electrode. The wavelengths of light that are absorbed by the CdS nanoparticles can be tuned by controlling their size.

## Metals on the Nanoscale

Metals also have unusual properties on the 1–100-nm length scale. Fundamentally, this is because the *mean free path* of an electron in a metal at room temperature is typically about 1–100 nm. The mean free path of an electron is the average distance it can move before it bumps into something (another electron, an atom, or the surface of the metal) and “scatters.” So when the particle size of a metal is 100 nm or less, one might expect unusual effects to occur.

Although it was not fully understood, people have known for hundreds of years that metals are different when they are very finely divided. As early as the 1400s, the makers of stained-glass windows knew that gold dispersed in molten glass made the glass a beautiful deep red (Figure 12.46 ▶). Much later, in 1857, Michael Faraday (Chapter 20.5) reported that dispersions of small particles of gold could be made stable and were deeply colored—some of the original colloidal solutions that he made are still in the Royal Institution of Great Britain’s Faraday Museum in London (Figure 12.47 ▶). We will examine colloids more closely in Section 13.6. Other physical and chemical properties of metallic nanoparticles are also different than bulk properties. Gold particles less than 20 nm in diameter melt at a far lower temperature than bulk gold, and between 2 and 3 nm gold is no longer a “noble,” unreactive metal; in this size range it becomes chemically reactive.

At nanoscale dimensions, silver has properties analogous to those of gold in its beautiful colors, although it is more reactive than gold. Currently, there is great interest in research laboratories around the world in taking advantage of the unusual optical properties of metal nanoparticles for applications in biomedical imaging and chemical detection.

## Carbon Nanotubes

We have already seen that elemental carbon is extraordinarily interesting. In its *sp*<sup>3</sup>-hybridized solid-state form, it is diamond; in its *sp*<sup>2</sup>-hybridized solid-state form, it is graphite; in its molecular form it is C<sub>60</sub>. (Section 11.8) Soon after the discovery of C<sub>60</sub>, chemists discovered carbon nanotubes. You can think of these as sheets of graphite rolled up and capped at one or both ends by half of a C<sub>60</sub>

▶ **Figure 12.46 Stained-glass window from Milan Cathedral in Italy.** The red color is due to gold nanoparticles. *Fototeca della Veneranda Fabbrica del Duomo di Milano.*

▶ **Figure 12.47 The solutions of colloidal gold nanoparticles made by Michael Faraday in the 1850s.** These are on display in the Faraday Museum, London.

▲ **Figure 12.48 Atomic models of carbon nanotubes.** Left: “Armchair” nanotube, which shows metallic behavior. Right: “Zigzag” nanotube, which can be either semiconducting or metallic, depending on tube diameter.

molecule (Figure 12.48 ◀). Carbon nanotubes are made in a manner similar to that used to make  $C_{60}$ . They can be made in either *multiwall* or *single-walled* forms. Multiwall carbon nanotubes consist of tubes within tubes, nested together; single-walled carbon nanotubes consist of single tubes. Single-walled carbon nanotubes can be 1000 nm long or even longer, but are only about 1 nm in diameter. Depending on the diameter of the graphite sheet and how it is rolled up, carbon nanotubes can behave as either semiconductors or metals.

The fact that carbon nanotubes can be made either semiconducting or metallic without any doping is unique among all solid-state materials, and a great deal of work is ongoing to make carbon-based electronic devices. In 2003 chemists learned how to separate metallic carbon nanotubes from semiconducting ones. Because the basic elements of the transistor are semiconductors and metals,

there is great interest in building nanoscale electronic circuits using only carbon nanotubes. The first report of a field effect transistor (FET, related to the MOS-FET) using a single carbon nanotube as the channel appeared in 1998.

Carbon nanotubes are also being explored for their mechanical properties. The carbon-carbon bonded framework of the nanotubes means that the imperfections that might appear in a metal nanowire of similar dimensions are nearly absent. Experiments on individual carbon nanotubes suggest that they are stronger than steel if steel were the dimensions of a carbon nanotube. Carbon nanotubes have also been spun into fibers with polymers, adding great strength and toughness to the composite material.

### ■ SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

A *conducting polymer* is a polymer that can conduct electricity. Some polymers can be made semiconducting; others can be nearly metallic. Polyacetylene is an example of a polymer that is a semiconductor. It can also be doped to increase its conductivity.

Polyacetylene is made from acetylene in a reaction that looks simple but is actually tricky to do:

- What is the hybridization of the carbon atoms, and the geometry around those atoms, in acetylene and in polyacetylene?
- Write a balanced equation to make polyacetylene from acetylene.
- Acetylene is a gas at room temperature and pressure (298 K, 1.00 atm). How many grams of polyacetylene can you make from a 5.00-L vessel of acetylene gas at room temperature and room pressure? Assume acetylene behaves ideally, and that the polymerization reaction occurs with 100% yield.
- Using the average bond enthalpies in Table 8.4, predict whether the formation of polyacetylene from acetylene is endothermic or exothermic.

### SOLUTION

**Analyze:** For part (a), we need to recall what we have learned about  $sp$ ,  $sp^2$ , and  $sp^3$  hybridization and geometry. ∞ (Section 9.5) For part (b), we need to write a balanced equation. For part (c), we need to use the ideal-gas equation. ∞ (Section 10.4) For part (d), we need to recall the definitions of endothermic and exothermic, and how bond enthalpies can be used to predict overall reaction enthalpies. ∞ (Section 8.8)

**Plan:** For part (a), we should draw out the chemical structures of the reactant and product. For part (b), we need to make sure the equation is properly balanced. For part (c), we need to convert from liters of gas to moles of gas, using the ideal-gas

equation ( $PV = nRT$ ); then we need to convert from moles of acetylene gas to moles of polyacetylene using the answer from part (b); then, we can convert to grams of polyacetylene. For part (d), we need to recall that  $\Delta H_{\text{rxn}} = \sum(\text{bond enthalpies of bonds broken}) - \sum(\text{bond enthalpies of bonds formed})$ .

**Solve:**

(a) Carbon always forms four bonds. Thus, each C atom must have a single bond to H and a triple bond to the other C atom in acetylene. As a result, each C atom has two electron domains and must be  $sp$  hybridized. This  $sp$  hybridization also means that the  $\text{H}-\text{C}-\text{C}$  angles in acetylene are  $180^\circ$ , and the molecule is linear.

We can write out the partial structure of polyacetylene as follows:

Each carbon is identical but now has three bonding electron domains that surround it. Therefore, the hybridization of each carbon atom is  $sp^2$ , and each carbon has local trigonal planar geometry, with  $120^\circ$  angles.

(b) We can write:

Note that all atoms originally present in acetylene end up in the polyacetylene product.

(c) We can use the ideal-gas equation as follows:

$$\begin{aligned} PV &= nRT \\ (1.00 \text{ atm})(5.00 \text{ L}) &= n(0.08206 \text{ L atm/K mol})(298 \text{ K}) \\ n &= 0.204 \text{ mol} \end{aligned}$$

Acetylene has a molar mass of 26.0 g/mol; therefore, the mass of 0.204 mol is

$$(0.204 \text{ mol})(26.0 \text{ g/mol}) = 5.32 \text{ g acetylene}$$

Note that from the answer to part (b), all the atoms in acetylene go into polyacetylene. Due to conservation of mass, then, the mass of polyacetylene produced must also be 5.32 g, if we assume 100% yield.

(d) Let's consider the case for  $n = 1$ . We note that the reactant side of the equation in part (b) has one  $\text{C}\equiv\text{C}$  triple bond and two  $\text{C}-\text{H}$  single bonds. The product side of the equation in part (b) has one  $\text{C}=\text{C}$  double bond, one  $\text{C}-\text{C}$  single bond (to link to the adjacent monomer), and two  $\text{C}-\text{H}$  single bonds. Therefore, we are breaking one  $\text{C}\equiv\text{C}$  triple bond and are forming one  $\text{C}=\text{C}$  double bond and one  $\text{C}-\text{C}$  single bond. Accordingly, the enthalpy change for polyacetylene formation is:

$$\begin{aligned} \Delta H_{\text{rxn}} &= (\text{C}\equiv\text{C triple bond enthalpy}) - (\text{C}=\text{C double bond enthalpy}) \\ &\quad - (\text{C}-\text{C single bond enthalpy}) \\ \Delta H_{\text{rxn}} &= (839 \text{ kJ/mol}) - (614 \text{ kJ/mol}) - (348 \text{ kJ/mol}) \\ &= -123 \text{ kJ/mol} \end{aligned}$$

Because  $\Delta H$  is a negative number, the reaction releases heat, and is exothermic.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Section 12.1** In this chapter we consider the classification of materials according to their bonding (ionic, metallic, or covalent) and electrical conductivity (**insulators**, **metals**, or **semiconductors**). Ionic solids are typically insulators. Metallic solids are typically good conductors of electricity. Covalent-network solids can be either semiconductors or insulators.

**Section 12.2** In extended solids, continuous **bands** rather than discrete molecular orbitals are the best way to picture electron energy levels. Metals have a partially filled band, which makes it easy for electrons to move between filled and empty molecular orbitals in the solid. Semiconductors and insulators have an energy gap known as the **band gap** that separates the filled **valence band** and

the empty **conduction band**. In such materials electrons have to be excited over the band gap for the material to conduct electricity.

**Section 12.3 Elemental semiconductors** contain a single element while **compound semiconductors** contain two or more elements. In a typical semiconductor the valence band is made up of bonding molecular orbitals and the conduction band of antibonding molecular orbitals. The size of the band gap increases (a) as the bond distance decreases, due to increased orbital overlap, and (b) as the difference in electronegativity between the two elements increases, due to increased bond polarity.

**Doping** semiconductors changes their ability to conduct electricity by orders of magnitude. An n-type semiconductor is one that is doped so that there are excess electrons in the conduction band; a p-type semiconductor is one that is doped so that there are excess **holes** in the valence band.

The reasons for silicon's preeminence in electronics are its abundance, low cost, and ability to be grown into highly pure crystals, as well as the ability of its native oxide to grow on it in perfect registry with the atoms underneath. The design of the **transistor**, the heart of integrated circuitry, relies on the junction between n-type and p-type silicon. Solar cells are also based on a junction between an n-type and a p-type material. In a **solar cell**, photons with energies larger than its band gap energy can be absorbed near the p-n junction leading to the conversion from optical energy to electrical energy.

**Light emitting diodes (LEDs)** operate like a solar cell in reverse. Electrons in the conduction band from the n-type semiconductor are forced to the junction where they meet holes from the p-type semiconductor. The electron falls into the empty hole and its energy is converted into light whose photons have energy equal to the band gap.

**Section 12.4** Ceramics are inorganic solids with generally high thermal stability, usually formed through three-dimensional network bonding. The bonding in ceramics may be either covalent or ionic, and ceramics may be crystalline or amorphous. The **sol-gel process** plays an important role in the processing of commercial ceramics. The process begins with the formation of a *sol*, a suspension of very small, uniformly sized particles, which is then transformed to a *gel*, where the particles form an interconnected network. Finally, the small particles are compressed and heated at high temperature. They coalesce through a process known as sintering.

**Section 12.5** A **superconductor** is a material that is capable of conducting an electrical current without any apparent resistance when cooled below its **superconducting transition temperature**,  $T_c$ . Since discovery of the phenomenon in 1911, many elements and compounds have been found to be superconducting when cooled to very low temperatures. **Superconducting ceramics** such as  $\text{YBa}_2\text{Cu}_3\text{O}_7$  are capable of superconductivity at temperatures higher than that for any nonceramic superconductor.

**Section 12.6** **Polymers** are molecules of high molecular mass formed by joining together large numbers of small molecules, called **monomers**. In an **addition polymerization** reaction, the molecules form new linkages by opening existing  $\pi$  bonds. Polyethylene forms, for example, when the carbon-carbon double bonds of ethylene open up. In a **condensation polymerization** reaction, the monomers are joined by **splitting** out a small molecule from between them. The various kinds of nylon are formed, for example, by removing a water molecule from between an amine and a carboxylic acid. A polymer formed from two different monomers is called a **copolymer**.

**Plastics** are materials that can be formed into various shapes, usually by the application of heat and pressure. **Thermoplastic** polymers can be reshaped, perhaps through heating, in contrast to **thermosetting plastics**, which are formed into objects through an irreversible chemical process and cannot readily be reshaped. An **elastomer** is a material that exhibits elastic behavior; that is, it returns to its original shape following stretching or bending.

Polymers are largely amorphous, but some materials possess a degree of **crystallinity**. For a given chemical composition, the crystallinity depends on the molecular mass and the degree of branching along the main polymer chain. High-density polyethylene, for example, with little side-chain branching and a high molecular mass, has a higher degree of crystallinity than low-density polyethylene, which has a lower molecular mass and a relatively high degree of branching. Polymer properties are also strongly affected by **cross-linking**, in which short chains of atoms connect the long polymer chains. Rubber is cross-linked by short chains of sulfur atoms in the process called **vulcanization**.

**Section 12.7** A **biomaterial** is any material that has a biomedical application. Biomaterials are typically in contact with body tissues and fluids. They must be **biocompatible**, which means that they are not toxic, nor do they cause an inflammatory response. They must meet physical requirements, such as long-term reliability, strength, and flexibility or hardness, depending on the application. They must also meet chemical requirements of nonreactivity in the biological environment, or of biodegradability. Biomaterials are commonly polymers with special properties matched to the application.

**Section 12.8** A **liquid crystal** is a substance that exhibits one or more ordered phases at a temperature above the melting point of the solid. In a **nematic liquid crystalline phase** the molecules are aligned along a common direction, but the ends of the molecules are not lined up. In a **smectic liquid crystalline phase** the ends of the molecules are lined up so that the molecules form sheets. Nematic and smectic liquid crystalline phases are generally composed of molecules with fairly rigid, elongated shapes, with polar groups along the molecules to help retain relative alignment through dipole-dipole interactions. The **cholesteric liquid crystalline phase** is composed of molecules that align as in nematic liquid crystalline phases, but

with each molecule twisted with respect to its neighbors, to form a helical structure.

**Section 12.9 Nanotechnology** is the manipulation of matter, and fabrication of devices, on the 1–100 nm scale. The unusual properties that semiconductors, metals, and carbon have on the size scale of 1–100 nm are explored. Quantum dots are semiconductor particles with diameters of 1–10 nm. In this size range the material's band gap

energy becomes size-dependent. Metal nanoparticles have different chemical and physical properties in the 1–100-nm size range. Gold, for example, is more reactive and no longer has a golden color. Carbon nanotubes are sheets of graphite rolled up, and they can behave as either semiconductors or metals depending on how the sheet was rolled. Applications of these **nanomaterials** are being developed now for imaging, electronics, and medicine.

## KEY SKILLS

- Understand the relationship between the type of bonding that holds atoms together in a material and the electrical conductivity of the material.
- Understand how molecular orbitals combine to form bands and be able to differentiate the electronic band structures of metals, semiconductors, and insulators.
- Be able to recognize elemental and compound semiconductors from empirical formulas. Be able to use the periodic table to qualitatively compare the band gap energies of semiconductors.
- Understand how n-type and p-type doping can be used to control the conductivity of semiconductors and how the most important semiconductor devices, the silicon chip, LEDs, and solar cells, operate.
- Understand how forming solid solutions can control the band gaps of semiconductors.
- Be familiar with the bonding and properties of ceramics.
- Understand how the electrical and magnetic properties of superconductors differ from ordinary conductors. Understand the differences between conventional superconductors and high  $T_c$  superconductors.
- Understand how polymers are formed from monomers. Be able to recognize the features of a molecule that allow it to react to form a polymer. Understand the differences between addition polymerization and condensation polymerization.
- Understand how the interactions between polymer chains impact the physical properties of polymers.
- Be familiar with the characteristics and applications of biomaterials.
- Understand how the molecular arrangements characteristic of nematic, smectic, and cholesteric liquid crystals differ from ordinary liquids and from each other. Be able to recognize the features of a molecule that favor formation of a liquid crystalline phase.
- Understand how the properties of bulk semiconductors and metals change as the size of the crystals decreases into the nanometer length scale.
- Be familiar with the structures and unique properties of carbon nanotubes.

## VISUALIZING CONCEPTS

**12.1** Based on the following band structures, which material is a metal? [Section 12.2]

**12.2** The band structures below both belong to semiconductors. One is AlAs and the other GaAs. Which is which? [Section 12.3]

- 12.3** Shown below are cartoons of two different polymers. Based on these cartoons, which polymer would you expect to be denser? Which one would have the higher melting point? [Section 12.6]

- 12.4** Which picture best represents molecules that are in a liquid crystalline phase? [Section 12.8]

- 12.5** Consider the molecules shown below. (a) Which of these would be most likely to form an addition polymer? (b) Which would be most likely to form a condensation polymer? (c) Which would be most likely to form a liquid crystal? [Sections 12.6 and 12.8]

- 12.6** The three plots to the right show the conductivity as a function of temperature for three different types of materials: a semiconductor with a small band gap, a metallic

conductor, and a superconductor. Which plot corresponds to which material? (*Hint*: Remember in a semiconductor thermal energy is needed to excite electrons from the valence band to the conduction band.) [Sections 12.1, 12.3, and 12.5]

## EXERCISES

### Classes of Materials and Electronic Structure of Materials

- 12.7** Classify each of the following materials as metal, semiconductor, or insulator: (a) GaN (b) B (c) ZnO (d) Pb
- 12.8** Classify each of the following materials as metal, semiconductor, or insulator: (a) InAs (b) MgO (c) HgS (d) Sn
- 12.9** The molecular orbital diagrams for linear chains of hydrogen atoms with two and four atoms in the chain are shown in Figure 12.1. Construct a molecular orbital diagram for a chain containing six hydrogen atoms and use it to answer the following questions. (a) How many molecular orbitals are there in the diagram? (b) How many nodes are there in the lowest energy molecular orbital? (c) How many nodes are there in the highest energy molecular orbital? (d) How many nodes are there in the highest occupied molecular orbital (HOMO)? (e) How many nodes are there in the lowest unoccupied molecular orbital (LUMO)?
- 12.10** Repeat exercise 12.9 for a linear chain of eight hydrogen atoms.
- 12.11** State whether each statement is true or false, and why.  
 (a) Semiconductors have a larger band gap than insulators.  
 (b) Doping a semiconductor makes it more conductive.  
 (c) Metals have delocalized electrons.  
 (d) Most metal oxides are insulators.
- 12.12** State whether each statement is true or false, and why.  
 (a) A typical band gap energy for an insulator is 400 kJ/mol.  
 (b) The conduction band is higher in energy than the valence band.  
 (c) Electrons can conduct well if they are in a filled valence band.  
 (d) Holes refer to empty atomic sites in a solid crystal.

## Semiconductors

- 12.13** For each of the following pairs of semiconductors, which one will have the larger band gap: (a) CdS or CdTe (b) GaN or InP (c) GaAs or InAs?
- 12.14** For each of the following pairs of semiconductors, which one will have the larger band gap: (a) InP or InAs (b) Ge or AlP (c) AgI or CdTe?
- 12.15** If you want to dope GaAs to make an n-type semiconductor with an element to replace Ga, which element(s) would you pick?
- 12.16** If you want to dope GaAs to make a p-type semiconductor with an element to replace As, which element(s) would you pick?
- 12.17** What advantages does silicon have over other semiconductors for use in integrated circuits?
- 12.18** Why is it important for Si crystals to be 99.999999999% pure, as opposed to 99% pure, for silicon chips?
- 12.19** What material is traditionally used to make the gate in a MOSFET transistor? What material is used in the next generation transistors?
- 12.20** Look up the diameter of a silicon atom, in Å. The channel length in a Pentium 4 processor chip is 65 nm long. How many silicon atoms does this correspond to?
- 12.21** Silicon has a band gap of 1.1 eV at room temperature. (a) What wavelength of light would a photon of this energy correspond to? (b) Draw a vertical line at this wavelength in the figure shown, which shows the light output of the sun as a function of wavelength. Does silicon absorb all, none or a portion of the visible light that comes from the sun?
- 12.22** Cadmium telluride is an important material for solar cells. (a) What is the band gap of CdTe? (b) What wavelength of light would a photon of this energy correspond to? (c) Draw a vertical line at this wavelength in the figure shown with exercise 12.21, which shows the light output of the Sun as a function of wavelength. (d) With respect to silicon, does CdTe absorb a larger or smaller portion of the solar spectrum?
- 12.23** The semiconductor GaP has a band gap of 2.2 eV. Green LEDs are made from pure GaP. What wavelength of light would be emitted from an LED made from GaP?
- 12.24** The first LEDs were made from GaAs, which has a band gap of 1.43 eV. What wavelength of light would be emitted from an LED made from GaAs? What region of the electromagnetic spectrum does this light correspond to: UV, Visible, or IR?
- 12.25** GaAs and GaP make solid solutions that have the same crystal structure as the parent materials, with As and P randomly distributed through the crystal.  $\text{GaP}_x\text{As}_{1-x}$  exists for any value of  $x$ . If we assume that the band gap varies linearly with composition between  $x = 0$  and  $x = 1$ , estimate the band gap for  $\text{GaP}_{0.5}\text{As}_{0.5}$ . What wavelength of light does this correspond to?
- 12.26** Red light-emitting diodes are made from GaAs and GaP solid solutions,  $\text{GaP}_x\text{As}_{1-x}$  (see exercise 12.25). The original red LEDs emitted light with a wavelength of 660 nm. If we assume that the band gap varies linearly with composition between  $x = 0$  and  $x = 1$ , estimate the composition (the value of  $x$ ) that is used in these LEDs.

## Ceramics

- 12.27** Metals, such as Al or Fe, and many plastics are recyclable. With the exception of many glasses, such as bottle glass, ceramic materials in general are not recyclable. What characteristics of ceramics make them less readily recyclable?
- 12.28** It is desirable to construct automobiles out of lightweight materials to maximize fuel economy. All of the ceramics listed in Table 12.3 are less dense than steel. Why do you think ceramic materials are not more widely used in the construction of automobiles?
- 12.29** Why is the formation of very small, uniformly sized and shaped particles important for many applications of ceramic materials?
- 12.30** Describe the general chemical steps in a sol-gel process, beginning with  $\text{Zr}(s)$  and  $\text{CH}_3\text{CH}_2\text{OH}(l)$ . Indicate whether each step is an oxidation-reduction reaction (refer to Section 4.4), condensation reaction, or other process.
- 12.31** The hardnesses of several substances according to a scale known as the Knoop value are as follows:

Substance	Knoop Value
Ag	60
$\text{CaCO}_3$	135
MgO	370
Soda-lime glass	530
Cr	935
$\text{ZrB}_2$	1550
$\text{Al}_2\text{O}_3$	2100
TaC	2000

Which of the materials in this list would you classify as a ceramic? What were your criteria for making this classification? Does classification as a ceramic correlate with Knoop hardness? If you think it does, is hardness alone a sufficient criterion to determine whether a substance is a ceramic? Explain.

- 12.32 Silicon carbide, SiC, has the three-dimensional structure shown in the figure.

- (a) Name another compound that has the same structure. (b) Would you expect the bonding in SiC to be predominantly ionic, metallic, or covalent? (c) How do the bonding and structure of SiC lead to its high thermal stability (to 2700 °C) and exceptional hardness?

## Superconductors

- 12.33 To what does the term *superconductivity* refer? Why might superconductive materials be of value?
- 12.34 What are the differences in the electrical and magnetic properties of an excellent metallic conductor of electricity (such as silver) and a superconducting substance (such as Nb<sub>3</sub>Sn) below its superconducting transition temperature?
- 12.35 The following graph shows the resistivity (a measure of electrical resistance) of MgB<sub>2</sub> as a function of temperature in the region from about 4 K to 100 K. What is the significance of the sharp drop in resistivity below 40 K?

- 12.36 (a) What is the superconducting transition temperature,  $T_c$ ? (b) The discovery by Müller and Bednorz of superconductivity in a copper oxide ceramic at 35 K set off a frantic scramble among physicists and chemists to find materials that exhibit superconductivity at higher temperatures. What is the significance of achieving  $T_c$  values above 77 K?

- 12.37 Explain how the Meissner effect can be used to levitate trains. What can the tracks and train wheels be made of, and which one would be more likely to be cooled?

- 12.38 The group 4B metal nitrides (TiN, ZrN, and HfN) as well as the group 5B metal nitrides (VN, NbN, and TaN) are all superconductors at low temperature. Niobium(III) nitride, which has the highest  $T_c$ , superconducts below 16.1 K. All of these compounds have crystal structures that are analogous to the sodium chloride structure. Scandium nitride also adopts the sodium chloride structure, but it is not a superconductor. (a) At room temperature will NbN be a metallic conductor or an insulator? (b) At room temperature will ScN be a metallic conductor or an insulator? (c) Why do you think the properties of ScN are so different than the group 4B and 5B metal nitrides? (*Hint*: Consider the electron configuration of the metal cation.)

## Polymers

- 12.39 What is a monomer? Give three examples of monomers, taken from the examples given in this chapter.

- 12.40 The structure of decane is shown in Practice Exercise 12.5. Decane is not considered a polymer, whereas polyethylene is. What is the distinction?

- 12.41 An ester is a compound formed by a condensation reaction between a carboxylic acid and an alcohol. Use the index to find the discussion of esters in Chapter 25, and give an example of a reaction forming an ester. How might this kind of reaction be extended to form a polymer (a polyester)?

- 12.42 Write a chemical equation for formation of a polymer via a condensation reaction from the monomers succinic acid (HOOCCH<sub>2</sub>CH<sub>2</sub>COOH) and ethylenediamine (H<sub>2</sub>NCH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>).

- 12.43 Draw the structure of the monomer(s) employed to form each of the following polymers shown in Table 12.5 (a) polyvinyl chloride, (b) nylon 6,6, (c) polyethylene terephthalate.

- 12.44 Write the chemical equation that represents the formation of (a) polychloroprene from chloroprene

(Polychloroprene is used in highway-pavement seals, expansion joints, conveyor belts, and wire and cable jackets.); (b) polyacrylonitrile from acrylonitrile

(Polyacrylonitrile is used in home furnishings, craft yarns, clothing, and many other items.)

- 12.45 The nylon Nomex<sup>®</sup>, a condensation polymer, has the following structure:

Draw the structures of the two monomers that yield Nomex<sup>®</sup>.

- 12.46 Proteins are polymers formed by condensation reactions of amino acids, which have the general structure

## Biomaterials

- 12.51 Neoprene is a polymer of chlorobutadiene.

The polymer can be used to form flexible tubing that is resistant to chemical attack from a variety of chemical reagents. Suppose it is proposed to use neoprene tubing as a coating for the wires running to the heart from an implanted pacemaker. What questions would you ask to determine whether it might be suitable for such an application?

- 12.52 On the basis of the structure shown in Table 12.5 for polystyrene and polyurethane, which of these two classes of polymer would you expect to form the most effective interface with biological systems? Explain.
- 12.53 Patients who receive vascular grafts formed from polymer material such as Dacron<sup>®</sup> are required to take anti-coagulation drugs on a continuing basis to prevent blood clots. Why? What advances in such vascular implants are needed to make this precaution unnecessary?

## Liquid Crystals

- 12.57 In what ways are a nematic liquid crystalline phase and an ordinary liquid the same, and in what ways do they differ?
- 12.58 In contrast to ordinary liquids, liquid crystals are said to possess "order." What does this mean?
- 12.59 Describe what is occurring at the molecular level as a substance passes from the solid to the nematic liquid crystalline to the isotropic (normal) liquid phase upon heating.
- 12.60 What observations made by Reinitzer on cholesteryl benzoate suggested that this substance possesses a liquid crystalline phase?
- 12.61 The molecules shown in Figure 12.39 possess polar groups (that is, groupings of atoms that give rise to sizable

In this structure, R represents —H, —CH<sub>3</sub>, or another group of atoms. Draw the general structure for a polyamino acid polymer formed by condensation polymerization of the molecule shown here.

- 12.47 What molecular features make a polymer flexible? Explain how cross-linking affects the chemical and physical properties of the polymer.
- 12.48 What molecular structural features cause high-density polyethylene to be denser than low-density polyethylene?
- 12.49 Are high molecular masses and a high degree of crystallinity always desirable properties of a polymer? Explain.
- 12.50 Briefly describe each of the following: (a) elastomer, (b) thermoplastic, (c) thermosetting plastic, (d) plasticizer.

- 12.54 Several years ago a biomedical company produced and marketed a new, efficient heart valve implant. It was later withdrawn from the market, however, because patients using it suffered from severe loss of red blood cells. Describe what properties of the valve could have been responsible for this result.

- 12.55 Skin cells from the body do not differentiate when they are simply placed in a tissue culture medium; that is, they do not organize into the structure of skin, with different layers and different cell types. What is needed to cause such differentiation to occur? Indicate the most important requirements on any material used.
- 12.56 If you were going to attempt to grow skin cells in a medium that affords an appropriate scaffolding for the cells and you had only two fabrics available, one made from polystyrene and the other from polyethylene terephthalate (Table 12.5), which would you choose for your experiments? Explain.

dipole moments within the molecules). How might the presence of polar groups enhance the tendency toward liquid crystal formation?

- 12.62 Liquid crystalline phases tend to be more viscous than the isotropic, or normal, liquid phase of the same substance. Why?
- 12.63 The smectic liquid crystalline phase can be said to be more highly ordered than the nematic. In what sense is this true?
- 12.64 One of the more effective liquid crystalline substances employed in LCDs is this molecule.

By comparing this structure with the structural formulas and models shown in Figure 12.39, describe the features of the molecule that promote its liquid crystalline behavior.

- 12.65 Describe how a cholesteric liquid crystal phase differs from a nematic phase.

## Nanomaterials

- 12.67 Explain why “bands” may not be the most accurate description of bonding in a solid when the solid has nanoscale dimensions.
- 12.68 CdS has a band gap of 2.4 eV. If large crystals of CdS are illuminated with ultraviolet light they emit light equal to the band gap energy. (a) What color is the emitted light? (b) Would appropriately sized CdS quantum dots be able to emit blue light? (c) What about red light?
- 12.69 True or false:
- The band gap of a semiconductor decreases as the particle size decreases, in the 1–10-nm range.
  - The light that is emitted from a semiconductor, upon external stimulation, is longer and longer in wavelength as the particle size of the semiconductor decreases.

- 12.66 It often happens that a substance possessing a smectic liquid crystalline phase just above the melting point passes into a nematic liquid crystalline phase at a higher temperature. Account for this type of behavior in terms of the ideas developed in Chapter 11 relating molecular energies to temperature.

- 12.70 True or false:

If you want a semiconductor that emits blue light, you could either use a material that has a band gap corresponding to the energy of a blue photon or you could use a material that has a smaller band gap, but make a nanoparticle out of it of the right size.

- 12.71 Gold is a face-centered cubic structure that has a unit cell edge length of 4.08 Å (Figure 11.34). How many gold atoms are there in a sphere that is 20 nm in diameter? Recall that the volume of a sphere is  $\frac{4}{3}\pi r^3$ .
- 12.72 Cadmium telluride, CdTe, takes the zinc blende structure (Section 11.8) with a unit cell edge length of 6.49 Å. There are four cadmium atoms and four tellurium atoms per unit cell. How many of each type of atom are there in a cubic crystal with an edge length of 5 nm?

## ADDITIONAL EXERCISES

- 12.73 One major difference in the behavior of semiconductors and metals is that semiconductors increase their conductivity as you heat them (up to a point), but the conductivity of a metal decreases as you heat it. Suggest an explanation.
- 12.74 What properties of the typical nematic liquid crystalline molecule are likely to cause it to reorient when it is placed in an electrical field that is perpendicular to the direction of orientation of the molecules?
- 12.75 Teflon<sup>®</sup> is a polymer formed by the polymerization of  $F_2C=CF_2$ . Draw the structure of a section of this polymer. What type of polymerization reaction is required to form it?
- 12.76 Classify each of the following as a ceramic, polymer, or liquid crystal.

- 12.77 Ceramics are generally brittle, subject to crack failure, and stable to high temperatures. In contrast, plastics are generally deformable under stress and have limited thermal stability. Discuss these differences in terms of the structures and bonding in the two classes of materials.
- 12.78 A watch with a liquid crystal display (LCD) does not function properly when it is exposed to low temperatures during a trip to Antarctica. Explain why the LCD might not function well at low temperature.
- 12.79 The temperature range over which a liquid possesses liquid crystalline behavior is rather narrow (for examples, see Figure 12.39). Why?
- 12.80 Suppose that a liquid crystalline material such as cholesteryl benzoate is warmed to well above its liquid crystalline range and then cooled. On cooling, the sample unexpectedly remains clear until it reaches a temperature just below the melting point, at which time it solidifies. What explanation can you give for this behavior?
- 12.81 Hydrogen bonding between polyamide chains plays an important role in determining the properties of a nylon such as nylon 6,6 (Table 12.5). Draw the structural formulas for two adjacent chains of nylon 6,6, and show where hydrogen-bonding interactions could occur between them.
- [12.82] A particular liquid crystalline substance has the phase diagram shown in the figure. By analogy with the phase diagram for a non-liquid crystalline substance (Section 11.6), identify the phase present in each area.

## INTEGRATIVE EXERCISES

**[12.84]** Employing the bond enthalpy values listed in Table 8.4, estimate the molar enthalpy change occurring upon (a) polymerization of ethylene, (b) formation of nylon 6,6, (c) formation of polyethylene terephthalate (PET).

**[12.85]** Although polyethylene can twist and turn in random ways, as illustrated in Figure 12.24, the most stable form is a linear one with the carbon backbone oriented as shown in the figure below:

The solid wedges in the figure indicate bonds from carbon that come out of the plane of the page; the dotted wedges indicate bonds that lie behind the plane of the page.

- (a) What is the hybridization of orbitals at each carbon atom? What angles do you expect between the bonds?
- (b) Now imagine that the polymer is polypropylene rather than polyethylene. Draw structures for polypropylene in which (i) the  $\text{CH}_3$  groups all lie on the same side of the plane of the paper (this form is called isotactic polypropylene); (ii) the  $\text{CH}_3$  groups lie on alternating sides of the plane (syndiotactic polypropylene); or (iii) the  $\text{CH}_3$  groups are randomly distributed on either side (atactic polypropylene). Which of these forms would you expect to have the highest crystallinity and melting point, and which the lowest? Explain in terms of intermolecular interactions and molecular shapes.
- (c) Polypropylene fibers have been employed in athletic wear. The product is said to be superior to cotton or polyester clothing in wicking moisture away from the body through the fabric to the outside. Explain the difference between polypropylene and polyester or cotton (which has many  $-\text{OH}$  groups along the molecular chain), in terms of intermolecular interactions with water.

**12.86** In the superconducting ceramic  $\text{YBa}_2\text{Cu}_3\text{O}_7$ , what is the average oxidation state of copper, assuming that Y and Ba are in their expected oxidation states? Yttrium can be replaced with a rare-earth element such as La, and Ba can be replaced with other similar elements without fundamentally changing the superconducting properties of the material. However, general replacement of copper by any other element leads to a loss of superconductivity.

**12.83** In fabricating microelectronics circuits, a ceramic conductor such as  $\text{TiSi}_2$  is employed to connect various regions of a transistor with the outside world, notably aluminum wires. The  $\text{TiSi}_2$  is deposited as a thin film via chemical vapor deposition, in which  $\text{TiCl}_4(\text{g})$  and  $\text{SiH}_4(\text{g})$  are reacted at the Si surface. Write a balanced equation for the reaction, assuming that the other products are  $\text{H}_2$  and  $\text{HCl}$ . Why might  $\text{TiSi}_2$  behave better as a conducting interconnect on Si than on a metal such as Cu?

In what respects is the electron configuration of copper different from that of the other two metallic elements in this compound?

**12.87** A sample of the superconducting oxide  $\text{HgBa}_2\text{Ca}_2\text{Cu}_3\text{O}_{8+x}$  is found to contain 14.99% oxygen by mass. (a) Assuming that all other elements are present in the ratios represented by the formula, what is the value of  $x$  in the formula? (b) Which of the metallic elements in the compound is (are) most likely to have noninteger average charges? Explain your answer. (c) Which of the metallic ions in the substance is likely to have the largest ionic radius? Which will have the smallest?

**12.88** (a) In polyvinyl chloride shown on Table 12.5, which bonds have the lowest average bond enthalpy? (b) In the thermal conversion of polyvinyl chloride to diamond, at high pressure, which bonds are most likely to rupture first on heating the material? (c) Employing the values of average bond enthalpy in Table 8.4, estimate the overall enthalpy change for converting PVC to diamond.

**12.89** Consider *para*-azoxyanisole, which is a nematic liquid crystal in the temperature range of  $21^\circ\text{C}$  to  $47^\circ\text{C}$ :

- (a) Write out the Lewis structure for this molecule, showing all lone-pair electrons as well as bonds. (b) Describe the hybrid orbitals employed by each of the two nitrogens. What bond angles do you anticipate about the nitrogen atom that is bonded to oxygen? (c) Replacing one of the  $-\text{OCH}_3$  groups in *para*-azoxyanisole by a  $-\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$  group causes the melting point of the substance to drop; the liquid crystal range changes to  $19^\circ\text{C}$  to  $76^\circ\text{C}$ . Explain why this substitution produces the observed changes in properties. (d) How would you expect the density of *para*-azoxyanisole to change upon melting at  $117^\circ\text{C}$ ? Upon passing from the nematic to the isotropic liquid state at  $137^\circ\text{C}$ ? Explain.
- [12.90]** Silicon has diamond structure (Figure 12.3) with unit cell edge length of  $5.43\text{ \AA}$  and eight atoms per unit cell. (a) How many silicon atoms are there in  $1\text{ cm}^3$  of material? (b) Suppose you dope that  $1\text{-cm}^3$  sample of silicon with 1 ppm of phosphorus that will increase the conductivity by a factor of a million. How many milligrams of phosphorus are required?

CHAPTER  
13

PROPERTIES  
OF SOLUTIONS

A TROPICAL BEACH. Ocean water is a complex aqueous solution of many dissolved substances of which sodium chloride is highest in concentration.

*Dana Edmunds/PacificStock.com*

## WHAT'S AHEAD

---

### 13.1 The Solution Process

We begin by considering what happens at a molecular level when a substance dissolves, paying particular attention to the role of *intermolecular forces* in the process. Two important aspects of the solution process are the changes in *energy* and the changes in how particles are distributed in space as a result of the solution process.

### 13.2 Saturated Solutions and Solubility

We will see that in *saturated solutions* the dissolved and undissolved solutes are in *equilibrium*. The amount of solute in a saturated solution defines its *solubility*, the extent to which a particular solute dissolves in a particular solvent.

### 13.3 Factors Affecting Solubility

We next consider the major factors affecting solubility. The nature of the solute and solvent determines the kinds of intermolecular forces between and within them and strongly influences solubility. Temperature also influences solubility: Most solids are more soluble in water at higher temperatures, whereas gases are less soluble in water at higher temperatures. In addition, the solubility of gases increases with increasing pressure.

### 13.4 Ways of Expressing Concentration

We observe that many physical properties of solutions depend on their concentration, and we examine several common ways of expressing concentration.

### 13.5 Colligative Properties

We observe that solutes affect the properties of solutions. The physical properties of solutions that depend only on concentration and not on the identity of the solute are called *colligative properties*. These properties include the extent to which the solute lowers the vapor pressure, increases the boiling point, and decreases the freezing point of the solvent. The osmotic pressure of a solution is also a colligative property.

### 13.6 Colloids

We close the chapter by investigating *colloids*, mixtures in which particles larger than typical molecular sizes are dispersed in another component.

**ON A WARM DAY AT THE BEACH**, we are unlikely to consider chemistry while we enjoy the water and warmth of the sun. But as we breathe the air, swim in the water, and walk on the sand, we are experiencing the three states of matter.

In Chapter 10 and 11, we explored the properties

of gases, liquids, and solids. Most of the discussion focused on pure substances. However, the matter that we encounter in our daily lives, such as air, seawater, and sand, is usually composed of mixtures. In this chapter we examine mixtures, although we limit ourselves to those that are homogeneous. As we have noted in earlier chapters, a homogeneous mixture is called a *solution*. ∞ (Sections 1.2 and 4.1)

When we think of solutions, we usually first think about liquids, such as a solution of salt in water, like the seawater shown in this chapter's opening photo. Sterling silver, which is used in jewelry, is also a solution—a homogeneous distribution of about 7% copper in silver. Sterling silver is an example of

a solid solution. Numerous examples of solutions abound in the world around us—some solid, some liquid, and some gas. For example, the air we breathe is a solution of several gases; brass is a solid solution of zinc in copper; and the fluids that run through our bodies are solutions that carry a variety of essential nutrients, salts, and other materials.

Each of the substances in a solution is called a *component* of the solution. As we saw in Chapter 4, the *solvent* is normally the component present in the greatest amount. Other components are called *solutes*. Because liquid solutions are the most common, we will focus our attention on them in this chapter. Our primary goal is to examine the physical properties of solutions, comparing them with the properties of their components. We will be particularly concerned with *aqueous solutions*, which contain water as the solvent and a gas, liquid, or solid as a solute.

### 13.1 THE SOLUTION PROCESS

A solution is formed when one substance disperses uniformly throughout another. As we noted in the introduction, solutions may be gases, liquids, or solids. Each of these possibilities is listed in Table 13.1 ▼.

The ability of substances to form solutions depends on two general factors: (1) the types of intermolecular interactions involved in the solution process, and (2) the natural tendency of substances to spread into larger volumes when not restrained in some way. We begin our discussion of the solution process by examining the role of intermolecular interactions.

#### The Effect of Intermolecular Forces

Any of the various kinds of intermolecular forces that we discussed in Chapter 11 can operate between solute and solvent particles in a solution. Ion–dipole forces, for example, dominate in solutions of ionic substances in water. Dispersion forces, on the other hand, dominate when a nonpolar substance such as  $C_6H_{14}$  dissolves in another nonpolar one like  $CCl_4$ . Indeed, a major factor determining whether a solution forms is the relative strengths of intermolecular forces between and among the solute and solvent particles. That is, the extent to which one substance is able to dissolve in another depends on the relative magnitudes of the solute–solvent, solute–solute, and solvent–solvent interactions involved in the solution process.

Solutions form when the magnitudes of the attractive forces between solute and solvent particles are comparable to or greater than those that exist between the solute particles themselves or between the solvent particles themselves. For example, the ionic substance NaCl dissolves readily in water because the attractive interactions between the ions and the polar  $H_2O$  molecules (solute–solvent interactions) overcome the attraction between the ions in the solid NaCl

TABLE 13.1 ■ Examples of Solutions

State of Solution	State of Solvent	State of Solute	Example
Gas	Gas	Gas	Air
Liquid	Liquid	Gas	Oxygen in water
Liquid	Liquid	Liquid	Alcohol in water
Liquid	Liquid	Solid	Salt in water
Solid	Solid	Gas	Hydrogen in palladium
Solid	Solid	Liquid	Mercury in silver
Solid	Solid	Solid	Silver in gold

▲ **Figure 13.1 Dissolution of an ionic solid in water.** (a) A crystal of the ionic solid is hydrated by water molecules, with the oxygen atoms of the water molecules oriented toward the cations (purple) and the hydrogens oriented toward the anions (green). (b, c) As the solid dissolves, the individual ions are removed from the solid surface and become completely separate hydrated species in solution.

(solute–solute interactions) and between  $\text{H}_2\text{O}$  molecules in the solvent (solvent–solvent interactions). Let’s examine this solution process more closely, paying attention to these various attractive forces.

When  $\text{NaCl}$  is added to water (Figure 13.1▲), the water molecules orient themselves on the surface of the  $\text{NaCl}$  crystals. The positive end of the water dipole is oriented toward the  $\text{Cl}^-$  ions, and the negative end of the water dipole is oriented toward the  $\text{Na}^+$  ions. The ion–dipole attractions between the ions and water molecules are strong enough to pull the ions from their positions in the crystal.

Once separated from the crystal, the  $\text{Na}^+$  and  $\text{Cl}^-$  ions are surrounded by water molecules, as shown in Figure 13.1(b and c) and Figure 13.2▶. We learned in Section 4.1 that interactions such as this between solute and solvent molecules are known as **solvation**. When the solvent is water, the interactions are also referred to as **hydration**.

In addition to the solvent–solute interactions (the ion–dipole attractions between  $\text{H}_2\text{O}$  molecules and the  $\text{Na}^+$  and  $\text{Cl}^-$  ions) and the solute–solute interactions (between the  $\text{Na}^+$  and  $\text{Cl}^-$  ions in the solid), we must consider one other interaction: the solvent–solvent interaction (in this case the hydrogen-bonding attractions between  $\text{H}_2\text{O}$  molecules). In forming the solution, the water molecules must make room for the hydrated  $\text{Na}^+$  and  $\text{Cl}^-$  ions in their midst, causing some water molecules to move apart.

### GIVE IT SOME THOUGHT

Why doesn’t  $\text{NaCl}$  dissolve in nonpolar solvents such as hexane,  $\text{C}_6\text{H}_{14}$ ?

### Energy Changes and Solution Formation

We can analyze the roles played by the solute–solvent, solute–solute, and solvent–solvent interactions by examining the energy changes associated with each. Let’s continue to analyze the process of dissolving  $\text{NaCl}$  in water as an example of how energy considerations provide insight into the solution process.

We have observed that sodium chloride dissolves in water because the water molecules have a strong enough attraction for the  $\text{Na}^+$  and  $\text{Cl}^-$  ions to overcome the attraction of these two ions for one another in the crystal. In addition, water molecules must separate from one another to form spaces in the solvent that the  $\text{Na}^+$  and  $\text{Cl}^-$  ions will occupy. Thus, we can think of the overall energetics of solution formation as having three components—associated

▲ **Figure 13.2 Hydrated  $\text{Na}^+$  and  $\text{Cl}^-$  ions.** The negative ends of the water dipoles point toward the positive ion, and the positive ends point toward the negative ion.

► **Figure 13.3 Enthalpy contributions to  $\Delta H_{\text{soln}}$ .** The enthalpy changes  $\Delta H_1$  and  $\Delta H_2$  represent endothermic processes, requiring an input of energy, whereas  $\Delta H_3$  represents an exothermic process.

with breaking the solute-solute and the solvent-solvent interactions and forming the solute-solvent interactions—as illustrated schematically in Figure 13.3. The overall enthalpy change in forming a solution,  $\Delta H_{\text{soln}}$ , is the sum of three terms associated with these three processes:

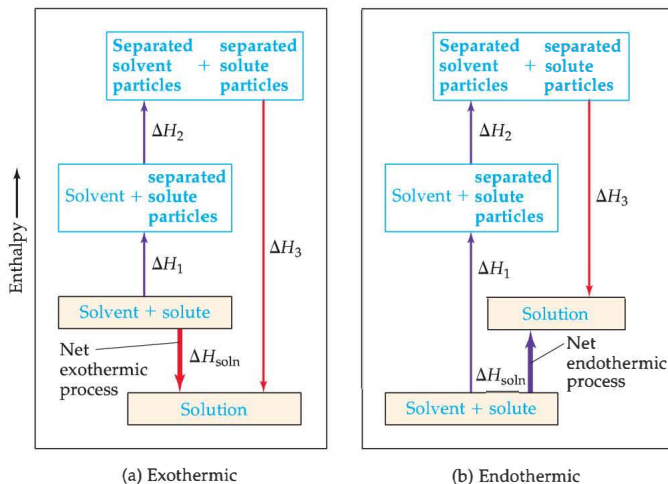

$$\Delta H_{\text{soln}} = \Delta H_1 + \Delta H_2 + \Delta H_3 \quad [13.1]$$

Regardless of the particular solute being considered, separation of the solute particles from one another requires an input of energy to overcome their attractive interactions. The process is therefore endothermic ( $\Delta H_1 > 0$ ). Separation of solvent molecules to accommodate the solute also always requires energy ( $\Delta H_2 > 0$ ). The third component, which arises from the attractive interactions between solute and solvent, is always exothermic ( $\Delta H_3 < 0$ ).

As shown in Figure 13.4, the three enthalpy terms in Equation 13.1 can be added together to give either a negative or a positive sum, depending on the relative magnitudes of the terms. Thus, the formation of a solution can be either exothermic or endothermic. For example, when magnesium sulfate,  $\text{MgSO}_4$ , is added to water, the resultant solution gets quite warm:  $\Delta H_{\text{soln}} = -91.2 \text{ kJ/mol}$ . In contrast, the dissolution of ammonium nitrate ( $\text{NH}_4\text{NO}_3$ ) is endothermic:  $\Delta H_{\text{soln}} = 26.4 \text{ kJ/mol}$ . These particular substances have been used to make the instant heat packs and ice packs that are used to treat athletic injuries (Figure 13.5). The packs consist of a pouch of water and a dry chemical,  $\text{MgSO}_4$  for hot packs and  $\text{NH}_4\text{NO}_3$  for cold packs. When the pack is squeezed, the seal separating the solid from the water is broken and a solution forms, either increasing or decreasing the temperature.

In Chapter 5 we learned that the enthalpy change in a process can provide information about the extent to which a process will occur.  $\infty$  (Section 5.4) Processes that are exothermic tend to proceed spontaneously. A solution will not form if  $\Delta H_{\text{soln}}$  is too endothermic. The solvent-solute interaction must be

◀ **Figure 13.4 Enthalpy changes accompanying the solution process.** The three processes are illustrated in Figure 13.3. The diagram on the left (a) illustrates a net exothermic process ( $\Delta H_{\text{soln}} < 0$ ); that on the right (b) shows a net endothermic process ( $\Delta H_{\text{soln}} > 0$ ).

strong enough to make  $\Delta H_3$  comparable in magnitude to  $\Delta H_1 + \Delta H_2$ . This fact explains why ionic solutes such as NaCl do not dissolve in nonpolar liquids such as gasoline. The nonpolar hydrocarbon molecules of the gasoline would experience only weak attractive interactions with the ions, and these interactions would not compensate for the energies required to separate the ions from one another.

By similar reasoning, a polar liquid such as water does not form solutions with a nonpolar liquid such as octane ( $\text{C}_8\text{H}_{18}$ ). The water molecules experience strong hydrogen-bonding interactions with one another. ∞ (Section 11.2) These attractive forces must be overcome to disperse the water molecules throughout the nonpolar liquid. The energy required to separate the  $\text{H}_2\text{O}$  molecules is not recovered in the form of attractive interactions between  $\text{H}_2\text{O}$  and  $\text{C}_8\text{H}_{18}$  molecules.

### GIVE IT SOME THOUGHT

Label the following processes as exothermic or endothermic: (a) forming solvent–solute interactions, (b) breaking solvent–solvent interactions.

## Solution Formation, Spontaneity, and Entropy

When carbon tetrachloride ( $\text{CCl}_4$ ) and hexane ( $\text{C}_6\text{H}_{14}$ ) are mixed, they dissolve in one another in all proportions. Both substances are nonpolar, and they have similar boiling points ( $77^\circ\text{C}$  for  $\text{CCl}_4$  and  $69^\circ\text{C}$  for  $\text{C}_6\text{H}_{14}$ ). It is therefore reasonable to suppose that the magnitudes of the attractive forces (London dispersion forces) among molecules in the two substances and in their solution are comparable. When the two substances are mixed, dissolving occurs spontaneously; that is, it occurs without any extra input of energy from outside the system. Processes that occur spontaneously involve two distinct factors. The most obvious factor is energy, which we have used to analyze the dissolving of NaCl in water. The other factor is the distribution of each component into a larger volume—the tendency in nature for substances to mix and spread out into larger volumes.

▲ **Figure 13.5 Endothermic dissolution.** Ammonium nitrate instant ice packs are often used to treat athletic injuries. To activate the pack, the container is kneaded. The kneading breaks an interior seal separating solid  $\text{NH}_4\text{NO}_3$  from water. The heat of solution of  $\text{NH}_4\text{NO}_3$  is positive, so the temperature of the solution decreases.

▲ **Figure 13.6 increasing randomness in a solution process.** A homogeneous solution of  $\text{CCl}_4$  and  $\text{C}_6\text{H}_{14}$  forms when a barrier separating the two liquids is removed. Each  $\text{CCl}_4$  molecule of the solution in (b) is more dispersed in space than it was in the left compartment in (a), and each  $\text{C}_6\text{H}_{14}$  molecule in (b) is more dispersed than it was in the right compartment in (a).

We see the influence of energy all around us. If you let go of a book, it falls to the floor because of gravity. At its initial height, the book has a higher potential energy than it has when it is on the floor. Unless the book is restrained, it falls; and as it does, potential energy is converted into kinetic energy. When the book strikes the floor, the kinetic energy is converted largely into heat energy, which is dispersed throughout the surroundings. The book has lost energy to its surroundings in this process. This fact leads us to the first basic principle identifying spontaneous processes and the direction they take: *Processes in which the energy content of the system decreases tend to occur spontaneously.* Spontaneous processes tend to be exothermic. ∞ (Section 5.4, “Strategies in Chemistry: Using Enthalpy as a Guide”) Change tends to occur in the direction that leads to a lower energy or lower enthalpy for the system.

Some spontaneous processes, however, do not result in lower energy for a system, and even some endothermic processes occur spontaneously. For example,  $\text{NH}_4\text{NO}_3$  readily dissolves in water, even though the solution process is endothermic. Processes such as this are characterized by a more dispersed state of one or more components, resulting in an overall increase in the randomness of the system. In this example the densely ordered solid,  $\text{NH}_4\text{NO}_3$ , is dispersed throughout the solution as separated  $\text{NH}_4^+$  and  $\text{NO}_3^-$  ions. The mixing of  $\text{CCl}_4$  and  $\text{C}_6\text{H}_{14}$  provides another simple example.

Suppose that we could suddenly remove a barrier that separates 500 mL of  $\text{CCl}_4$  from 500 mL of  $\text{C}_6\text{H}_{14}$ , as shown in Figure 13.6(a) ◀. Before the barrier is removed, each liquid occupies a volume of 500 mL. All the  $\text{CCl}_4$  molecules are in the 500 mL to the left of the barrier, and all the  $\text{C}_6\text{H}_{14}$  molecules are in the 500 mL to the right. When equilibrium has been established after the barrier has been removed, the two liquids together occupy a volume of about 1000 mL. Formation of a homogeneous solution has increased the degree of dispersal, or randomness, because the molecules of each substance are now mixed and distributed in a volume twice as large as that which they occupied individually before mixing. The degree of randomness in the system, sometimes referred to as disorder, is given by a thermodynamic quantity called **entropy**. This example illustrates our second basic principle: *Processes occurring at a constant temperature in which the randomness or dispersal in space (entropy) of the system increases tend to occur spontaneously.*

When molecules of different types are brought together, mixing—hence an increased dispersal—occurs spontaneously unless the molecules are restrained by sufficiently strong intermolecular forces or by physical barriers. Thus, gases spontaneously mix and expand unless restrained by their containers; in this case intermolecular forces are too weak to restrain the molecules. However, because strong bonds hold sodium and chloride ions together, sodium chloride does not spontaneously dissolve in gasoline.

We will discuss spontaneous processes again in Chapter 19. At that time we will consider the balance between the tendencies toward lower enthalpy and toward increased entropy in greater detail. For the moment, we need to be aware that the solution process involves two factors: a change in enthalpy and a change in entropy. In most cases the *formation of solutions is favored by the increase in entropy that accompanies mixing.* Consequently, a solution will form unless solute–solute or solvent–solvent interactions are too strong relative to the solute–solvent interactions.

### GIVE IT SOME THOUGHT

Silver chloride,  $\text{AgCl}$ , is essentially insoluble in water. Would you expect a significant change in the entropy of the system when 10 g of  $\text{AgCl}$  is added to 500 mL of water?

**▲ Figure 13.7 The nickel-acid reaction is not a simple dissolution.** (a) Nickel metal and hydrochloric acid. (b) Nickel reacts slowly with hydrochloric acid, forming  $\text{NiCl}_2(aq)$  and  $\text{H}_2(g)$ . (c)  $\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}$  is obtained when the solution from (b) is evaporated to dryness. Because the residue left after evaporation is chemically different from either reactant, we know what takes place is a chemical reaction rather than merely a solution process.

### Solution Formation and Chemical Reactions

In all our discussions of solutions, we must be careful to distinguish the physical process of solution formation from chemical reactions that lead to a solution. For example, nickel metal is dissolved on contact with hydrochloric acid solution because the following chemical reaction occurs:

In this instance the chemical form of the substance being dissolved is changed from Ni to  $\text{NiCl}_2$ . If the solution is evaporated to dryness,  $\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}(s)$ , not  $\text{Ni}(s)$ , is recovered (Figure 13.7 ▶). When  $\text{NaCl}(s)$  is dissolved in water, on the other hand, no chemical reaction occurs. If the solution is evaporated to dryness,  $\text{NaCl}$  is recovered. Our focus throughout this chapter is on solutions from which the solute can be recovered unchanged from the solution.

### A Closer Look

#### HYDRATES

**F**requently, hydrated ions remain in crystalline salts that are obtained by evaporation of water from aqueous solutions. Common examples include  $\text{FeCl}_3 \cdot 6 \text{H}_2\text{O}$  [iron(III) chloride hexahydrate] and  $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$  [copper(II)sulfate pentahydrate]. The  $\text{FeCl}_3 \cdot 6 \text{H}_2\text{O}$  consists of  $\text{Fe}(\text{H}_2\text{O})_6^{3+}$  and  $\text{Cl}^-$  ions; the  $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$  consists of  $\text{Cu}(\text{H}_2\text{O})_4^{2+}$  and  $\text{SO}_4(\text{H}_2\text{O})_2^{2-}$  ions. Water molecules can also occur in positions in the crystal lattice that are not specifically associated with either a cation or an anion.  $\text{BaCl}_2 \cdot 2 \text{H}_2\text{O}$  (barium chloride dihydrate) is an example. Compounds such as  $\text{FeCl}_3 \cdot 6 \text{H}_2\text{O}$ ,  $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$ , and  $\text{BaCl}_2 \cdot 2 \text{H}_2\text{O}$ , which contain a salt and water combined in definite proportions, are known as *hydrates*. The water associated with them is called *water of hydration*. Figure 13.8 ▶ shows an example of a hydrate and the corresponding anhydrous (water-free) substance.

*Related Exercises:* 13.4, 13.107

**▲ Figure 13.8 Hydrates and anhydrous salts.** Hydrated cobalt(II) chloride,  $\text{CoCl}_2 \cdot 6 \text{H}_2\text{O}$  (left), and anhydrous  $\text{CoCl}_2$  (right).

**SAMPLE EXERCISE 13.1** Assessing Entropy Change

In the process illustrated below, water vapor reacts with excess solid sodium sulfate to form the hydrated form of the salt. The chemical reaction is

Essentially all of the water vapor in the closed container is consumed in this reaction. If we consider our system to consist initially of  $\text{Na}_2\text{SO}_4(\text{s})$  and  $10 \text{H}_2\text{O}(\text{g})$ , (a) does the system become more or less ordered in this process, and (b) does the entropy of the system increase or decrease?

**SOLUTION**

**Analyze:** We are asked to determine whether the reaction of water vapor with the solid salt causes the system to become more or less dispersed, or random, and to determine whether the process results in a higher or lower entropy for the system.

**Plan:** We need to examine the initial and final states and judge whether the process has made the system more or less dispersed. Depending on our answer to that question, we can determine whether the entropy has increased or decreased.

**Solve:** (a) In the course of forming the hydrate of  $\text{Na}_2\text{SO}_4(\text{s})$ , the water vapor moves from the vapor state, in which it is dispersed throughout the entire volume of the container, to the solid state, where it is confined to the  $\text{Na}_2\text{SO}_4 \cdot 10 \text{H}_2\text{O}(\text{s})$  lattice. This means that the water vapor becomes less dispersed (more ordered, or less random). (b) When a system becomes less dispersed, or more ordered, its entropy is decreased.

**PRACTICE EXERCISE**

Does the entropy of the system increase or decrease when the stopcock is opened to allow mixing of the two gases in this apparatus?

**Answer:** The entropy increases because each gas eventually becomes dispersed in twice the volume it originally occupied.

**▲ Figure 13.9 Dynamic equilibrium in a saturated solution.** In a solution in which excess ionic solute is present, ions on the surface of the solute are continuously passing into the solution as hydrated species, while hydrated ions from the solution are deposited on the surfaces of the solute. At equilibrium in a saturated solution, the two processes occur at equal rates.

**13.2 SATURATED SOLUTIONS AND SOLUBILITY**

As a solid solute begins to dissolve in a solvent, the concentration of solute particles in solution increases, thus increasing the chances of the solute particles colliding with the surface of the solid (Figure 13.9 ◀). Because of such a collision, the solute particle may become reattached to the solid. This process, which is the opposite of the solution process, is called **crystallization**. Thus, two opposing processes occur in a solution in contact with undissolved solute. This situation is represented in a chemical equation by use of two half arrows:

(a) A seed crystal of  $\text{NaCH}_3\text{COO}$  being added to the supersaturated solution. (b) Excess  $\text{NaCH}_3\text{COO}$  crystallizes from the solution. (c) The solution arrives at saturation.

▲ **Figure 13.10 Sodium acetate readily forms a supersaturated solution in water.**

When the rates of these opposing processes become equal, there is no further net increase in the amount of solute in solution. A dynamic equilibrium is established similar to the one between evaporation and condensation discussed in Section 11.5.

A solution that is in equilibrium with undissolved solute is **saturated**. Additional solute will not dissolve if added to a saturated solution. The amount of solute needed to form a saturated solution in a given quantity of solvent is known as the **solubility** of that solute. That is, *the solubility is the maximum amount of solute that will dissolve in a given amount of solvent at a specified temperature, given that excess solute is present*. For example, the solubility of  $\text{NaCl}$  in water at  $0^\circ\text{C}$  is 35.7 g per 100 mL of water. This is the maximum amount of  $\text{NaCl}$  that can be dissolved in water to give a stable equilibrium solution at that temperature.

If we dissolve less solute than that needed to form a saturated solution, the solution is **unsaturated**. Thus, a solution containing only 10.0 g of  $\text{NaCl}$  per 100 mL of water at  $0^\circ\text{C}$  is unsaturated because it has the capacity to dissolve more solute.

Under suitable conditions it is sometimes possible to form solutions that contain a greater amount of solute than that needed to form a saturated solution. Such solutions are **supersaturated**. For example, considerably more sodium acetate ( $\text{NaCH}_3\text{COO}$ ) can dissolve in water at high temperatures than at low temperatures. When a saturated solution of sodium acetate is made at a high temperature and then slowly cooled, all of the solute may remain dissolved even though the solubility decreases as the temperature decreases. Because the solute in a supersaturated solution is present in a concentration higher than the equilibrium concentration, supersaturated solutions are unstable. Supersaturated solutions result for much the same reason as supercooled liquids (Section 11.4). For crystallization to occur, the molecules or ions of solute must arrange themselves properly to form crystals. The addition of a small crystal of the solute (a seed crystal) provides a template for crystallization of the excess solute, leading to a saturated solution in contact with excess solid (Figure 13.10▲).

### GIVE IT SOME THOUGHT

Is a supersaturated solution of sodium acetate a stable equilibrium solution?

## 13.3 FACTORS AFFECTING SOLUBILITY

The extent to which one substance dissolves in another depends on the nature of both the solute and the solvent.  $\rightleftharpoons$  (Section 13.1) It also depends on temperature and, at least for gases, on pressure. Let's consider these factors more closely.

**TABLE 13.2** ■ Solubilities of Gases in Water at 20 °C, with 1 atm Gas Pressure

Gas	Solubility (M)
N <sub>2</sub>	$0.69 \times 10^{-3}$
CO	$1.04 \times 10^{-3}$
O <sub>2</sub>	$1.38 \times 10^{-3}$
Ar	$1.50 \times 10^{-3}$
Kr	$2.79 \times 10^{-3}$

**Hexane is insoluble in water.** Hexane is the top layer because it is less dense than water.

## Solute–Solvent Interactions

One factor determining solubility is the natural tendency of substances to mix (the tendency of systems to move toward a more dispersed, or random, state). ∞ (Section 13.2) If this were the only factor involved, however, we would expect all substances to be completely soluble in one another. This is clearly not the case. So what other factors are involved? As we saw in Section 13.1, the relative forces of attraction among the solute and solvent molecules also play very important roles in the solution process.

Although the tendency toward dispersal and the various interactions among solute and solvent particles are all involved in determining the solubilities, considerable insight can often be gained by focusing on the interaction between the solute and solvent. The data in Table 13.2 ◀ show, for example, that the solubilities of various simple gases in water increase with increasing molecular mass or polarity. The attractive forces between the gas and solvent molecules are mainly of the London dispersion type, which increase with increasing size and mass of the gas molecules. ∞ (Section 11.2) Thus, the data indicate that the solubilities of gases in water increase as the attraction between the solute (gas) and solvent (water) increases. In general, when other factors are comparable, the stronger the attractions are between solute and solvent molecules, the greater the solubility.

Because of favorable dipole–dipole attractions between solvent molecules and solute molecules, polar liquids tend to dissolve readily in polar solvents. Water is both polar and able to form hydrogen bonds. ∞ (Section 11.2) Thus, polar molecules, especially those that can form hydrogen bonds with water molecules, tend to be soluble in water. For example, acetone, a polar molecule with the structural formula shown in the margin, mixes in all proportions with water. Acetone has a strongly polar C=O bond and pairs of nonbonding electrons on the O atom that can form hydrogen bonds with water.

Pairs of liquids such as acetone and water that mix in all proportions are **miscible**, whereas those that do not dissolve in one another are **immiscible**. Gasoline, which is a mixture of hydrocarbons, is immiscible with water. Hydrocarbons are nonpolar substances because of several factors: The C—C bonds are nonpolar, the C—H bonds are nearly nonpolar, and the shapes of the molecules are symmetrical enough to cancel much of the weak C—H bond dipoles. The attraction between the polar water molecules and the nonpolar hydrocarbon molecules is not sufficiently strong to allow the formation of a solution. Nonpolar liquids tend to be insoluble in polar liquids. As a result, hexane (C<sub>6</sub>H<sub>14</sub>) does not dissolve in water, as the photo in the margin shows.

The series of compounds in Table 13.3 ▼ demonstrates that polar liquids tend to dissolve in other polar liquids and nonpolar liquids in nonpolar ones. These organic compounds all contain the OH group attached to a C atom. Organic compounds with this molecular feature are called *alcohols*. The O—H bond is polar and is able to form hydrogen bonds. For example, CH<sub>3</sub>CH<sub>2</sub>OH molecules can form hydrogen bonds with water molecules as well as with each other (Figure 13.11 ►). As a result, the solute–solute, solvent–solvent, and solute–solvent forces

**TABLE 13.3** ■ Solubilities of Some Alcohols in Water and in Hexane\*

Alcohol	Solubility in H <sub>2</sub> O	Solubility in C <sub>6</sub> H <sub>14</sub>
CH <sub>3</sub> OH (methanol)	∞	0.12
CH <sub>3</sub> CH <sub>2</sub> OH (ethanol)	∞	∞
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> OH (propanol)	∞	∞
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH (butanol)	0.11	∞
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH (pentanol)	0.030	∞
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH (hexanol)	0.0058	∞

\*Expressed in mol alcohol/100 g solvent at 20 °C. The infinity symbol (∞) indicates that the alcohol is completely miscible with the solvent.

are not greatly different within a mixture of  $\text{CH}_3\text{CH}_2\text{OH}$  and  $\text{H}_2\text{O}$ . No major change occurs in the environments of the molecules as they are mixed. Therefore, the increased dispersal (entropy) of the two components into a larger combined volume as they mix plays a significant role in the formation of the solution. Ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ), therefore, is completely miscible with water.

The number of carbon atoms in an alcohol affects its solubility in water. As the length of the carbon chain increases, the polar OH group becomes an ever smaller part of the molecule, and the molecule behaves more like a hydrocarbon. The solubility of the alcohol in water decreases correspondingly. On the other hand, the solubility of the alcohol in a nonpolar solvent like hexane ( $\text{C}_6\text{H}_{14}$ ) increases as the nonpolar hydrocarbon chain increases in length.

One way to enhance the solubility of a substance in water is to increase the number of polar groups it contains. For example, increasing the number of OH groups along a carbon chain of a solute increases the extent of hydrogen bonding between that solute and water, thereby increasing solubility. Glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) has five OH groups on a six-carbon framework, which makes the molecule very soluble in water (83 g dissolves in 100 mL of water at  $17.5^\circ\text{C}$ ). The glucose molecule is shown in Figure 13.12 ▼.

▲ **Figure 13.11** Hydrogen-bonding interactions. (a) Between two ethanol molecules and (b) between an ethanol molecule and a water molecule.

## HYDROGEN BONDING AND AQUEOUS SOLUBILITY

*The presence of OH groups capable of hydrogen bonding with water enhances the aqueous solubility of organic molecules.*

▲ **Figure 13.12** Structure and solubility.

Vitamins have unique chemical structures that affect their solubilities in different parts of the human body. Vitamins B and C are water soluble, for example, whereas vitamins A, D, E, and K are soluble in nonpolar solvents and in the fatty tissue of the body (which is nonpolar). Because of their water solubility, vitamins B and C are not stored to any appreciable extent in the body, and so foods containing these vitamins should be included in the daily diet. In contrast, the fat-soluble vitamins are stored in sufficient quantities to keep vitamin-deficiency diseases from appearing even after a person has subsisted for a long period on a vitamin-deficient diet.

The different solubility patterns of the water-soluble vitamins and the fat-soluble ones can be rationalized in terms of

the structures of the molecules. The chemical structures of vitamin A (retinol) and of vitamin C (ascorbic acid) are shown in Figure 13.13. Notice that the vitamin A molecule is an alcohol with a very long carbon chain. Because the OH group is such a small part of the molecule, the molecule resembles the long-chain alcohols listed in Table 13.3. This vitamin is nearly nonpolar. In contrast, the vitamin C molecule is smaller and has more OH groups that can form hydrogen bonds with water. It is somewhat like glucose, which was discussed earlier. It is a more polar substance.

**Related Exercises:** 13.7, 13.44

**▲ Figure 13.13 Vitamins A and C.** (a) The molecular structure of vitamin A, a fat-soluble vitamin. The molecule is composed largely of carbon-carbon and carbon-hydrogen bonds, so it is nearly nonpolar. (b) The molecular structure of vitamin C, a water-soluble vitamin. Notice the OH groups and the other oxygen atoms in the molecule, which can interact with water molecules by hydrogen bonding.

Examination of different combinations of solvents and solutes such as those considered in the preceding paragraphs has led to an important generalization: *Substances with similar intermolecular attractive forces tend to be soluble in one another.* This generalization is often simply stated as “like dissolves like.” Nonpolar substances are more likely to be soluble in nonpolar solvents; ionic and polar solutes are more likely to be soluble in polar solvents. Network solids such as diamond and quartz are not soluble in either polar or nonpolar solvents because of the strong bonding forces within the solid.

### GIVE IT SOME THOUGHT

Suppose the hydrogens on the OH groups in glucose (Figure 13.12) were replaced with methyl groups,  $\text{CH}_3$ . Would you expect the water solubility of the resulting molecule to be higher than, lower than, or about the same as the solubility of glucose?

**SAMPLE EXERCISE 13.2** | Predicting Solubility Patterns

Predict whether each of the following substances is more likely to dissolve in the nonpolar solvent carbon tetrachloride ( $\text{CCl}_4$ ) or in water:  $\text{C}_7\text{H}_{16}$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{HCl}$ , and  $\text{I}_2$ .

**SOLUTION**

**Analyze:** We are given two solvents, one that is nonpolar ( $\text{CCl}_4$ ) and the other that is polar ( $\text{H}_2\text{O}$ ), and asked to determine which will be the best solvent for each solute listed.

**Plan:** By examining the formulas of the solutes, we can predict whether they are ionic or molecular. For those that are molecular, we can predict whether they are polar or nonpolar. We can then apply the idea that the nonpolar solvent will be best for the nonpolar solutes, whereas the polar solvent will be best for the ionic and polar solutes.

**Solve:**  $\text{C}_7\text{H}_{16}$  is a hydrocarbon, so it is molecular and nonpolar.  $\text{Na}_2\text{SO}_4$ , a compound containing a metal and nonmetals, is ionic.  $\text{HCl}$ , a diatomic molecule containing two nonmetals that differ in electronegativity, is polar.  $\text{I}_2$ , a diatomic molecule with atoms of equal electronegativity, is nonpolar. We would therefore predict that  $\text{C}_7\text{H}_{16}$  and  $\text{I}_2$  (the nonpolar solutes) would be more soluble in the nonpolar  $\text{CCl}_4$  than in polar  $\text{H}_2\text{O}$ , whereas water would be the better solvent for  $\text{Na}_2\text{SO}_4$  and  $\text{HCl}$  (the ionic and polar covalent solutes).

**PRACTICE EXERCISE**

Arrange the following substances in order of increasing solubility in water:

**Answer:**  $\text{C}_5\text{H}_{12} < \text{C}_5\text{H}_{11}\text{Cl} < \text{C}_5\text{H}_{11}\text{OH} < \text{C}_5\text{H}_{10}(\text{OH})_2$  (in order of increasing polarity and hydrogen-bonding ability)

**Pressure Effects**

The solubilities of solids and liquids are not appreciably affected by pressure, whereas the solubility of a gas in any solvent is increased as the pressure over the solvent increases. We can understand the effect of pressure on the solubility of a gas by considering the dynamic equilibrium illustrated in Figure 13.14. Suppose that we have a gaseous substance distributed between the gas and solution phases. When equilibrium is established, the rate at which gas molecules enter the solution equals the rate at which solute molecules escape from the solution to enter the gas phase. The small arrows in Figure 13.14(a) represent the rates of these opposing processes. Now suppose that we exert added pressure on the piston and compress the gas above the solution, as shown in Figure 13.14(b). If we reduced the volume to half its original value, the pressure of the gas would increase to about twice its original value. The rate at which gas molecules strike the surface to enter the solution phase would therefore increase. As a result, the solubility of the gas in the solution would increase until equilibrium is again established; that is, solubility increases until the rate at which gas molecules enter the solution equals the rate at which solute molecules escape from the solution. Thus, *the solubility of the gas increases in direct proportion to its partial pressure above the solution.*

(a)

(b)

**▲ Figure 13.14 Effect of pressure on gas solubility.** When the pressure is increased, as in (b), the rate at which gas molecules enter the solution increases. The concentration of solute molecules at equilibrium increases in proportion to the pressure.

▲ **Figure 13.15 Solubility decreases as pressure decreases.** CO<sub>2</sub> bubbles out of solution when a carbonated beverage is opened, because the CO<sub>2</sub> partial pressure above the solution is reduced.

The relationship between pressure and the solubility of a gas is expressed by a simple equation known as **Henry's law**:

$$S_g = kP_g \quad [13.4]$$

Here,  $S_g$  is the solubility of the gas in the solution phase (usually expressed as molarity),  $P_g$  is the partial pressure of the gas over the solution, and  $k$  is a proportionality constant known as the *Henry's law constant*. The Henry's law constant is different for each solute–solvent pair. It also varies with temperature. As an example, the solubility of N<sub>2</sub> gas in water at 25 °C and 0.78 atm pressure is  $5.3 \times 10^{-4} M$ . The Henry's law constant for N<sub>2</sub> in water at 25 °C is thus given by  $(5.3 \times 10^{-4} \text{ mol/L})/0.78 \text{ atm} = 6.8 \times 10^{-4} \text{ mol/L}\cdot\text{atm}$ . If the partial pressure of N<sub>2</sub> is doubled, Henry's law predicts that the solubility in water at 25 °C will also double, to  $1.36 \times 10^{-3} M$ .

Bottlers use the effect of pressure on solubility in producing carbonated beverages such as beer and many soft drinks. These are bottled under a carbon dioxide pressure greater than 1 atm. When the bottles are opened to the air, the partial pressure of CO<sub>2</sub> above the solution decreases. Hence, the solubility of CO<sub>2</sub> decreases, and CO<sub>2</sub>(g) escapes from the solution as bubbles (Figure 13.15 ◀).

### ■ SAMPLE EXERCISE 13.3 | A Henry's Law Calculation

Calculate the concentration of CO<sub>2</sub> in a soft drink that is bottled with a partial pressure of CO<sub>2</sub> of 4.0 atm over the liquid at 25 °C. The Henry's law constant for CO<sub>2</sub> in water at this temperature is  $3.1 \times 10^{-2} \text{ mol/L}\cdot\text{atm}$ .

#### SOLUTION

**Analyze:** We are given the partial pressure of CO<sub>2</sub>,  $P_{\text{CO}_2}$ , and the Henry's law constant,  $k$ , and asked to calculate the concentration of CO<sub>2</sub> in the solution.

**Plan:** With the information given, we can use Henry's law, Equation 13.4, to calculate the solubility,  $S_{\text{CO}_2}$ .

## Chemistry and Life

### BLOOD GASES AND DEEP-SEA DIVING

Because the solubility of gases increases with increasing pressure, divers who breathe compressed air (Figure 13.16 ▶) must be concerned about the solubility of gases in their blood. Although the gases are not very soluble at sea level, their solubilities can become appreciable at deep levels where their partial pressures are greater. Thus, deep-sea divers must ascend slowly to prevent dissolved gases from being released rapidly from blood and other fluids in the body. These bubbles affect nerve impulses and give rise to the affliction known as decompression sickness, or “the bends,” which is painful and potentially fatal. Nitrogen is the main problem because it has the highest partial pressure in air and because it can be removed only through the respiratory system. Oxygen, in contrast, is consumed in metabolism.

Deep-sea divers sometimes substitute helium for nitrogen in the air that they breathe, because helium has a much lower solubility in biological fluids than N<sub>2</sub>. For example, divers working at a depth of 100 ft experience a pressure of about 4 atm. At this pressure a mixture of 95% helium and 5% oxygen will give an oxygen partial pressure of about 0.2 atm, which is the partial pressure of oxygen in normal air at 1 atm. If the oxygen partial pressure becomes too great, the urge to breathe is reduced, CO<sub>2</sub> is not removed from the body, and

CO<sub>2</sub> poisoning occurs. At excessive concentrations in the body, carbon dioxide acts as a neurotoxin, interfering with nerve conduction and transmission.

**Related Exercises:** 13.55, 13.56, 13.105

▲ **Figure 13.16 Solubility increases as pressure increases.** Divers who use compressed gases must be concerned about the solubility of the gases in their blood. Doug Perrine/PacificStock.com

**Solve:**  $S_{\text{CO}_2} = kP_{\text{CO}_2} = (3.1 \times 10^{-2} \text{ mol/L}\cdot\text{atm})(4.0 \text{ atm}) = 0.12 \text{ mol/L} = 0.12 \text{ M}$

**Check:** The units are correct for solubility, and the answer has two significant figures consistent with both the partial pressure of  $\text{CO}_2$  and the value of Henry's constant.

### PRACTICE EXERCISE

Calculate the concentration of  $\text{CO}_2$  in a soft drink after the bottle is opened and equilibrates at  $25^\circ\text{C}$  under a  $\text{CO}_2$  partial pressure of  $3.0 \times 10^{-4} \text{ atm}$ .

**Answer:**  $9.3 \times 10^{-6} \text{ M}$

## Temperature Effects

The solubility of most solid solutes in water increases as the temperature of the solution increases. Figure 13.17  $\blacktriangledown$  shows this effect for several ionic substances in water. There are exceptions to this rule, however, as seen for  $\text{Ce}_2(\text{SO}_4)_3$ , whose solubility curve slopes downward with increasing temperature.

In contrast to solid solutes, the solubility of gases in water decreases with increasing temperature (Figure 13.18  $\blacktriangledown$ ). If a glass of cold tap water is warmed, you can see bubbles of air on the inside of the glass. Similarly, carbonated beverages go flat as they are allowed to warm. As the temperature of the solution increases, the solubility of  $\text{CO}_2$  decreases, and  $\text{CO}_2(\text{g})$  escapes from the solution.

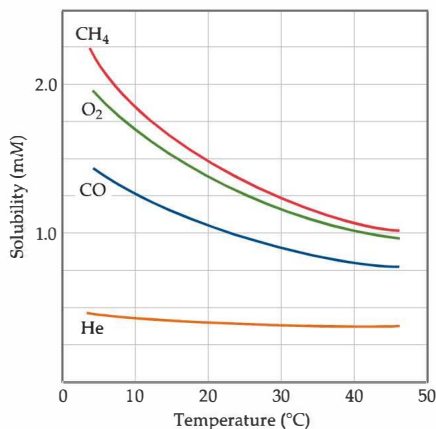

The decreased solubility of  $\text{O}_2$  in water as temperature increases is one of the effects of thermal pollution of lakes and streams. The effect is particularly serious in deep lakes because warm water is less dense than cold water. It therefore tends to remain on top of cold water, at the surface. This situation impedes the dissolving of oxygen into the deeper layers, thus stifling the respiration of all aquatic life needing oxygen. Fish may suffocate and die under these conditions.

### GIVE IT SOME THOUGHT

Why do bubbles form on the inside wall of a cooking pot when water is heated on the stove, even though the temperature is well below the boiling point of water?

$\blacktriangle$  **Figure 13.17** Solubilities of several ionic compounds in water as a function of temperature.

$\blacktriangle$  **Figure 13.18** Variation of gas solubility with temperature. Note that solubilities are in units of millimoles per liter (mmol/L), for a constant total pressure of 1 atm in the gas phase.

## 13.4 WAYS OF EXPRESSING CONCENTRATION

The concentration of a solution can be expressed either qualitatively or quantitatively. The terms *dilute* and *concentrated* are used to describe a solution qualitatively. A solution with a relatively small concentration of solute is said to be *dilute*; one with a large concentration is said to be *concentrated*. We use several different ways to express concentration in quantitative terms, and we examine four of these in this section: mass percentage, mole fraction, molarity, and molality.

### Mass Percentage, ppm, and ppb

One of the simplest quantitative expressions of concentration is the **mass percentage** of a component in a solution, given by

$$\text{Mass \% of component} = \frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 100 \quad [13.5]$$

where we have abbreviated "solution" as "soln." Percent means per hundred. Thus, a solution of hydrochloric acid that is 36% HCl by mass contains 36 g of HCl for each 100 g of solution.

We often express the concentrations of very dilute solution in **parts per million (ppm)**, or parts per billion (ppb). These quantities are similar to mass percentage but use  $10^6$  (a million) or  $10^9$  (a billion), respectively, in place of 100 as a multiplier for the ratio of the mass of solute to the mass of solution. Thus, parts per million is defined as

$$\text{ppm of component} = \frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 10^6 \quad [13.6]$$

A solution whose solute concentration is 1 ppm contains 1 g of solute for each million ( $10^6$ ) grams of solution or, equivalently, 1 mg of solute per kilogram of solution. Because the density of water is 1 g/mL, 1 kg of a dilute aqueous solution will have a volume very close to 1 L. Thus, 1 ppm also corresponds to 1 mg of solute per liter of aqueous solution.

The acceptable maximum concentrations of toxic or carcinogenic substances in the environment are often expressed in ppm or ppb. For example, the maximum allowable concentration of arsenic in drinking water in the United States is 0.010 ppm; that is, 0.010 mg of arsenic per liter of water. This concentration corresponds to 10 ppb.

### GIVE IT SOME THOUGHT

A solution of  $\text{SO}_2$  in water contains 0.00023 g of  $\text{SO}_2$  per liter of solution. What is the concentration of  $\text{SO}_2$  in ppm? In ppb?

### SAMPLE EXERCISE 13.4 | Calculation of Mass-Related Concentrations

(a) A solution is made by dissolving 13.5 g of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in 0.100 kg of water. What is the mass percentage of solute in this solution? (b) A 2.5-g sample of groundwater was found to contain  $5.4 \mu\text{g}$  of  $\text{Zn}^{2+}$ . What is the concentration of  $\text{Zn}^{2+}$  in parts per million?

#### SOLUTION

**(a) Analyze:** We are given the number of grams of solute (13.5 g) and the number of grams of solvent (0.100 kg = 100 g). From this we must calculate the mass percentage of solute.

**Plan:** We can calculate the mass percentage by using Equation 13.5. The mass of the solution is the sum of the mass of solute (glucose) and the mass of solvent (water).

$$\text{Solve: Mass \% of glucose} = \frac{\text{mass glucose}}{\text{mass soln}} \times 100 = \frac{13.5 \text{ g}}{13.5 \text{ g} + 100 \text{ g}} \times 100 = 11.9\%$$

**Comment:** The mass percentage of water in this solution is  $(100 - 11.9)\% = 88.1\%$ .

**(b) Analyze:** In this case we are given the number of micrograms of solute. Because  $1 \mu\text{g}$  is  $1 \times 10^{-6} \text{ g}$ ,  $5.4 \mu\text{g} = 5.4 \times 10^{-6} \text{ g}$ .

**Plan:** We calculate the parts per million using Equation 13.6.

$$\text{Solve: ppm} = \frac{\text{mass of solute}}{\text{mass of soln}} \times 10^6 = \frac{5.4 \times 10^{-6} \text{ g}}{2.5 \text{ g}} \times 10^6 = 2.2 \text{ ppm}$$

### ■ PRACTICE EXERCISE

(a) Calculate the mass percentage of NaCl in a solution containing 1.50 g of NaCl in 50.0 g of water. (b) A commercial bleaching solution contains 3.62 mass % sodium hypochlorite, NaOCl. What is the mass of NaOCl in a bottle containing 2.50 kg of bleaching solution?

**Answers:** (a) 2.91%, (b) 90.5 g of NaOCl

## Mole Fraction, Molarity, and Molality

Concentration expressions are often based on the number of moles of one or more components of the solution. The three most commonly used are mole fraction, molarity, and molality.

Recall from Section 10.6 that the *mole fraction* of a component of a solution is given by

$$\text{Mole fraction of component} = \frac{\text{moles of component}}{\text{total moles of all components}} \quad [13.7]$$

The symbol  $X$  is commonly used for mole fraction, with a subscript to indicate the component of interest. For example, the mole fraction of HCl in a hydrochloric acid solution is represented as  $X_{\text{HCl}}$ . Thus, a solution containing 1.00 mol of HCl (36.5 g) and 8.00 mol of water (144 g) has a mole fraction of HCl of  $X_{\text{HCl}} = (1.00 \text{ mol}) / (1.00 \text{ mol} + 8.00 \text{ mol}) = 0.111$ . Mole fractions have no units because the units in the numerator and the denominator cancel. The sum of the mole fractions of all components of a solution must equal 1. Thus, in the aqueous HCl solution,  $X_{\text{H}_2\text{O}} = 1.000 - 0.111 = 0.889$ . Mole fractions are very useful when dealing with gases as we saw in Section 10.6 but have limited use when dealing with liquid solutions.

Recall from Section 4.5 that the *molarity* ( $M$ ) of a solute in a solution is defined as

$$\text{Molarity} = \frac{\text{moles solute}}{\text{liters soln}} \quad [13.8]$$

For example, if you dissolve 0.500 mol of  $\text{Na}_2\text{CO}_3$  in enough water to form 0.250 L of solution, then the solution has a concentration of  $(0.500 \text{ mol}) / (0.250 \text{ L}) = 2.00 \text{ M}$  in  $\text{Na}_2\text{CO}_3$ . Molarity is especially useful for relating the volume of a solution to the quantity of solute it contains, as we saw in our discussions of titrations. [↔ \(Section 4.6\)](#)

The **molality** of a solution, denoted  $m$ , is a unit that we have not encountered in previous chapters. This concentration unit equals the number of moles of solute per kilogram of solvent:

$$\text{Molality} = \frac{\text{moles of solute}}{\text{kilograms of solvent}} \quad [13.9]$$

Thus, if you form a solution by mixing 0.200 mol of NaOH (8.00 g) and 0.500 kg of water (500 g), the concentration of the solution is  $(0.200 \text{ mol}) / (0.500 \text{ kg}) = 0.400 \text{ m}$  (that is, 0.400 molal) in NaOH.

The definitions of molarity and molality are similar enough that they can be easily confused. Molarity depends on the *volume of solution*, whereas molality depends on the *mass of solvent*. When water is the solvent, the molality and molarity of dilute solutions are numerically about the same because 1 kg of solvent is nearly the same as 1 kg of solution, and 1 kg of the solution has a volume of about 1 L.

The molality of a given solution does not vary with temperature because masses do not vary with temperature. Molarity, however, changes with temperature because the expansion or contraction of the solution changes its volume. Thus molality is often the concentration unit of choice when a solution is to be used over a range of temperatures.

### GIVE IT SOME THOUGHT

If an aqueous solution is very dilute, will the molality of the solution be (a) greater than its molarity, (b) nearly the same as its molarity, or (c) smaller than its molarity?

#### SAMPLE EXERCISE 13.5 | Calculation of Molality

A solution is made by dissolving 4.35 g glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in 25.0 mL of water at 25 °C. Calculate the molality of glucose in the solution. Water has a density of 1.00 g/mL.

#### SOLUTION

**Analyze:** We are asked to calculate a molality. To do this, we must determine the number of moles of solute (glucose) and the number of kilograms of solvent (water).

**Plan:** We use the molar mass of  $\text{C}_6\text{H}_{12}\text{O}_6$  to convert grams to moles. We use the density of water to convert milliliters to kilograms. The molality equals the number of moles of solute divided by the number of kilograms of solvent (Equation 13.9).

**Solve:** Use the molar mass of glucose, 180.2 g/mol, to convert grams to moles:

$$\text{Mol C}_6\text{H}_{12}\text{O}_6 = (4.35 \text{ g C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.2 \text{ g C}_6\text{H}_{12}\text{O}_6} \right) = 0.0241 \text{ mol C}_6\text{H}_{12}\text{O}_6$$

Because water has a density of 1.00 g/mL, the mass of the solvent is

$$(25.0 \text{ mL})(1.00 \text{ g/mL}) = 25.0 \text{ g} = 0.0250 \text{ kg}$$

Finally, use Equation 13.9 to obtain the molality:

$$\text{Molality of C}_6\text{H}_{12}\text{O}_6 = \frac{0.0241 \text{ mol C}_6\text{H}_{12}\text{O}_6}{0.0250 \text{ kg H}_2\text{O}} = 0.964 \text{ m}$$

#### PRACTICE EXERCISE

What is the molality of a solution made by dissolving 36.5 g of naphthalene ( $\text{C}_{10}\text{H}_8$ ) in 425 g of toluene ( $\text{C}_7\text{H}_8$ )?

**Answer:** 0.670 m

## Conversion of Concentration Units

Sometimes the concentration of a given solution needs to be known in several different concentration units. It is possible to interconvert concentration units as shown in Sample Exercises 13.6 and 13.7.

#### SAMPLE EXERCISE 13.6 | Calculation of Mole Fraction and Molality

An aqueous solution of hydrochloric acid contains 36% HCl by mass. (a) Calculate the mole fraction of HCl in the solution. (b) Calculate the molality of HCl in the solution.

#### SOLUTION

**Analyze:** We are asked to calculate the concentration of the solute, HCl, in two related concentration units, given only the percentage by mass of the solute in the solution.

**Plan:** In converting concentration units based on the mass or moles of solute and solvent (mass percentage, mole fraction, and molality), it is useful to assume a certain total mass of solution. Let's assume that there is exactly 100 g of solution. Because the solution is 36% HCl, it contains 36 g of HCl and  $(100 - 36) \text{ g} = 64 \text{ g}$  of  $\text{H}_2\text{O}$ . We must convert grams of solute (HCl) to moles to calculate either mole fraction or molality. We must convert grams of solvent ( $\text{H}_2\text{O}$ ) to moles to calculate mole fractions, and to kilograms to calculate molality.

**Solve:** (a) To calculate the mole fraction of HCl, we convert the masses of HCl and  $\text{H}_2\text{O}$  to moles and then use Equation 13.7:

$$\text{Moles HCl} = (36 \text{ g HCl}) \left( \frac{1 \text{ mol HCl}}{36.5 \text{ g HCl}} \right) = 0.99 \text{ mol HCl}$$

$$\text{Moles H}_2\text{O} = (64 \text{ g H}_2\text{O}) \left( \frac{1 \text{ mol H}_2\text{O}}{18 \text{ g H}_2\text{O}} \right) = 3.6 \text{ mol H}_2\text{O}$$

$$X_{\text{HCl}} = \frac{\text{moles HCl}}{\text{moles H}_2\text{O} + \text{moles HCl}} = \frac{0.99}{3.6 + 0.99} = \frac{0.99}{4.6} = 0.22$$

(b) To calculate the molality of HCl in the solution, we use Equation 13.9. We calculated the number of moles of HCl in part (a), and the mass of solvent is  $64 \text{ g} = 0.064 \text{ kg}$ :

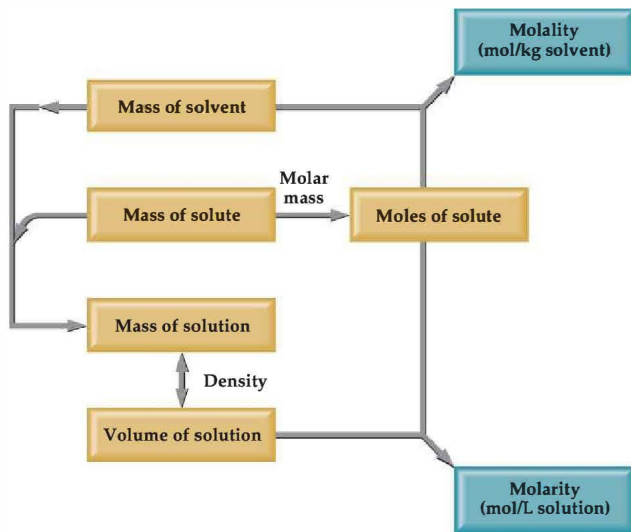

$$\text{Molality of HCl} = \frac{0.99 \text{ mol HCl}}{0.064 \text{ kg H}_2\text{O}} = 15 \text{ m}$$

### PRACTICE EXERCISE

A commercial bleach solution contains 3.62 mass % NaOCl in water. Calculate (a) the mole fraction and (b) the molality of NaOCl in the solution.

**Answers:** (a)  $9.00 \times 10^{-3}$ , (b) 0.505 m.

To interconvert molality and molarity, we need to know the density of the solution. Figure 13.19 outlines the calculation of the molarity and molality of a solution from the mass of solute and the mass of solvent. The mass of the solution is the sum of masses of the solvent and solute. The volume of the solution can be calculated from its mass and density.

**▲ Figure 13.19 Calculating molality and molarity.** This diagram summarizes the calculation of molality and molarity from the mass of the solute, the mass of the solvent, and the density of the solution.

**SAMPLE EXERCISE 13.7** | Calculation of Molarity Using the Density of the Solution

A solution with a density of 0.876 g/mL contains 5.0 g of toluene ( $C_7H_8$ ) and 225 g of benzene. Calculate the molarity of the solution.

**SOLUTION**

**Analyze:** Our goal is to calculate the molarity of a solution, given the masses of solute (5.0 g) and solvent (225 g) and the density of the solution (0.876 g/mL).

**Plan:** The molarity of a solution is the number of moles of solute divided by the number of liters of solution (Equation 13.8). The number of moles of solute ( $C_7H_8$ ) is calculated from the number of grams of solute and its molar mass. The volume of the solution is obtained from the mass of the solution (mass of solute + mass of solvent = 5.0 g + 225 g = 230 g) and its density.

**Solve:** The number of moles of solute is 
$$\text{Moles } C_7H_8 = (5.0 \text{ g } C_7H_8) \left( \frac{1 \text{ mol } C_7H_8}{92 \text{ g } C_7H_8} \right) = 0.054 \text{ mol}$$

The density of the solution is used to convert the mass of the solution to its volume:

$$\text{Milliliters soln} = (230 \text{ g}) \left( \frac{1 \text{ mL}}{0.876 \text{ g}} \right) = 263 \text{ mL}$$

Molarity is moles of solute per liter of solution:

$$\text{Molarity} = \left( \frac{\text{moles } C_7H_8}{\text{liter soln}} \right) = \left( \frac{0.054 \text{ mol } C_7H_8}{263 \text{ mL soln}} \right) \left( \frac{1000 \text{ mL soln}}{1 \text{ L soln}} \right) = 0.21 \text{ M}$$

**Check:** The magnitude of our answer is reasonable. Rounding moles to 0.05 and liters to 0.25 gives a molarity of

$$(0.05 \text{ mol}) / (0.25 \text{ L}) = 0.2 \text{ M}$$

The units for our answer (mol/L) are correct, and the answer, 0.21 M, has two significant figures, corresponding to the number of significant figures in the mass of solute (2).

**Comment:** Because the mass of the solvent (0.225 kg) and the volume of the solution (0.263 L) are similar in magnitude, the molarity and molality are also similar in magnitude:

$$(0.054 \text{ mol } C_7H_8) / (0.225 \text{ kg solvent}) = 0.24 \text{ m}$$

**PRACTICE EXERCISE**

A solution containing equal masses of glycerol ( $C_3H_8O_3$ ) and water has a density of 1.10 g/mL. Calculate (a) the molality of glycerol, (b) the mole fraction of glycerol, (c) the molarity of glycerol in the solution.

**Answers:** (a) 10.9 m, (b)  $X_{C_3H_8O_3} = 0.163$ , (c) 5.97 M

## 13.5 COLLIGATIVE PROPERTIES

Some physical properties of solutions differ in important ways from those of the pure solvent. For example, pure water freezes at 0 °C, but aqueous solutions freeze at lower temperatures. Ethylene glycol is added to the water in radiators of cars as an antifreeze to lower the freezing point of the solution. It also raises the boiling point of the solution above that of pure water, making it possible to operate the engine at a higher temperature.

The lowering of the freezing point and the raising of the boiling point are physical properties of solutions that depend on the *quantity* (concentration) but not the *kind* or *identity* of the solute particles. Such properties are called **colligative properties**. (*Colligative* means “depending on the collection”; colligative properties depend on the collective effect of the number of solute particles.) In addition to the decrease in freezing point and the increase in boiling point, vapor-pressure reduction and osmotic pressure are colligative properties. As we examine each of these, notice how the concentration of the solute affects the property relative to that of the pure solvent.

### Lowering the Vapor Pressure

We learned in Section 11.5 that a liquid in a closed container will establish equilibrium with its vapor. When that equilibrium is reached, the pressure exerted by the vapor is called the *vapor pressure*. A substance that has no measurable vapor pressure is *nonvolatile*, whereas one that exhibits a vapor pressure is *volatile*.

When we compare the vapor pressures of various solvents with those of their solutions, we find that adding a nonvolatile solute to a solvent always lowers the vapor pressure. This effect is illustrated in Figure 13.20. The extent to which a nonvolatile solute lowers the vapor pressure is proportional to its concentration. This relationship is expressed by **Raoult's law**, which states that the partial pressure exerted by solvent vapor above a solution,  $P_A$ , equals the product of the mole fraction of the solvent in the solution,  $X_A$ , times the vapor pressure of the pure solvent,  $P_A^\circ$ :

$$P_A = X_A P_A^\circ \quad [13.10]$$

For example, the vapor pressure of water is 17.5 torr at 20 °C. Imagine holding the temperature constant while adding glucose ( $C_6H_{12}O_6$ ) to the water so that the resulting solution has  $X_{H_2O} = 0.800$  and  $X_{C_6H_{12}O_6} = 0.200$ . According to Equation 13.10, the vapor pressure of water over the solution will be 80.0% of that of pure water:

$$P_{H_2O} = (0.800)(17.5 \text{ torr}) = 14.0 \text{ torr}$$

In other words, the presence of the nonvolatile solute lowers the vapor pressure of the volatile solvent by  $17.5 \text{ torr} - 14.0 \text{ torr} = 3.5 \text{ torr}$ .

Raoult's law predicts that when we increase the mole fraction of nonvolatile solute particles in a solution, the vapor pressure over the solution will be reduced. In fact, the reduction in vapor pressure depends on the total concentration of solute particles, regardless of whether they are molecules or ions. Remember that vapor-pressure lowering is a colligative property, so it depends on the concentration of solute particles and not on their kind.

**▲ Figure 13.20 Vapor-pressure lowering.** The vapor pressure over a solution formed by a volatile solvent and a nonvolatile solute (b) is lower than that of the solvent alone (a). The extent of the decrease in the vapor pressure upon addition of the solute depends on the concentration of the solute.

### GIVE IT SOME THOUGHT

Adding 1 mol of NaCl to 1 kg of water reduces the vapor pressure of water more than adding 1 mol of  $C_6H_{12}O_6$ . Explain.

### SAMPLE EXERCISE 13.8 | Calculation of Vapor-Pressure Lowering

Glycerin ( $C_3H_8O_3$ ) is a nonvolatile nonelectrolyte with a density of 1.26 g/mL at 25 °C. Calculate the vapor pressure at 25 °C of a solution made by adding 50.0 mL of glycerin to 500.0 mL of water. The vapor pressure of pure water at 25 °C is 23.8 torr (Appendix B), and its density is 1.00 g/mL.

#### SOLUTION

**Analyze:** Our goal is to calculate the vapor pressure of a solution, given the volumes of solute and solvent and the density of the solute.

**Plan:** We can use Raoult's law (Equation 13.10) to calculate the vapor pressure of a solution. The mole fraction of the solvent in the solution,  $X_A$ , is the ratio of the number of moles of solvent ( $H_2O$ ) to total moles of solution (moles  $C_3H_8O_3$  + moles  $H_2O$ ).

**Solve:** To calculate the mole fraction of water in the solution, we must determine the number of moles of  $C_3H_8O_3$  and  $H_2O$ :

$$\text{Moles } C_3H_8O_3 = (50.0 \text{ mL } C_3H_8O_3) \left( \frac{1.26 \text{ g } C_3H_8O_3}{1 \text{ mL } C_3H_8O_3} \right) \left( \frac{1 \text{ mol } C_3H_8O_3}{92.1 \text{ g } C_3H_8O_3} \right) = 0.684 \text{ mol}$$

$$\text{Moles } H_2O = (500.0 \text{ mL } H_2O) \left( \frac{1.00 \text{ g } H_2O}{1 \text{ mL } H_2O} \right) \left( \frac{1 \text{ mol } H_2O}{18.0 \text{ g } H_2O} \right) = 27.8 \text{ mol}$$

$$X_{H_2O} = \frac{\text{mol } H_2O}{\text{mol } H_2O + \text{mol } C_3H_8O_3} = \frac{27.8}{27.8 + 0.684} = 0.976$$

We now use Raoult's law to calculate the vapor pressure of water for the solution:

$$P_{H_2O} = X_{H_2O} P_{H_2O}^\circ = (0.976)(23.8 \text{ torr}) = 23.2 \text{ torr}$$

The vapor pressure of the solution has been lowered by 0.6 torr relative to that of pure water.

#### PRACTICE EXERCISE

The vapor pressure of pure water at 110 °C is 1070 torr. A solution of ethylene glycol and water has a vapor pressure of 1.00 atm at 110 °C. Assuming that Raoult's law is obeyed, what is the mole fraction of ethylene glycol in the solution?

**Answer:** 0.290

An ideal gas obeys the ideal-gas equation (Section 10.4), and an **ideal solution** obeys Raoult's law. Real solutions best approximate ideal behavior when the solute concentration is low and when the solute and solvent have similar molecular sizes and similar types of intermolecular attractions.

Many solutions do not obey Raoult's law exactly: They are not ideal solutions. If the intermolecular forces between solvent and solute are weaker than those between solvent and solvent and between solute and solute, then the vapor pressure tends to be greater than predicted by Raoult's law. Conversely, when the interactions between solute and solvent are exceptionally strong, as might be the case when hydrogen bonding exists, the vapor pressure is lower than Raoult's law predicts. Although you should be aware that these departures from ideal solution occur, we will ignore them for the remainder of this chapter.

### GIVE IT SOME THOUGHT

In Raoult's law,  $P_A = X_A P_A^\circ$ , what are the meanings of  $P_A$  and  $P_A^\circ$ ?

## A Closer Look

### IDEAL SOLUTIONS WITH TWO OR MORE VOLATILE COMPONENTS

**S**olutions sometimes have two or more volatile components. Gasoline, for example, is a complex solution containing several volatile substances. To gain some understanding of such mixtures, consider an ideal solution containing two components, A and B. The partial pressures of A and B vapors above the solution are given by Raoult's law:

$$P_A = X_A P_A^\circ \quad \text{and} \quad P_B = X_B P_B^\circ$$

The total vapor pressure over the solution is the sum of the partial pressures of each volatile component:

$$P_{\text{total}} = P_A + P_B = X_A P_A^\circ + X_B P_B^\circ$$

Consider, for example, a mixture of benzene ( $C_6H_6$ ) and toluene ( $C_7H_8$ ) containing 1.0 mol of benzene and 2.0 mol of toluene ( $X_{\text{ben}} = 0.33$  and  $X_{\text{tol}} = 0.67$ ). At 20 °C the vapor pressures of the pure substances are

$$\text{Benzene: } P_{\text{ben}}^\circ = 75 \text{ torr}$$

$$\text{Toluene: } P_{\text{tol}}^\circ = 22 \text{ torr}$$

Thus, the partial pressures of benzene and toluene above the solution are

$$P_{\text{ben}} = (0.33)(75 \text{ torr}) = 25 \text{ torr}$$

$$P_{\text{tol}} = (0.67)(22 \text{ torr}) = 15 \text{ torr}$$

The total vapor pressure is

$$P_{\text{total}} = 25 \text{ torr} + 15 \text{ torr} = 40 \text{ torr}$$

The vapor, therefore, is richer in benzene, the more volatile component. The mole fraction of benzene in the vapor is given by the ratio of its vapor pressure to the total pressure (Equation 10.15):

$$X_{\text{ben in vapor}} = \frac{P_{\text{ben}}}{P_{\text{total}}} = \frac{25 \text{ torr}}{40 \text{ torr}} = 0.63$$

Although benzene constitutes only 33% of the molecules in the solution, it makes up 63% of the molecules in the vapor.

When ideal solutions are in equilibrium with their vapor, the more volatile component of the mixture will be relatively

richer in the vapor. This fact forms the basis of *distillation*, a technique used to separate (or partially separate) mixtures containing volatile components. Distillation is the procedure by which a moonshiner obtains whiskey using a still and by which petrochemical plants achieve the separation of crude petroleum into gasoline, diesel fuel, lubricating oil, and so forth (Figure 13.21). Distillation is also used routinely on a small scale in the laboratory. A specially designed *fractional distillation* apparatus can achieve in a single operation a degree of separation that would be equivalent to several successive simple distillations.

*Related Exercises:* 13.63, 13.64

▲ **Figure 13.21 Separating volatile components.** In an industrial distillation tower, such as the ones shown here, the components of a volatile organic mixture are separated according to boiling-point range.

## Boiling-Point Elevation

In Sections 11.5 and 11.6 we examined the vapor pressures of pure substances and how they can be used to construct phase diagrams. How will the phase diagram of a solution, and hence its boiling and freezing points, differ from those of the pure solvent? The addition of a nonvolatile solute lowers the vapor pressure of the solution. Thus, as shown in Figure 13.22, the vapor-pressure curve of the solution (blue line) will be shifted downward relative to the vapor-pressure curve of the pure liquid (black line); at any given temperature the vapor pressure of the solution is lower than that of the pure liquid. Recall that the normal boiling point of a liquid is the temperature at which its vapor pressure equals 1 atm.  $\infty$  (Section 11.5) At the normal boiling point of the pure liquid, the vapor pressure of the solution will be less than 1 atm (Figure 13.22).

Therefore, a higher temperature is required to attain a vapor pressure of 1 atm. Thus, *the boiling point of the solution is higher than that of the pure liquid.*

The increase in boiling point relative to that of the pure solvent,  $\Delta T_b$ , is a positive quantity obtained by subtracting the boiling point of the pure solvent from the boiling point of the solution. The value of  $\Delta T_b$  is directly proportional to the concentration of the solution expressed by its molality,  $m$ :

$$\Delta T_b = K_b m \quad [13.11]$$

The magnitude of  $K_b$ , which is called the **molal boiling-point-elevation constant**, depends only on the solvent. Some typical values for several common solvents are given in Table 13.4. Because solutions generally do not behave ideally, however, the constants listed in Table 13.4 serve well only for solutions that are not too concentrated.

For water,  $K_b$  is  $0.51\text{ }^\circ\text{C}/m$ ; therefore, a  $1\text{ }m$  aqueous solution of sucrose or any other aqueous solution that is  $1\text{ }m$  in nonvolatile solute particles will boil  $0.51\text{ }^\circ\text{C}$  higher than pure water. The boiling-point elevation is proportional to the concentration of solute particles, regardless of whether the particles are molecules or ions. When NaCl dissolves in water, 2 mol of solute particles (1 mol of  $\text{Na}^+$  and 1 mol of  $\text{Cl}^-$ ) are formed for each mole of NaCl that dissolves. Therefore, a  $1\text{ }m$  aqueous solution of NaCl is  $1\text{ }m$  in  $\text{Na}^+$  and  $1\text{ }m$  in  $\text{Cl}^-$ , making it  $2\text{ }m$  in total solute particles. As a result, the boiling-point elevation of a  $1\text{ }m$  aqueous solution of NaCl is approximately  $(2\text{ }m)(0.51\text{ }^\circ\text{C}/m) = 1\text{ }^\circ\text{C}$ , twice as large as a  $1\text{ }m$  solution of a nonelectrolyte such as sucrose. Thus, to properly predict the effect of a particular solute on the boiling point (or any other colligative property), it is important to know whether the solute is an electrolyte or a nonelectrolyte.  $\infty$  (Sections 4.1 and 4.3)

### GIVE IT SOME THOUGHT

An unknown solute dissolved in water causes the boiling point to increase by  $0.51\text{ }^\circ\text{C}$ . Does this mean that the concentration of the solute is  $1.0\text{ }m$ ?

▲ **Figure 13.22** Phase diagrams for a pure solvent and for a solution of a nonvolatile solute. The vapor pressure of the solid solvent is unaffected by the presence of solute if the solid freezes out without containing a significant concentration of solute, as is usually the case.

**TABLE 13.4** ■ Molal Boiling-Point-Elevation and Freezing-Point-Depression Constants

Solvent	Normal Boiling Point ( $^\circ\text{C}$ )	$K_b$ ( $^\circ\text{C}/m$ )	Normal Freezing Point ( $^\circ\text{C}$ )	$K_f$ ( $^\circ\text{C}/m$ )
Water, $\text{H}_2\text{O}$	100.0	0.51	0.0	1.86
Benzene, $\text{C}_6\text{H}_6$	80.1	2.53	5.5	5.12
Ethanol, $\text{C}_2\text{H}_5\text{OH}$	78.4	1.22	-114.6	1.99
Carbon tetrachloride, $\text{CCl}_4$	76.8	5.02	-22.3	29.8
Chloroform, $\text{CHCl}_3$	61.2	3.63	-63.5	4.68

## Freezing-Point Depression

When a solution freezes, crystals of pure solvent usually separate out; the solute molecules are not normally soluble in the solid phase of the solvent. When aqueous solutions are partially frozen, for example, the solid that separates out is almost always pure ice. As a result, the part of the phase diagram in Figure 13.22 that represents the vapor pressure of the solid is the same as that for the pure liquid. The vapor-pressure curves for the liquid and solid phases meet at the triple point.  $\rightleftharpoons$  (Section 11.6) In Figure 13.22 we see that the triple point of the solution must be at a lower temperature than that in the pure liquid because the solution has a lower vapor pressure than the pure liquid.

The freezing point of a solution is the temperature at which the first crystals of pure solvent begin to form in equilibrium with the solution. Recall from Section 11.6 that the line representing the solid-liquid equilibrium rises nearly vertically from the triple point. Because the triple-point temperature of the solution is lower than that of the pure liquid, *the freezing point of the solution is lower than that of the pure liquid*. The decrease in freezing point,  $\Delta T_f$ , is a positive quantity obtained by subtracting the freezing point of the solution from the freezing point of the pure solvent.

Like the boiling-point elevation,  $\Delta T_f$  is directly proportional to the molality of the solute:

$$\Delta T_f = K_f m \quad [13.12]$$

The values of  $K_f$ , the **molal freezing-point-depression constant**, for several common solvents are given in Table 13.4. For water,  $K_f$  is  $1.86\text{ }^\circ\text{C}/m$ ; therefore, a  $1\text{ }m$  aqueous solution of sucrose or any other aqueous solution that is  $1\text{ }m$  in nonvolatile solute particles (such as  $0.5\text{ }m\text{ NaCl}$ ) will freeze  $1.86\text{ }^\circ\text{C}$  lower than pure water. The freezing-point lowering caused by solutes explains the use of antifreeze in cars and the use of calcium chloride ( $\text{CaCl}_2$ ) to melt ice on roads during winter.

**Antifreeze being added to an automobile radiator.** Antifreeze consists of an aqueous solution of ethylene glycol,  $\text{CH}_2(\text{OH})\text{CH}_2(\text{OH})$ .

### SAMPLE EXERCISE 13.9 Calculation of Boiling-Point Elevation and Freezing-Point Lowering

Automotive antifreeze consists of ethylene glycol,  $\text{CH}_2(\text{OH})\text{CH}_2(\text{OH})$ , a nonvolatile nonelectrolyte. Calculate the boiling point and freezing point of a 25.0 mass % solution of ethylene glycol in water.

#### SOLUTION

**Analyze:** We are given that a solution contains 25.0 mass % of a nonvolatile, nonelectrolyte solute and asked to calculate the boiling and freezing points of the solution. To do this, we need to calculate the boiling-point elevation and freezing-point depression.

**Plan:** To calculate the boiling-point elevation and the freezing-point depression using Equations 13.11 and 12, we must express the concentration of the solution as molality. Let's assume for convenience that we have 1000 g of solution. Because the solution is 25.0 mass % ethylene glycol, the masses of ethylene glycol and water in the solution are 250 and 750 g, respectively. Using these quantities, we can calculate the molality of the solution, which we use with the molal boiling-point-elevation and freezing-point-depression constants (Table 13.4) to calculate  $\Delta T_b$  and  $\Delta T_f$ . We add  $\Delta T_b$  to the boiling point and subtract  $\Delta T_f$  from the freezing point of the solvent to obtain the boiling point and freezing point of the solution.

**Solve:** The molality of the solution is calculated as follows:

$$\begin{aligned} \text{Molality} &= \frac{\text{moles C}_2\text{H}_6\text{O}_2}{\text{kilograms H}_2\text{O}} = \left( \frac{250\text{ g C}_2\text{H}_6\text{O}_2}{750\text{ g H}_2\text{O}} \right) \left( \frac{1\text{ mol C}_2\text{H}_6\text{O}_2}{62.1\text{ g C}_2\text{H}_6\text{O}_2} \right) \left( \frac{1000\text{ g H}_2\text{O}}{1\text{ kg H}_2\text{O}} \right) \\ &= 5.37\text{ }m \end{aligned}$$

We can now use Equations 13.11 and 13.12 to calculate the changes in the boiling and freezing points:

$$\Delta T_b = K_b m = (0.51\text{ }^\circ\text{C}/m)(5.37\text{ }m) = 2.7\text{ }^\circ\text{C}$$

$$\Delta T_f = K_f m = (1.86\text{ }^\circ\text{C}/m)(5.37\text{ }m) = 10.0\text{ }^\circ\text{C}$$

Hence, the boiling and freezing points of the solution are

$$\begin{aligned}\text{Boiling point} &= (\text{normal bp of solvent}) + \Delta T_b \\ &= 100.0\text{ }^\circ\text{C} + 2.7\text{ }^\circ\text{C} = 102.7\text{ }^\circ\text{C}\end{aligned}$$

$$\begin{aligned}\text{Freezing point} &= (\text{normal fp of solvent}) - \Delta T_f \\ &= 0.0\text{ }^\circ\text{C} - 10.0\text{ }^\circ\text{C} = -10.0\text{ }^\circ\text{C}\end{aligned}$$

**Comment:** Notice that the solution is a liquid over a larger temperature range than the pure solvent.

### ■ PRACTICE EXERCISE

Calculate the freezing point of a solution containing 0.600 kg of  $\text{CHCl}_3$  and 42.0 g of eucalyptol ( $\text{C}_{10}\text{H}_{18}\text{O}$ ), a fragrant substance found in the leaves of eucalyptus trees. (See Table 13.4.)

**Answer:**  $-65.6\text{ }^\circ\text{C}$

### ■ SAMPLE EXERCISE 13.10 | Freezing-Point Depression in Aqueous Solutions

List the following aqueous solutions in order of their expected freezing point: 0.050  $m$   $\text{CaCl}_2$ , 0.15  $m$   $\text{NaCl}$ , 0.10  $m$   $\text{HCl}$ , 0.050  $m$   $\text{CH}_3\text{COOH}$ , 0.10  $m$   $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ .

#### SOLUTION

**Analyze:** We must order five aqueous solutions according to expected freezing points, based on molalities and the solute formulas.

**Plan:** The lowest freezing point will correspond to the solution with the greatest concentration of solute particles. To determine the total concentration of solute particles in each case, we must determine whether the substance is a nonelectrolyte or an electrolyte and consider the number of ions formed when an electrolyte ionizes.

**Solve:**  $\text{CaCl}_2$ ,  $\text{NaCl}$ , and  $\text{HCl}$  are strong electrolytes,  $\text{CH}_3\text{COOH}$  (acetic acid) is a weak electrolyte, and  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  is a nonelectrolyte. The molality of each solution in total particles is as follows:

$$0.050\text{ }m\text{ CaCl}_2 \Rightarrow 0.050\text{ }m\text{ in Ca}^{2+}\text{ and }0.10\text{ }m\text{ in Cl}^- \Rightarrow 0.15\text{ }m\text{ in particles}$$

$$0.15\text{ }m\text{ NaCl} \Rightarrow 0.15\text{ }m\text{ Na}^+\text{ and }0.15\text{ }m\text{ in Cl}^- \Rightarrow 0.30\text{ }m\text{ in particles}$$

$$0.10\text{ }m\text{ HCl} \Rightarrow 0.10\text{ }m\text{ H}^+\text{ and }0.10\text{ }m\text{ in Cl}^- \Rightarrow 0.20\text{ }m\text{ in particles}$$

$$0.050\text{ }m\text{ CH}_3\text{COOH} \Rightarrow \text{weak electrolyte} \Rightarrow \text{between }0.050\text{ }m\text{ and }0.10\text{ }m\text{ in particles}$$

$$0.10\text{ }m\text{ C}_{12}\text{H}_{22}\text{O}_{11} \Rightarrow \text{nonelectrolyte} \Rightarrow 0.10\text{ }m\text{ in particles}$$

Because the freezing points depend on the total molality of particles in solution, the expected ordering is 0.15  $m$   $\text{NaCl}$  (lowest freezing point), 0.10  $m$   $\text{HCl}$ , 0.050  $m$   $\text{CaCl}_2$ , 0.10  $m$   $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ , and 0.050  $m$   $\text{CH}_3\text{COOH}$  (highest freezing point).

### ■ PRACTICE EXERCISE

Which of the following solutes will produce the largest increase in boiling point upon addition to 1 kg of water: 1 mol of  $\text{Co}(\text{NO}_3)_2$ , 2 mol of  $\text{KCl}$ , 3 mol of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ )?

**Answer:** 2 mol of  $\text{KCl}$  because it contains the highest concentration of particles, 2  $m$   $\text{K}^+$  and 2  $m$   $\text{Cl}^-$ , giving 4  $m$  in all

## Osmosis

Certain materials, including many membranes in biological systems and synthetic substances such as cellophane, are *semipermeable*. When in contact with a solution, they allow some molecules to pass through their network of tiny pores but not others. Most importantly, semipermeable membranes generally allow small solvent molecules such as water to pass through but block larger solute molecules or ions. This selectivity gives rise to some interesting and important applications.

Consider a situation in which only solvent molecules are able to pass through a membrane. If such a membrane is placed between two solutions of different concentration, solvent molecules move in both directions through the membrane. The concentration of *solvent* is higher in the solution containing less solute, however, so the rate with which solvent passes from the less concentrated (lower solute concentration) to the more concentrated solution (higher solute concentration) is greater than the rate in the opposite direction. Thus, there is a net movement of solvent molecules from the less concentrated solution into the more concentrated one. In this process, called **osmosis**, the *net movement of solvent is always toward the solution with the higher solute concentration*.

Osmosis is illustrated in Figure 13.23. Let's begin with two solutions of different concentration separated by a semipermeable membrane. Because the solution on the left is more concentrated than the one on the right, there is a net movement of *solvent* through the membrane from right to left, as if the solutions

▲ Figure 13.23 Osmosis.

were driven to attain equal concentrations. As a result, the liquid levels in the two arms become unequal. Eventually, the pressure difference resulting from the unequal heights of the liquid in the two arms becomes so large that the net flow of solvent ceases, as shown in the center panel. Alternatively, we may apply pressure to the left arm of the apparatus, as shown in the panel on the right, to halt the net flow of solvent. The pressure required to prevent osmosis by pure solvent is the **osmotic pressure**,  $\Pi$  of the solution. The osmotic pressure obeys a law similar in form to the ideal-gas law,  $\Pi V = nRT$  where  $V$  is the volume of the solution,  $n$  is the number of moles of solute,  $R$  is the ideal-gas constant, and  $T$  is the temperature on the Kelvin scale. From this equation, we can write

$$\Pi = \left(\frac{n}{V}\right)RT = MRT \quad [13.13]$$

where  $M$  is the molarity of the solution.

If two solutions of identical osmotic pressure are separated by a semipermeable membrane, no osmosis will occur. The two solutions are *isotonic*. If one solution is of lower osmotic pressure, it is *hypotonic* with respect to the more concentrated solution. The more concentrated solution is *hypertonic* with respect to the dilute solution.

### GIVE IT SOME THOUGHT

Of two KBr solutions, one 0.5 *m* and the other 0.20 *m*, which is hypotonic with respect to the other?

Osmosis plays a very important role in living systems. The membranes of red blood cells, for example, are semipermeable. Placing a red blood cell in a solution that is *hypertonic* relative to the intracellular solution (the solution within the cells) causes water to move out of the cell, as shown in Figure 13.24(a). This causes the cell to shrivel, a process called *crenation*. Placing the cell in a solution that is *hypotonic* relative to the intracellular fluid causes water to move into the cell, as illustrated in Figure 13.24(b). This may cause the cell to rupture, a process called *hemolysis*.

People who need body fluids or nutrients replaced but cannot be fed orally are given solutions by intravenous (IV) infusion, which feeds nutrients directly into the veins. To prevent crenation or hemolysis of red blood cells, the IV solutions must be isotonic with the intracellular fluids of the cells.

(a) Crenation

(b) Hemolysis

▲ **Figure 13.24 Osmosis through red blood cell wall.** The blue arrows represent the net movement of water molecules.

### SAMPLE EXERCISE 13.11 | Calculations Involving Osmotic Pressure

The average osmotic pressure of blood is 7.7 atm at 25 °C. What molarity of glucose ( $C_6H_{12}O_6$ ) will be isotonic with blood?

#### SOLUTION

**Analyze:** We are asked to calculate the concentration of glucose in water that would be isotonic with blood, given that the osmotic pressure of blood at 25 °C is 7.7 atm.

**Plan:** Because we are given the osmotic pressure and temperature, we can solve for the concentration, using Equation 13.13.

**Solve:**

$$\begin{aligned} \Pi &= MRT \\ M &= \frac{\Pi}{RT} = \frac{7.7 \text{ atm}}{\left(0.0821 \frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(298 \text{ K})} = 0.31 \text{ M} \end{aligned}$$

**Comment:** In clinical situations the concentrations of solutions are generally expressed as mass percentages. The mass percentage of a 0.31 *M* solution of glucose is 5.3%. The concentration of NaCl that is isotonic with blood is 0.16 *M*, because NaCl ionizes to form two particles, Na<sup>+</sup> and Cl<sup>-</sup> (a 0.155 *M* solution of NaCl is 0.310 *M* in particles). A 0.16 *M* solution of NaCl is 0.9 mass % in NaCl. This kind of solution is known as a physiological saline solution.

#### ■ PRACTICE EXERCISE

What is the osmotic pressure at 20 °C of a 0.0020 *M* sucrose (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>) solution?  
**Answer:** 0.048 atm, or 37 torr

## A Closer Look

### COLLIGATIVE PROPERTIES OF ELECTROLYTE SOLUTIONS

The colligative properties of solutions depend on the total concentration of solute particles, regardless of whether the particles are ions or molecules. Thus, we would expect a 0.100 *m* solution of NaCl to have a freezing-point depression of  $(0.200\text{ }m)(1.86\text{ }^{\circ}\text{C}/m) = 0.372\text{ }^{\circ}\text{C}$  because it is 0.100 *m* in Na<sup>+</sup> (*aq*) and 0.100 *m* in Cl<sup>-</sup> (*aq*). The measured freezing-point depression is only 0.348 °C, however, and the situation is similar for other strong electrolytes. A 0.100 *m* solution of KCl, for example, freezes at -0.344 °C.

The difference between the expected and observed colligative properties for strong electrolytes is due to electrostatic attractions between ions. As the ions move about in solution, ions of opposite charge collide and “stick together” for brief moments. While they are together, they behave as a single particle called an *ion pair* (Figure 13.25 ▼). The number of independent particles is thereby reduced, causing a reduction in the freezing-point depression (as well as in the boiling-point elevation, the vapor-pressure reduction, and the osmotic pressure).

▲ **Figure 13.25 Ion pairing and colligative properties.** A solution of NaCl contains not only separated Na<sup>+</sup>(*aq*) and Cl<sup>-</sup>(*aq*) ions but ion pairs as well. Ion pairing becomes more prevalent as the solution concentration increases and has an effect on all the colligative properties of the solution.

One measure of the extent to which electrolytes dissociate is the *van't Hoff factor*, *i*. This factor is the ratio of the actual value of a colligative property to the value calculated, assuming the substance to be a nonelectrolyte. Using the freezing-point depression, for example, we have

$$i = \frac{\Delta T_f (\text{measured})}{\Delta T_f (\text{calculated for nonelectrolyte})} \quad [13.14]$$

The ideal value of *i* can be determined for a salt from the number of ions per formula unit. For NaCl, for example, the ideal van't Hoff factor is 2 because NaCl consists of one Na<sup>+</sup> and one Cl<sup>-</sup> per formula unit; for K<sub>2</sub>SO<sub>4</sub> it is 3 because K<sub>2</sub>SO<sub>4</sub> consists of two K<sup>+</sup> and one SO<sub>4</sub><sup>2-</sup>. In the absence of any information about the actual value of *i* for a solution, we will use the ideal value in calculations.

Table 13.5 ▼ gives the observed van't Hoff factors for several substances at different dilutions. Two trends are evident in these data. First, dilution affects the value of *i* for electrolytes; the more dilute the solution, the more closely *i* approaches the ideal or limiting value. Thus, the extent of ion pairing in electrolyte solutions decreases upon dilution. Second, the lower the charges on the ions, the less *i* departs from the limiting value because the extent of ion pairing decreases as the ionic charges decrease. Both trends are consistent with simple electrostatics: The force of interaction between charged particles decreases as their separation increases and as their charges decrease.

**Related Exercises:** 13.79, 13.80, 13.99, 13.102

TABLE 13.5 ■ van't Hoff Factors for Several Substances at 25 °C

Compound	Concentration			Limiting Value
	0.100 <i>m</i>	0.0100 <i>m</i>	0.00100 <i>m</i>	
Sucrose	1.00	1.00	1.00	1.00
NaCl	1.87	1.94	1.97	2.00
K <sub>2</sub> SO <sub>4</sub>	2.32	2.70	2.84	3.00
MgSO <sub>4</sub>	1.21	1.53	1.82	2.00

There are many interesting biological examples of osmosis. A cucumber placed in concentrated brine loses water via osmosis and shrivels into a pickle. If a carrot that has become limp because of water loss to the atmosphere is placed in water, the water moves into the carrot through osmosis, making it firm once again. People who eat a lot of salty food retain water in tissue cells and intercellular space because of osmosis. The resultant swelling or puffiness is called *edema*. Water moves from soil into plant roots and subsequently into the upper portions of the plant at least in part because of osmosis. Bacteria on salted meat or candied fruit lose water through osmosis, shrivel, and die—thus preserving the food.

The movement of a substance from an area where its concentration is high to an area where it is low is spontaneous. Biological cells transport water and other select materials through their membranes, permitting nutrients to enter and waste materials to exit. In some cases substances must be moved across the cell membrane from an area of low concentration to one of high concentration. This movement—called *active transport*—is not spontaneous, so cells must expend energy to do it.

### GIVE IT SOME THOUGHT

Is the osmotic pressure of a 0.10 *M* solution of NaCl greater than, less than, or equal to that of a 0.10 *M* solution of KBr?

## Determination of Molar Mass

The colligative properties of solutions provide a useful means of experimentally determining molar mass. Any of the four colligative properties can be used, as shown in Sample Exercises 13.12 and 13.13.

### SAMPLE EXERCISE 13.12 | Molar Mass from Freezing-Point Depression

A solution of an unknown nonvolatile nonelectrolyte was prepared by dissolving 0.250 g of the substance in 40.0 g of CCl<sub>4</sub>. The boiling point of the resultant solution was 0.357 °C higher than that of the pure solvent. Calculate the molar mass of the solute.

#### SOLUTION

**Analyze:** Our goal is to calculate the molar mass of a solute based on knowledge of the boiling-point elevation of its solution in CCl<sub>4</sub>,  $\Delta T_b = 0.357$  °C, and the masses of solute and solvent. Table 13.4 gives  $K_b$  for the solvent (CCl<sub>4</sub>),  $K_b = 5.02$  °C/*m*.

**Plan:** We can use Equation 13.11,  $\Delta T_b = K_b m$ , to calculate the molality of the solution. Then we can use molality and the quantity of solvent (40.0 g CCl<sub>4</sub>) to calculate the number of moles of solute. Finally, the molar mass of the solute equals the number of grams per mole, so we divide the number of grams of solute (0.250 g) by the number of moles we have just calculated.

**Solve:** From Equation 13.11 we have

$$\text{Molality} = \frac{\Delta T_b}{K_b} = \frac{0.357\text{ }^\circ\text{C}}{5.02\text{ }^\circ\text{C}/m} = 0.0711\text{ }m$$

Thus, the solution contains 0.0711 mol of solute per kilogram of solvent. The solution was prepared using 40.0 g = 0.0400 kg of solvent (CCl<sub>4</sub>). The number of moles of solute in the solution is therefore

$$(0.0400\text{ kg CCl}_4) \left( 0.0711 \frac{\text{mol solute}}{\text{kg CCl}_4} \right) = 2.84 \times 10^{-3}\text{ mol solute}$$

The molar mass of the solute is the number of grams per mole of the substance:

$$\text{Molar mass} = \frac{0.250\text{ g}}{2.84 \times 10^{-3}\text{ mol}} = 88.0\text{ g/mol}$$

### PRACTICE EXERCISE

Camphor (C<sub>10</sub>H<sub>16</sub>O) melts at 179.8 °C, and it has a particularly large freezing-point-depression constant,  $K_f = 40.0$  °C/*m*. When 0.186 g of an organic substance of unknown molar mass is dissolved in 22.01 g of liquid camphor, the freezing point of the mixture is found to be 176.7 °C. What is the molar mass of the solute?

**Answer:** 110 g/mol

**SAMPLE EXERCISE 13.13** | Molar Mass from Osmotic Pressure

The osmotic pressure of an aqueous solution of a certain protein was measured to determine the protein's molar mass. The solution contained 3.50 mg of protein dissolved in sufficient water to form 5.00 mL of solution. The osmotic pressure of the solution at 25 °C was found to be 1.54 torr. Treating the protein as a nonelectrolyte, calculate its molar mass.

**SOLUTION**

**Analyze:** Our goal is to calculate the molar mass of a high-molecular-mass protein, based on its osmotic pressure and a knowledge of the mass of protein and solution volume.

**Plan:** The temperature ( $T = 25\text{ }^{\circ}\text{C}$ ) and osmotic pressure ( $\Pi = 1.54\text{ torr}$ ) are given, and we know the value of  $R$  so we can use Equation 13.13 to calculate the molarity of the solution,  $M$ . In doing so, we must convert temperature from  $^{\circ}\text{C}$  to  $\text{K}$  and the osmotic pressure from torr to atm. We then use the molarity and the volume of the solution (5.00 mL) to determine the number of moles of solute. Finally, we obtain the molar mass by dividing the mass of the solute (3.50 mg) by the number of moles of solute.

**Solve:** Solving Equation 13.13 for molarity gives

$$\text{Molarity} = \frac{\Pi}{RT} = \frac{(1.54\text{ torr})\left(\frac{1\text{ atm}}{760\text{ torr}}\right)}{\left(0.0821\frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(298\text{ K})} = 8.28 \times 10^{-5}\frac{\text{mol}}{\text{L}}$$

Because the volume of the solution is 5.00 mL =  $5.00 \times 10^{-3}\text{ L}$ , the number of moles of protein must be

$$\text{Moles} = (8.28 \times 10^{-5}\text{ mol/L})(5.00 \times 10^{-3}\text{ L}) = 4.14 \times 10^{-7}\text{ mol}$$

The molar mass is the number of grams per mole of the substance. The sample has a mass of 3.50 mg =  $3.50 \times 10^{-3}\text{ g}$ . The molar mass is the number of grams divided by the number of moles:

$$\text{Molar mass} = \frac{\text{grams}}{\text{moles}} = \frac{3.50 \times 10^{-3}\text{ g}}{4.14 \times 10^{-7}\text{ mol}} = 8.45 \times 10^3\text{ g/mol}$$

**Comment:** Because small pressures can be measured easily and accurately, osmotic pressure measurements provide a useful way to determine the molar masses of large molecules.

**PRACTICE EXERCISE**

A sample of 2.05 g of polystyrene of uniform polymer chain length was dissolved in enough toluene to form 0.100 L of solution. The osmotic pressure of this solution was found to be 1.21 kPa at 25 °C. Calculate the molar mass of the polystyrene.

*Answer:*  $4.20 \times 10^4\text{ g/mol}$

**13.6 COLLOIDS**

When finely divided clay particles are dispersed throughout water, they eventually settle out of the water because of gravity. The dispersed clay particles are much larger than most molecules and consist of many thousands or even millions of atoms. In contrast, the dispersed particles of a solution are of molecular size. Between these extremes lie dispersed particles that are larger than typical molecules, but not so large that the components of the mixture separate under the influence of gravity. These intermediate types of dispersions or suspensions are called **colloidal dispersions**, or simply **colloids**. Colloids form the dividing line between solutions and heterogeneous mixtures. Like solutions, colloids can be gases, liquids, or solids. Examples of each are listed in Table 13.6 ►.

TABLE 13.6 ■ Types of Colloids

Phase of Colloid	Dispersing (solutelike) Substance	Dispersed (solventlike) Substance	Colloid Type	Example
Gas	Gas	Gas	—	None (all are solutions)
Gas	Gas	Liquid	Aerosol	Fog
Gas	Gas	Solid	Aerosol	Smoke
Liquid	Liquid	Gas	Foam	Whipped cream
Liquid	Liquid	Liquid	Emulsion	Milk
Liquid	Liquid	Solid	Sol	Paint
Solid	Solid	Gas	Solid foam	Marshmallow
Solid	Solid	Liquid	Solid emulsion	Butter
Solid	Solid	Solid	Solid sol	Ruby glass

The size of the dispersed particles is used to classify a mixture as a colloid. Colloid particles range in diameter from approximately 5 to 1000 nm. Solute particles are smaller. The colloid particle may consist of many atoms, ions, or molecules, or it may even be a single giant molecule. The hemoglobin molecule, for example, which carries oxygen in blood, has molecular dimensions of  $65 \text{ \AA} \times 55 \text{ \AA} \times 50 \text{ \AA}$  and a molar mass of 64,500 g/mol.

Although colloid particles may be so small that the dispersion appears uniform even under a microscope, they are large enough to scatter light very effectively. Consequently, most colloids appear cloudy or opaque unless they are very dilute. (Homogenized milk is a colloid.) Furthermore, because they scatter light, a light beam can be seen as it passes through a colloidal suspension, as shown in Figure 13.26 ▶. This scattering of light by colloidal particles, known as the **Tyndall effect**, makes it possible to see the light beam of an automobile on a dusty dirt road or the sunlight coming through a forest canopy [Figure 13.27(a) ▼]. Not all wavelengths are scattered to the same extent. As a result, brilliant red sunsets are seen when the sun is near the horizon and the air contains dust, smoke, or other particles of colloidal size [Figure 13.27(b)].

### Hydrophilic and Hydrophobic Colloids

The most important colloids are those in which the dispersing medium is water. These colloids may be **hydrophilic** (water loving) or **hydrophobic** (water fearing). Hydrophilic colloids are most like the solutions that we have previously examined. In the human body the extremely large molecules that make up such important substances as enzymes and antibodies are kept in suspension by interaction with surrounding water molecules. The molecules fold in such a way that the hydrophobic groups are away from the water molecules,

▲ **Figure 13.26 Tyndall effect in the laboratory.** The glass on the left contains a colloidal suspension; that on the right contains a solution. The path of the beam through the colloidal suspension is visible because the light is scattered by the colloidal particles. Light is not scattered by the individual solute molecules in the solution.

◀ **Figure 13.27 Tyndall effect in nature.** (a) Scattering of sunlight by colloidal particles in the misty air of a forest. (b) The scattering of light by smoke or dust particles produces a rich red sunset.

▲ **Figure 13.28 Hydrophilic colloids.** Examples of hydrophilic groups on the surface of a giant molecule (macromolecule) that help to keep the molecule suspended in water.

on the “inside” of the folded molecule, while the hydrophilic, polar groups are on the surface, interacting with the water molecules. These hydrophilic groups generally contain oxygen or nitrogen and often carry a charge. Some examples are shown in Figure 13.28 ◀.

Hydrophobic colloids can be prepared in water only if they are stabilized in some way. Otherwise, their natural lack of affinity for water causes them to separate from the water. Hydrophobic colloids can be stabilized by adsorption of ions on their surface, as shown in Figure 13.29 ▼. (*Adsorption* means to adhere to a surface. It differs from *absorption*, which means to pass into the interior, as when a sponge absorbs water.) These adsorbed ions can interact with water, thereby stabilizing the colloid. At the same time, the mutual repulsion between colloid particles with adsorbed ions of the same charge keeps the particles from colliding and getting larger.

Hydrophobic colloids can also be stabilized by the presence of hydrophilic groups on their surfaces. Small droplets of oil are hydrophobic, for example, so they do not remain suspended in water. Instead, they aggregate, forming an oil slick on the surface of the water. Sodium stearate (Figure 13.30 ◀), or any similar substance having one end that is hydrophilic (polar, or charged) and one that is hydrophobic (nonpolar), will stabilize a suspension of oil in water. Stabilization results from the interaction of the hydrophobic ends of the stearate ions with the oil droplet and the hydrophilic ends with the water as shown in Figure 13.31 ►.

▲ **Figure 13.29 Hydrophobic colloids.** Schematic illustration of how adsorbed ions stabilize a hydrophobic colloid in water.

Sodium stearate

▲ **Figure 13.30 Sodium stearate.**

### GIVE IT SOME THOUGHT

Why don't the oil droplets emulsified by sodium stearate coagulate to form larger oil droplets?

The stabilization of colloids has an interesting application in our own digestive system. When fats in our diet reach the small intestine, a hormone causes the gallbladder to excrete a fluid called bile. Among the components of bile are compounds that have chemical structures similar to sodium stearate; that is, they have a hydrophilic (polar) end and a hydrophobic (nonpolar) end. These compounds emulsify the fats present in the intestine and thus permit digestion and absorption of fat-soluble vitamins through the intestinal wall. The term *emulsify* means “to form an emulsion,” a suspension of one liquid in another, as in milk, for example (Table 13.6). A substance that aids in the formation of an emulsion is called an emulsifying agent. If you read the labels on foods and other materials, you will find that a variety of chemicals are used as emulsifying agents. These chemicals typically have a hydrophilic end and a hydrophobic end.

◀ **Figure 13.31** Stabilization of an emulsion of oil in water by stearate ions.

## Chemistry and Life

### SICKLE-CELL ANEMIA

Our blood contains a complex protein called *hemoglobin* that carries oxygen from our lungs to other parts of our body. In the genetic disease known as *sickle-cell anemia*, hemoglobin molecules are abnormal and have a lower solubility, especially in their unoxygenated form. Consequently, as much as 85% of the hemoglobin in red blood cells crystallizes from solution.

The reason for the insolubility of hemoglobin in sickle-cell anemia can be traced to a structural change in one part of an amino acid side chain. Normal hemoglobin molecules have an amino acid in their makeup that has the following side chain protruding from the main body of the molecule:

This side chain terminates in a polar group, which contributes to the solubility of the hemoglobin molecule in water. In the hemoglobin molecules of persons suffering from sickle-cell anemia, the side chain is of a different type:

This abnormal group of atoms is nonpolar (hydrophobic), and its presence leads to the aggregation of this defective form of hemoglobin into particles too large to remain suspended in biological fluids. It also causes the cells to distort into a sickle shape, as shown in Figure 13.32 ▼. The sickled cells tend to clog the capillaries, causing severe pain, physical weakness, and the gradual deterioration of the vital organs. The disease is hereditary, and if both parents carry the defective genes, it is likely that their children will possess only abnormal hemoglobin.

◀ **Figure 13.32** Normal and sickled red blood cells. Normal red blood cells are about  $1 \times 10^{-3}$  mm in diameter.

## Removal of Colloidal Particles

Colloidal particles frequently must be removed from a dispersing medium, as in the removal of smoke from smokestacks or butterfat from milk. Because colloidal particles are so small, they cannot be separated by simple filtration. Instead, the colloidal particles must be enlarged in a process called *coagulation*. The resultant larger particles can then be separated by filtration or merely by allowing them to settle out of the dispersing medium.

Heating the mixture or adding an electrolyte may bring about coagulation. Heating the colloidal dispersion increases the particle motion and so the number of collisions. The particles increase in size as they stick together after colliding. The addition of electrolytes neutralizes the surface charges of the particles, thereby removing the electrostatic repulsions that prevent them from coming together. Wherever rivers empty into oceans or other salty bodies of water, for example, the suspended clay in the river is deposited as a delta when it mixes with the electrolytes in the salt water.

Semipermeable membranes can also be used to separate ions from colloidal particles because the ions can pass through the membrane but the colloidal particles cannot. This type of separation is known as *dialysis* and is used to purify blood in artificial kidney machines. Our kidneys normally remove the waste products of metabolism from blood. In a kidney machine, blood is circulated through a dialyzing tube immersed in a washing solution. The washing solution contains the same concentrations and kinds of ions as blood but is lacking the molecules and ions that are waste products. Wastes therefore dialyze out of the blood, but the ions and large colloidal particles such as proteins do not.

### **SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

A 0.100-L solution is made by dissolving 0.441 g of  $\text{CaCl}_2(s)$  in water. (a) Calculate the osmotic pressure of this solution at  $27^\circ\text{C}$ , assuming that it is completely dissociated into its component ions. (b) The measured osmotic pressure of this solution is 2.56 atm at  $27^\circ\text{C}$ . Explain why it is less than the value calculated in (a), and calculate the van't Hoff factor,  $i$ , for the solute in this solution. (See the "A Closer Look" box on Colligative Properties of Electrolyte Solutions in Section 13.5.) (c) The enthalpy of solution for  $\text{CaCl}_2$  is  $\Delta H = -81.3 \text{ kJ/mol}$ . If the final temperature of the solution is  $27.0^\circ\text{C}$ , what was its initial temperature? (Assume that the density of the solution is  $1.00 \text{ g/mL}$ , that its specific heat is  $4.18 \text{ J/g}\cdot\text{K}$ , and that the solution loses no heat to its surroundings.)

### **SOLUTION**

(a) The osmotic pressure is given by Equation 13.13,  $\Pi = MRT$ . We know the temperature,  $T = 27^\circ\text{C} = 300 \text{ K}$ , and the gas constant,  $R = 0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K}$ . We can calculate the molarity of the solution from the mass of  $\text{CaCl}_2$  and the volume of the solution:

$$\text{Molarity} = \left( \frac{0.441 \text{ g CaCl}_2}{0.100 \text{ L}} \right) \left( \frac{1 \text{ mol CaCl}_2}{111.0 \text{ g CaCl}_2} \right) = 0.0397 \text{ mol CaCl}_2/\text{L}$$

Soluble ionic compounds are strong electrolytes.  $\rightleftharpoons$  (Sections 4.1 and 4.3) Thus,  $\text{CaCl}_2$  consists of metal cations ( $\text{Ca}^{2+}$ ) and nonmetal anions ( $\text{Cl}^-$ ). When completely dissociated, each  $\text{CaCl}_2$  unit forms three ions (one  $\text{Ca}^{2+}$  and two  $\text{Cl}^-$ ). Hence the total concentration of ions in the solution is  $(3)(0.0397 \text{ M}) = 0.119 \text{ M}$ , and the calculated osmotic pressure is

$$\Pi = MRT = (0.119 \text{ mol/L})(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(300 \text{ K}) = 2.93 \text{ atm}$$

(b) The actual values of colligative properties of electrolytes are less than those calculated, because the electrostatic interactions between ions limit their independent movements. In this case the van't Hoff factor, which measures the extent to which

electrolytes actually dissociate into ions, is given by

$$i = \frac{II(\text{measured})}{II(\text{calculated for nonelectrolyte})} = \frac{2.56 \text{ atm}}{(0.0397 \text{ mol/L})(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(300 \text{ K})} = 2.62$$

Thus, the solution behaves as if the  $\text{CaCl}_2$  has dissociated into 2.62 particles instead of the ideal 3.

(c) If the solution is 0.0397 M in  $\text{CaCl}_2$  and has a total volume of 0.100 L, the number of moles of solute is  $(0.100 \text{ L})(0.0397 \text{ mol/L}) = 0.00397 \text{ mol}$ . Hence the quantity of heat generated in forming the solution is  $(0.00397 \text{ mol})(-81.3 \text{ kJ/mol}) = -0.323 \text{ kJ}$ . The solution absorbs this heat, causing its temperature to increase. The relationship between temperature change and heat is given by Equation 5.22:

$$q = (\text{specific heat})(\text{grams})(\Delta T)$$

The heat absorbed by the solution is  $q = +0.323 \text{ kJ} = 323 \text{ J}$ . The mass of the 0.100 L of solution is  $(100 \text{ mL})(1.00 \text{ g/mL}) = 100 \text{ g}$  (to 3 significant figures). Thus the temperature change is

$$\Delta T = \frac{q}{(\text{specific heat of solution})(\text{grams of solution})} = \frac{323 \text{ J}}{(4.18 \text{ J/g}\cdot\text{K})(100 \text{ g})} = 0.773 \text{ K}$$

A kelvin has the same size as a degree Celsius.  $\infty$  (Section 1.4) Because the solution temperature increases by 0.773 °C, the initial temperature was  $27.0 \text{ }^\circ\text{C} - 0.773 \text{ }^\circ\text{C} = 26.2 \text{ }^\circ\text{C}$ .

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Section 13.1** Solutions form when one substance disperses uniformly throughout another. The attractive interaction of solvent molecules with solute is called **solvation**. When the solvent is water, the interaction is called **hydration**. The dissolution of ionic substances in water is promoted by hydration of the separated ions by the polar water molecules. The overall enthalpy change upon solution formation may be either positive or negative. Solution formation is favored both by a negative enthalpy change (exothermic process) and by an increased dispersal in space of the components of the solution, corresponding to a positive **entropy** change.

**Section 13.2** The equilibrium between a saturated solution and undissolved solute is dynamic; the process of solution and the reverse process, **crystallization**, occur simultaneously. In a solution in equilibrium with undissolved solute, the two processes occur at equal rates, giving a **saturated** solution. If there is less solute present than is needed to saturate the solution, the solution is **unsaturated**. When solute concentration is greater than the equilibrium concentration value, the solution is **supersaturated**. This is an unstable condition, and separation of some solute from the solution will occur if the process is initiated with a solute seed crystal. The amount of solute needed to form a saturated solution at any particular temperature is the **solubility** of that solute at that temperature.

**Section 13.3** The solubility of one substance in another depends on the tendency of systems to become more random, by becoming more dispersed in space, and on the relative intermolecular solute–solute and solvent–solvent energies compared with solute–solvent interactions. Polar and ionic solutes tend to dissolve in polar solvents, and nonpolar solutes tend to dissolve in nonpolar solvents (“like dissolves like”). Liquids that mix in all proportions are **miscible**; those that do not dissolve significantly in one another are **immiscible**. Hydrogen-bonding interactions between solute and solvent often play an important role in determining solubility; for example, ethanol and water, whose molecules form hydrogen bonds with each other, are miscible. The solubilities of gases in a liquid are generally proportional to the pressure of the gas over the solution, as expressed by **Henry’s law**:  $S_g = kP_g$ . The solubilities of most solid solutes in

water increase as the temperature of the solution increases. In contrast, the solubilities of gases in water generally decrease with increasing temperature.

**Section 13.4** Concentrations of solutions can be expressed quantitatively by several different measures, including **mass percentage** [(mass solute/mass solution)  $\times 10^2$ ], **parts per million (ppm)** [(mass solute/mass solution)  $\times 10^6$ ], **parts per billion (ppb)** [(mass solute/mass solution)  $\times 10^9$ ], and **mole fraction** [mol solute/(mol solute + mol solvent)]. Molarity,  $M$ , is defined as moles of solute per liter of solution; **molality**,  $m$ , is defined as moles of solute per kg of solvent. Molarity can be converted to these other concentration units if the density of the solution is known.

**Section 13.5** A physical property of a solution that depends on the concentration of solute particles present, regardless of the nature of the solute, is a **colligative property**. Colligative properties include vapor-pressure lowering, freezing-point lowering, boiling-point elevation, and osmotic pressure. **Raoult's law** expresses the lowering of vapor pressure. An **ideal solution** obeys Raoult's law. Differences in solvent-solute as compared with solvent-solvent and solute-solute intermolecular forces cause many solutions to depart from ideal behavior.

A solution containing a nonvolatile solute possesses a higher boiling point than the pure solvent. The **molal boiling-point-elevation constant**,  $K_b$ , represents the increase in boiling point for a 1  $m$  solution of solute particles as compared with the pure solvent. Similarly, the **molal freezing-point-depression constant**,  $K_f$ , measures the lowering of the freezing point of a solution for a 1  $m$  solution of solute particles. The temperature changes are given by the equations  $\Delta T_b = K_b m$  and  $\Delta T_f = K_f m$ .

When NaCl dissolves in water, two moles of solute particles are formed for each mole of dissolved salt. The boiling point or freezing point is thus elevated or depressed, respectively, approximately twice as much as that of a nonelectrolyte solution of the same concentration. Similar considerations apply to other strong electrolytes.

**Osmosis** is the movement of solvent molecules through a semipermeable membrane from a less concentrated to a more concentrated solution. This net movement of solvent generates an **osmotic pressure**,  $\Pi$ , which can be measured in units of gas pressure, such as atm. The osmotic pressure of a solution as compared with pure solvent is proportional to the solution molarity:  $\Pi = MRT$ . Osmosis is a very important process in living systems, in which cell walls act as semipermeable membranes, permitting the passage of water, but restricting the passage of ionic and macromolecular components.

**Section 13.6** Particles that are large on the molecular scale but still small enough to remain suspended indefinitely in a solvent system form **colloids**, or **colloidal dispersions**. Colloids, which are intermediate between solutions and heterogeneous mixtures, have many practical applications. One useful physical property of colloids, the scattering of visible light, is referred to as the **Tyndall effect**. Aqueous colloids are classified as **hydrophilic** or **hydrophobic**. Hydrophilic colloids are common in living organisms, in which large molecular aggregates (enzymes, antibodies) remain suspended because they have many polar, or charged, atomic groups on their surfaces that interact with water. Hydrophobic colloids, such as small droplets of oil, may remain in suspension through adsorption of charged particles on their surfaces.

## KEY SKILLS

- Understand how enthalpy and entropy changes affect solution formation.
- Understand the relationship between intermolecular forces and solubility, including use of the "like dissolves like" rule.
- Describe the effect of temperature on the solubility of solids and gases.
- Describe the relationship between the partial pressure of a gas and its solubility.
- Be able to calculate the concentration of a solution in terms of molarity, molality, mole fraction, percent composition, and parts per million and be able to interconvert between them.
- Describe what a colligative property is and explain the difference between the effects of nonelectrolytes and electrolytes on colligative properties.
- Be able to calculate the vapor pressure of a solvent over a solution.
- Be able to calculate the boiling point elevation and freezing point depression of a solution.
- Be able to calculate the osmotic pressure of a solution.

## KEY EQUATIONS

- $S_g = kP_g$  [13.4] Henry's law, relating gas solubility to partial pressure
- Mass % of component =  $\frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 100$  [13.5] Defining concentration in terms of mass percent
- ppm of component =  $\frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 10^6$  [13.6] Defining concentration in terms of parts per million (ppm)
- Mole fraction of component =  $\frac{\text{moles of component}}{\text{total moles of all components}}$  [13.7] Defining concentration in terms of mole fraction
- Molarity =  $\frac{\text{moles solute}}{\text{liters soln}}$  [13.8] Defining concentration in terms of molarity
- Molality =  $\frac{\text{moles of solute}}{\text{kilograms of solvent}}$  [13.9] Defining concentration in terms of molality
- $P_A = X_A P_A^\circ$  [13.10] Raoult's law, calculating vapor pressure of solvent above a solution
- $\Delta T_b = K_b m$  [13.11] Calculating the boiling point elevation of a solution
- $\Delta T_f = K_f m$  [13.12] Calculating the freezing point depression of a solution
- $\Pi = \left(\frac{n}{V}\right)RT = MRT$  [13.13] Calculating the osmotic pressure of a solution

## VISUALIZING CONCEPTS

13.1 This figure shows the interaction of a cation with surrounding water molecules.

Would you expect the energy of ion-solvent interaction to be greater for  $\text{Na}^+$  or  $\text{Li}^+$ ? Explain. [Section 13.1]

- 13.2 Why do ionic substances with higher lattice energies tend to be less soluble in water than those with lower lattice energies? [Section 13.1]
- 13.3 Rank the contents of the following containers in order of increasing entropy. [Section 13.1]

13.4 A quantity of the pink solid on the left in Figure 13.8 is placed in a warming oven and heated for a time. It slowly turns from pink to the deep blue color of the solid on the right. What has occurred? [Section 13.1]

13.5 Which of the following is the best representation of a saturated solution? Explain your reasoning. [Section 13.2]

- 13.6 The solubility of Xe in water at 20 °C is approximately  $5 \times 10^{-3} M$ . Compare this with the solubilities of Ar and Kr in water (Table 13.2) and explain what properties of the rare gas atoms account for the variation in solubility. [Section 13.3]
- 13.7 The structures of vitamins E and B<sub>6</sub> are shown below. Predict which is largely water soluble and which is largely fat soluble. Explain. [Section 13.3]

- 13.8 If you wanted to prepare a solution of CO in water at 25 °C in which the CO concentration was 2.5 mM, what pressure of CO would you need to use? (See Figure 13.18.) [Section 13.3]
- 13.9 The figure shows two identical volumetric flasks containing the same solution at two temperatures.
- (a) Does the molarity of the solution change with the change in temperature? Explain.
- (b) Does the molality of the solution change with the change in temperature? Explain. [Section 13.4]

- 13.10 The following diagram shows the vapor pressure curves of a volatile solvent and a solution of that solvent containing a nonvolatile solute. (a) Which line represents the solution? (b) What are the normal boiling points of the solvent and the solution? [Section 13.5]

- 13.11 Suppose you had a balloon made of some highly flexible semipermeable membrane. The balloon is filled completely with a 0.2 M solution of some solute and is submerged in a 0.1 M solution of the same solute:

Initially, the volume of solution in the balloon is 0.25 L. Assuming the volume outside the semipermeable membrane is large, as the illustration shows, what would you expect for the solution volume inside the balloon once the system has come to equilibrium through osmosis? [Section 13.5]

- 13.12 The molecule *n*-octylglucoside, shown here, is widely used in biochemical research as a nonionic detergent for “solubilizing” large hydrophobic protein molecules. What characteristics of this molecule are important for its use in this way? [Section 13.6]

## EXERCISES

## The Solution Process

- 13.13** In general, the attractive intermolecular forces between solvent and solute particles must be comparable or greater than solute–solute interactions for significant solubility to occur. Explain this statement in terms of the overall energetics of solution formation.
- 13.14** (a) Considering the energetics of solute–solute, solvent–solvent, and solute–solvent interactions, explain why NaCl dissolves in water but not in benzene ( $C_6H_6$ ). (b) What factors cause a cation to be strongly hydrated?
- 13.15** Indicate the type of solute–solvent interaction (Section 11.2) that should be most important in each of the following solutions: (a)  $CCl_4$  in benzene ( $C_6H_6$ ), (b) methanol ( $CH_3OH$ ) in water, (c) KBr in water, (d) HCl in acetonitrile ( $CH_3CN$ ).
- 13.16** Indicate the principal type of solute–solvent interaction in each of the following solutions, and rank the solutions from weakest to strongest solute–solvent interaction: (a) KCl in water, (b)  $CH_2Cl_2$  in benzene ( $C_6H_6$ ), (c) methanol ( $CH_3OH$ ) in water.
- 13.17** (a) In Equation 13.1 which of the energy terms for dissolving an ionic solid would correspond to the lattice energy? (b) Which energy terms in this equation are always exothermic?
- 13.18** The schematic diagram of the solution process as the net sum of three steps in Figure 13.4 does not show the relative magnitudes of the three components because these will vary from case to case. For the dissolution of  $NH_4NO_3$  in water, which of the three enthalpy changes would you expect to be much smaller than the other two? Explain.
- 13.19** When two nonpolar organic liquids such as hexane ( $C_6H_{14}$ ) and heptane ( $C_7H_{16}$ ) are mixed, the enthalpy change that occurs is generally quite small. (a) Use the energy diagram in Figure 13.4 to explain why. (b) Given that  $\Delta H_{soln} \approx 0$ , explain why hexane and heptane spontaneously form a solution.
- 13.20** The enthalpy of solution of KBr in water is about +198 kJ/mol. Nevertheless, the solubility of KBr in water is relatively high. Why does the solution process occur even though it is endothermic?

## Saturated Solutions; Factors Affecting Solubility

- 13.21** The solubility of  $Cr(NO_3)_3 \cdot 9H_2O$  in water is 208 g per 100 g of water at 15 °C. A solution of  $Cr(NO_3)_3 \cdot 9H_2O$  in water at 35 °C is formed by dissolving 324 g in 100 g water. When this solution is slowly cooled to 15 °C, no precipitate forms. (a) What term describes this solution? (b) What action might you take to initiate crystallization? Use molecular-level processes to explain how your suggested procedure works.
- 13.22** The solubility of  $MnSO_4 \cdot H_2O$  in water at 20 °C is 70 g per 100 mL of water. (a) Is a 1.22 M solution of  $MnSO_4 \cdot H_2O$  in water at 20 °C saturated, supersaturated, or unsaturated? (b) Given a solution of  $MnSO_4 \cdot H_2O$  of unknown concentration, what experiment could you perform to determine whether the new solution is saturated, supersaturated, or unsaturated?
- 13.23** By referring to Figure 13.17, determine whether the addition of 40.0 g of each of the following ionic solids to 100 g of water at 40 °C will lead to a saturated solution: (a)  $NaNO_3$ , (b) KCl, (c)  $K_2Cr_2O_7$ , (d)  $Pb(NO_3)_2$ .
- 13.24** By referring to Figure 13.17, determine the mass of each of the following salts required to form a saturated solution in 250 g of water at 30 °C: (a)  $KClO_3$ , (b)  $Pb(NO_3)_2$ , (c)  $Ce_2(SO_4)_3$ .
- 13.25** Water and glycerol,  $CH_2(OH)CH(OH)CH_2OH$ , are miscible in all proportions. What does this mean? How do the OH groups of the alcohol molecule contribute to this miscibility?
- 13.26** Oil and water are immiscible. What does this mean? Explain in terms of the structural features of their respective molecules and the forces between them.
- 13.27** (a) Would you expect stearic acid,  $CH_3(CH_2)_{16}COOH$ , to be more soluble in water or in carbon tetrachloride? Explain. (b) Which would you expect to be more soluble in water, cyclohexane or dioxane? Explain.

- 13.28** Consider a series of carboxylic acids whose general formula is  $CH_3(CH_2)_nCOOH$ . How would you expect the solubility of these compounds in water and in hexane to change as  $n$  increases? Explain.
- 13.29** Which of the following in each pair is likely to be more soluble in hexane,  $C_6H_{14}$ : (a)  $CCl_4$  or  $CaCl_2$ ; (b) benzene ( $C_6H_6$ ) or glycerol,  $CH_2(OH)CH(OH)CH_2OH$ ; (c) octanoic acid,  $CH_3CH_2CH_2CH_2CH_2CH_2CH_2COOH$ , or acetic acid,  $CH_3COOH$ . Explain your answer in each case.
- 13.30** Which of the following in each pair is likely to be more soluble in water: (a) cyclohexane ( $C_6H_{12}$ ) or glucose ( $C_6H_{12}O_6$ ) (Figure 13.12); (b) propionic acid ( $CH_3CH_2COOH$ ) or sodium propionate ( $CH_3CH_2COONa$ ); (c) HCl or ethyl chloride ( $CH_3CH_2Cl$ )? Explain in each case.

- 13.31** (a) Explain why carbonated beverages must be stored in sealed containers. (b) Once the beverage has been opened, why does it maintain more carbonation when refrigerated than at room temperature?
- 13.32** Explain why pressure affects the solubility of  $O_2$  in water, but not the solubility of NaCl in water.
- 13.33** The Henry's law constant for helium gas in water at 30 °C is  $3.7 \times 10^{-4} M/\text{atm}$  and the constant for  $N_2$  at 30 °C is  $6.0 \times 10^{-4} M/\text{atm}$ . If the two gases are each present at 1.5 atm pressure, calculate the solubility of each gas.
- 13.34** The partial pressure of  $O_2$  in air at sea level is 0.21 atm. Using the data in Table 13.2, together with Henry's law, calculate the molar concentration of  $O_2$  in the surface water of a mountain lake saturated with air at 20 °C and an atmospheric pressure of 650 torr.

## Concentrations of Solutions

- 13.35** (a) Calculate the mass percentage of  $Na_2SO_4$  in a solution containing 10.6 g  $Na_2SO_4$  in 483 g water. (b) An ore contains 2.86 g of silver per ton of ore. What is the concentration of silver in ppm?
- 13.36** (a) What is the mass percentage of iodine ( $I_2$ ) in a solution containing 0.035 mol  $I_2$  in 115 g of  $CCl_4$ ? (b) Seawater contains 0.0079 g  $Sr^{2+}$  per kilogram of water. What is the concentration of  $Sr^{2+}$  measured in ppm?
- 13.37** A solution is made containing 14.6 g of  $CH_3OH$  in 184 g  $H_2O$ . Calculate (a) the mole fraction of  $CH_3OH$ , (b) the mass percent of  $CH_3OH$ , (c) the molality of  $CH_3OH$ .
- 13.38** A solution is made containing 25.5 g phenol ( $C_6H_5OH$ ) in 425 g ethanol ( $C_2H_5OH$ ). Calculate (a) the mole fraction of phenol, (b) the mass percent of phenol, (c) the molality of phenol.
- 13.39** Calculate the molarity of the following aqueous solutions: (a) 0.540 g  $Mg(NO_3)_2$  in 250.0 mL of solution, (b) 22.4 g  $LiClO_4 \cdot 3H_2O$  in 125 mL of solution, (c) 25.0 mL of 3.50 M  $HNO_3$  diluted to 0.250 L.
- 13.40** What is the molarity of each of the following solutions: (a) 15.0 g  $Al_2(SO_4)_3$  in 0.350 L solution, (b) 5.25 g  $Mn(NO_3)_2 \cdot 2H_2O$  in 175 mL of solution, (c) 35.0 mL of 9.00 M  $H_2SO_4$  diluted to 0.500 L?
- 13.41** Calculate the molality of each of the following solutions: (a) 8.66 g benzene ( $C_6H_6$ ) dissolved in 23.6 g carbon tetrachloride ( $CCl_4$ ), (b) 4.80 g NaCl dissolved in 0.350 L of water.
- 13.42** (a) What is the molality of a solution formed by dissolving 1.25 mol of KCl in 16.0 mol of water? (b) How many grams of sulfur ( $S_8$ ) must be dissolved in 100.0 g naphthalene ( $C_{10}H_8$ ) to make a 0.12 *m* solution?
- 13.43** A sulfuric acid solution containing 571.6 g of  $H_2SO_4$  per liter of solution has a density of 1.329 g/cm<sup>3</sup>. Calculate (a) the mass percentage, (b) the mole fraction, (c) the molality, (d) the molarity of  $H_2SO_4$  in this solution.
- 13.44** Ascorbic acid (vitamin C,  $C_6H_8O_6$ ) is a water-soluble vitamin. A solution containing 80.5 g of ascorbic acid dissolved in 210 g of water has a density of 1.22 g/mL at 55 °C. Calculate (a) the mass percentage, (b) the mole fraction, (c) the molality, (d) the molarity of ascorbic acid in this solution.
- 13.45** The density of acetonitrile ( $CH_3CN$ ) is 0.786 g/mL and the density of methanol ( $CH_3OH$ ) is 0.791 g/mL. A solution is made by dissolving 22.5 mL  $CH_3OH$  in 98.7 mL  $CH_3CN$ . (a) What is the mole fraction of methanol in the solution? (b) What is the molality of the solution? (c) Assuming that the volumes are additive, what is the molarity of  $CH_3OH$  in the solution?
- 13.46** The density of toluene ( $C_7H_8$ ) is 0.867 g/mL, and the density of thiophene ( $C_4H_4S$ ) is 1.065 g/mL. A solution is made by dissolving 9.08 g of thiophene in 250.0 mL of toluene. (a) Calculate the mole fraction of thiophene in the solution. (b) Calculate the molality of thiophene in the solution. (c) Assuming that the volumes of the solute and solvent are additive, what is the molarity of thiophene in the solution?
- 13.47** Calculate the number of moles of solute present in each of the following aqueous solutions: (a) 600 mL of 0.250 M  $SrBr_2$ , (b) 86.4 g of 0.180 *m* KCl, (c) 124.0 g of a solution that is 6.45% glucose ( $C_6H_{12}O_6$ ) by mass.
- 13.48** Calculate the number of moles of solute present in each of the following solutions: (a) 185 mL of 1.50 M  $HNO_3(aq)$ , (b) 50.0 mg of an aqueous solution that is 1.25 *m* NaCl, (c) 75.0 g of an aqueous solution that is 1.50% sucrose ( $C_{12}H_{22}O_{11}$ ) by mass.
- 13.49** Describe how you would prepare each of the following aqueous solutions, starting with solid KBr: (a) 0.75 L of  $1.5 \times 10^{-2}$  M KBr, (b) 125 g of 0.180 *m* KBr, (c) 1.85 L of a solution that is 12.0% KBr by mass (the density of the solution is 1.10 g/mL), (d) a 0.150 M solution of KBr that contains just enough KBr to precipitate 16.0 g of AgBr from a solution containing 0.480 mol of  $AgNO_3$ .
- 13.50** Describe how you would prepare each of the following aqueous solutions: (a) 150 L of 0.110 M  $(NH_4)_2SO_4$  solution, starting with solid  $(NH_4)_2SO_4$ ; (b) 120 g of a solution that is 0.65 *m* in  $Na_2CO_3$ , starting with the solid solute; (c) 1.20 L of a solution that is 15.0%  $Pb(NO_3)_2$  by mass (the density of the solution is 1.16 g/mL), starting with solid solute; (d) a 0.50 M solution of HCl that would just neutralize 5.5 g of  $Ba(OH)_2$  starting with 6.0 M HCl.
- 13.51** Commercial aqueous nitric acid has a density of 1.42 g/mL and is 16 M. Calculate the percent  $HNO_3$  by mass in the solution.
- 13.52** Commercial concentrated aqueous ammonia is 28%  $NH_3$  by mass and has a density of 0.90 g/mL. What is the molarity of this solution?
- 13.53** Brass is a substitutional alloy consisting of a solution of copper and zinc. A particular sample of red brass consisting of 80.0% Cu and 20.0% Zn by mass has a density of 8750 kg/m<sup>3</sup>. (a) What is the molality of Zn in the solid solution? (b) What is the molarity of Zn in the solution?

- 13.54 Caffeine ( $C_8H_{10}N_4O_2$ ) is a stimulant found in coffee and tea. If a solution of caffeine in chloroform ( $CHCl_3$ ) as a solvent has a concentration of 0.0750 *m*, calculate (a) the percent caffeine by mass, (b) the mole fraction of caffeine.

- 13.55 During a typical breathing cycle the  $CO_2$  concentration in the expired air rises to a peak of 4.6% by volume. Calculate the partial pressure of the  $CO_2$  at this point, assuming 1 atm pressure. What is the molarity of the  $CO_2$  in air at this point, assuming a body temperature of 37 °C?
- 13.56 Breathing air that contains 4.0% by volume  $CO_2$  over time causes rapid breathing, throbbing headache, and nausea, among other symptoms. What is the concentration of  $CO_2$  in such air in terms of (a) mol percentage, (b) molarity, assuming 1 atm pressure, and a body temperature of 37 °C?

## Colligative Properties

- 13.57 List four properties of a solution that depend on the total concentration but not the type of particle or particles present as solute. Write the mathematical expression that describes how each of these properties depends on concentration.
- 13.58 How does increasing the concentration of a nonvolatile solute in water affect the following properties: (a) vapor pressure, (b) freezing point, (c) boiling point; (d) osmotic pressure?
- 13.59 Consider two solutions, one formed by adding 10 g of glucose ( $C_6H_{12}O_6$ ) to 1 L of water and the other formed by adding 10 g of sucrose ( $C_{12}H_{22}O_{11}$ ) to 1 L of water. Are the vapor pressures over the two solutions the same? Why or why not?
- 13.60 (a) What is an *ideal solution*? (b) The vapor pressure of pure water at 60 °C is 149 torr. The vapor pressure of water over a solution at 60 °C containing equal numbers of moles of water and ethylene glycol (a nonvolatile solute) is 67 torr. Is the solution ideal according to Raoult's law? Explain.
- 13.61 (a) Calculate the vapor pressure of water above a solution prepared by adding 22.5 g of lactose ( $C_{12}H_{22}O_{11}$ ) to 200.0 g of water at 338 K. (Vapor-pressure data for water are given in Appendix B.) (b) Calculate the mass of propylene glycol ( $C_3H_8O_2$ ) that must be added to 0.340 kg of water to reduce the vapor pressure by 2.88 torr at 40 °C.
- 13.62 (a) Calculate the vapor pressure of water above a solution prepared by dissolving 32.5 g of glycerin ( $C_3H_8O_3$ ) in 125 g of water at 343 K. (The vapor pressure of water is given in Appendix B.) (b) Calculate the mass of ethylene glycol ( $C_2H_6O_2$ ) that must be added to 1.00 kg of ethanol ( $C_2H_5OH$ ) to reduce its vapor pressure by 10.0 torr at 35 °C. The vapor pressure of pure ethanol at 35 °C is  $1.00 \times 10^2$  torr.
- 13.63 At 63.5 °C the vapor pressure of  $H_2O$  is 175 torr, and that of ethanol ( $C_2H_5OH$ ) is 400 torr. A solution is made by mixing equal masses of  $H_2O$  and  $C_2H_5OH$ . (a) What is the mole fraction of ethanol in the solution? (b) Assuming ideal-solution behavior, what is the vapor pressure of the solution at 63.5 °C? (c) What is the mole fraction of ethanol in the vapor above the solution?
- 13.64 At 20 °C the vapor pressure of benzene ( $C_6H_6$ ) is 75 torr, and that of toluene ( $C_7H_8$ ) is 22 torr. Assume that benzene and toluene form an ideal solution. (a) What is the composition in mole fractions of a solution that has a vapor pressure of 35 torr at 20 °C? (b) What is the mole fraction of benzene in the vapor above the solution described in part (a)?
- 13.65 (a) Why does a 0.10 *m* aqueous solution of NaCl have a higher boiling point than a 0.10 *m* aqueous solution of  $C_6H_{12}O_6$ ? (b) Calculate the boiling point of each solution. (c) The experimental boiling point of the NaCl solution is lower than that calculated, assuming that NaCl is completely dissociated in solution. Why is this the case?
- 13.66 Arrange the following aqueous solutions, each 10% by mass in solute, in order of increasing boiling point: glucose ( $C_6H_{12}O_6$ ), sucrose ( $C_{12}H_{22}O_{11}$ ), sodium nitrate ( $NaNO_3$ ).
- 13.67 List the following aqueous solutions in order of increasing boiling point: 0.120 *m* glucose, 0.050 *m* LiBr, 0.050 *m*  $Zn(NO_3)_2$ .
- 13.68 List the following aqueous solutions in order of decreasing freezing point: 0.040 *m* glycerin ( $C_3H_8O_3$ ), 0.020 *m* KBr, 0.030 *m* phenol ( $C_6H_5OH$ ).
- 13.69 Using data from Table 13.4, calculate the freezing and boiling points of each of the following solutions: (a) 0.22 *m* glycerol ( $C_3H_8O_3$ ) in ethanol, (b) 0.240 mol of naphthalene ( $C_{10}H_8$ ) in 2.45 mol of chloroform, (c) 2.04 g KBr and 4.82 g glucose ( $C_6H_{12}O_6$ ) in 188 g of water.
- 13.70 Using data from Table 13.4, calculate the freezing and boiling points of each of the following solutions: (a) 0.30 *m* glucose in ethanol; (b) 20.0 g of decane,  $C_{10}H_{22}$ , in 45.5 g  $CHCl_3$ ; (c) 0.45 mol ethylene glycol and 0.15 mol KBr in 150 g  $H_2O$ .

- 13.71** How many grams of ethylene glycol ( $C_2H_6O_2$ ) must be added to 1.00 kg of water to produce a solution that freezes at  $-5.00^\circ C$ ?
- 13.72** What is the freezing point of an aqueous solution that boils at  $105.0^\circ C$ ?
- 13.73** What is the osmotic pressure formed by dissolving 44.2 mg of aspirin ( $C_9H_8O_4$ ) in 0.358 L of water at  $25^\circ C$ ?
- 13.74** Seawater contains 3.4 g of salts for every liter of solution. Assuming that the solute consists entirely of NaCl (over 90% is), calculate the osmotic pressure of seawater at  $20^\circ C$ .
- 13.75** Adrenaline is the hormone that triggers the release of extra glucose molecules in times of stress or emergency. A solution of 0.64 g of adrenaline in 36.0 g of  $CCl_4$  elevates the boiling point by  $0.49^\circ C$ . Is the molar mass of adrenaline calculated from the boiling point elevation in agreement with the following structural formula?

- 13.76** Lauryl alcohol is obtained from coconut oil and is used to make detergents. A solution of 5.00 g of lauryl alcohol in 0.100 kg of benzene freezes at  $4.1^\circ C$ . What is the approximate molar mass of lauryl alcohol?
- 13.77** Lysozyme is an enzyme that breaks bacterial cell walls. A solution containing 0.150 g of this enzyme in 210 mL of solution has an osmotic pressure of 0.953 torr at  $25^\circ C$ . What is the molar mass of lysozyme?
- 13.78** A dilute aqueous solution of an organic compound soluble in water is formed by dissolving 2.35 g of the compound in water to form 0.250 L solution. The resulting solution has an osmotic pressure of 0.605 atm at  $25^\circ C$ . Assuming that the organic compound is a nonelectrolyte, what is its molar mass?
- [13.79]** The osmotic pressure of a 0.010 M aqueous solution of  $CaCl_2$  is found to be 0.674 atm at  $25^\circ C$ . (a) Calculate the van't Hoff factor,  $i$ , for the solution. (b) How would you expect the value of  $i$  to change as the solution becomes more concentrated? Explain.
- [13.80]** Based on the data given in Table 13.5, which solution would give the larger freezing-point lowering, a 0.030 m solution of NaCl or a 0.020 m solution of  $K_2SO_4$ ? How do you explain the departure from ideal behavior and the differences observed between the two salts?

## Colloids

- 13.81** (a) Why is there no colloid in which both the dispersed substance and the dispersing substance are gases? (b) Michael Faraday first prepared ruby-red colloids of gold particles in water that were stable for indefinite times.  $\infty$  (Section 12.6) To the unaided eye these brightly colored colloids are not distinguishable from solutions. How could you determine whether a given colored preparation is a solution or colloid?
- 13.82** (a) Many proteins that remain homogeneously distributed in water have molecular masses in the range of 30,000 amu and larger. In what sense is it appropriate to consider such suspensions to be colloids rather than solutions? Explain. (b) What general name is given to a colloidal dispersion of one liquid in another? What is an emulsifying agent?
- 13.83** Indicate whether each of the following is a hydrophilic or a hydrophobic colloid: (a) butterfat in homogenized milk, (b) hemoglobin in blood, (c) vegetable oil in a salad dressing, (d) colloidal gold particles in water.
- 13.84** Explain how each of the following factors helps determine the stability or instability of a colloidal dispersion: (a) particulate mass, (b) hydrophobic character, (c) charges on colloidal particles.
- 13.85** Colloidal suspensions of proteins, such as a gelatin, can often be caused to separate into two layers by addition of a solution of an electrolyte. Given that protein molecules may carry electrical charges on their outer surface as illustrated in Figure 13.28, what do you believe happens when the electrolyte solution is added?
- 13.86** Explain how (a) a soap such as sodium stearate stabilizes a colloidal dispersion of oil droplets in water; (b) milk curdles upon addition of an acid.

## ADDITIONAL EXERCISES

- 13.87 Butylated hydroxytoluene (BHT) has the following molecular structure:

It is widely used as a preservative in a variety of foods, including dried cereals. Based on its structure, would you expect BHT to be more soluble in water or in hexane ( $C_6H_{14}$ )? Explain.

- 13.88 A saturated solution of sucrose ( $C_{12}H_{22}O_{11}$ ) is made by dissolving excess table sugar in a flask of water. There are 50 g of undissolved sucrose crystals at the bottom of the flask in contact with the saturated solution. The flask is stoppered and set aside. A year later a single large crystal of mass 50 g is at the bottom of the flask. Explain how this experiment provides evidence for a dynamic equilibrium between the saturated solution and the undissolved solute.
- 13.89 Fish need at least 4 ppm dissolved  $O_2$  for survival. (a) What is this concentration in mol/L? (b) What partial pressure of  $O_2$  above the water is needed to obtain this concentration at 10 °C? (The Henry's law constant for  $O_2$  at this temperature is  $1.71 \times 10^{-3}$  mol/L-atm.)
- 13.90 The presence of the radioactive gas radon (Rn) in well water obtained from aquifers that lie in rock deposits presents a possible health hazard in parts of the United States. (a) Assuming that the solubility of radon in water with 1 atm pressure of the gas over the water at 30 °C is  $7.27 \times 10^{-3}$  M, what is the Henry's law constant for radon in water at this temperature? (b) A sample consisting of various gases contains  $3.5 \times 10^{-6}$  mole fraction of radon. This gas at a total pressure of 32 atm is shaken with water at 30 °C. Calculate the molar concentration of radon in the water.
- 13.91 Glucose makes up about 0.10% by mass of human blood. Calculate the concentration in (a) ppm, (b) molality. What further information would you need to determine the molarity of the solution?
- 13.92 The maximum allowable concentration of lead in drinking water is 9.0 ppb. (a) Calculate the molarity of lead in a 9.0-ppb solution. What assumption did you have to make in your calculation? (b) How many grams of lead are in a swimming pool containing 9.0 ppb lead in  $60 \text{ m}^3$  of water?
- 13.93 Acetonitrile ( $CH_3CN$ ) is a polar organic solvent that dissolves a wide range of solutes, including many salts. The density of a 1.80 M LiBr solution in acetonitrile is  $0.826 \text{ g/cm}^3$ . Calculate the concentration of the solution in (a) molality, (b) mole fraction of LiBr, (c) mass percentage of  $CH_3CN$ .
- 13.94 A "canned heat" product used to warm chafing dishes consists of a homogeneous mixture of ethanol ( $C_2H_5OH$ ) and paraffin that has an average formula of  $C_{24}H_{50}$ . What mass of  $C_2H_5OH$  should be added to 620 kg of the paraffin in formulating the mixture if the vapor pressure of ethanol at 35 °C over the mixture is to be 8 torr? The vapor pressure of pure ethanol at 35 °C is 100 torr.
- [13.95] Two beakers are placed in a sealed box at 25 °C. One beaker contains 30.0 mL of a 0.050 M aqueous solution of a nonvolatile nonelectrolyte. The other beaker contains 30.0 mL of a 0.035 M aqueous solution of NaCl. The water vapor from the two solutions reaches equilibrium. (a) In which beaker does the solution level rise, and in which one does it fall? (b) What are the volumes in the two beakers when equilibrium is attained, assuming ideal behavior?
- 13.96 A solution contains 0.115 mol  $H_2O$  and an unknown number of moles of sodium chloride. The vapor pressure of the solution at 30 °C is 25.7 torr. The vapor pressure of pure water at this temperature is 31.8 torr. Calculate the number of moles of sodium chloride in the solution. (Hint: remember that sodium chloride is a strong electrolyte.)
- 13.97 Show that the vapor-pressure reduction,  $\Delta P_{\text{solvent}}$ , associated with the addition of a nonvolatile solute to a volatile solvent is given by the equation  $\Delta P_{\text{solvent}} = X_{\text{solute}} \times P_{\text{solvent}}^{\circ}$ .
- 13.98 A car owner who knows no chemistry has to put antifreeze in his car's radiator. The instructions recommend a mixture of 30% ethylene glycol and 70% water. Thinking he will improve his protection he uses pure ethylene glycol. He is saddened to find that the solution does not provide as much protection as he hoped. Why not?
- 13.99 Calculate the freezing point of a 0.100 m aqueous solution of  $K_2SO_4$ , (a) ignoring interionic attractions, and (b) taking interionic attractions into consideration by using the van't Hoff factor (Table 13.5).
- 13.100 When 10.0 g of mercuric nitrate,  $Hg(NO_3)_2$ , is dissolved in 1.00 kg of water, the freezing point of the solution is  $-0.162$  °C. When 10.0 g of mercuric chloride ( $HgCl_2$ ) is dissolved in 1.00 kg of water, the solution freezes at  $-0.0685$  °C. Use these data to determine which is the stronger electrolyte,  $Hg(NO_3)_2$  or  $HgCl_2$ .

- 13.101** Carbon disulfide ( $\text{CS}_2$ ) boils at  $46.30^\circ\text{C}$  and has a density of  $1.261\text{ g/mL}$ . (a) When  $0.250\text{ mol}$  of a nondissociating solute is dissolved in  $400.0\text{ mL}$  of  $\text{CS}_2$ , the solution boils at  $47.46^\circ\text{C}$ . What is the molal boiling-point-elevation constant for  $\text{CS}_2$ ? (b) When  $5.39\text{ g}$  of a nondissociating unknown is dissolved in  $50.0\text{ mL}$  of  $\text{CS}_2$ , the solution boils at  $47.08^\circ\text{C}$ . What is the molecular weight of the unknown?
- [13.102]** A  $40.0\%$  by weight solution of  $\text{KSCN}$  in water at  $20^\circ\text{C}$  has a density of  $1.22\text{ g/mL}$ . (a) What is the mole fraction of  $\text{KSCN}$  in the solution, and what are the molarity and molality? (b) Given the calculated mole fraction of salt in the solution, comment on the total number of water molecules available to hydrate each anion and cation.

## INTEGRATIVE EXERCISES

- 13.104** Fluorocarbons (compounds that contain both carbon and fluorine) were, until recently, used as refrigerants. The compounds listed in the following table are all gases at  $25^\circ\text{C}$ , and their solubilities in water at  $25^\circ\text{C}$  and  $1\text{ atm}$  fluorocarbon pressure are given as mass percentages. (a) For each fluorocarbon, calculate the molality of a saturated solution. (b) Explain why the molarity of each of the solutions should be very close numerically to the molality. (c) Based on their molecular structures, account for the differences in solubility of the four fluorocarbons. (d) Calculate the Henry's law constant at  $25^\circ\text{C}$  for  $\text{CHClF}_2$ , and compare its magnitude to that for  $\text{N}_2$  ( $6.8 \times 10^{-4}\text{ mol/L}\cdot\text{atm}$ ). Can you account for the difference in magnitude?

Fluorocarbon	Solubility (mass %)
$\text{CF}_4$	0.0015
$\text{CClF}_3$	0.009
$\text{CCl}_2\text{F}_2$	0.028
$\text{CHClF}_2$	0.30

- [13.105]** At ordinary body temperature ( $37^\circ\text{C}$ ) the solubility of  $\text{N}_2$  in water in contact with air at ordinary atmospheric pressure ( $1.0\text{ atm}$ ) is  $0.015\text{ g/L}$ . Air is approximately  $78\text{ mol}\%$   $\text{N}_2$ . Calculate the number of moles of  $\text{N}_2$  dissolved per liter of blood, which is essentially an aqueous solution. At a depth of  $100\text{ ft}$  in water, the pressure is  $4.0\text{ atm}$ . What is the solubility of  $\text{N}_2$  from air in blood at this pressure? If a scuba diver suddenly surfaces from this depth, how many milliliters of  $\text{N}_2$  gas, in the form of tiny bubbles, are released into the bloodstream from each liter of blood?
- [13.106]** Consider the following values for enthalpy of vaporization ( $\text{kJ/mol}$ ) of several organic substances:

	30.4		28.5
Acetaldehyde		Ethylene oxide	
	32.0		24.7
Acetone		Cyclopropane	

What ion pairing (if any) would you expect to find in the solution? Would you expect the colligative properties of such a solution to be those predicted by the formulas given in this chapter? Explain.

- [13.103]** A lithium salt used in lubricating grease has the formula  $\text{LiC}_n\text{H}_{2n+1}\text{O}_2$ . The salt is soluble in water to the extent of  $0.036\text{ g}$  per  $100\text{ g}$  of water at  $25^\circ\text{C}$ . The osmotic pressure of this solution is found to be  $57.1\text{ torr}$ . Assuming that molality and molarity in such a dilute solution are the same and that the lithium salt is completely dissociated in the solution, determine an appropriate value of  $n$  in the formula for the salt.

- (a) Use variations in the intermolecular forces operating in these organic liquids to account for their variations in heats of vaporization. (b) How would you expect the solubilities of these substances to vary in hexane as solvent? In ethanol? Use intermolecular forces, including hydrogen-bonding interactions where applicable, to explain your responses.
- [13.107]** The enthalpies of solution of hydrated salts are generally more positive than those of anhydrous materials. For example,  $\Delta H$  of solution for  $\text{KOH}$  is  $-57.3\text{ kJ/mol}$  whereas that for  $\text{KOH}\cdot\text{H}_2\text{O}$  is  $-14.6\text{ kJ/mol}$ . Similarly,  $\Delta H_{\text{soln}}$  for  $\text{NaClO}_4$  is  $+13.8\text{ kJ/mol}$ , whereas that for  $\text{NaClO}_4\cdot\text{H}_2\text{O}$  is  $+22.5\text{ kJ/mol}$ . Use the enthalpy contributions to the solution process depicted in Figure 13.4 to explain this effect.
- [13.108]** A textbook on chemical thermodynamics states, "The heat of solution represents the difference between the lattice energy of the crystalline solid and the solvation energy of the gaseous ions." (a) Draw a simple energy diagram to illustrate this statement. (b) A salt such as  $\text{NaBr}$  is insoluble in most polar nonaqueous solvents such as acetonitrile ( $\text{CH}_3\text{CN}$ ) or nitromethane ( $\text{CH}_3\text{NO}_2$ ), but salts of large cations, such as tetramethylammonium bromide [ $(\text{CH}_3)_4\text{NBr}$ ], are generally more soluble. Use the thermochemical cycle you drew in part (a) and the factors that determine the lattice energy (Section 8.2) to explain this fact.

- 13.109** (a) A sample of hydrogen gas is generated in a closed container by reacting  $2.050\text{ g}$  of zinc metal with  $15.0\text{ mL}$  of  $1.00\text{ M}$  sulfuric acid. Write the balanced equation for the reaction, and calculate the number of moles of hydrogen formed, assuming that the reaction is complete. (b) The volume over the solution is  $122\text{ mL}$ . Calculate the partial pressure of the hydrogen gas in this volume at  $25^\circ\text{C}$ , ignoring any solubility of the gas in the solution. (c) The Henry's law constant for hydrogen in water at  $25^\circ\text{C}$  is  $7.8 \times 10^{-4}\text{ mol/L}\cdot\text{atm}$ . Estimate the number of moles of hydrogen gas that remain dissolved in the solution. What fraction of the gas molecules in the system is dissolved in the solution? Was it reasonable to ignore any dissolved hydrogen in part (b)?
- [13.110]** The following table presents the solubilities of several gases in water at  $25^\circ\text{C}$  under a total pressure of gas and water vapor of  $1\text{ atm}$ . (a) What volume of  $\text{CH}_4(\text{g})$  under

standard conditions of temperature and pressure is contained in 4.0 L of a saturated solution at 25 °C? (b) Explain the variation in solubility among the hydrocarbons listed (the first three compounds), based on their molecular structures and intermolecular forces. (c) Compare the solubilities of O<sub>2</sub>, N<sub>2</sub>, and NO, and account for the variations based on molecular structures and intermolecular forces. (d) Account for the much larger values observed for H<sub>2</sub>S and SO<sub>2</sub> as compared with the other gases listed. (e) Find several pairs of substances with the same or nearly the same molecular masses (for example, C<sub>2</sub>H<sub>4</sub> and N<sub>2</sub>), and use intermolecular interactions to explain the differences in their solubilities.

Gas	Solubility (mM)
CH <sub>4</sub> (methane)	1.3
C <sub>2</sub> H <sub>6</sub> (ethane)	1.8
C <sub>2</sub> H <sub>4</sub> (ethylene)	4.7
N <sub>2</sub>	0.6
O <sub>2</sub>	1.2
NO	1.9
H <sub>2</sub> S	99
SO <sub>2</sub>	1476

- [13.111] Consider the process illustrated in Figure 13.23, the net movement of solvent from the more dilute to the more concentrated solution through the semipermeable membrane. Is there a change in entropy of the system in going from the left to center panels? Explain. (*Hint*: Imagine that the more dilute solution on the right hand side of the apparatus is pure solvent.)

- [13.112] When 0.55 g of pure benzoic acid (C<sub>6</sub>H<sub>5</sub>COOH) is dissolved in 32.0 g of benzene (C<sub>6</sub>H<sub>6</sub>), the freezing point of the solution is 0.36 °C lower than the freezing point value of 5.5 °C for the pure solvent. (a) Calculate the molecular weight of benzoic acid in benzene. (b) Use the structure of the solute to account for the observed value:

- [13.113] At 35 °C the vapor pressure of acetone, (CH<sub>3</sub>)<sub>2</sub>CO, is 360 torr, and that of chloroform, CHCl<sub>3</sub>, is 300 torr. Acetone and chloroform can form weak hydrogen bonds between one another as follows:

A solution composed of an equal number of moles of acetone and chloroform has a vapor pressure of 250 torr at 35 °C. (a) What would be the vapor pressure of the solution if it exhibited ideal behavior? (b) Use the existence of hydrogen bonds between acetone and chloroform molecules to explain the deviation from ideal behavior. (c) Based on the behavior of the solution, predict whether the mixing of acetone and chloroform is an exothermic ( $\Delta H_{\text{soln}} < 0$ ) or endothermic ( $\Delta H_{\text{soln}} > 0$ ) process.

bursts of light.

## WHAT'S AHEAD

---

### 14.1 Factors that Affect Reaction Rates

We explore four experimental variables that affect reaction rates: concentration, physical states of reactants, temperature, and catalysts. These factors can be understood in terms of the collisions among reactant molecules that lead to reaction.

### 14.2 Reaction Rates

We consider how to express *reaction rates* and how the rates of disappearance of reactants and the rates of appearance of products are related to the stoichiometry of the reaction.

### 14.3 Concentration and Rate

We then examine how the effect of concentration on rate is expressed quantitatively by *rate laws* and how rate laws can be determined experimentally.

### 14.4 The Change of Concentration with Time

We learn that rate equations can be written to express how concentrations change with time. We will look at two simple kinds of such rate equations.

### 14.5 Temperature and Rate

We next consider the effect of temperature on rate and the fact that reactions require a minimum input of energy called the *activation energy* to occur.

### 14.6 Reaction Mechanisms

We then examine the *mechanisms* of reactions, the step-by-step molecular pathways leading from reactants to products.

### 14.7 Catalysis

We end the chapter with a discussion of how *catalysts* speed reaction rates, including a discussion of biological catalysts, called *enzymes*.

## CHEMISTRY IS, BY ITS VERY NATURE, CONCERNED WITH CHANGE.

Chemical reactions convert substances with well-defined properties into other materials with different properties.

Much of our study of chemical reactions concerns the formation of new substances from a given set

of reactants. It is equally important to understand how rapidly chemical reactions occur.

The rates of reactions span an enormous range, from those that are complete within fractions of seconds, such as explosions, to those that take thousands or even millions of years, such as the formation of diamonds or other minerals in Earth's crust (Figure 14.1 ♥). The fireworks shown in this chapter-opening photograph require very rapid reactions, both to propel them skyward and to produce their colorful bursts of light. The chemicals used in the fireworks are chosen both to give the desired colors and to do so very rapidly. The characteristic red, blue, and green colors are produced by salts of strontium, copper, and barium, respectively.

▲ **Figure 14.1 Reaction rates.** The rates of chemical reactions span a range of time scales. For example, explosions are rapid, occurring in seconds or fractions of seconds; corrosion can take years; and the weathering of rocks takes place over thousands or even millions of years.

The area of chemistry that is concerned with the speeds, or rates, of reactions is called **chemical kinetics**. Chemical kinetics is a subject of broad importance. It relates, for example, to how quickly a medicine is able to work, to whether the formation and depletion of ozone in the upper atmosphere are in balance, and to industrial challenges such as the development of catalysts to synthesize new materials.

Our goal in this chapter is to understand how to determine the rates at which reactions occur and to consider the factors that control these rates. For example, what factors determine how rapidly food spoils? How does one design a fast-setting material for dental fillings? What determines the rate at which steel rusts? What controls the rate at which fuel burns in an automobile engine? Although we will not address these specific questions, we will see that the rates of all chemical reactions are subject to the same basic principles.

## 14.1 FACTORS THAT AFFECT REACTION RATES

Before we examine the quantitative aspects of chemical kinetics, such as how rates are measured, let's examine the key factors that influence the rates of reactions. Because reactions involve the breaking and forming of bonds, the speeds of reactions depend on the nature of the reactants themselves. Four factors allow us to change the rates at which particular reactions occur:

1. *The physical state of the reactants.* Reactants must come together to react. The more readily molecules collide with each other, the more rapidly they react. Most of the reactions we consider are homogeneous, involving either gases or liquid solutions. When reactants are in different phases, as when one is a gas and another a solid, the reaction is limited to their area of contact. Thus, reactions that involve solids tend to proceed faster if the surface area of the solid is increased. For example, a medicine in the form of a fine powder will dissolve in the stomach and enter the bloodstream more quickly than the same medicine in the form of a tablet.
2. *The concentrations of the reactants.* Most chemical reactions proceed faster if the concentration of one or more of the reactants is increased. For example, steel wool burns with difficulty in air, which contains 20%  $O_2$ , but bursts into a brilliant white flame in pure oxygen (Figure 14.2▶). As concentration increases, the frequency with which the reactant molecules collide increases, leading to increased rates.
3. *The temperature at which the reaction occurs.* The rates of chemical reactions increase as temperature is increased. We refrigerate perishable foods such as milk for this reason. The bacterial reactions that lead to the spoiling of milk proceed much more rapidly at room temperature than they do at the lower temperature of a refrigerator. Increasing temperature increases the kinetic energies of molecules. ∞ (Section 10.7) As molecules move more rapidly, they collide more frequently and also with higher energy, leading to increased reaction rates.

4. *The presence of a catalyst.* Catalysts are agents that increase reaction rates without being used up. They affect the kinds of collisions (the mechanism) that lead to reaction. Catalysts play a crucial role in our lives. The physiology of most living species depends on *enzymes*, protein molecules that act as catalysts, increasing the rates of selected biochemical reactions.

On a molecular level, reaction rates depend on the frequency of collisions between molecules. The greater the frequency of collisions, the greater is the rate of reaction. For a collision to lead to a reaction, however, it must occur with sufficient energy to stretch bonds to a critical length and with suitable orientation for new bonds to form in the proper locations. We will consider these factors as we proceed through this chapter.

(a)

(b)

▲ **Figure 14.2 Effect of concentration on rate.** (a) When heated in air, steel wool glows red-hot but oxidizes slowly. (b) When the red-hot steel wool is placed in an atmosphere of pure oxygen, it burns vigorously, forming  $\text{Fe}_2\text{O}_3$  at a much faster rate. The difference in behavior is due to the different concentrations of  $\text{O}_2$  in the two environments.

### GIVE IT SOME THOUGHT

How does increasing the partial pressures of the reactive components of a gaseous mixture affect the rate at which the components react with one another?

## 14.2 REACTION RATES

The *speed* of an event is defined as the *change* that occurs in a given interval of *time*: Whenever we talk about speed, we necessarily bring in the notion of time. For example, the speed of a car is expressed as the change in the car's position over a certain period of time. The units of this speed are usually miles per hour (mi/hr)—that is, the quantity that is changing (position, measured in miles) divided by a time interval (hours).

Similarly, the speed of a chemical reaction—its **reaction rate**—is the change in the concentration of reactants or products per unit of time. Thus, the units for reaction rate are usually molarity per second ( $M/s$ )—that is, the change in concentration (measured in molarity) divided by a time interval (seconds).

Let's consider a simple hypothetical reaction,  $\text{A} \longrightarrow \text{B}$ , depicted in Figure 14.3▼. Each red sphere represents 0.01 mol of A, each blue sphere represents 0.01 mol of B, and the container has a volume of 1.00 L. At the beginning of the reaction there is 1.00 mol A, so the concentration is  $1.00 \text{ mol/L} = 1.00 \text{ M}$ . After 20 s the concentration of A has fallen to 0.54 M, whereas the concentration of B has risen to 0.46 M. The sum of the concentrations is still 1.00 M because 1 mol

◀ **Figure 14.3 Progress of a hypothetical reaction  $\text{A} \longrightarrow \text{B}$ .** Each red sphere represents 0.01 mol A, each blue sphere represents 0.01 mol B, and the vessel has a volume of 1.00 L. (a) At time zero the vessel contains 1.00 mol A (100 red spheres) and 0 mol B (no blue spheres). (b) After 20 s the vessel contains 0.54 mol A and 0.46 mol B. (c) After 40 s the vessel contains 0.30 mol A and 0.70 mol B.

of B is produced for each mole of A that reacts. After 40 s the concentration of A is 0.30 M and that of B is 0.70 M.

The rate of this reaction can be expressed either as the rate of disappearance of reactant A or as the rate of appearance of product B. The *average* rate of appearance of B over a particular time interval is given by the change in concentration of B divided by the change in time:

$$\begin{aligned}\text{Average rate of appearance of B} &= \frac{\text{change in concentration of B}}{\text{change in time}} \\ &= \frac{[\text{B}] \text{ at } t_2 - [\text{B}] \text{ at } t_1}{t_2 - t_1} = \frac{\Delta[\text{B}]}{\Delta t} \quad [14.1]\end{aligned}$$

We use brackets around a chemical formula, as in [B], to indicate the concentration of the substance in molarity. The Greek letter delta,  $\Delta$ , is read “change in” and is always equal to the final quantity minus the initial quantity.  $\Rightarrow$  (Section 5.2) The average rate of appearance of B over the 20-s interval from the beginning of the reaction ( $t_1 = 0$  s to  $t_2 = 20$  s) is given by

$$\text{Average rate} = \frac{0.46 \text{ M} - 0.00 \text{ M}}{20 \text{ s} - 0 \text{ s}} = 2.3 \times 10^{-2} \text{ M/s}$$

We could equally well express the rate of the reaction with respect to the change of concentration of the reactant, A. In this case we would be describing the rate of disappearance of A, which we express as

$$\text{Average rate of disappearance of A} = -\frac{\Delta[\text{A}]}{\Delta t} \quad [14.2]$$

Notice the minus sign in this equation. By convention, *rates are always expressed as positive quantities*. Because [A] is decreasing with time,  $\Delta[\text{A}]$  is a negative number. We use the negative sign to convert the negative  $\Delta[\text{A}]$  to a positive rate. Because one molecule of A is consumed for every molecule of B that forms, the average rate of disappearance of A equals the average rate of appearance of B, as calculation shows:

$$\text{Average rate} = -\frac{\Delta[\text{A}]}{\Delta t} = -\frac{0.54 \text{ M} - 1.00 \text{ M}}{20 \text{ s} - 0 \text{ s}} = 2.3 \times 10^{-2} \text{ M/s}$$

#### **SAMPLE EXERCISE 14.1** | Calculating an Average Rate of Reaction

From the data given in the caption of Figure 14.3, calculate the average rate at which A disappears over the time interval from 20 s to 40 s.

#### **SOLUTION**

**Analyze:** We are given the concentration of A at 20 s (0.54 M) and at 40 s (0.30 M) and asked to calculate the average rate of reaction over this time interval.

**Plan:** The average rate is given by the change in concentration,  $\Delta[\text{A}]$ , divided by the corresponding change in time,  $\Delta t$ . Because A is a reactant, a minus sign is used in the calculation to make the rate a positive quantity.

$$\text{Solve: Average rate} = -\frac{\Delta[\text{A}]}{\Delta t} = -\frac{0.30 \text{ M} - 0.54 \text{ M}}{40 \text{ s} - 20 \text{ s}} = 1.2 \times 10^{-2} \text{ M/s}$$

#### **PRACTICE EXERCISE**

For the reaction pictured in Figure 14.3, calculate the average rate of appearance of B over the time interval from 0 to 40 s.

*Answer:*  $1.8 \times 10^{-2} \text{ M/s}$

TABLE 14.1 ■ Rate Data for Reaction of  $C_4H_9Cl$  with Water

Time, $t$ (s)	$[C_4H_9Cl](M)$	Average Rate ( $M/s$ )
0.0	0.1000	$1.9 \times 10^{-4}$
50.0	0.0905	$1.7 \times 10^{-4}$
100.0	0.0820	$1.6 \times 10^{-4}$
150.0	0.0741	$1.4 \times 10^{-4}$
200.0	0.0671	$1.22 \times 10^{-4}$
300.0	0.0549	$1.01 \times 10^{-4}$
400.0	0.0448	$0.80 \times 10^{-4}$
500.0	0.0368	$0.560 \times 10^{-4}$
800.0	0.0200	
10,000	0	

### Change of Rate with Time

Now, let's consider an actual chemical reaction, one that occurs when butyl chloride ( $C_4H_9Cl$ ) is placed in water. The products formed are butyl alcohol ( $C_4H_9OH$ ) and hydrochloric acid:

Suppose that we prepare a 0.1000  $M$  aqueous solution of  $C_4H_9Cl$  and then measure the concentration of  $C_4H_9Cl$  at various times after time zero (the time the reactants are mixed, thereby initiating the reaction). The resultant data are shown in the first two columns of Table 14.1 ▲. We can use these data to calculate the average rate of disappearance of  $C_4H_9Cl$  over the intervals between measurements; these rates are given in the third column. Notice that the average rate decreases over each 50-s interval for the first several measurements and continues to decrease over even larger intervals through the remaining measurements. *It is typical for rates to decrease as a reaction proceeds, because the concentration of reactants decreases.* The change in rate as the reaction proceeds is also seen in a graph of the concentration of  $C_4H_9Cl$  versus time (Figure 14.4 ►). Notice how the steepness of the curve decreases with time, indicating a decreasing rate of reaction.

### GIVE IT SOME THOUGHT

Why do the rates of reactions decrease as concentrations decrease?

### Instantaneous Rate

Graphs showing how the concentration of a reactant or product changes with time, such as the graph in Figure 14.4, allow us to evaluate the **instantaneous rate**, the rate at a particular moment in the reaction. The instantaneous rate is determined from the slope (or tangent) of this curve at the point of interest. We have drawn two tangents in Figure 14.4, one at  $t = 0$  and the other at  $t = 600$  s. The slopes of these tangents give the instantaneous rates at these times.\* For example, to determine the instantaneous rate at 600 s, we draw the tangent to the curve at this time, then construct horizontal and vertical lines to

▲ **Figure 14.4** Concentration of butyl chloride ( $C_4H_9Cl$ ) as a function of time. The dots represent the experimental data from the first two columns of Table 14.1, and the red curve is drawn to connect the data points smoothly. Lines are drawn that are tangent to the curve at  $t = 0$  and  $t = 600$  s. The slope of each tangent is defined as the vertical change divided by the horizontal change:  $\Delta[C_4H_9Cl]/\Delta t$ . The reaction rate at any time is related to the slope of the tangent to the curve at that time. Because  $C_4H_9Cl$  is disappearing, the rate is equal to the negative of the slope.

\*You may wish to review briefly the idea of graphical determination of slopes by referring to Appendix A. If you are familiar with calculus, you may recognize that the average rate approaches the instantaneous rate as the time interval approaches zero. This limit, in the notation of calculus, is represented as  $-d[C_4H_9Cl]/dt$ .

form the right triangle shown. The slope is the ratio of the height of the vertical side to the length of the horizontal side:

$$\begin{aligned}\text{Instantaneous rate} &= -\frac{\Delta[\text{C}_4\text{H}_9\text{Cl}]}{\Delta t} = -\frac{(0.017 - 0.042) \text{ M}}{(800 - 400)\text{s}} \\ &= 6.3 \times 10^{-5} \text{ M/s}\end{aligned}$$

In discussions that follow, the term “rate” means “instantaneous rate,” unless indicated otherwise. The instantaneous rate at  $t = 0$  is called the *initial rate* of the reaction.

To understand better the difference between average rate and instantaneous rate, imagine that you have just driven 98 mi in 2.0 hr. Your average speed is 49 mi/hr, whereas your instantaneous speed at any moment is the speedometer reading at that time.

#### **SAMPLE EXERCISE 14.2** Calculating an Instantaneous Rate of Reaction

Using Figure 14.4, calculate the instantaneous rate of disappearance of  $\text{C}_4\text{H}_9\text{Cl}$  at  $t = 0$  (the initial rate).

#### **SOLUTION**

**Analyze:** We are asked to determine an instantaneous rate from a graph of concentration versus time.

**Plan:** To obtain the instantaneous rate at  $t = 0$ , we must determine the slope of the curve at  $t = 0$ . The tangent is drawn on the graph. The slope of this straight line equals the change in the vertical axis divided by the corresponding change in the horizontal axis (that is, change in molarity over change in time).

**Solve:** The straight line falls from  $[\text{C}_4\text{H}_9\text{Cl}] = 0.100 \text{ M}$  to  $0.060 \text{ M}$  in the time change from 0 s to 210 s, as indicated by the tan triangle shown in Figure 14.4. Thus, the initial rate is

$$\text{Rate} = -\frac{\Delta[\text{C}_4\text{H}_9\text{Cl}]}{\Delta t} = -\frac{(0.060 - 0.100) \text{ M}}{(210 - 0) \text{ s}} = 1.9 \times 10^{-4} \text{ M/s}$$

#### **PRACTICE EXERCISE**

Using Figure 14.4, determine the instantaneous rate of disappearance of  $\text{C}_4\text{H}_9\text{Cl}$  at  $t = 300 \text{ s}$ .

**Answer:**  $1.1 \times 10^{-4} \text{ M/s}$

### GIVE IT SOME THOUGHT

Figure 14.4 shows two triangles that are used to determine the slope of the curve at two different times. How do you determine how large a triangle to draw when determining the slope of a curve at a particular point?

## Reaction Rates and Stoichiometry

During our earlier discussion of the hypothetical reaction  $\text{A} \longrightarrow \text{B}$ , we saw that the stoichiometry requires that the rate of disappearance of A equals the rate of appearance of B. Likewise, the stoichiometry of Equation 14.3 indicates that 1 mol of  $\text{C}_4\text{H}_9\text{OH}$  is produced for each mole of  $\text{C}_4\text{H}_9\text{Cl}$  consumed. Therefore, the rate of appearance of  $\text{C}_4\text{H}_9\text{OH}$  equals the rate of disappearance of  $\text{C}_4\text{H}_9\text{Cl}$ :

$$\text{Rate} = -\frac{\Delta[\text{C}_4\text{H}_9\text{Cl}]}{\Delta t} = \frac{\Delta[\text{C}_4\text{H}_9\text{OH}]}{\Delta t}$$

What happens when the stoichiometric relationships are not one to one? For example, consider this reaction:

We can measure the rate of disappearance of HI or the rate of appearance of either  $\text{H}_2$  or  $\text{I}_2$ . Because 2 mol of HI disappear for each mole of  $\text{H}_2$  or  $\text{I}_2$  that forms, the rate of disappearance of HI is twice the rate of appearance of either  $\text{H}_2$  or  $\text{I}_2$ . To equate the rates, we must therefore divide the rate of disappearance of HI by 2 (its coefficient in the balanced chemical equation):

$$\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{HI}]}{\Delta t} = \frac{\Delta[\text{H}_2]}{\Delta t} = \frac{\Delta[\text{I}_2]}{\Delta t}$$

In general, for the reaction

the rate is given by

$$\text{Rate} = -\frac{1}{a} \frac{\Delta[\text{A}]}{\Delta t} = -\frac{1}{b} \frac{\Delta[\text{B}]}{\Delta t} = \frac{1}{c} \frac{\Delta[\text{C}]}{\Delta t} = \frac{1}{d} \frac{\Delta[\text{D}]}{\Delta t} \quad [14.4]$$

When we speak of the rate of a reaction without specifying a particular reactant or product, we will mean it in this sense.\*

### SAMPLE EXERCISE 14.3 | Relating Rates at Which Products Appear and Reactants Disappear

- (a) How is the rate at which ozone disappears related to the rate at which oxygen appears in the reaction  $2 \text{O}_3(g) \longrightarrow 3 \text{O}_2(g)$ ?  
 (b) If the rate at which  $\text{O}_2$  appears,  $\Delta[\text{O}_2]/\Delta t$ , is  $6.0 \times 10^{-5} \text{ M/s}$  at a particular instant, at what rate is  $\text{O}_3$  disappearing at this same time,  $-\Delta[\text{O}_3]/\Delta t$ ?

#### SOLUTION

**Analyze:** We are given a balanced chemical equation and asked to relate the rate of appearance of the product to the rate of disappearance of the reactant.

**Plan:** We can use the coefficients in the chemical equation as shown in Equation 14.4 to express the relative rates of reactions.

**Solve:** (a) Using the coefficients in the balanced equation and the relationship given by Equation 14.4, we have:

$$\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{O}_3]}{\Delta t} = \frac{1}{3} \frac{\Delta[\text{O}_2]}{\Delta t}$$

(b) Solving the equation from part (a) for the rate at which  $\text{O}_3$  disappears,  $-\Delta[\text{O}_3]/\Delta t$  we have:

$$-\frac{\Delta[\text{O}_3]}{\Delta t} = \frac{2}{3} \frac{\Delta[\text{O}_2]}{\Delta t} = \frac{2}{3} (6.0 \times 10^{-5} \text{ M/s}) = 4.0 \times 10^{-5} \text{ M/s}$$

**Check:** We can directly apply a stoichiometric factor to convert the  $\text{O}_2$  formation rate to the rate at which the  $\text{O}_3$  disappears:

$$-\frac{\Delta[\text{O}_3]}{\Delta t} = \left( 6.0 \times 10^{-5} \frac{\text{mol O}_2/\text{L}}{\text{s}} \right) \left( \frac{2 \text{ mol O}_3}{3 \text{ mol O}_2} \right) = 4.0 \times 10^{-5} \frac{\text{mol O}_3/\text{L}}{\text{s}} = 4.0 \times 10^{-5} \text{ M/s}$$

### PRACTICE EXERCISE

The decomposition of  $\text{N}_2\text{O}_5$  proceeds according to the following equation:

If the rate of decomposition of  $\text{N}_2\text{O}_5$  at a particular instant in a reaction vessel is  $4.2 \times 10^{-7} \text{ M/s}$ , what is the rate of appearance of (a)  $\text{NO}_2$ , (b)  $\text{O}_2$ ?

**Answers:** (a)  $8.4 \times 10^{-7} \text{ M/s}$ , (b)  $2.1 \times 10^{-7} \text{ M/s}$

\*Equation 14.4 does not hold true if substances other than C and D are formed in significant amounts during the course of the reaction. For example, sometimes intermediate substances build in concentration before forming the final products. In that case, the relationship between the rate of disappearance of reactants and the rate of appearance of products will not be given by Equation 14.4. All reactions whose rates we consider in this chapter obey Equation 14.4.

## A Closer Look

### USING SPECTROSCOPIC METHODS TO MEASURE REACTION RATES

A variety of techniques can be used to monitor the concentration of a reactant or product during a reaction. Spectroscopic methods, which rely on the ability of substances to absorb (or emit) electromagnetic radiation, are some of the most useful. Spectroscopic kinetic studies are often performed with the reaction mixture in the sample compartment of the spectrometer. The spectrometer is set to measure the light absorbed at a wavelength characteristic of one of the reactants or products. In the decomposition of  $\text{HI}(g)$  into  $\text{H}_2(g)$  and  $\text{I}_2(g)$  for example, both  $\text{HI}$  and  $\text{H}_2$  are colorless, whereas  $\text{I}_2$  is violet. During the course of the reaction, the color increases in intensity as  $\text{I}_2$  forms. Thus, visible light of appropriate wavelength can be used to monitor the reaction.

Figure 14.5  $\blacktriangledown$  shows the basic components of a spectrometer. The spectrometer measures the amount of light absorbed by the sample by comparing the intensity of the light emitted

from the light source with the intensity of the light that emerges from the sample. As the concentration of  $\text{I}_2$  increases and its color becomes more intense, the amount of light absorbed by the reaction mixture increases, causing less light to reach the detector.

**Beer's law** relates the amount of light being absorbed to the concentration of the substance absorbing the light:

$$A = abc \quad [14.5]$$

In this equation,  $A$  is the measured absorbance,  $a$  is the molar absorptivity constant (a characteristic of the substance being monitored),  $b$  is the path length through which the radiation must pass, and  $c$  is the molar concentration of the absorbing substance. Thus, the concentration is directly proportional to absorbance.

Basic components of a spectrometer.

## 14.3 THE RATE LAW: THE EFFECT OF CONCENTRATION ON RATE

One way of studying the effect of concentration on reaction rate is to determine the way in which the rate at the beginning of a reaction (the initial rate) depends on the starting concentrations. To illustrate this approach, consider the following reaction:

We might study the rate of this reaction by measuring the concentration of  $\text{NH}_4^+$  or  $\text{NO}_2^-$  as a function of time or by measuring the volume of  $\text{N}_2$  collected. Because the stoichiometric coefficients on  $\text{NH}_4^+$ ,  $\text{NO}_2^-$ , and  $\text{N}_2$  are all the same, all of these rates will be equal.

Table 14.2  $\blacktriangledown$  shows the initial reaction rate for various starting concentrations of  $\text{NH}_4^+$  and  $\text{NO}_2^-$ . These data indicate that changing either  $[\text{NH}_4^+]$  or

**TABLE 14.2** ■ Rate Data for the Reaction of Ammonium and Nitrite Ions in Water at 25 °C

Experiment Number	Initial $\text{NH}_4^+$ Concentration (M)	Initial $\text{NO}_2^-$ Concentration (M)	Observed Initial Rate (M/s)
1	0.0100	0.200	$5.4 \times 10^{-7}$
2	0.0200	0.200	$10.8 \times 10^{-7}$
3	0.0400	0.200	$21.5 \times 10^{-7}$
4	0.200	0.0202	$10.8 \times 10^{-7}$
5	0.200	0.0404	$21.6 \times 10^{-7}$
6	0.200	0.0808	$43.3 \times 10^{-7}$

$[\text{NO}_2^-]$  changes the reaction rate. Notice that if we double  $[\text{NH}_4^+]$  while holding  $[\text{NO}_2^-]$  constant, the rate doubles (compare experiments 1 and 2). If  $[\text{NH}_4^+]$  is increased by a factor of 4 with  $[\text{NO}_2^-]$  left unchanged (compare experiments 1 and 3), the rate changes by a factor of 4, and so forth. These results indicate that the rate is proportional to  $[\text{NH}_4^+]$ . When  $[\text{NO}_2^-]$  is similarly varied while  $[\text{NH}_4^+]$  is held constant, the rate is affected in the same manner. Thus, the rate is also directly proportional to the concentration of  $\text{NO}_2^-$ . We can express the way in which the rate depends on the concentrations of the reactants,  $\text{NH}_4^+$  and  $\text{NO}_2^-$ , in terms of the following equation:

$$\text{Rate} = k[\text{NH}_4^+][\text{NO}_2^-] \quad [14.6]$$

An equation such as Equation 14.6, which shows how the rate depends on the concentrations of reactants, is called a **rate law**. For a general reaction,

the rate law generally has the form

$$\text{Rate} = k[\text{A}]^m[\text{B}]^n \quad [14.7]$$

The constant  $k$  in the rate law is called the **rate constant**. The magnitude of  $k$  changes with temperature and therefore determines how temperature affects rate, as we will see in Section 14.5. The exponents  $m$  and  $n$  are typically small whole numbers (usually 0, 1, or 2). We will consider these exponents more closely very shortly.

If we know the rate law for a reaction and its rate for a set of reactant concentrations, we can calculate the value of the rate constant,  $k$ . For example, using the data in Table 14.2 and the results from experiment 1, we can substitute into Equation 14.6

$$5.4 \times 10^{-7} \text{ M/s} = k(0.0100 \text{ M})(0.200 \text{ M})$$

Solving for  $k$  gives

$$k = \frac{5.4 \times 10^{-7} \text{ M/s}}{(0.0100 \text{ M})(0.200 \text{ M})} = 2.7 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$$

You may wish to verify that this same value of  $k$  is obtained using any of the other experimental results given in Table 14.2.

Once we have both the rate law and the value of the rate constant for a reaction, we can calculate the rate of reaction for any set of concentrations. For example, using Equation 14.6 and  $k = 2.7 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$ , we can calculate the rate for  $[\text{NH}_4^+] = 0.100 \text{ M}$  and  $[\text{NO}_2^-] = 0.100 \text{ M}$ :

$$\text{Rate} = (2.7 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1})(0.100 \text{ M})(0.100 \text{ M}) = 2.7 \times 10^{-6} \text{ M/s}$$

### GIVE IT SOME THOUGHT

(a) What is a rate law? (b) What is the name of the quantity  $k$  in any rate law?

## Reaction Orders: The Exponents in the Rate Law

The rate laws for most reactions have the general form

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots \quad [14.8]$$

The exponents  $m$  and  $n$  in a rate law are called **reaction orders**. For example, consider again the rate law for the reaction of  $\text{NH}_4^+$  with  $\text{NO}_2^-$ :

$$\text{Rate} = k[\text{NH}_4^+][\text{NO}_2^-]$$

Because the exponent of  $[\text{NH}_4^+]$  is 1, the rate is *first order* in  $\text{NH}_4^+$ . The rate is also first order in  $\text{NO}_2^-$ . (The exponent "1" is not shown explicitly in rate laws.) The **overall reaction order** is the sum of the orders with respect to each reactant in the rate law. Thus, the rate law has an overall reaction order of  $1 + 1 = 2$ , and the reaction is *second order overall*.

The exponents in a rate law indicate how the rate is affected by the concentration of each reactant. Because the rate at which  $\text{NH}_4^+$  reacts with  $\text{NO}_2^-$  depends on  $[\text{NH}_4^+]$  raised to the first power, the rate doubles when  $[\text{NH}_4^+]$  doubles, triples when  $[\text{NH}_4^+]$  triples, and so forth. Doubling or tripling  $[\text{NO}_2^-]$  likewise doubles or triples the rate. If a rate law is second order with respect to a reactant,  $[\text{A}]^2$ , then doubling the concentration of that substance causes the reaction rate to quadruple ( $[2]^2 = 4$ ), whereas tripling the concentration causes the rate to increase ninefold ( $[3]^2 = 9$ ).

The following are some additional examples of rate laws:

Although the exponents in a rate law are sometimes the same as the coefficients in the balanced equation, this is not necessarily the case, as seen in Equations 14.9 and 14.10. *The values of these exponents must be determined experimentally.* In most rate laws, reaction orders are 0, 1, or 2. However, we also occasionally encounter rate laws in which the reaction order is fractional (such as Equation 14.10) or even negative.

### GIVE IT SOME THOUGHT

The experimentally determined rate law for the reaction  $2 \text{NO}(\text{g}) + 2 \text{H}_2(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{g})$  is  $\text{rate} = k[\text{NO}]^2[\text{H}_2]$ . (a) What are the reaction orders in this rate law? (b) Does doubling the concentration of NO have the same effect on rate as doubling the concentration of  $\text{H}_2$ ?

### SAMPLE EXERCISE 14.4 Relating a Rate Law to the Effect of Concentration on Rate

Consider a reaction  $\text{A} + \text{B} \longrightarrow \text{C}$  for which  $\text{rate} = k[\text{A}][\text{B}]^2$ . Each of the following boxes represents a reaction mixture in which A is shown as red spheres and B as purple ones. Rank these mixtures in order of increasing rate of reaction.

### SOLUTION

**Analyze:** We are given three boxes containing different numbers of spheres representing mixtures containing different reactant concentrations. We are asked to use the given rate law and the compositions of the boxes to rank the mixtures in order of increasing reaction rates.

**Plan:** Because all three boxes have the same volume, we can put the number of spheres of each kind into the rate law and calculate the rate for each box.

**Solve:** Box 1 contains 5 red spheres and 5 purple spheres, giving the following rate:

$$\text{Box 1: Rate} = k(5)(5)^2 = 125k$$

Box 2 contains 7 red spheres and 3 purple spheres:

$$\text{Box 2: Rate} = k(7)(3)^2 = 63k$$

Box 3 contains 3 red spheres and 7 purple spheres:

$$\text{Box 3: Rate} = k(3)(7)^2 = 147k$$

The slowest rate is  $63k$  (box 2), and the highest is  $147k$  (box 3). Thus, the rates vary in the order  $2 < 1 < 3$ .

**Check:** Each box contains 10 spheres. The rate law indicates that in this case [B] has a greater influence on rate than [A] because B has a higher reaction order. Hence, the mixture with the highest concentration of B (most purple spheres) should react fastest. This analysis confirms the order  $2 < 1 < 3$ .

### ■ PRACTICE EXERCISE

Assuming that rate =  $k[A][B]$ , rank the mixtures represented in this Sample Exercise in order of increasing rate.

**Answer:**  $2 = 3 < 1$

## Units of Rate Constants

The units of the rate constant depend on the overall reaction order of the rate law. In a reaction that is second order overall, for example, the units of the rate constant must satisfy the equation:

$$\text{Units of rate} = (\text{units of rate constant})(\text{units of concentration})^2$$

Hence, in our usual units of concentration and time

$$\text{Units of rate constant} = \frac{\text{units of rate}}{(\text{units of concentration})^2} = \frac{M/s}{M^2} = M^{-1} s^{-1}$$

### ■ SAMPLE EXERCISE 14.5 | Determining Reaction Orders and Units for Rate Constants

(a) What are the overall reaction orders for the reactions described in Equations 14.9 and 14.10? (b) What are the units of the rate constant for the rate law in Equation 14.9?

#### SOLUTION

**Analyze:** We are given two rate laws and asked to express (a) the overall reaction order for each and (b) the units for the rate constant for the first reaction.

**Plan:** The overall reaction order is the sum of the exponents in the rate law. The units for the rate constant,  $k$ , are found by using the normal units for rate ( $M/s$ ) and concentration ( $M$ ) in the rate law and applying algebra to solve for  $k$ .

**Solve:** (a) The rate of the reaction in Equation 14.9 is first order in  $N_2O_5$  and first order overall. The reaction in Equation 14.10 is first order in  $CHCl_3$  and one-half order in  $Cl_2$ . The overall reaction order is three halves.

(b) For the rate law for Equation 14.9, we have

$$\text{Units of rate} = (\text{units of rate constant})(\text{units of concentration})$$

So

$$\text{Units of rate constant} = \frac{\text{units of rate}}{\text{units of concentration}} = \frac{M/s}{M} = s^{-1}$$

Notice that the units of the rate constant change as the overall order of the reaction changes.

### ■ PRACTICE EXERCISE

(a) What is the reaction order of the reactant  $H_2$  in Equation 14.11? (b) What are the units of the rate constant for Equation 14.11?

**Answers:** (a) 1, (b)  $M^{-1} s^{-1}$

### Using Initial Rates to Determine Rate Laws

The rate law for any chemical reaction must be determined experimentally; it cannot be predicted by merely looking at the chemical equation. We often determine the rate law for a reaction by the same method we applied to the data in Table 14.2: We observe the effect of changing the initial concentrations of the reactants on the initial rate of the reaction.

We have seen that the rate laws for most reactions have the general form

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots$$

Thus, the task of determining the rate law becomes one of determining the reaction orders,  $m$  and  $n$ . In most reactions the reaction orders are 0, 1, or 2. If a reaction is zero order in a particular reactant, changing its concentration will have no effect on rate (as long as some of the reactant is present) because any concentration raised to the zero power equals 1. On the other hand, we have seen that when a reaction is first order in a reactant, changes in the concentration of that reactant will produce proportional changes in the rate. Thus, doubling the concentration will double the rate, and so forth. Finally, when the rate law is second order in a particular reactant, doubling its concentration increases the rate by a factor of  $2^2 = 4$ , tripling its concentration causes the rate to increase by a factor of  $3^2 = 9$ , and so forth.

In working with rate laws, it is important to realize that the *rate* of a reaction depends on concentration, but the *rate constant* does not. As we will see later in this chapter, the rate constant (and hence the reaction rate) is affected by temperature and by the presence of a catalyst.

#### SAMPLE EXERCISE 14.6 | Determining a Rate Law from Initial Rate Data

The initial rate of a reaction  $A + B \longrightarrow C$  was measured for several different starting concentrations of A and B, and the results are as follows:

Experiment Number	[A] (M)	[B] (M)	Initial Rate (M/s)
1	0.100	0.100	$4.0 \times 10^{-5}$
2	0.100	0.200	$4.0 \times 10^{-5}$
3	0.200	0.100	$16.0 \times 10^{-5}$

Using these data, determine (a) the rate law for the reaction, (b) the rate constant, (c) the rate of the reaction when  $[A] = 0.050 M$  and  $[B] = 0.100 M$ .

#### SOLUTION

**Analyze:** We are given a table of data that relates concentrations of reactants with initial rates of reaction and asked to determine (a) the rate law, (b) the rate constant, and (c) the rate of reaction for a set of concentrations not listed in the table.

**Plan:** (a) We assume that the rate law has the following form:  $\text{Rate} = k[A]^m[B]^n$  so we must use the given data to deduce the reaction orders  $m$  and  $n$ . We do so by determining how changes in the concentration change the rate. (b) Once we know  $m$  and  $n$ , we can use the rate law and one of the sets of data to determine the rate constant  $k$ . (c) Now that we know both the rate constant and the reaction orders, we can use the rate law with the given concentrations to calculate rate.

**Solve:** (a) As we move from experiment 1 to experiment 2, [A] is held constant and [B] is doubled. Thus, this pair of experiments shows how [B] affects the rate, allowing us to deduce the order of the rate law with respect to B. Because the rate remains the same when [B] is doubled, the concentration of B has no effect on the reaction rate. The rate law is therefore zero order in B (that is,  $n = 0$ ).

In experiments 1 and 3, [B] is held constant so these data show how [A] affects rate. Holding [B] constant while doubling [A] increases the rate fourfold. This result indicates that rate is proportional to  $[A]^2$  (that is, the reaction is second order in A). Hence, the rate law is

$$\text{Rate} = k[A]^2[B]^0 = k[A]^2$$

This rate law could be reached in a more formal way by taking the ratio of the rates from two experiments:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{4.0 \times 10^{-5} \text{ M/s}}{4.0 \times 10^{-5} \text{ M/s}} = 1$$

Using the rate law, we have

$$1 = \frac{\text{rate 2}}{\text{rate 1}} = \frac{k[0.100 \text{ M}]^m [0.200 \text{ M}]^n}{k[0.100 \text{ M}]^m [0.100 \text{ M}]^n} = \frac{[0.200]^n}{[0.100]^n} = 2^n$$

$2^n$  equals 1 under only one condition:

$$n = 0$$

We can deduce the value of  $m$  in a similar fashion:

$$\frac{\text{Rate 3}}{\text{Rate 1}} = \frac{16.0 \times 10^{-5} \text{ M/s}}{4.0 \times 10^{-5} \text{ M/s}} = 4$$

Using the rate law gives

$$4 = \frac{\text{rate 3}}{\text{rate 1}} = \frac{k[0.200 \text{ M}]^m [0.100 \text{ M}]^n}{k[0.100 \text{ M}]^m [0.100 \text{ M}]^n} = \frac{[0.200]^m}{[0.100]^m} = 2^m$$

Because  $2^m = 4$ , we conclude that

$$m = 2$$

(b) Using the rate law and the data from experiment 1, we have

$$k = \frac{\text{rate}}{[\text{A}]^2} = \frac{4.0 \times 10^{-5} \text{ M/s}}{(0.100 \text{ M})^2} = 4.0 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1}$$

(c) Using the rate law from part (a) and the rate constant from part (b), we have

$$\text{Rate} = k[\text{A}]^2 = (4.0 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1})(0.050 \text{ M})^2 = 1.0 \times 10^{-5} \text{ M/s}$$

Because [B] is not part of the rate law, it is irrelevant to the rate, if there is at least some B present to react with A.

**Check:** A good way to check our rate law is to use the concentrations in experiment 2 or 3 and see if we can correctly calculate the rate. Using data from experiment 3, we have

$$\text{Rate} = k[\text{A}]^2 = (4.0 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1})(0.200 \text{ M})^2 = 1.6 \times 10^{-4} \text{ M/s}$$

Thus, the rate law correctly reproduces the data, giving both the correct number and the correct units for the rate.

### PRACTICE EXERCISE

The following data were measured for the reaction of nitric oxide with hydrogen:

Experiment Number	[NO] (M)	[H <sub>2</sub> ] (M)	Initial Rate (M/s)
1	0.10	0.10	$1.23 \times 10^{-3}$
2	0.10	0.20	$2.46 \times 10^{-3}$
3	0.20	0.10	$4.92 \times 10^{-3}$

(a) Determine the rate law for this reaction. (b) Calculate the rate constant. (c) Calculate the rate when [NO] = 0.050 M and [H<sub>2</sub>] = 0.150 M

**Answers:** (a) rate =  $k[\text{NO}]^2[\text{H}_2]$ ; (b)  $k = 1.2 \text{ M}^{-2} \text{ s}^{-1}$ ; (c) rate =  $4.5 \times 10^{-4} \text{ M/s}$

## 14.4 THE CHANGE OF CONCENTRATION WITH TIME

The rate laws that we have examined so far enable us to calculate the rate of a reaction from the rate constant and reactant concentrations. These rate laws can also be converted into equations that show the relationship between the concentrations of the reactants or products and time. The mathematics required to accomplish this conversion involves calculus. We do not expect you to be able to perform the calculus operations; however, you should be able to use the resulting equations. We will apply this conversion to two of the simplest rate laws: those that are first order overall and those that are second order overall.

### First-Order Reactions

A **first-order reaction** is one whose rate depends on the concentration of a single reactant raised to the first power. For a reaction of the type  $A \longrightarrow \text{products}$  the rate law may be first order:

$$\text{Rate} = -\frac{\Delta[A]}{\Delta t} = k[A]$$

This form of a rate law, which expresses how rate depends on concentration, is called the *differential rate law*. Using an operation from calculus called integration, this relationship can be transformed into an equation that relates the concentration of A at the start of the reaction,  $[A]_0$ , to its concentration at any other time  $t$ ,  $[A]_t$ :

$$\ln[A]_t - \ln[A]_0 = -kt \quad \text{or} \quad \ln \frac{[A]_t}{[A]_0} = -kt \quad [14.12]$$

This form of the rate law is called the *integrated rate law*. The function “ln” in Equation 14.12 is the natural logarithm (Appendix A.2). Equation 14.12 can also be rearranged and written as follows:

$$\ln[A]_t = -kt + \ln[A]_0 \quad [14.13]$$

Equations 14.12 and 14.13 can be used with any concentration units, as long as the units are the same for both  $[A]_t$  and  $[A]_0$ .

For a first-order reaction, Equation 14.12 or 14.13 can be used in several ways. Given any three of the following quantities, we can solve for the fourth:  $k$ ,  $t$ ,  $[A]_0$ , and  $[A]_t$ . Thus, you can use these equations, for example, to determine (1) the concentration of a reactant remaining at any time after the reaction has started, (2) the time required for a given fraction of a sample to react, or (3) the time required for a reactant concentration to fall to a certain level.

#### SAMPLE EXERCISE 14.7 | Using the Integrated First-Order Rate Law

The decomposition of a certain insecticide in water follows first-order kinetics with a rate constant of  $1.45 \text{ yr}^{-1}$  at  $12^\circ\text{C}$ . A quantity of this insecticide is washed into a lake on June 1, leading to a concentration of  $5.0 \times 10^{-7} \text{ g/cm}^3$ . Assume that the average temperature of the lake is  $12^\circ\text{C}$ . (a) What is the concentration of the insecticide on June 1 of the following year? (b) How long will it take for the concentration of the insecticide to decrease to  $3.0 \times 10^{-7} \text{ g/cm}^3$ ?

#### SOLUTION

**Analyze:** We are given the rate constant for a reaction that obeys first-order kinetics, as well as information about concentrations and times, and asked to calculate how much reactant (insecticide) remains after one year. We must also determine the time interval needed to reach a particular insecticide concentration. Because the exercise gives time in (a) and asks for time in (b), we know that the integrated rate law, Equation 14.13, is required.

**Plan:** (a) We are given  $k = 1.45 \text{ yr}^{-1}$ ,  $t = 1.00 \text{ yr}$  and  $[\text{insecticide}]_0 = 5.0 \times 10^{-7} \text{ g/cm}^3$ , and so Equation 14.13 can be solved for  $[\text{insecticide}]_t$ . (b) We have  $k = 1.45 \text{ yr}^{-1}$ ,  $[\text{insecticide}]_0 = 5.0 \times 10^{-7} \text{ g/cm}^3$ , and  $[\text{insecticide}]_t = 3.0 \times 10^{-7} \text{ g/cm}^3$ , and so we can solve Equation 14.13 for time,  $t$ .

**Solve:** (a) Substituting the known quantities into Equation 14.13, we have

$$\ln[\text{insecticide}]_{t=1 \text{ yr}} = -(1.45 \text{ yr}^{-1})(1.00 \text{ yr}) + \ln(5.0 \times 10^{-7})$$

We use the ln function on a calculator to evaluate the second term on the right, giving

$$\ln[\text{insecticide}]_{t=1 \text{ yr}} = -1.45 + (-14.51) = -15.96$$

To obtain  $[\text{insecticide}]_{t=1 \text{ yr}}$ , we use the inverse natural logarithm, or  $e^x$ , function on the calculator:

$$[\text{insecticide}]_{t=1 \text{ yr}} = e^{-15.96} = 1.2 \times 10^{-7} \text{ g/cm}^3$$

Note that the concentration units for  $[A]_t$  and  $[A]_0$  must be the same.

(b) Again substituting into Equation 14.13, with  $[\text{insecticide}]_t = 3.0 \times 10^{-7} \text{ g/cm}^3$ , gives

$$\ln(3.0 \times 10^{-7}) = -(1.45 \text{ yr}^{-1})(t) + \ln(5.0 \times 10^{-7})$$

Solving for  $t$  gives

$$\begin{aligned} t &= -[\ln(3.0 \times 10^{-7}) - \ln(5.0 \times 10^{-7})]/1.45 \text{ yr}^{-1} \\ &= -(-15.02 + 14.51)/1.45 \text{ yr}^{-1} = 0.35 \text{ yr} \end{aligned}$$

**Check:** In part (a) the concentration remaining after 1.00 yr (that is,  $1.2 \times 10^{-7} \text{ g/cm}^3$ ) is less than the original concentration ( $5.0 \times 10^{-7} \text{ g/cm}^3$ ), as it should be. In (b) the given concentration ( $3.0 \times 10^{-7} \text{ g/cm}^3$ ) is greater than that remaining after 1.00 yr, indicating that the time must be less than a year. Thus,  $t = 0.35 \text{ yr}$  is a reasonable answer.

### PRACTICE EXERCISE

The decomposition of dimethyl ether,  $(\text{CH}_3)_2\text{O}$ , at  $510^\circ\text{C}$  is a first-order process with a rate constant of  $6.8 \times 10^{-4} \text{ s}^{-1}$ :

If the initial pressure of  $(\text{CH}_3)_2\text{O}$  is 135 torr, what is its pressure after 1420 s?

**Answer:** 51 torr

Equation 14.13 can be used to verify whether a reaction is first order and to determine its rate constant. This equation has the form of the general equation for a straight line,  $y = mx + b$ , in which  $m$  is the slope and  $b$  is the  $y$ -intercept of the line (Appendix A.4):

$$\ln[A]_t = -k \cdot t + \ln[A]_0$$

$$y = m \cdot x + b$$

For a first-order reaction, therefore, a graph of  $\ln[A]_t$  versus time gives a straight line with a slope of  $-k$  and a  $y$ -intercept of  $\ln[A]_0$ . A reaction that is not first order will not yield a straight line.

As an example, consider the conversion of methyl isonitrile ( $\text{CH}_3\text{NC}$ ) to acetonitrile ( $\text{CH}_3\text{CN}$ ) (Figure 14.6). Because experiments show that the reaction is first order, we can write the rate equation:

$$\ln[\text{CH}_3\text{NC}]_t = -kt + \ln[\text{CH}_3\text{NC}]_0$$

Figure 14.7(a) shows how the pressure of methyl isonitrile varies with time as it rearranges in the gas phase at  $198.9^\circ\text{C}$ . We can use pressure as a unit of concentration for a gas because from the ideal-gas law the pressure is directly proportional to the number of moles per unit volume. Figure 14.7(b) shows a plot of the natural logarithm of the pressure versus time, a plot that yields a straight line. The slope of this line is  $-5.1 \times 10^{-5} \text{ s}^{-1}$ . (You should verify this for yourself, remembering that your result may vary slightly from ours because of inaccuracies associated with reading the graph.) Because the slope of the line equals  $-k$ , the rate constant for this reaction equals  $5.1 \times 10^{-5} \text{ s}^{-1}$ .

Methyl isonitrile

Acetonitrile

**▲ Figure 14.6 A first-order reaction.** The transformation of methyl isonitrile ( $\text{CH}_3\text{NC}$ ) to acetonitrile ( $\text{CH}_3\text{CN}$ ) is a first-order process. Methyl isonitrile and acetonitrile are isomers, molecules that have the same atoms arranged differently. This reaction is called an isomerization reaction.

### GIVE IT SOME THOUGHT

What do the  $y$ -intercepts in Figure 14.7(a) and (b) represent?

(a)

(b)

**◀ Figure 14.7 Kinetic data for conversion of methyl isonitrile.** (a) Variation in the partial pressure of methyl isonitrile ( $\text{CH}_3\text{NC}$ ) with time during the reaction  $\text{CH}_3\text{NC} \longrightarrow \text{CH}_3\text{CN}$  at  $198.9^\circ\text{C}$ . (b) A plot of the natural logarithm of the  $\text{CH}_3\text{NC}$  pressure as a function of time. The fact that a straight line fits the data confirms that the rate law is first order.

## Second-Order Reactions

A **second-order reaction** is one whose rate depends on the reactant concentration raised to the second power or on the concentrations of two different reactants, each raised to the first power. For simplicity, let's consider reactions of the type  $A \longrightarrow \text{products}$  or  $A + B \longrightarrow \text{products}$  that are second order in just one reactant, A:

$$\text{Rate} = -\frac{\Delta[A]}{\Delta t} = k[A]^2$$

With the use of calculus, this differential rate law can be used to derive the following integrated rate law:

$$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0} \quad [14.14]$$

This equation, like Equation 14.13, has four variables,  $k$ ,  $t$ ,  $[A]_0$ , and  $[A]_t$ , and any one of these can be calculated knowing the other three. Equation 14.14 also has the form of a straight line ( $y = mx + b$ ). If the reaction is second order, a plot of  $1/[A]_t$  versus  $t$  will yield a straight line with a slope equal to  $k$  and a  $y$ -intercept equal to  $1/[A]_0$ . One way to distinguish between first- and second-order rate laws is to graph both  $\ln[A]_t$  and  $1/[A]_t$  against  $t$ . If the  $\ln[A]_t$  plot is linear, the reaction is first order; if the  $1/[A]_t$  plot is linear, the reaction is second order.

### SAMPLE EXERCISE 14.8 Determining Reaction Order from the Integrated Rate Law

The following data were obtained for the gas-phase decomposition of nitrogen dioxide at 300 °C,  $\text{NO}_2(\text{g}) \longrightarrow \text{NO}(\text{g}) + \frac{1}{2}\text{O}_2(\text{g})$ :

Time (s)	$[\text{NO}_2]$ (M)
0.0	0.01000
50.0	0.00787
100.0	0.00649
200.0	0.00481
300.0	0.00380

Is the reaction first or second order in  $\text{NO}_2$ ?

#### SOLUTION

**Analyze:** We are given the concentrations of a reactant at various times during a reaction and asked to determine whether the reaction is first or second order.

**Plan:** We can plot  $\ln[\text{NO}_2]$  and  $1/[\text{NO}_2]$  against time. One or the other will be linear, indicating whether the reaction is first or second order.

**Solve:** To graph  $\ln[\text{NO}_2]$  and  $1/[\text{NO}_2]$  against time, we will first prepare the following table from the data given:

Time (s)	$[\text{NO}_2]$ (M)	$\ln[\text{NO}_2]$	$1/[\text{NO}_2]$
0.0	0.01000	-4.605	100
50.0	0.00787	-4.845	127
100.0	0.00649	-5.037	154
200.0	0.00481	-5.337	208
300.0	0.00380	-5.573	263

As Figure 14.8 shows, only the plot of  $1/[\text{NO}_2]$  versus time is linear. Thus, the reaction obeys a second-order rate law:  $\text{Rate} = k[\text{NO}_2]^2$ . From the slope of this straight-line graph, we determine that  $k = 0.543 \text{ M}^{-1} \text{ s}^{-1}$  for the disappearance of  $\text{NO}_2$ .

▲ **Figure 14.8 Kinetic data for decomposition of NO<sub>2</sub>.** The reaction is  $\text{NO}_2(g) \longrightarrow \text{NO}(g) + \frac{1}{2} \text{O}_2(g)$ , and the data were collected at 300 °C. (a) A plot of  $\ln[\text{NO}_2]$  versus time is not linear, indicating that the reaction is not first order in NO<sub>2</sub>. (b) A plot of  $1/[\text{NO}_2]$  versus time is linear, indicating that the reaction is second order in NO<sub>2</sub>.

### PRACTICE EXERCISE

Consider again the decomposition of NO<sub>2</sub> discussed in the Sample Exercise. The reaction is second order in NO<sub>2</sub> with  $k = 0.543 \text{ M}^{-1} \text{ s}^{-1}$ . If the initial concentration of NO<sub>2</sub> in a closed vessel is 0.0500 M, what is the remaining concentration after 0.500 h? *Answer:* Using Equation 14.14, we find  $[\text{NO}_2] = 1.00 \times 10^{-3} \text{ M}$

## Half-life

The **half-life** of a reaction,  $t_{1/2}$ , is the time required for the concentration of a reactant to reach one-half of its initial value,  $[\text{A}]_{t_{1/2}} = \frac{1}{2}[\text{A}]_0$ . The half-life is a convenient way to describe how fast a reaction occurs, especially if it is a first-order process. A fast reaction will have a short half-life.

We can determine the half-life of a first-order reaction by substituting  $[\text{A}]_{t_{1/2}}$  into Equation 14.12:

$$\begin{aligned} \ln \frac{\frac{1}{2}[\text{A}]_0}{[\text{A}]_0} &= -kt_{1/2} \\ \ln \frac{1}{2} &= -kt_{1/2} \\ t_{1/2} &= -\frac{\ln \frac{1}{2}}{k} = \frac{0.693}{k} \end{aligned} \quad [14.15]$$

From Equation 14.15, we see that  $t_{1/2}$  for a first-order rate law does not depend on the starting concentration. Consequently, the half-life remains constant throughout the reaction. If, for example, the concentration of the reactant is 0.120 M at some moment in the reaction, it will be  $\frac{1}{2}(0.120 \text{ M}) = 0.060 \text{ M}$  after one half-life. After one more half-life passes, the concentration will drop to 0.030 M, and so on. Equation 14.15 also indicates that we can calculate  $t_{1/2}$  for a first-order reaction if  $k$  is known, or  $k$  if  $t_{1/2}$  is known.

The change in concentration over time for the first-order rearrangement of methyl isonitrile at 198.9 °C is graphed in Figure 14.9. The first half-life is shown at 13,600 s (that is, 3.78 h). At a time 13,600 s later, the isonitrile concentration has decreased to one-half of one-half, or one-fourth the original concentration. In a first-order reaction, the concentration of the reactant decreases by  $\frac{1}{2}$  in each of a series of regularly spaced time intervals, namely,  $t_{1/2}$ . The concept of half-life is widely used in describing radioactive decay, a first-order process that we will discuss in detail in Section 21.4.

▼ **Figure 14.9 Half-life of a first-order reaction.** Pressure of methyl isonitrile as a function of time showing two successive half-lives of the isomerization reaction depicted in Figure 14.6.

## Chemistry Put to Work

## METHYL BROMIDE IN THE ATMOSPHERE

Several small molecules containing carbon–chlorine or carbon–bromine bonds, when present in the stratosphere, are capable of reacting with ozone ( $O_3$ ) and thus contributing to the destruction of Earth’s ozone layer. Whether a halogen-containing molecule contributes significantly to destruction of the ozone layer depends in part on the molecule’s average lifetime in the atmosphere. It takes quite a long time for molecules formed at Earth’s surface to diffuse through the lower atmosphere (called the troposphere) and move into the stratosphere, where the ozone layer is located (Figure 14.10). Decomposition in the lower atmosphere competes with diffusion into the stratosphere.

The much-discussed chlorofluorocarbons, or CFCs, contribute to the destruction of the ozone layer because they have long lifetimes in the troposphere. Thus, they persist long enough for a substantial fraction of the molecules to find their way to the stratosphere.

Another simple molecule that has the potential to destroy the stratospheric ozone layer is methyl bromide ( $CH_3Br$ ). This substance has a wide range of uses, including antifungal treatment of plant seeds, and has therefore been produced in large quantities in the past (about 150 million pounds per year worldwide in 1997). In the stratosphere, the C–Br bond is broken through absorption of short-wavelength radiation. The resultant Br atoms then catalyze decomposition of  $O_3$ .

Methyl bromide is removed from the lower atmosphere by a variety of mechanisms, including a slow reaction with ocean water:

To determine the potential importance of  $CH_3Br$  in destruction of the ozone layer, it is important to know how rapidly the reaction in Equation 14.16 and all other reactions together remove  $CH_3Br$  from the atmosphere before it can diffuse into the stratosphere.

Scientists have carried out research to estimate the average lifetime of  $CH_3Br$  in Earth’s atmosphere. Such an estimate is difficult to make. It cannot be done in laboratory-based experiments because the conditions that exist in the atmosphere above the planet are too complex to be simulated in the laboratory. Instead, scientists gathered nearly 4000 samples of the

▲ **Figure 14.10 Distribution and fate of methyl bromide in the atmosphere.** Some  $CH_3Br$  is removed from the atmosphere by decomposition, and some diffuses upward into the stratosphere, where it contributes to destruction of the ozone layer. The relative rates of decomposition and diffusion determine how extensively methyl bromide is involved in destruction of the ozone layer.

atmosphere during aircraft flights all over the Pacific Ocean and analyzed them for the presence of several trace organic substances, including methyl bromide. From a detailed analysis of the concentrations, it was possible to estimate the *atmospheric residence time* for  $CH_3Br$ .

The atmospheric residence time is related to the half-life for  $CH_3Br$  in the lower atmosphere, assuming that it decomposes by a first-order process. From the experimental data, the half-life for methyl bromide in the lower atmosphere is estimated to be  $0.8 \pm 0.1$  yr. That is, a collection of  $CH_3Br$  molecules present at any given time will, on average, be 50% decomposed after 0.8 years, 75% decomposed after 1.6 years, and so on. A half-life of 0.8 years, while comparatively short, is still sufficiently long so that  $CH_3Br$  contributes significantly to the destruction of the ozone layer. In 1997 an international agreement was reached to phase out use of methyl bromide in developed countries by 2005. However, in recent years exemptions for critical agricultural use have been requested and granted. Nevertheless, worldwide production was down to 30 million pounds worldwide in 2005, two-thirds of which is used in the United States.

**Related Exercise:** 14-111

## GIVE IT SOME THOUGHT

If a solution containing 10.0 g of a substance reacts by first-order kinetics, how many grams remain after 3 half-lives?

### SAMPLE EXERCISE 14.9 Determining the Half-life of a First-Order Reaction

The reaction of  $C_4H_9Cl$  with water is a first-order reaction. Figure 14.4 shows how the concentration of  $C_4H_9Cl$  changes with time at a particular temperature. (a) From that graph, estimate the half-life for this reaction. (b) Use the half-life from (a) to calculate the rate constant.

**SOLUTION**

**Analyze:** We are asked to estimate the half-life of a reaction from a graph of concentration versus time and then to use the half-life to calculate the rate constant for the reaction.

**Plan:** (a) To estimate a half-life, we can select a concentration and then determine the time required for the concentration to decrease to half of that value. (b) Equation 14.15 is used to calculate the rate constant from the half-life.

**Solve:** (a) From the graph, we see that the initial value of  $[\text{C}_4\text{H}_9\text{Cl}]$  is 0.100 M. The half-life for this first-order reaction is the time required for  $[\text{C}_4\text{H}_9\text{Cl}]$  to decrease to 0.050 M, which we can read off the graph. This point occurs at approximately 340 s. (b) Solving Equation 14.15 for  $k$ , we have

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{340 \text{ s}} = 2.0 \times 10^{-3} \text{ s}^{-1}$$

**Check:** At the end of the second half-life, which should occur at 680 s, the concentration should have decreased by yet another factor of 2, to 0.025 M. Inspection of the graph shows that this is indeed the case.

**PRACTICE EXERCISE**

(a) Using Equation 14.15, calculate  $t_{1/2}$  for the decomposition of the insecticide described in Sample Exercise 14.7. (b) How long does it take for the concentration of the insecticide to reach one-quarter of the initial value?

**Answers:** (a)  $0.478 \text{ yr} = 1.51 \times 10^7 \text{ s}$ ; (b) it takes two half-lives,  $2(0.478 \text{ yr}) = 0.956 \text{ yr}$

In contrast to the behavior of first-order reactions, the half-life for second-order and other reactions depends on reactant concentrations and therefore changes as the reaction progresses. Using Equation 14.14, we find that the half-life of a second-order reaction is

$$t_{1/2} = \frac{1}{k[\text{A}]_0} \quad [14.17]$$

In this case the half-life depends on the initial concentration of reactant—the lower the initial concentration, the greater the half-life.

**GIVE IT SOME THOUGHT**

How does the half-life of a second-order reaction change as the reaction proceeds?

**14.5 TEMPERATURE AND RATE**

The rates of most chemical reactions increase as the temperature rises. For example, dough rises faster at room temperature than when refrigerated, and plants grow more rapidly in warm weather than in cold. We can literally see the effect of temperature on reaction rate by observing a chemiluminescence reaction (one that produces light). The characteristic glow of fireflies is a familiar example of chemiluminescence. Another is the light produced by Cyalume® light sticks, which contain chemicals that produce chemiluminescence when mixed. As seen in Figure 14.11, these light sticks produce a brighter light at higher temperature. The amount of light produced is greater because the rate of the reaction is faster at the higher temperature. Although the light stick glows more brightly initially, its luminescence also dies out more rapidly.

How is this experimentally observed temperature effect reflected in the rate expression? The faster rate at higher temperature is due to an increase in the rate constant with increasing temperature. For example, let's reconsider the first-order reaction  $\text{CH}_3\text{NC} \longrightarrow \text{CH}_3\text{CN}$

▼ **Figure 14.11** Temperature affects the rate of the chemiluminescence reaction in Cyalume® light sticks. The light stick in hot water (left) glows more brightly than the one in cold water (right); at the higher temperature, the reaction is initially faster and produces a brighter light.

Higher temperature

Lower temperature

▲ **Figure 14.12** Dependence of rate constant on temperature. The data show the variation in the first-order rate constant for the rearrangement of methyl isonitrile as a function of temperature. The four points indicated are used in connection with Sample Exercise 14.11.

(Figure 14.6). Figure 14.12 shows the rate constant for this reaction as a function of temperature. The rate constant, and hence the rate of the reaction, increases rapidly with temperature, approximately doubling for each 10 °C rise.

### The Collision Model

We have seen that reaction rates are affected both by the concentrations of reactants and by temperature. The **collision model**, which is based on the kinetic-molecular theory (Section 10.7), accounts for both of these effects at the molecular level. The central idea of the collision model is that molecules must collide to react. The greater the number of collisions occurring per second, the greater is the reaction rate. As the concentration of reactant molecules increases, therefore, the number of collisions increases, leading to an increase in reaction rate. According to the kinetic-molecular theory of gases, increasing the temperature increases molecular speeds. As molecules move faster, they collide more forcefully (with more energy) and more frequently, increasing reaction rates.

For a reaction to occur, though, more is required than simply a collision. For most reactions, only a tiny fraction of the collisions leads to a reaction. For example, in a mixture of  $H_2$  and  $I_2$  at ordinary temperatures and pressures, each molecule undergoes about  $10^{10}$  collisions per second. If every collision between  $H_2$  and  $I_2$  resulted in the formation of  $HI$ , the reaction would be over in much less than a second. Instead, at room temperature the reaction proceeds very slowly. Only about one in every  $10^{13}$  collisions produces a reaction. What keeps the reaction from occurring more rapidly?

### GIVE IT SOME THOUGHT

What is the central idea of the collision model?

### The Orientation Factor

In most reactions, molecules must be oriented in a certain way during collisions for a reaction to occur. The relative orientations of the molecules during their collisions determine whether the atoms are suitably positioned to form new bonds. For example, consider the reaction of  $Cl$  atoms with  $NOCl$ :

The reaction will take place if the collision brings  $Cl$  atoms together to form  $Cl_2$  as shown in Figure 14.13(a). In contrast, the collision shown in Figure 14.13(b) will be ineffective and will not yield products. Indeed, a great many collisions do not lead to reaction, merely because the molecules are not suitably oriented. Another factor, however, is usually even more important in determining whether particular collisions result in reaction.

### Activation Energy

In 1888 the Swedish chemist Svante Arrhenius suggested that molecules must possess a certain minimum amount of energy to react. According to the collision model, this energy comes from the kinetic energies of the colliding molecules. Upon collision, the kinetic energy of the molecules can be used to stretch, bend, and ultimately break bonds, leading to chemical reactions. That is, the kinetic energy is used to change the potential energy of the molecule. If molecules are moving too slowly, with too little kinetic energy, they merely bounce off one another without changing. To react, colliding molecules must have a total kinetic energy equal to or greater than some minimum value. The minimum energy required to initiate a chemical reaction is called the **activation energy**,  $E_a$ . The value of  $E_a$  varies from reaction to reaction.

▲ **Figure 14.13 Molecular collisions and chemical reactions.** Two possible ways that Cl atoms and NOCl molecules can collide are shown. (a) If molecules are oriented properly, a sufficiently energetic collision will lead to reaction. (b) If the orientation of the colliding molecules is wrong, no reaction occurs.

The situation during reactions is rather like that shown in Figure 14.14 ▶. The player on the putting green needs to move her ball over the hill to the vicinity of the cup. To do this, she must impart enough kinetic energy with the putter to move the ball to the top of the hill. If she does not impart enough energy, the ball will roll partway up the hill and then back down. In the same way, molecules may require a certain minimum energy to break existing bonds during a chemical reaction. In the rearrangement of methyl isonitrile to acetonitrile, for example, we might imagine the reaction passing through an intermediate state in which the  $\text{N}\equiv\text{C}$  portion of the molecule is sitting sideways:

The change in the potential energy of the molecule during the reaction is shown in Figure 14.15 ▼. The diagram shows that energy must be supplied to stretch the bond between the  $\text{H}_3\text{C}$  group and the  $\text{N}\equiv\text{C}$  group to allow the  $\text{N}\equiv\text{C}$  group to rotate. After the  $\text{N}\equiv\text{C}$  group has twisted sufficiently, the  $\text{C}-\text{C}$  bond begins to form, and the energy of the molecule drops. Thus, the barrier represents the energy necessary to force the molecule through the relatively unstable intermediate state to the final product. The energy difference between that of the starting molecule and the highest energy along the reaction pathway is the activation energy,  $E_a$ . The particular arrangement of atoms at the top of the barrier is called the **activated complex**, or **transition state**.

The conversion of  $\text{H}_3\text{C}-\text{N}\equiv\text{C}$  to  $\text{H}_3\text{C}-\text{C}\equiv\text{N}$  is exothermic. Figure 14.15 therefore shows the product as having a lower energy than the reactant. The energy change for the reaction,  $\Delta E$ , has no effect on the rate of the reaction. *The rate depends on the magnitude of  $E_a$ ; generally, the lower  $E_a$  is, the faster the reaction.* Notice that the reverse reaction is endothermic. The activation barrier for the reverse reaction is equal to the sum of  $\Delta E$  and  $E_a$  for the forward reaction.

▲ **Figure 14.14 An energy barrier.** To move the golf ball to the vicinity of the cup, the player must impart enough kinetic energy to the ball to enable it to surmount the barrier represented by the hill. This situation is analogous to a chemical reaction, in which molecules must gain enough energy through collisions to enable them to overcome the barrier to chemical reaction.

► **Figure 14.15 Energy profile for methyl isonitrile isomerization.**

The methyl isonitrile molecule must surmount the activation-energy barrier before it can form the product, acetonitrile. The horizontal axis is variously labeled “reaction pathway,” as here, or “progress of reaction.”

▲ **Figure 14.16 The effect of temperature on the distribution of kinetic energies.**

At the higher temperature, a larger number of molecules have higher kinetic energies. Thus, a larger fraction at any one instant will have more than the minimum energy required for reaction.

How does any particular methyl isonitrile molecule acquire sufficient energy to overcome the activation barrier? It does so through collisions with other molecules. Recall from the kinetic-molecular theory of gases that, at any given instant, gas molecules are distributed in energy over a wide range. (Section 10.7) Figure 14.16 shows the distribution of kinetic energies for two different temperatures, comparing them with the minimum energy needed for reaction,  $E_a$ . At the higher temperature a much greater fraction of the molecules has kinetic energy greater than  $E_a$ , which leads to a much greater rate of reaction.

The fraction of molecules that has an energy equal to or greater than  $E_a$  is given by the expression

$$f = e^{-E_a/RT} \quad [14.18]$$

In this equation  $R$  is the gas constant (8.314 J/mol·K) and  $T$  is absolute temperature. To get an idea of the magnitude of  $f$ , let's suppose that  $E_a$  is 100 kJ/mol, a value typical of many reactions, and that  $T$  is 300 K, around room temperature. The calculated value of  $f$  is  $3.9 \times 10^{-18}$ , an extremely small number! At 310 K the fraction is  $f = 1.4 \times 10^{-17}$ . Thus, a 10-degree increase in temperature produces a 3.6-fold increase in the fraction of molecules possessing at least 100 kJ/mol of energy.

### GIVE IT SOME THOUGHT

Why isn't collision frequency the only factor affecting a reaction rate?

### The Arrhenius Equation

Arrhenius noted that for most reactions the increase in rate with increasing temperature is nonlinear, as shown in Figure 14.12. He found that most reaction-rate data obeyed an equation based on three factors: (a) the fraction of molecules possessing an energy of  $E_a$  or greater, (b) the number of collisions

occurring per second, and (c) the fraction of collisions that have the appropriate orientation. These three factors are incorporated into the **Arrhenius equation**:

$$k = Ae^{-E_a/RT} \quad [14.19]$$

In this equation  $k$  is the rate constant,  $E_a$  is the activation energy,  $R$  is the gas constant (8.314 J/mol-K), and  $T$  is the absolute temperature. The **frequency factor**,  $A$ , is constant, or nearly so, as temperature is varied. This factor is related to the frequency of collisions and the probability that the collisions are favorably oriented for reaction.\* As the magnitude of  $E_a$  increases,  $k$  decreases because the fraction of molecules that possess the required energy is smaller. Thus, *reaction rates decrease as  $E_a$  increases*.

### SAMPLE EXERCISE 14.10 | Relating Energy Profiles to Activation Energies and Speeds of Reaction

Consider a series of reactions having the following energy profiles:

Rank the reactions from slowest to fastest assuming that they have nearly the same frequency factors.

#### SOLUTION

The lower the activation energy, the faster the reaction. The value of  $\Delta E$  does not affect the rate. Hence the order is (2) < (3) < (1).

#### PRACTICE EXERCISE

Imagine that these reactions are reversed. Rank these reverse reactions from slowest to fastest.

**Answer:** (2) < (1) < (3) because  $E_a$  values are 40, 25, and 15 kJ/mol, respectively

## Determining the Activation Energy

Taking the natural log of both sides of Equation 14.19, we have

$$\ln k = -\frac{E_a}{RT} + \ln A \quad [14.20]$$

$$\begin{array}{c} \updownarrow \\ y = mx + b \end{array}$$

As shown, Equation 14.20 has the form of the equation for a straight line. A graph of  $\ln k$  versus  $1/T$  will be a line with a slope equal to  $-E_a/R$  and a  $y$ -intercept equal to  $\ln A$ . Thus, the activation energy can be determined by measuring  $k$  at a series of temperatures, graphing  $\ln k$  versus  $1/T$ , and then calculating  $E_a$  from the slope of the resultant line.

We can also use Equation 14.20 to evaluate  $E_a$  in a nongraphical way if we know the rate constant of a reaction at two or more temperatures. For example,

\*Because the frequency of collisions increases with temperature,  $A$  also has some temperature dependence, but it is small compared to the exponential term. Therefore,  $A$  is considered approximately constant.

suppose that at two different temperatures,  $T_1$  and  $T_2$ , a reaction has rate constants  $k_1$  and  $k_2$ . For each condition, we have

$$\ln k_1 = -\frac{E_a}{RT_1} + \ln A \quad \text{and} \quad \ln k_2 = -\frac{E_a}{RT_2} + \ln A$$

Subtracting  $\ln k_2$  from  $\ln k_1$  gives

$$\ln k_1 - \ln k_2 = \left(-\frac{E_a}{RT_1} + \ln A\right) - \left(-\frac{E_a}{RT_2} + \ln A\right)$$

Simplifying this equation and rearranging it gives

$$\ln \frac{k_1}{k_2} = \frac{E_a}{R} \left(\frac{1}{T_2} - \frac{1}{T_1}\right) \quad [14.21]$$

Equation 14.21 provides a convenient way to calculate the rate constant,  $k_1$ , at some temperature,  $T_1$ , when we know the activation energy and the rate constant,  $k_2$ , at some other temperature,  $T_2$ .

### SAMPLE EXERCISE 14.11 | Determining the Energy of Activation

The following table shows the rate constants for the rearrangement of methyl isonitrile at various temperatures (these are the data in Figure 14.12):

Temperature (°C)	$k$ (s <sup>-1</sup> )
189.7	$2.52 \times 10^{-5}$
198.9	$5.25 \times 10^{-5}$
230.3	$6.30 \times 10^{-4}$
251.2	$3.16 \times 10^{-3}$

(a) From these data, calculate the activation energy for the reaction. (b) What is the value of the rate constant at 430.0 K?

#### SOLUTION

**Analyze:** We are given rate constants,  $k$ , measured at several temperatures and asked to determine the activation energy,  $E_a$ , and the rate constant,  $k$ , at a particular temperature.

**Plan:** We can obtain  $E_a$  from the slope of a graph of  $\ln k$  versus  $1/T$ . Once we know  $E_a$ , we can use Equation 14.21 together with the given rate data to calculate the rate constant at 430.0 K.

**Solve:** (a) We must first convert the temperatures from degrees Celsius to kelvins. We then take the inverse of each temperature,  $1/T$ , and the natural log of each rate constant,  $\ln k$ . This gives us the table shown at the right:

$T$ (K)	$1/T$ (K <sup>-1</sup> )	$\ln k$
462.9	$2.160 \times 10^{-3}$	-10.589
472.1	$2.118 \times 10^{-3}$	-9.855
503.5	$1.986 \times 10^{-3}$	-7.370
524.4	$1.907 \times 10^{-3}$	-5.757

A graph of  $\ln k$  versus  $1/T$  results in a straight line, as shown in Figure 14.17.

**Figure 14.17 Graphical determination of activation energy.** The natural logarithm of the rate constant for the rearrangement of methyl isonitrile is plotted as a function of  $1/T$ . The linear relationship is predicted by the Arrhenius equation giving a slope equal to  $-E_a/R$ .

The slope of the line is obtained by choosing two well-separated points, as shown, and using the coordinates of each:

$$\text{Slope} = \frac{\Delta y}{\Delta x} = \frac{-6.6 - (-10.4)}{0.00195 - 0.00215} = -1.9 \times 10^4$$

Because logarithms have no units, the numerator in this equation is dimensionless. The denominator has the units of  $1/T$ , namely,  $\text{K}^{-1}$ . Thus, the overall units for the slope are  $\text{K}$ . The slope equals  $-E_a/R$ . We use the value for the molar gas constant  $R$  in units of  $\text{J/mol}\cdot\text{K}$  (Table 10.2). We thus obtain

$$\begin{aligned}\text{Slope} &= -\frac{E_a}{R} \\ E_a &= -(\text{slope})(R) = -(-1.9 \times 10^4 \text{ K}) \left( 8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) \left( \frac{1 \text{ kJ}}{1000 \text{ J}} \right) \\ &= 1.6 \times 10^2 \text{ kJ/mol} = 160 \text{ kJ/mol}\end{aligned}$$

We report the activation energy to only two significant figures because we are limited by the precision with which we can read the graph in Figure 14.17.

(b) To determine the rate constant,  $k_1$ , at  $T_1 = 430.0 \text{ K}$ , we can use Equation 14.21 with  $E_a = 160 \text{ kJ/mol}$ , and one of the rate constants and temperatures from the given data, such as  $k_2 = 2.52 \times 10^{-5} \text{ s}^{-1}$  and  $T_2 = 462.9 \text{ K}$ :

$$\ln \left( \frac{k_1}{2.52 \times 10^{-5} \text{ s}^{-1}} \right) = \left( \frac{160 \text{ kJ/mol}}{8.314 \text{ J/mol}\cdot\text{K}} \right) \left( \frac{1}{462.9 \text{ K}} - \frac{1}{430.0 \text{ K}} \right) \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) = -3.18$$

Thus,

$$\begin{aligned}\frac{k_1}{2.52 \times 10^{-5} \text{ s}^{-1}} &= e^{-3.18} = 4.15 \times 10^{-2} \\ k_1 &= (4.15 \times 10^{-2})(2.52 \times 10^{-5} \text{ s}^{-1}) = 1.0 \times 10^{-6} \text{ s}^{-1}\end{aligned}$$

Note that the units of  $k_1$  are the same as those of  $k_2$ .

### PRACTICE EXERCISE

Using the data in Sample Exercise 14.11, calculate the rate constant for the rearrangement of methyl isonitrile at  $280 \text{ }^\circ\text{C}$ .

**Answer:**  $2.2 \times 10^{-2} \text{ s}^{-1}$

## 14.6 REACTION MECHANISMS

A balanced equation for a chemical reaction indicates the substances present at the start of the reaction and those produced as the reaction proceeds. It provides no information, however, about how the reaction occurs. The process by which a reaction occurs is called the **reaction mechanism**. At the most sophisticated level, a reaction mechanism will describe in great detail the order in which bonds are broken and formed and the changes in relative positions of the atoms in the course of the reaction. We will begin with more rudimentary descriptions of how reactions occur, considering further the nature of the collisions leading to reaction.

### Elementary Reactions

We have seen that reactions take place because of collisions between reacting molecules. For example, the collisions between molecules of methyl isonitrile ( $\text{CH}_3\text{NC}$ ) can provide the energy to allow the  $\text{CH}_3\text{NC}$  to rearrange:

Similarly, the reaction of NO and O<sub>3</sub> to form NO<sub>2</sub> and O<sub>2</sub> appears to occur as a result of a single collision involving suitably oriented and sufficiently energetic NO and O<sub>3</sub> molecules:

Both of these processes occur in a single event or step and are called **elementary reactions** (or elementary processes).

The number of molecules that participate as reactants in an elementary reaction defines its **molecularity**. If a single molecule is involved, the reaction is **unimolecular**. The rearrangement of methyl isonitrile is a unimolecular process. Elementary reactions involving the collision of two reactant molecules are **bimolecular**. The reaction between NO and O<sub>3</sub> (Equation 14.22) is bimolecular. Elementary reactions involving the simultaneous collision of three molecules are **termolecular**. Termolecular reactions are far less probable than unimolecular or bimolecular processes and are rarely encountered. The chance that four or more molecules will collide simultaneously with any regularity is even more remote; consequently, such collisions are never proposed as part of a reaction mechanism.

### GIVE IT SOME THOUGHT

What is the molecularity of this elementary reaction?

## Multistep Mechanisms

The net change represented by a balanced chemical equation often occurs by a *multistep mechanism*, which consists of a sequence of elementary reactions. For example, consider the reaction of NO<sub>2</sub> and CO:

Below 225 °C, this reaction appears to proceed in two elementary reactions (or two *elementary steps*), each of which is bimolecular. First, two NO<sub>2</sub> molecules collide, and an oxygen atom is transferred from one to the other. The resultant NO<sub>3</sub> then collides with a CO molecule and transfers an oxygen atom to it:

Thus, we say that the reaction occurs by a two-step mechanism.

*The chemical equations for the elementary reactions in a multistep mechanism must always add to give the chemical equation of the overall process. In the present example the sum of the two elementary reactions is*

Simplifying this equation by eliminating substances that appear on both sides of the arrow gives Equation 14.23, the net equation for the process. Because NO<sub>3</sub> is neither a reactant nor a product in the overall reaction—it is formed in one elementary reaction and consumed in the next—it is called an **intermediate**. Multistep mechanisms involve one or more intermediates.

### SAMPLE EXERCISE 14.12 | Determining Molecularity and Identifying Intermediates

It has been proposed that the conversion of ozone into O<sub>2</sub> proceeds by a two-step mechanism:

- (a) Describe the molecularity of each elementary reaction in this mechanism.  
 (b) Write the equation for the overall reaction. (c) Identify the intermediate(s).

### SOLUTION

**Analyze:** We are given a two-step mechanism and asked for (a) the molecularities of each of the two elementary reactions, (b) the equation for the overall process, and (c) the intermediate.

**Plan:** The molecularity of each elementary reaction depends on the number of reactant molecules in the equation for that reaction. The overall equation is the sum of the equations for the elementary reactions. The intermediate is a substance formed in one step of the mechanism and used in another and therefore not part of the equation for the overall reaction.

**Solve:** (a) The first elementary reaction involves a single reactant and is consequently unimolecular. The second reaction, which involves two reactant molecules, is bimolecular.

(b) Adding the two elementary reactions gives

Because  $\text{O}(\text{g})$  appears in equal amounts on both sides of the equation, it can be eliminated to give the net equation for the chemical process:

(c) The intermediate is  $\text{O}(\text{g})$ . It is neither an original reactant nor a final product but is formed in the first step of the mechanism and consumed in the second.

### PRACTICE EXERCISE

For the reaction

the proposed mechanism is

- (a) Is the proposed mechanism consistent with the equation for the overall reaction?  
 (b) What is the molecularity of each step of the mechanism? (c) Identify the intermediate(s).

**Answers:** (a) Yes, the two equations add to yield the equation for the reaction. (b) The first elementary reaction is unimolecular, and the second one is bimolecular. (c)  $\text{Mo}(\text{CO})_5$

## Rate Laws for Elementary Reactions

In Section 14.3 we stressed that rate laws must be determined experimentally; they cannot be predicted from the coefficients of balanced chemical equations. We are now in a position to understand why this is so. Every reaction is made up of a series of one or more elementary steps, and the rate laws and relative speeds of these steps will dictate the overall rate law. Indeed, the rate law for a reaction can be determined from its mechanism, as we will see shortly. Thus, our next challenge in kinetics is to arrive at reaction mechanisms that lead to rate laws that are consistent with those observed experimentally. We will start by examining the rate laws of elementary reactions.

Elementary reactions are significant in a very important way: *If a reaction is an elementary reaction, then its rate law is based directly on its molecularity.* For example, consider a unimolecular process:

As the number of A molecules increases, the number that react in a given interval of time will increase proportionally. Thus, the rate of a unimolecular process will be first order:

$$\text{Rate} = k[\text{A}]$$

TABLE 14.3 ■ Elementary Reactions and Their Rate Laws

Molecularity	Elementary Reaction	Rate Law
Unimolecular	$A \longrightarrow \text{products}$	Rate = $k[A]$
Bimolecular	$A + A \longrightarrow \text{products}$	Rate = $k[A]^2$
Bimolecular	$A + B \longrightarrow \text{products}$	Rate = $k[A][B]$
Termolecular	$A + A + A \longrightarrow \text{products}$	Rate = $k[A]^3$
Termolecular	$A + A + B \longrightarrow \text{products}$	Rate = $k[A]^2[B]$
Termolecular	$A + B + C \longrightarrow \text{products}$	Rate = $k[A][B][C]$

In the case of bimolecular elementary steps, the rate law is second order, as in the following example:

The second-order rate law follows directly from the collision theory. If we double the concentration of A, the number of collisions between molecules of A and B will double; likewise, if we double [B], the number of collisions will double. Therefore, the rate law will be first order in both [A] and [B], and second order overall.

The rate laws for all feasible elementary reactions are given in Table 14.3 ▲. Notice how the rate law for each kind of elementary reaction follows directly from the molecularity of that reaction. It is important to remember, however, that we cannot tell by merely looking at a balanced chemical equation whether the reaction involves one or several elementary steps.

#### ■ SAMPLE EXERCISE 14.13 | Predicting the Rate Law for an Elementary Reaction

If the following reaction occurs in a single elementary reaction, predict its rate law:

#### SOLUTION

**Analyze:** We are given the equation and asked for its rate law, assuming that it is an elementary process.

**Plan:** Because we are assuming that the reaction occurs as a single elementary reaction, we are able to write the rate law using the coefficients for the reactants in the equation as the reaction orders.

**Solve:** The reaction is bimolecular, involving one molecule of  $\text{H}_2$  with one molecule of  $\text{Br}_2$ . Thus, the rate law is first order in each reactant and second order overall:

$$\text{Rate} = k[\text{H}_2][\text{Br}_2]$$

**Comment:** Experimental studies of this reaction show that the reaction actually has a very different rate law:

$$\text{Rate} = k[\text{H}_2][\text{Br}_2]^{1/2}$$

Because the experimental rate law differs from the one obtained by assuming a single elementary reaction, we can conclude that the mechanism cannot occur by a single elementary step. It must, therefore, involve two or more elementary steps.

#### ■ PRACTICE EXERCISE

Consider the following reaction:  $2 \text{NO}(\text{g}) + \text{Br}_2(\text{g}) \longrightarrow 2 \text{NOBr}(\text{g})$ . (a) Write the rate law for the reaction, assuming it involves a single elementary reaction. (b) Is a single-step mechanism likely for this reaction?

**Answers:** (a) Rate =  $k[\text{NO}]^2[\text{Br}_2]$  (b) No, because termolecular reactions are very rare.

## The Rate-Determining Step for a Multistep Mechanism

As with the reaction in Sample Exercise 14.13, most chemical reactions occur by mechanisms that involve two or more elementary reactions. Each of these steps of the mechanism has its own rate constant and activation energy. Often one of the steps is much slower than the others. The overall rate of a reaction cannot

exceed the rate of the slowest elementary step of its mechanism. Because the slow step limits the overall reaction rate, it is called the **rate-determining step** (or *rate-limiting step*).

To understand the concept of a rate-determining step, consider a toll road with two toll plazas (Figure 14.18). We will measure the rate at which cars pass through the second toll plaza. Cars enter the toll road at point 1 and pass through toll plaza A. They then pass an intermediate point 2 before passing through toll plaza B and arriving at point 3. We can therefore envision this trip along the toll road as occurring in two elementary steps:

- Step 1: Point 1  $\longrightarrow$  point 2 (through plaza A)  
 Step 2: Point 2  $\longrightarrow$  point 3 (through plaza B)  
 Overall: Point 1  $\longrightarrow$  point 3 (through plaza A and B)

Now suppose that several of the gates at toll plaza A are malfunctioning, so that traffic backs up behind it as depicted in Figure 14.18(a). The rate at which cars can get to point 3 is limited by the rate at which they can get through the traffic jam at plaza A. Thus, step 1 is the rate-determining step of the journey along the toll road. If, however, traffic flows quickly through plaza A but gets backed up at plaza B, as depicted in Figure 14.18(b), the number of cars builds up in the intermediate region between the plazas. In this case step 2 is rate determining: The rate at which cars can travel the toll road is limited by the rate at which they can pass through plaza B.

In the same way, *the slowest step in a multistep reaction limits the overall rate*. By analogy to Figure 14.18(a), the rate of a faster step following the rate-determining step does not speed up the overall rate. If the slow step is not the first one, as in Figure 14.18(b), the faster preceding steps produce intermediate products that accumulate before being consumed in the slow step. In either case *the rate-determining step governs the rate law for the overall reaction*.

### GIVE IT SOME THOUGHT

Why can't the rate law for a reaction generally be deduced from the balanced equation for the reaction?

### Mechanisms with a Slow Initial Step

We can most easily see the relationship between the slow step in a mechanism and the rate law for the overall reaction by considering an example in which the first step in a multistep mechanism is the slow, rate-determining step. As an example, consider the reaction of  $\text{NO}_2$  and  $\text{CO}$  to produce  $\text{NO}$  and  $\text{CO}_2$  (Equation 14.23). Below  $225^\circ\text{C}$ , it is found experimentally that the rate law for this reaction is second order in  $\text{NO}_2$  and zero order in  $\text{CO}$ :  $\text{Rate} = k[\text{NO}_2]^2$ . Can we propose a reaction mechanism that is consistent with this rate law? Consider the following two-step mechanism:\*

Step 2 is much faster than step 1; that is,  $k_2 \gg k_1$ . The intermediate  $\text{NO}_3(\text{g})$  is slowly produced in step 1 and is immediately consumed in step 2.

\*The subscript on the rate constant identifies the elementary step involved. Thus,  $k_1$  is the rate constant for step 1,  $k_2$  is the rate constant for step 2, and so forth. A negative subscript refers to the rate constant for the reverse of an elementary step. For example,  $k_{-1}$  is the rate constant for the reverse of the first step.

▲ **Figure 14.18 Rate-determining step.** The flow of traffic on a toll road illustrates how a rate-determining step controls reaction rate. The flow is limited by the flow of traffic through the slower toll plaza. In (a) the rate at which cars can reach point 3 is limited by how quickly they can get through plaza A. In this case, getting from point 1 to point 2 is the rate-determining step. In (b), getting from point 2 to point 3 is the rate-determining step.

Because step 1 is slow and step 2 is fast, step 1 is rate determining. Thus, the rate of the overall reaction depends on the rate of step 1, and the rate law of the overall reaction equals the rate law of step 1. Step 1 is a bimolecular process that has the rate law

$$\text{Rate} = k_1[\text{NO}_2]^2$$

Thus, the rate law predicted by this mechanism agrees with the one observed experimentally. CO is absent from the rate law because it reacts in a step that follows the rate-determining step.

#### SAMPLE EXERCISE 14.14 | Determining the Rate Law for a Multistep Mechanism

The decomposition of nitrous oxide,  $\text{N}_2\text{O}$ , is believed to occur by a two-step mechanism:

(a) Write the equation for the overall reaction. (b) Write the rate law for the overall reaction.

#### SOLUTION

**Analyze:** Given a multistep mechanism with the relative speeds of the steps, we are asked to write the overall reaction and the rate law for that overall reaction.

**Plan:** (a) Find the overall reaction by adding the elementary steps and eliminating the intermediates. (b) The rate law for the overall reaction will be that of the slow, rate-determining step.

**Solve:** (a) Adding the two elementary reactions gives

Omitting the intermediate,  $\text{O}(\text{g})$ , which occurs on both sides of the equation, gives the overall reaction:

(b) The rate law for the overall reaction is just the rate law for the slow, rate-determining elementary reaction. Because that slow step is a unimolecular elementary reaction, the rate law is first order:

$$\text{Rate} = k[\text{N}_2\text{O}]$$

#### PRACTICE EXERCISE

Ozone reacts with nitrogen dioxide to produce dinitrogen pentoxide and oxygen:

The reaction is believed to occur in two steps:

The experimental rate law is  $\text{rate} = k[\text{O}_3][\text{NO}_2]$ . What can you say about the relative rates of the two steps of the mechanism?

**Answer:** Because the rate law conforms to the molecularity of the first step, that must be the rate-determining step. The second step must be much faster than the first one.

### Mechanisms with a Fast Initial Step

It is less straightforward to derive the rate law for a mechanism in which an intermediate is a reactant in the rate-determining step. This situation arises in multistep mechanisms when the first step is fast and therefore *not* the rate-determining one.

Let's consider one example: the gas-phase reaction of nitric oxide (NO) with bromine ( $\text{Br}_2$ ).

The experimentally determined rate law for this reaction is second order in NO and first order in  $\text{Br}_2$ :

$$\text{Rate} = k[\text{NO}]^2[\text{Br}_2] \quad [14.25]$$

We seek a reaction mechanism that is consistent with this rate law. One possibility is that the reaction occurs in a single termolecular step:

As noted in Practice Exercise 14.13, this does not seem likely because termolecular processes are so rare.

Let's consider an alternative mechanism that does not invoke a termolecular step:

In this mechanism, step 1 actually involves two processes: a forward reaction and its reverse.

Because step 2 is the slow, rate-determining step, the rate law for that step governs the rate of the overall reaction:

$$\text{Rate} = k[\text{NOBr}_2][\text{NO}] \quad [14.27]$$

However,  $\text{NOBr}_2$  is an intermediate generated in step 1. Intermediates are usually unstable molecules that have a low, unknown concentration. Thus, our rate law depends on the unknown concentration of an intermediate.

Fortunately, with the aid of some assumptions, we can express the concentration of the intermediate ( $\text{NOBr}_2$ ) in terms of the concentrations of the starting reactants (NO and  $\text{Br}_2$ ). We first assume that  $\text{NOBr}_2$  is intrinsically unstable and that it does not accumulate to a significant extent in the reaction mixture. There are two ways for  $\text{NOBr}_2$  to be consumed once it is formed: It can either react with NO to form NOBr or reform NO and  $\text{Br}_2$ . The first of these possibilities is step 2, a slow process. The second is the reverse of step 1, a unimolecular process:

Because step 2 is slow, we assume that most of the  $\text{NOBr}_2$  falls apart according to Equation 14.28. Thus, we have both the forward and reverse reactions of step 1 occurring much faster than step 2. Because the forward and reverse processes of step 1 occur rapidly with respect to the reaction in step 2, they establish an equilibrium. We have seen examples of dynamic equilibrium before, in the equilibrium between a liquid and its vapor  $\rightleftharpoons$  (Section 11.5) and between a solid solute and its solution.  $\rightleftharpoons$  (Section 13.3) As in any dynamic equilibrium, the rates of the forward and reverse reactions are equal. Thus, we can equate the rate expression for the forward reaction in step 1 with the rate expression for the reverse reaction:

$$\begin{array}{ccc} k_1[\text{NO}][\text{Br}_2] & = & k_{-1}[\text{NOBr}_2] \\ \text{Rate of forward reaction} & & \text{Rate of reverse reaction} \end{array}$$

Solving for  $[\text{NOBr}_2]$ , we have

$$[\text{NOBr}_2] = \frac{k_1}{k_{-1}}[\text{NO}][\text{Br}_2]$$

Substituting this relationship into the rate law for the rate-determining step (Equation 14.27), we have

$$\text{Rate} = k_2 \frac{k_1}{k_{-1}} [\text{NO}][\text{Br}_2][\text{NO}] = k[\text{NO}]^2[\text{Br}_2]$$

This result is consistent with the experimental rate law (Equation 14.25). The experimental rate constant,  $k$ , equals  $k_2k_1/k_{-1}$ . This mechanism, which involves only unimolecular and bimolecular processes, is far more probable than the single termolecular step (Equation 14.26).

In general, *whenever a fast step precedes a slow one, we can solve for the concentration of an intermediate by assuming that an equilibrium is established in the fast step.*

### SAMPLE EXERCISE 14.15 | Deriving the Rate Law for a Mechanism with a Fast Initial Step

Show that the following mechanism for Equation 14.24 also produces a rate law consistent with the experimentally observed one:

#### SOLUTION

**Analyze:** We are given a mechanism with a fast initial step and asked to write the rate law for the overall reaction.

**Plan:** The rate law of the slow elementary step in a mechanism determines the rate law for the overall reaction. Thus, we first write the rate law based on the molecularity of the slow step. In this case the slow step involves the intermediate  $\text{N}_2\text{O}_2$  as a reactant. Experimental rate laws, however, do not contain the concentrations of intermediates; instead they are expressed in terms of the concentrations of starting substances. Thus, we must relate the concentration of  $\text{N}_2\text{O}_2$  to the concentration of NO by assuming that an equilibrium is established in the first step.

**Solve:** The second step is rate determining, so the overall rate is

$$\text{Rate} = k_2[\text{N}_2\text{O}_2][\text{Br}_2]$$

We solve for the concentration of the intermediate  $\text{N}_2\text{O}_2$  by assuming that an equilibrium is established in step 1; thus, the rates of the forward and reverse reactions in step 1 are equal:

$$k_1[\text{NO}]^2 = k_{-1}[\text{N}_2\text{O}_2]$$

Solving for the concentration of the intermediate,  $\text{N}_2\text{O}_2$ , gives

$$[\text{N}_2\text{O}_2] = \frac{k_1}{k_{-1}} [\text{NO}]^2$$

Substituting this expression into the rate expression gives

$$\text{Rate} = k_2 \frac{k_1}{k_{-1}} [\text{NO}]^2 [\text{Br}_2] = k[\text{NO}]^2 [\text{Br}_2]$$

Thus, this mechanism also yields a rate law consistent with the experimental one.

#### PRACTICE EXERCISE

The first step of a mechanism involving the reaction of bromine is

What is the expression relating the concentration of  $\text{Br}(g)$  to that of  $\text{Br}_2(g)$ ?

$$\text{Answer: } [\text{Br}] = \left( \frac{k_1}{k_{-1}} [\text{Br}_2] \right)^{1/2}$$

## 14.7 CATALYSIS

A **catalyst** is a substance that changes the speed of a chemical reaction without undergoing a permanent chemical change itself in the process. Catalysts are very common; most reactions in the body, the atmosphere, and the oceans occur with the help of catalysts. Much industrial chemical research is devoted to the search for new and more effective catalysts for reactions of commercial importance. Extensive research efforts also are devoted to finding means of inhibiting or removing certain catalysts that promote undesirable reactions, such as those that corrode metals, age our bodies, and cause tooth decay.

### Homogeneous Catalysis

A catalyst that is present in the same phase as the reacting molecules is called a **homogeneous catalyst**. Examples abound both in solution and in the gas phase. Consider, for example, the decomposition of aqueous hydrogen peroxide,  $\text{H}_2\text{O}_2(aq)$ , into water and oxygen:

In the absence of a catalyst, this reaction occurs extremely slowly.

Many different substances are capable of catalyzing the reaction represented by Equation 14.29, including bromide ion,  $\text{Br}^-(aq)$ , as shown in Figure 14.19▼.

▼ **Figure 14.19 Effect of catalyst.**  
( $\text{H}_2\text{O}$  molecules and  $\text{Na}^+$  ions are omitted from the molecular art for clarity.)

**HOMOGENEOUS CATALYSIS**

*A catalyst that is present in the same phase as the reacting molecules is a homogeneous catalyst.*

In the absence of a catalyst,  $\text{H}_2\text{O}_2(aq)$  decomposes very slowly.

Shortly after the addition of a small amount of  $\text{NaBr}(aq)$  to  $\text{H}_2\text{O}_2(aq)$ , the solution turns brown because  $\text{Br}_2$  is generated (Equation 14.30). The buildup of  $\text{Br}_2$  leads to rapid evolution of  $\text{O}_2$  according to Equation 14.31.

After all of the  $\text{H}_2\text{O}_2$  has decomposed, a colorless solution of  $\text{NaBr}(aq)$  remains. Thus,  $\text{NaBr}$  has catalyzed the reaction even though it is not consumed during the reaction.

The bromide ion reacts with hydrogen peroxide in acidic solution, forming aqueous bromine and water:

The brown color observed in the middle photograph of Figure 14.19 indicates the formation of  $\text{Br}_2(aq)$ . If this were the complete reaction, bromide ion would not be a catalyst, because it undergoes chemical change during the reaction. However, hydrogen peroxide also reacts with the  $\text{Br}_2(aq)$  generated in Equation 14.30:

The bubbling evident in Figure 14.19(b) is due to the formation of  $\text{O}_2(g)$ .

The sum of Equations 14.30 and 14.31 is just Equation 14.29:

▲ **Figure 14.20** Energy profiles for uncatalyzed and catalyzed reactions. The energy profiles for the uncatalyzed decomposition of hydrogen peroxide and for the reaction as catalyzed by  $\text{Br}^-$  are compared. The catalyzed reaction involves two successive steps, each of which has a lower activation energy than the uncatalyzed reaction. Notice that the energies of reactants and products are unchanged by the catalyst.

When  $\text{H}_2\text{O}_2$  has been completely decomposed, we are left with a colorless solution of  $\text{Br}^-(aq)$ , as seen in the photograph on the right in Figure 14.19. Bromide ion, therefore, is indeed a catalyst of the reaction because it speeds the overall reaction without itself undergoing any net change. It is added at the start of the reaction, reacts, and then reforms at the end. In contrast,  $\text{Br}_2$  is an intermediate because it is first formed (Equation 14.30) and then consumed (Equation 14.31). Neither the catalyst nor the intermediate appears in the chemical equation for the overall reaction. Notice, however, that the catalyst is there at the start of the reaction, whereas the intermediate is formed during the course of the reaction.

On the basis of the Arrhenius equation (Equation 14.19), the rate constant ( $k$ ) is determined by the activation energy ( $E_a$ ) and the frequency factor ( $A$ ). A catalyst may affect the rate of reaction by altering the value of either  $E_a$  or  $A$ . The most dramatic catalytic effects come from lowering  $E_a$ . As a general rule, a catalyst lowers the overall activation energy for a chemical reaction.

A catalyst usually lowers the overall activation energy for a reaction by providing a different mechanism for the reaction. In the decomposition of hydrogen peroxide, for example, two successive reactions of  $\text{H}_2\text{O}_2$ , with bromide and then with bromine, take place. Because these two reactions together serve as a catalytic pathway for hydrogen peroxide decomposition, both of them must have significantly lower activation energies than the uncatalyzed decomposition, as shown schematically in Figure 14.20 ◀.

### GIVE IT SOME THOUGHT

How does a catalyst increase the rate of a reaction?

## Heterogeneous Catalysis

A **heterogeneous catalyst** exists in a different phase from the reactant molecules, usually as a solid in contact with either gaseous reactants or with reactants in a liquid solution. Many industrially important reactions are catalyzed by the surfaces of solids. For example, hydrocarbon molecules are rearranged to form gasoline with the aid of what are called “cracking” catalysts (see the “Chemistry Put to Work” box in Section 25.3). Heterogeneous catalysts are often composed of metals or metal oxides. Because the catalyzed reaction occurs on the surface, special methods are often used to prepare catalysts so that they have very large surface areas.

The initial step in heterogeneous catalysis is usually **adsorption** of reactants. *Adsorption* refers to the binding of molecules to a surface, whereas

*absorption* refers to the uptake of molecules into the interior of another substance.  $\rightleftharpoons$  (Section 13.6) Adsorption occurs because the atoms or ions at the surface of a solid are extremely reactive. Unlike their counterparts in the interior of the substance, surface atoms and ions have unused bonding capacity. This unused bonding capability may be used to bond molecules from the gas or solution phase to the surface of the solid.

The reaction of hydrogen gas with ethylene gas to form ethane gas provides an example of heterogeneous catalysis:

Even though this reaction is exothermic, it occurs very slowly in the absence of a catalyst. In the presence of a finely powdered metal, however, such as nickel, palladium, or platinum, the reaction occurs rather easily at room temperature. The mechanism by which the reaction occurs is diagrammed in Figure 14.21  $\blacktriangledown$ . Both ethylene and hydrogen are adsorbed on the metal surface [Figure 14.21(a)]. Upon adsorption the H—H bond of  $\text{H}_2$  breaks, leaving two H atoms that are bonded to the metal surface, as shown in Figure 14.21(b). The hydrogen atoms are relatively free to move about the surface. When a hydrogen encounters an adsorbed ethylene molecule, it can form a  $\sigma$  bond to one of the carbon atoms, effectively destroying the C—C  $\pi$  bond and leaving an *ethyl group* ( $\text{C}_2\text{H}_5$ ) bonded to the surface via a metal-to-carbon  $\sigma$  bond [Figure 14.21(c)]. This  $\sigma$  bond is relatively weak, so when the other carbon atom also encounters a hydrogen atom, a sixth C—H  $\sigma$  bond is readily formed and an ethane molecule is released from the metal surface [Figure 14.21(d)]. The site is ready to adsorb another ethylene molecule and thus begin the cycle again.

**▲ Figure 14.21 Mechanism for reaction of ethylene with hydrogen on a catalytic surface.** (a) The hydrogen and ethylene are adsorbed at the metal surface. (b) The H—H bond is broken to give adsorbed hydrogen atoms. (c) These migrate to the adsorbed ethylene and bond to the carbon atoms. (d) As C—H bonds are formed, the adsorption of the molecule to the metal surface is decreased and ethane is released.

## Chemistry Put to Work

## CATALYTIC CONVERTERS

Heterogeneous catalysis plays a major role in the fight against urban air pollution. Two components of automobile exhausts that help form photochemical smog are nitrogen oxides and unburned hydrocarbons of various types (Section 18.4). In addition, automobile exhausts may contain considerable quantities of carbon monoxide. Even with the most careful attention to engine design, it is impossible under normal driving conditions to reduce the quantity of these pollutants to an acceptable level in the exhaust gases. It is therefore necessary to remove them from the exhaust before they are vented to the air. This removal is accomplished in the *catalytic converter*.

The catalytic converter, which is part of the exhaust system, must perform two distinct functions: (1) oxidation of CO and unburned hydrocarbons ( $C_xH_y$ ) to carbon dioxide and water, and (2) reduction of nitrogen oxides to nitrogen gas:

These two functions require two distinctly different catalysts, so the development of a successful catalyst system is a difficult challenge. The catalysts must be effective over a wide range of operating temperatures. They must continue to be active despite the fact that various components of the exhaust can block the active sites of the catalyst. And the catalysts must be sufficiently rugged to withstand exhaust gas turbulence and the mechanical shocks of driving under various conditions for thousands of miles.

Catalysts that promote the combustion of CO and hydrocarbons are, in general, the transition-metal oxides and the noble metals, such as platinum. A mixture of two different metal oxides, CuO and  $\text{Cr}_2\text{O}_3$ , might be used, for example. These materials are supported on a structure (Figure 14.22) that allows the best possible contact between the flowing exhaust gas and the catalyst surface. A honeycomb structure made from alumina ( $\text{Al}_2\text{O}_3$ ) and impregnated with the catalyst is employed. Such catalysts operate by first adsorbing oxygen gas, also present in the exhaust gas. This adsorption weakens the O—O bond in  $\text{O}_2$ , so that oxygen atoms are available for reaction with adsorbed CO to form  $\text{CO}_2$ . Hydrocarbon oxidation probably proceeds somewhat similarly, with

the hydrocarbons first being adsorbed followed by rupture of a C—H bond.

The most effective catalysts for reduction of NO to yield  $\text{N}_2$  and  $\text{O}_2$  are transition-metal oxides and noble metals, the same kinds of materials that catalyze the oxidation of CO and hydrocarbons. The catalysts that are most effective in one reaction, however, are usually much less effective in the other. It is therefore necessary to have two different catalytic components.

Catalytic converters are remarkably efficient heterogeneous catalysts. The automotive exhaust gases are in contact with the catalyst for only 100 to 400 ms. In this very short time, 96% of the hydrocarbons and CO is converted to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , and the emission of nitrogen oxides is reduced by 76%.

There are costs as well as benefits associated with the use of catalytic converters. Some of the metals used in the converters are very expensive. Catalytic converters currently account for about 35% of the platinum, 65% of the palladium, and 95% of the rhodium used annually. All of these metals, which come mainly from Russia and South Africa, are far more expensive than gold.

**Related Exercises:** 14.56, 14.75, and 14.76

▲ **Figure 14.22** Cross section of a catalytic converter. Automobiles are equipped with catalytic converters, which are part of their exhaust systems. The exhaust gases contain CO, NO,  $\text{NO}_2$ , and unburned hydrocarbons that pass over surfaces impregnated with catalysts. The catalysts promote the conversion of the exhaust gases into  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{N}_2$ .

## GIVE IT SOME THOUGHT

How does a homogeneous catalyst compare with a heterogeneous one regarding the ease of recovery of the catalyst from the reaction mixture?

## Enzymes

Many of the most interesting and important examples of catalysis involve reactions within living systems. The human body is characterized by an extremely complex system of interrelated chemical reactions. All these reactions must occur at carefully controlled rates to maintain life. A large number of

marvelously efficient biological catalysts known as **enzymes** are necessary for many of these reactions to occur at suitable rates. Most enzymes are large protein molecules with molecular weights ranging from about 10,000 to about 1 million amu. They are very selective in the reactions that they catalyze, and some are absolutely specific, operating for only one substance in only one reaction. The decomposition of hydrogen peroxide, for example, is an important biological process. Because hydrogen peroxide is strongly oxidizing, it can be physiologically harmful. For this reason, the blood and livers of mammals contain an enzyme, *catalase*, which catalyzes the decomposition of hydrogen peroxide into water and oxygen (Equation 14.29). Figure 14.23 ► shows the dramatic acceleration of this chemical reaction by the catalase in beef liver.

Although an enzyme is a large molecule, the reaction is catalyzed at a very specific location in the enzyme, called the **active site**. The substances that undergo reaction at this site are called **substrates**. The **lock-and-key model**, illustrated in Figure 14.24 ▼, provides a simple explanation for the specificity of an enzyme. The substrate is pictured as fitting neatly into a special place on the enzyme (the active site), much like a specific key fits into a lock. The active site is created by coiling and folding of the long protein molecule to form a space, something like a pocket, into which the substrate molecule fits. Figure 14.25 ► shows a model of the enzyme *lysozyme* with and without a bound substrate molecule.

The combination of the enzyme and the substrate is called the *enzyme-substrate complex*. Although Figure 14.24 shows both the active site and its complementary substrate as having rigid shapes, the active site is often fairly flexible. Thus, the active site may change shape as it binds the substrate. The binding between the substrate and the active site involves intermolecular forces such as dipole-dipole attractions, hydrogen bonds, and London dispersion forces. ⇄ (Section 11.2)

As the substrate molecules enter the active site, they are somehow activated, so that they are capable of extremely rapid reaction. This activation may result from the withdrawal or donation of electron density at a particular bond by the enzyme. In addition, in the process of fitting into the active site, the substrate molecule may be distorted and thus made more reactive. Once the reaction occurs, the products then depart, allowing another substrate molecule to enter.

▲ **Figure 14.24 The lock-and-key model for enzyme action.** The correct substrate is recognized by its ability to fit the active site of the enzyme, forming the enzyme-substrate complex. After the reaction of the substrate is complete, the products separate from the enzyme.

▲ **Figure 14.23 Effect of an enzyme.** Ground-up beef liver causes hydrogen peroxide to decompose rapidly into water and oxygen. The decomposition is catalyzed by the enzyme *catalase*. Grinding the liver breaks open the cells, so that the reaction takes place more rapidly. The frothing is due to escape of oxygen gas from the reaction mixture.

(a)

(b)

Nitrogen is one of the most essential elements in living organisms. It is found in many compounds that are vital to life, including proteins, nucleic acids, vitamins, and hormones. Plants use very simple nitrogen-containing compounds, especially  $\text{NH}_3$ ,  $\text{NH}_4^+$ , and  $\text{NO}_3^-$ , as starting materials from which such complex, biologically necessary compounds are formed. Animals are unable to synthesize the complex nitrogen compounds they require from the simple substances used by plants. Instead, they rely on more complicated precursors present in vitamin- and protein-rich foods.

Nitrogen is continually cycling through this biological arena in various forms, as shown in the simplified nitrogen cycle in Figure 14.26. For example, certain microorganisms

convert the nitrogen in animal waste and dead plants and animals into molecular nitrogen,  $\text{N}_2(\text{g})$ , which returns to the atmosphere. For the food chain to be sustained, there must be a means of reincorporating this atmospheric  $\text{N}_2$  in a form that plants can utilize. The process of converting  $\text{N}_2$  into compounds that plants can use is called *nitrogen fixation*. Fixing nitrogen is difficult;  $\text{N}_2$  is an exceptionally unreactive molecule, in large part because of its very strong  $\text{N}\equiv\text{N}$  triple bond. (Section 8.3) Some fixed nitrogen results from the action of lightning on the atmosphere, and some is produced industrially using a process we will discuss in Chapter 15. About 60% of fixed nitrogen, however, is a consequence of the action of a remarkable and complex enzyme called *nitrogenase*. This enzyme

◀ **Figure 14.26 Simplified picture of the nitrogen cycle.** The compounds of nitrogen in the soil are water-soluble species, such as  $\text{NH}_3$ ,  $\text{NO}_2^-$ , and  $\text{NO}_3^-$ , which can be washed out of the soil by groundwater. These nitrogen compounds are converted into biomolecules by plants and are incorporated into animals that eat the plants. Certain bacteria that release  $\text{N}_2$  to the atmosphere attack animal waste and dead plants and animals. Atmospheric  $\text{N}_2$  is fixed in the soil predominantly by the action of certain plants that contain the enzyme nitrogenase, thereby completing the cycle.

The activity of an enzyme is destroyed if some molecule in the solution is able to bind strongly to the active site and block the entry of the substrate. Such substances are called *enzyme inhibitors*. Nerve poisons and certain toxic metal ions such as lead and mercury are believed to act in this way to inhibit enzyme activity. Some other poisons act by attaching elsewhere on the enzyme, thereby distorting the active site so that the substrate no longer fits.

Enzymes are enormously more efficient than ordinary nonbiochemical catalysts. The number of individual catalyzed reaction events occurring at a particular active site, called the *turnover number*, is generally in the range of  $10^3$  to  $10^7$  per second. Such large turnover numbers correspond to very low activation energies.

### GIVE IT SOME THOUGHT

What names are given to the following aspects of enzymes and enzyme catalysis: (a) the place on the enzyme where catalysis occurs, (b) the substances that undergo catalysis?

▲ **Figure 14.27 The FeMo-cofactor of nitrogenase.** Nitrogenase is found in nodules in the roots of certain plants, such as the white clover roots shown at the left. The cofactor, which is thought to be the active site of the enzyme, contains seven Fe atoms and one Mo atom, linked by sulfur atoms. The molecules on the outside of the cofactor connect it to the rest of the protein.

is *not* present in humans or other animals; rather, it is found in bacteria that live in the root nodules of certain plants such as the legumes clover and alfalfa.

Nitrogenase converts  $\text{N}_2$  into  $\text{NH}_3$ , a process that, in the absence of a catalyst, has a very large activation energy. This process is a *reduction* of nitrogen—during the reaction, its oxidation state is reduced from 0 in  $\text{N}_2$  to  $-3$  in  $\text{NH}_3$ . The mechanism by which nitrogenase reduces  $\text{N}_2$  is not fully understood. Like many other enzymes, including catalase, the active site of nitrogenase contains transition-metal atoms; such enzymes are called *metalloenzymes*. Because transition metals can readily change oxidation state, metalloenzymes are especially useful for effecting transformations in which substrates are either oxidized or reduced.

It has been known for nearly 20 years that a portion of nitrogenase contains iron and molybdenum atoms. This portion, called the *FeMo-cofactor*, is thought to serve as the active site of the enzyme. The FeMo-cofactor of nitrogenase is a striking cluster of seven Fe atoms and one Mo atom, all linked by sulfur atoms (Figure 14.27 ▲).

It is one of the wonders of life that simple bacteria can contain beautifully complex and vitally important enzymes such as nitrogenase. Because of this enzyme, nitrogen is continually cycled between its comparatively inert role in the atmosphere and its critical role in living organisms; without it, life as we know it could not exist on Earth.

### ■ SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

Formic acid ( $\text{HCOOH}$ ) decomposes in the gas phase at elevated temperatures as follows:

The uncatalyzed decomposition reaction is determined to be first order. A graph of the partial pressure of  $\text{HCOOH}$  versus time for decomposition at 838 K is shown as the red curve in Figure 14.28 ►. When a small amount of solid  $\text{ZnO}$  is added to the reaction chamber, the partial pressure of acid versus time varies as shown by the blue curve in Figure 14.28.

- Estimate the half-life and first-order rate constant for formic acid decomposition.
- What can you conclude from the effect of added  $\text{ZnO}$  on the decomposition of formic acid?
- The progress of the reaction was followed by measuring the partial pressure of formic acid vapor at selected times. Suppose that, instead, we had plotted the concentration of formic acid in units of mol/L. What effect would this have had on the calculated value of  $k$ ?
- The pressure of formic acid vapor at the start of the reaction is  $3.00 \times 10^2$  torr. Assuming constant temperature and ideal-gas behavior, what is the pressure in the

▲ **Figure 14.28 Variation in pressure of  $\text{HCOOH}(g)$  as a function of time at 838 K.** The red line corresponds to decomposition when only gaseous  $\text{HCOOH}$  is present. The blue line corresponds to decomposition in the presence of added  $\text{ZnO}(s)$ .

system at the end of the reaction? If the volume of the reaction chamber is  $436 \text{ cm}^3$ , how many moles of gas occupy the reaction chamber at the end of the reaction?

(e) The standard heat of formation of formic acid vapor is  $\Delta H_f^\circ = -378.6 \text{ kJ/mol}$ . Calculate  $\Delta H^\circ$  for the overall reaction. If the activation energy ( $E_a$ ) for the reaction is  $184 \text{ kJ/mol}$ , sketch an approximate energy profile for the reaction, and label  $E_a$ ,  $\Delta H^\circ$ , and the transition state.

### SOLUTION

(a) The initial pressure of  $\text{HCOOH}$  is  $3.00 \times 10^2 \text{ torr}$ . On the graph we move to the level at which the partial pressure of  $\text{HCOOH}$  is  $1.50 \times 10^2 \text{ torr}$ , half the initial value. This corresponds to a time of about  $6.60 \times 10^2 \text{ s}$ , which is therefore the half-life. The first-order rate constant is given by Equation 14.15:  $k = 0.693/t_{1/2} = 0.693/660 \text{ s} = 1.05 \times 10^{-3} \text{ s}^{-1}$ .

(b) The reaction proceeds much more rapidly in the presence of solid  $\text{ZnO}$ , so the surface of the oxide must be acting as a catalyst for the decomposition of the acid. This is an example of heterogeneous catalysis.

(c) If we had graphed the concentration of formic acid in units of moles per liter, we would still have determined that the half-life for decomposition is 660 seconds, and we would have computed the same value for  $k$ . Because the units for  $k$  are  $\text{s}^{-1}$ , the value for  $k$  is independent of the units used for concentration.

(d) According to the stoichiometry of the reaction, two moles of product are formed for each mole of reactant. When reaction is completed, therefore, the pressure will be 600 torr, just twice the initial pressure, assuming ideal-gas behavior. (Because we are working at quite high temperature and fairly low gas pressure, assuming ideal-gas behavior is reasonable.) The number of moles of gas present can be calculated using the ideal-gas equation (Section 10.4):

$$n = \frac{PV}{RT} = \frac{(600/760 \text{ atm})(0.436 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(838 \text{ K})} = 5.00 \times 10^{-3} \text{ moles}$$

(e) We first calculate the overall change in energy,  $\Delta H^\circ$  (Section 5.7 and Appendix C), as in

$$\begin{aligned} \Delta H^\circ &= \Delta H_f^\circ(\text{CO}_2(\text{g})) + \Delta H_f^\circ(\text{H}_2(\text{g})) - \Delta H_f^\circ(\text{HCOOH}(\text{g})) \\ &= -393.5 \text{ kJ/mol} + 0 - (-378.6 \text{ kJ/mol}) \\ &= -14.9 \text{ kJ/mol} \end{aligned}$$

From this and the given value for  $E_a$ , we can draw an approximate energy profile for the reaction, in analogy to Figure 14.15.

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Introduction and Section 14.1** In this chapter we explored **chemical kinetics**, the area of chemistry that studies the rates of chemical reactions and the factors that affect them, namely, concentration, temperature, and catalysts.

**Section 14.2** **Reaction rates** are usually expressed as changes in concentration per unit time: Typically, for reactions in solution, rates are given in units of molarity per second  $M/s$ . For most reactions, a plot of molarity versus time shows that the rate slows down as the reaction proceeds. The **instantaneous rate** is the slope of a line drawn tangent to the concentration-versus-time curve at a specific time. Rates can be written in terms of the appearance of products or the disappearance of reactants; the stoichiometry of the reaction dictates the relationship between rates of appearance and disappearance. Spectroscopy is one technique that can be used to monitor the course of a reaction. According to **Beer's law**, the absorption of electromagnetic radiation by a substance at a particular wavelength is directly proportional to its concentration.

**Section 14.3** The quantitative relationship between rate and concentration is expressed by a **rate law**, which usually has the following form:

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots$$

The constant  $k$  in the rate law is called the **rate constant**; the exponents  $m$ ,  $n$ , and so forth are called **reaction orders** for the reactants. The sum of the reaction orders gives the **overall reaction order**. Reaction orders must be determined experimentally. The units of the rate constant depend on the overall reaction order. For a reaction in which the overall reaction order is 1,  $k$  has units of  $s^{-1}$ ; for one in which the overall reaction order is 2,  $k$  has units of  $M^{-1} s^{-1}$ .

**Section 14.4** Rate laws can be used to determine the concentrations of reactants or products at any time during a reaction. In a **first-order reaction** the rate is proportional to the concentration of a single reactant raised to the first power:  $\text{Rate} = k[A]$ . In such cases the integrated form of the rate law is  $\ln[A]_t = -kt + \ln[A]_0$ , where  $[A]_t$  is the concentration of reactant A at time  $t$ ,  $k$  is the rate constant, and  $[A]_0$  is the initial concentration of A. Thus, for a first-order reaction, a graph of  $\ln[A]$  versus time yields a straight line of slope  $-k$ .

A **second-order reaction** is one for which the overall reaction order is 2. If a second-order rate law depends on the concentration of only one reactant, then  $\text{rate} = k[A]^2$ , and the time dependence of  $[A]$  is given by the integrated form of the rate law:  $1/[A]_t = 1/[A]_0 + kt$ . In this case a graph of  $1/[A]_t$  versus time yields a straight line.

The **half-life** of a reaction,  $t_{1/2}$ , is the time required for the concentration of a reactant to drop to one-half of its original value. For a first-order reaction, the half-life depends only on the rate constant and not on the initial concentration:  $t_{1/2} = 0.693/k$ . The half-life of a second-order reaction depends on both the rate constant and the initial concentration of A:  $t_{1/2} = 1/k[A]_0$ .

**Section 14.5** The **collision model**, which assumes that reactions occur as a result of collisions between molecules, helps explain why the magnitudes of rate constants increase with increasing temperature. The greater the kinetic energy of the colliding molecules, the greater is the energy of collision. The minimum energy required for a reaction to occur is called the **activation energy**,  $E_a$ . A collision with energy  $E_a$  or greater can cause the atoms of the colliding molecules to reach the **activated complex** (or **transition state**), which is the highest energy arrangement in the pathway from reactants to products. Even if a collision is energetic enough, it may not lead to reaction; the reactants must also be correctly oriented relative to one another in order for a collision to be effective.

Because the kinetic energy of molecules depends on temperature, the rate constant of a reaction is very dependent on temperature. The relationship between  $k$  and temperature is given by the **Arrhenius equation**:  $k = Ae^{-E_a/RT}$ . The term  $A$  is called the **frequency factor**; it relates to the number of collisions that are favorably oriented for reaction. The Arrhenius equation is often used in logarithmic form:  $k = \ln A - E_a/RT$ . Thus, a graph of  $\ln k$  versus  $1/T$  yields a straight line with slope  $-E_a/R$ .

**Section 14.6** A **reaction mechanism** details the individual steps that occur in the course of a reaction. Each of these steps, called **elementary reactions**, has a well-defined rate law that depends on the number of molecules (the **molecularity**) of the step. Elementary reactions are defined as either **unimolecular**, **bimolecular**, or **termolecular**, depending on whether one, two, or three reactant molecules are involved, respectively. Termolecular elementary reactions are very rare. Unimolecular, bimolecular, and termolecular reactions follow rate laws that are first order overall, second order overall, and third order overall, respectively. Many reactions occur by a multistep mechanism, involving two or more elementary reactions, or steps. An **intermediate** is produced in one elementary step, is consumed in a later elementary step, and therefore does not appear in the overall equation for the reaction. When a mechanism has several elementary steps, the overall rate is limited by the slowest elementary step, called the **rate-determining step**. A fast elementary step that follows the rate-determining step will have no effect on the rate law of the reaction. A fast step

that precedes the rate-determining step often creates an equilibrium that involves an intermediate. For a mechanism to be valid, the rate law predicted by the mechanism must be the same as that observed experimentally.

**Section 14.7** A **catalyst** is a substance that increases the rate of a reaction without undergoing a net chemical change itself. It does so by providing a different mechanism for the reaction, one that has a lower activation energy. A **homogeneous catalyst** is one that is in the same phase as the reactants. A **heterogeneous catalyst** has a different phase from the reactants. Finely divided metals are often used as heterogeneous catalysts for solution-

and gas-phase reactions. Reacting molecules can undergo **binding**, or **adsorption**, at the surface of the catalyst. The adsorption of a reactant at specific sites on the surface makes bond breaking easier, lowering the activation energy. Catalysis in living organisms is achieved by **enzymes**, large protein molecules that usually catalyze a very specific reaction. The specific reactant molecules involved in an enzymatic reaction are called **substrates**. The site of the enzyme where the catalysis occurs is called the **active site**. In the **lock-and-key model** for enzyme catalysis, substrate molecules bind very specifically to the active site of the enzyme, after which they can undergo reaction.

## KEY SKILLS

- Understand the factors that affect the rate of chemical reactions.
- Be able to determine the rate of a reaction given time and concentration.
- Be able to relate the rate of formation of products and the rate of disappearance of reactants given the balanced chemical equation for the reaction.
- Understand the form and meaning of a rate law including the ideas of reaction order and rate constant.
- Be able to determine the rate law and rate constant for a reaction from a series of experiments given the measured rates for various concentrations of reactants.
- Be able to use the integrated form of a rate law to determine the concentration of a reactant at a given time.
- Explain how the activation energy affects a rate and be able to use the Arrhenius Equation.
- Be able to predict a rate law for a reaction having a multistep mechanism given the individual steps in the mechanism.
- Explain how a catalyst works.

## KEY EQUATIONS

- |  |  |
|--|--|
| • $\text{Rate} = -\frac{1}{a} \frac{\Delta[A]}{\Delta t} = -\frac{1}{b} \frac{\Delta[B]}{\Delta t} = \frac{1}{c} \frac{\Delta[C]}{\Delta t} = \frac{1}{d} \frac{\Delta[D]}{\Delta t}$ [14.4] | Relating rates to the components of a balanced chemical equation                     |
| • $\text{Rate} = k[A]^m[B]^n$ [14.7]   | General form of a rate law   |
| • $\ln[A]_t - \ln[A]_0 = -kt$ or $\ln \frac{[A]_t}{[A]_0} = -kt$ [14.12]   | The integrated form of a first-order rate law  |
| • $\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$ [14.14]   | The integrated form of the second-order rate law                                     |
| • $t_{1/2} = \frac{0.693}{k}$ [14.15]  | Relating the half-life and rate constant for a first-order reaction                  |
| • $k = Ae^{-E_a/RT}$ [14.19]   | The Arrhenius equation, which expresses how the rate constant depends on temperature |
| • $\ln k = -\frac{E_a}{RT} + \ln A$ [14.20]  | Linear form of the Arrhenius equation  |

## VISUALIZING CONCEPTS

- 14.1 Consider the following graph of the concentration of a substance over time. (a) Is X a reactant or product of the reaction? (b) Why is the average rate of the reaction greater between points 1 and 2 than between points 2 and 3? [Section 14.2]

- 14.2 You study the rate of a reaction, measuring both the concentration of the reactant and the concentration of the product as a function of time, and obtain the following results:

What chemical equation is consistent with this data:

- (a)  $A \rightarrow B$ , (b)  $B \rightarrow A$ , (c)  $A \rightarrow 2B$ ,  
 (d)  $B \rightarrow 2A$ . Explain your choice. [Section 14.2]
- 14.3 You perform a series of experiments for the reaction  $A \rightarrow B + C$  and find that the rate law has the form  $\text{rate} = k[A]^x$ . Determine the value of  $x$  in each of the following cases: (a) There is no rate change when  $[A]$  is tripled. (b) The rate increases by a factor of 9 when  $[A]$  is tripled. (c) When  $[A]$  is doubled, the rate increases by a factor of 8. [Section 14.3]

- 14.4 The following diagrams represent mixtures of  $\text{NO}(g)$  and  $\text{O}_2(g)$ . These two substances react as follows:

It has been determined experimentally that the rate is second order in  $\text{NO}$  and first order in  $\text{O}_2$ . Based on this

fact, which of the following mixtures will have the fastest initial rate? [Section 14.3]

- 14.5 A friend studies a first-order reaction and obtains the following three graphs for experiments done at two different temperatures. (a) Which two lines represent experiments done at the same temperature? What accounts for the difference in these two lines? In what way are they the same? (b) Which two lines represent experiments done with the same starting concentration but at different temperatures? Which line probably represents the lower temperature? How do you know? [Section 14.4]

- 14.6 (a) Given the following diagrams at  $t = 0$  and  $t = 30$ , what is the half-life of the reaction if it follows first-order kinetics?

- (b) After four half-life periods for a first-order reaction, what fraction of reactant remains? [Section 14.4]

- 14.7 The following diagram shows the reaction profile of a reaction. Label the components indicated by the boxes. [Section 14.5]

- 14.8 You study the effect of temperature on the rate of two reactions and graph the natural logarithm of the rate constant for each reaction as a function of  $1/T$ . How do the two graphs compare (a) if the activation energy of the second reaction is higher than the activation energy of the first reaction but the two reactions have the same frequency factor, and (b) if the frequency factor of the second reaction is higher than the frequency factor of the first reaction but the two reactions have the same activation energy? [Section 14.5]

- 14.9 Consider the diagram below, which represents two steps in an overall reaction. The red spheres are oxygen, the blue ones nitrogen, and the green ones fluorine. (a) Write the chemical equation for each step in the reaction. (b) Write the equation for the overall reaction. (c) Identify the intermediate in the mechanism. (d) Write the rate law for the overall reaction if the first step is the slow, rate-determining step. [Section 14.6]

- 14.10 Based on the following reaction profile, how many intermediates are formed in the reaction  $A \rightarrow C$ ? How many transition states are there? Which step is the fastest? Is the reaction  $A \rightarrow C$  exothermic or endothermic? [Section 14.6]

- 14.11 Draw a possible transition state for the bimolecular reaction depicted below. (The blue spheres are nitrogen atoms, and the red ones are oxygen atoms.) Use dashed lines to represent the bonds that are in the process of being broken or made in the transition state. [Section 14.6]

- 14.12 The following diagram represents an imaginary two-step mechanism. Let the red spheres represent element A, the green ones element B, and the blue ones element C. (a) Write the equation for the net reaction that is occurring. (b) Identify the intermediate. (c) Identify the catalyst. [Sections 14.6 and 14.7]

## EXERCISES

### Reaction Rates

- 14.13 (a) What is meant by the term *reaction rate*? (b) Name three factors that can affect the rate of a chemical reaction. (c) What information is necessary to relate the rate of disappearance of reactants to the rate of appearance of products?
- 14.14 (a) What are the units usually used to express the rates of reactions occurring in solution? (b) From your everyday experience, give two examples of the effects of temperature on the rates of reactions. (c) What is the difference between average rate and instantaneous rate?

- 14.15 Consider the following hypothetical aqueous reaction:  $A(aq) \rightarrow B(aq)$ . A flask is charged with 0.065 mol of A in a total volume of 100.0 mL. The following data are collected:

Time (min)	0	10	20	30	40
Moles of A	0.065	0.051	0.042	0.036	0.031

(a) Calculate the number of moles of B at each time in the table, assuming that there are no molecules of B at time zero. (b) Calculate the average rate of disappearance of A for each 10-min interval, in units of  $M/s$ . (c) Between  $t = 10$  min and  $t = 30$  min, what is the average rate of appearance of B in units of  $M/s$ ? Assume that the volume of the solution is constant.

- 14.16 A flask is charged with 0.100 mol of A and allowed to react to form B according to the hypothetical gas-phase reaction  $A(g) \longrightarrow B(g)$ . The following data are collected:

Time (s)	0	40	80	120	160
Moles of A	0.100	0.067	0.045	0.030	0.020

(a) Calculate the number of moles of B at each time in the table. (b) Calculate the average rate of disappearance of A for each 40-s interval, in units of  $mol/s$ . (c) What additional information would be needed to calculate the rate in units of concentration per time?

- 14.17 The isomerization of methyl isonitrile ( $CH_3NC$ ) to acetonitrile ( $CH_3CN$ ) was studied in the gas phase at  $215^\circ C$ , and the following data were obtained:

Time (s)	$[CH_3NC] (M)$
0	0.0165
2,000	0.0110
5,000	0.00591
8,000	0.00314
12,000	0.00137
15,000	0.00074

(a) Calculate the average rate of reaction, in  $M/s$ , for the time interval between each measurement. (b) Graph  $[CH_3NC]$  versus time, and determine the instantaneous rates in  $M/s$  at  $t = 5000$  s and  $t = 8000$  s.

- 14.18 The rate of disappearance of HCl was measured for the following reaction:

The following data were collected:

Time (min)	$[HCl] (M)$
0.0	1.85
54.0	1.58
107.0	1.36
215.0	1.02
430.0	0.580

- (a) Calculate the average rate of reaction, in  $M/s$ , for the time interval between each measurement. (b) Graph  $[HCl]$  versus time, and determine the instantaneous rates in  $M/min$  and  $M/s$  at  $t = 75.0$  min and  $t = 250$  min.

- 14.19 For each of the following gas-phase reactions, indicate how the rate of disappearance of each reactant is related to the rate of appearance of each product:

- 14.20 For each of the following gas-phase reactions, write the rate expression in terms of the appearance of each product or disappearance of each reactant:

- 14.21 (a) Consider the combustion of  $H_2(g)$ :  $2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(g)$ . If hydrogen is burning at the rate of  $0.85$  mol/s, what is the rate of consumption of oxygen? What is the rate of formation of water vapor? (b) The reaction  $2 NO(g) + Cl_2(g) \longrightarrow 2 NOCl(g)$  is carried out in a closed vessel. If the partial pressure of NO is decreasing at the rate of  $23$  torr/min, what is the rate of change of the total pressure of the vessel?

- 14.22 (a) Consider the combustion of ethylene,  $C_2H_4(g) + 3 O_2(g) \longrightarrow 2 CO_2(g) + 2 H_2O(g)$ . If the concentration of  $C_2H_4$  is decreasing at the rate of  $0.025$   $M/s$ , what are the rates of change in the concentrations of  $CO_2$  and  $H_2O$ ? (b) The rate of decrease in  $N_2H_4$  partial pressure in a closed reaction vessel from the reaction  $N_2H_4(g) + H_2(g) \longrightarrow 2 NH_3(g)$  is  $63$  torr/h. What are the rates of change of  $NH_3$  partial pressure and total pressure in the vessel?

## Rate Laws

- 14.23 A reaction  $A + B \longrightarrow C$  obeys the following rate law:  $Rate = k[B]^2$ . (a) If  $[A]$  is doubled, how will the rate change? Will the rate constant change? Explain. (b) What are the reaction orders for A and B? What is the overall reaction order? (c) What are the units of the rate constant?
- 14.24 Consider a hypothetical reaction between A, B, and C that is first order in A, zero order in B, and second order in C. (a) Write the rate law for the reaction. (b) How does the rate change when  $[A]$  is doubled and the other reactant concentrations are held constant? (c) How does the rate change when  $[B]$  is tripled and the other reac-

tant concentrations are held constant? (d) How does the rate change when  $[C]$  is tripled and the other reactant concentrations are held constant? (e) By what factor does the rate change when the concentrations of all three reactants are tripled?

- 14.25 The decomposition of  $N_2O_5$  in carbon tetrachloride proceeds as follows:  $2 N_2O_5 \longrightarrow 4 NO_2 + O_2$ . The rate law is first order in  $N_2O_5$ . At  $64^\circ C$  the rate constant is  $4.82 \times 10^{-3} s^{-1}$ . (a) Write the rate law for the reaction. (b) What is the rate of reaction when  $[N_2O_5] = 0.0240$   $M$ ? (c) What happens to the rate when the concentration of  $N_2O_5$  is doubled to  $0.0480$   $M$ ?

14.26 Consider the following reaction:

(a) The rate law for this reaction is first order in  $\text{H}_2$  and second order in  $\text{NO}$ . Write the rate law. (b) If the rate constant for this reaction at 1000 K is  $6.0 \times 10^4 \text{ M}^{-2} \text{ s}^{-1}$ , what is the reaction rate when  $[\text{NO}] = 0.035 \text{ M}$  and  $[\text{H}_2] = 0.015 \text{ M}$ ? (c) What is the reaction rate at 1000 K when the concentration of  $\text{NO}$  is increased to  $0.10 \text{ M}$ , while the concentration of  $\text{H}_2$  is  $0.010 \text{ M}$ ?

14.27 Consider the following reaction:

The rate law for this reaction is first order in  $\text{CH}_3\text{Br}$  and first order in  $\text{OH}^-$ . When  $[\text{CH}_3\text{Br}]$  is  $5.0 \times 10^{-3} \text{ M}$  and  $[\text{OH}^-]$  is  $0.050 \text{ M}$ , the reaction rate at 298 K is  $0.0432 \text{ M/s}$ . (a) What is the value of the rate constant? (b) What are the units of the rate constant? (c) What would happen to the rate if the concentration of  $\text{OH}^-$  were tripled?

14.28 The reaction between ethyl bromide ( $\text{C}_2\text{H}_5\text{Br}$ ) and hydroxide ion in ethyl alcohol at 330 K,  $\text{C}_2\text{H}_5\text{Br}(alc) + \text{OH}^-(alc) \longrightarrow \text{C}_2\text{H}_5\text{OH}(l) + \text{Br}^-(alc)$ , is first order each in ethyl bromide and hydroxide ion. When  $[\text{C}_2\text{H}_5\text{Br}]$  is  $0.0477 \text{ M}$  and  $[\text{OH}^-]$  is  $0.100 \text{ M}$ , the rate of disappearance of ethyl bromide is  $1.7 \times 10^{-7} \text{ M/s}$ . (a) What is the value of the rate constant? (b) What are the units of the rate constant? (c) How would the rate of disappearance of ethyl bromide change if the solution were diluted by adding an equal volume of pure ethyl alcohol to the solution?

14.29 The iodide ion reacts with hypochlorite ion (the active ingredient in chlorine bleaches) in the following way:  $\text{OCl}^- + \text{I}^- \longrightarrow \text{OI}^- + \text{Cl}^-$ . This rapid reaction gives the following rate data:

$[\text{OCl}^-] \text{ (M)}$	$[\text{I}^-] \text{ (M)}$	Rate (M/s)
$1.5 \times 10^{-3}$	$1.5 \times 10^{-3}$	$1.36 \times 10^{-4}$
$3.0 \times 10^{-3}$	$1.5 \times 10^{-3}$	$2.72 \times 10^{-4}$
$1.5 \times 10^{-3}$	$3.0 \times 10^{-3}$	$2.72 \times 10^{-4}$

(a) Write the rate law for this reaction. (b) Calculate the rate constant. (c) Calculate the rate when  $[\text{OCl}^-] = 2.0 \times 10^{-3} \text{ M}$  and  $[\text{I}^-] = 5.0 \times 10^{-4} \text{ M}$ .

14.30 The reaction  $2 \text{ClO}_2(aq) + 2 \text{OH}^-(aq) \longrightarrow \text{ClO}_3^-(aq) + \text{ClO}_2^-(aq) + \text{H}_2\text{O}(l)$  was studied with the following results:

Experiment	$[\text{ClO}_2] \text{ (M)}$	$[\text{OH}^-] \text{ (M)}$	Rate (M/s)
1	0.060	0.030	0.0248
2	0.020	0.030	0.00276
3	0.020	0.090	0.00828

(a) Determine the rate law for the reaction. (b) Calculate the rate constant. (c) Calculate the rate when  $[\text{ClO}_2] = 0.100 \text{ M}$  and  $[\text{OH}^-] = 0.050 \text{ M}$ .

14.31 The following data were measured for the reaction  $\text{BF}_3(g) + \text{NH}_3(g) \longrightarrow \text{F}_3\text{BNH}_3(g)$ :

Experiment	$[\text{BF}_3] \text{ (M)}$	$[\text{NH}_3] \text{ (M)}$	Initial Rate (M/s)
1	0.250	0.250	0.2130
2	0.250	0.125	0.1065
3	0.200	0.100	0.0682
4	0.350	0.100	0.1193
5	0.175	0.100	0.0596

(a) What is the rate law for the reaction? (b) What is the overall order of the reaction? (c) What is the value of the rate constant for the reaction? (d) What is the rate when  $[\text{BF}_3] = 0.100 \text{ M}$  and  $[\text{NH}_3] = 0.500 \text{ M}$ ?

14.32 The following data were collected for the rate of disappearance of  $\text{NO}$  in the reaction  $2 \text{NO}(g) + \text{O}_2(g) \longrightarrow 2 \text{NO}_2(g)$ :

Experiment	$[\text{NO}] \text{ (M)}$	$[\text{O}_2] \text{ (M)}$	Initial Rate (M/s)
1	0.0126	0.0125	$1.41 \times 10^{-2}$
2	0.0252	0.0125	$5.64 \times 10^{-2}$
3	0.0252	0.0250	$1.13 \times 10^{-1}$

(a) What is the rate law for the reaction? (b) What are the units of the rate constant? (c) What is the average value of the rate constant calculated from the three data sets? (d) What is the rate of disappearance of  $\text{NO}$  when  $[\text{NO}] = 0.0750 \text{ M}$  and  $[\text{O}_2] = 0.0100 \text{ M}$ ? (e) What is the rate of disappearance of  $\text{O}_2$  at the concentrations given in part (d)?

14.33 Consider the gas-phase reaction between nitric oxide and bromine at 273 °C:  $2 \text{NO}(g) + \text{Br}_2(g) \longrightarrow 2 \text{NOBr}(g)$ . The following data for the initial rate of appearance of  $\text{NOBr}$  were obtained:

Experiment	$[\text{NO}] \text{ (M)}$	$[\text{Br}_2] \text{ (M)}$	Initial Rate (M/s)
1	0.10	0.20	24
2	0.25	0.20	150
3	0.10	0.50	60
4	0.35	0.50	735

(a) Determine the rate law. (b) Calculate the average value of the rate constant for the appearance of  $\text{NOBr}$  from the four data sets. (c) How is the rate of appearance of  $\text{NOBr}$  related to the rate of disappearance of  $\text{Br}_2$ ? (d) What is the rate of disappearance of  $\text{Br}_2$  when  $[\text{NO}] = 0.075 \text{ M}$  and  $[\text{Br}_2] = 0.25 \text{ M}$ ?

14.34 Consider the reaction of peroxydisulfate ion ( $\text{S}_2\text{O}_8^{2-}$ ) with iodide ion ( $\text{I}^-$ ) in aqueous solution:

At a particular temperature the rate of disappearance of  $\text{S}_2\text{O}_8^{2-}$  varies with reactant concentrations in the following manner:

Experiment	$[\text{S}_2\text{O}_8^{2-}]$ (M)	$[\text{I}^-]$ (M)	Initial Rate (M/s)
1	0.018	0.036	$2.6 \times 10^{-6}$
2	0.027	0.036	$3.9 \times 10^{-6}$
3	0.036	0.054	$7.8 \times 10^{-6}$
4	0.050	0.072	$1.4 \times 10^{-5}$

## Change of Concentration with Time

**14.35** (a) Define the following symbols that are encountered in rate equations:  $[A]_0$ ,  $t_{1/2}$ ,  $[A]_t$ ,  $k$  (b) What quantity, when graphed versus time, will yield a straight line for a first-order reaction?

**14.36** (a) For a second-order reaction, what quantity, when graphed versus time, will yield a straight line? (b) How do the half-lives of first-order and second-order reactions differ?

**14.37** (a) The gas-phase decomposition of  $\text{SO}_2\text{Cl}_2$ ,  $\text{SO}_2\text{Cl}_2(\text{g}) \rightarrow \text{SO}_2(\text{g}) + \text{Cl}_2(\text{g})$ , is first order in  $\text{SO}_2\text{Cl}_2$ . At 600 K the half-life for this process is  $2.3 \times 10^5$  s. What is the rate constant at this temperature? (b) At 320 °C the rate constant is  $2.2 \times 10^{-5} \text{ s}^{-1}$ . What is the half-life at this temperature?

**14.38** Molecular iodine,  $\text{I}_2(\text{g})$ , dissociates into iodine atoms at 625 K with a first-order rate constant of  $0.271 \text{ s}^{-1}$ . (a) What is the half-life for this reaction? (b) If you start with 0.050 M  $\text{I}_2$  at this temperature, how much will remain after 5.12 s assuming that the iodine atoms do not recombine to form  $\text{I}_2$ ?

**14.39** As described in Exercise 14.37, the decomposition of sulfuryl chloride ( $\text{SO}_2\text{Cl}_2$ ) is a first-order process. The rate constant for the decomposition at 660 K is  $4.5 \times 10^{-2} \text{ s}^{-1}$ . (a) If we begin with an initial  $\text{SO}_2\text{Cl}_2$  pressure of 375 torr, what is the pressure of this substance after 65 s? (b) At what time will the pressure of  $\text{SO}_2\text{Cl}_2$  decline to one-tenth its initial value?

**14.40** The first-order rate constant for the decomposition of  $\text{N}_2\text{O}_5$ ,  $2 \text{N}_2\text{O}_5(\text{g}) \rightarrow 4 \text{NO}_2(\text{g}) + \text{O}_2(\text{g})$ , at 70 °C is  $6.82 \times 10^{-3} \text{ s}^{-1}$ . Suppose we start with 0.0250 mol of  $\text{N}_2\text{O}_5(\text{g})$  in a volume of 2.0 L. (a) How many moles of  $\text{N}_2\text{O}_5$  will remain after 5.0 min? (b) How many minutes will it take for the quantity of  $\text{N}_2\text{O}_5$  to drop to 0.010 mol? (c) What is the half-life of  $\text{N}_2\text{O}_5$  at 70 °C?

**14.41** The reaction

is first order in  $\text{SO}_2\text{Cl}_2$ . Using the following kinetic data, determine the magnitude of the first-order rate constant:

(a) Determine the rate law for the reaction. (b) What is the average value of the rate constant for the disappearance of  $\text{S}_2\text{O}_8^{2-}$  based on the four sets of data? (c) How is the rate of disappearance of  $\text{S}_2\text{O}_8^{2-}$  related to the rate of disappearance of  $\text{I}^-$ ? (d) What is the rate of disappearance of  $\text{I}^-$  when  $[\text{S}_2\text{O}_8^{2-}] = 0.025 \text{ M}$  and  $[\text{I}^-] = 0.050 \text{ M}$ ?

Time (s)	Pressure $\text{SO}_2\text{Cl}_2$ (atm)
0	1.000
2,500	0.947
5,000	0.895
7,500	0.848
10,000	0.803

**14.42** From the following data for the first-order gas-phase isomerization of  $\text{CH}_3\text{NC}$  at 215 °C, calculate the first-order rate constant and half-life for the reaction:

Time (s)	Pressure $\text{CH}_3\text{NC}$ (torr)
0	502
2,000	335
5,000	180
8,000	95.5
12,000	41.7
15,000	22.4

**14.43** Consider the data presented in Exercise 14.15. (a) By using appropriate graphs, determine whether the reaction is first order or second order. (b) What is the value of the rate constant for the reaction? (c) What is the half-life for the reaction?

**14.44** Consider the data presented in Exercise 14.16. (a) Determine whether the reaction is first order or second order. (b) What is the value of the rate constant? (c) What is the half-life?

**14.45** The gas-phase decomposition of  $\text{NO}_2$ ,  $2 \text{NO}_2(\text{g}) \rightarrow 2 \text{NO}(\text{g}) + \text{O}_2(\text{g})$ , is studied at 383 °C, giving the following data:

Time (s)	$[\text{NO}_2]$ (M)
0.0	0.100
5.0	0.017
10.0	0.0090
15.0	0.0062
20.0	0.0047

(a) Is the reaction first order or second order with respect to the concentration of  $\text{NO}_2$ ? (b) What is the value of the rate constant?

- 14.46 Sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ), which is commonly known as table sugar, reacts in dilute acid solutions to form two simpler sugars, glucose and fructose, both of which have the formula  $\text{C}_6\text{H}_{12}\text{O}_6$ . At  $23^\circ\text{C}$  and in  $0.5\text{ M HCl}$ , the following data were obtained for the disappearance of sucrose:

Time (min)	$[\text{C}_{12}\text{H}_{22}\text{O}_{11}] (\text{M})$
0	0.316
39	0.274
80	0.238
140	0.190
210	0.146

(a) Is the reaction first order or second order with respect to  $[\text{C}_{12}\text{H}_{22}\text{O}_{11}]$ ? (b) What is the value of the rate constant?

## Temperature and Rate

- 14.47 (a) What factors determine whether a collision between two molecules will lead to a chemical reaction? (b) According to the collision model, why does temperature affect the value of the rate constant?

- 14.48 (a) In which of the following reactions would you expect the orientation factor to be least important in leading to reaction?  $\text{NO} + \text{O} \longrightarrow \text{NO}_2$  or  $\text{H} + \text{Cl} \longrightarrow \text{HCl}$ ? (b) How does the kinetic-molecular theory help us understand the temperature dependence of chemical reactions?

- 14.49 Calculate the fraction of atoms in a sample of argon gas at  $400\text{ K}$  that has an energy of  $10.0\text{ kJ}$  or greater.

- 14.50 (a) The activation energy for the isomerization of methyl isonitrile (Figure 14.6) is  $160\text{ kJ/mol}$ . Calculate the fraction of methyl isonitrile molecules that has an energy of  $160.0\text{ kJ}$  or greater at  $500\text{ K}$ . (b) Calculate this fraction for a temperature of  $510\text{ K}$ . What is the ratio of the fraction at  $510\text{ K}$  to that at  $500\text{ K}$ ?

- 14.51 The gas-phase reaction  $\text{Cl}(\text{g}) + \text{HBr}(\text{g}) \longrightarrow \text{HCl}(\text{g}) + \text{Br}(\text{g})$  has an overall enthalpy change of  $-66\text{ kJ}$ . The activation energy for the reaction is  $7\text{ kJ}$ . (a) Sketch the energy profile for the reaction, and label  $E_a$  and  $\Delta E$ . (b) What is the activation energy for the reverse reaction?

- 14.52 For the elementary process  $\text{N}_2\text{O}_5(\text{g}) \longrightarrow \text{NO}_2(\text{g}) + \text{NO}_3(\text{g})$  the activation energy ( $E_a$ ) and overall  $\Delta E$  are  $154\text{ kJ/mol}$ , and  $136\text{ kJ/mol}$ , respectively. (a) Sketch the energy profile for this reaction, and label  $E_a$  and  $\Delta E$ . (b) What is the activation energy for the reverse reaction?

- 14.53 Based on their activation energies and energy changes and assuming that all collision factors are the same, which of the following reactions would be fastest and which would be slowest? Explain your answer.

- (a)  $E_a = 45\text{ kJ/mol}$ ;  $\Delta E = -25\text{ kJ/mol}$   
 (b)  $E_a = 35\text{ kJ/mol}$ ;  $\Delta E = -10\text{ kJ/mol}$   
 (c)  $E_a = 55\text{ kJ/mol}$ ;  $\Delta E = 10\text{ kJ/mol}$

- 14.54 Which of the reactions in Exercise 14.53 will be fastest in the reverse direction? Which will be slowest? Explain.

- 14.55 A certain first-order reaction has a rate constant of  $2.75 \times 10^{-2}\text{ s}^{-1}$  at  $20^\circ\text{C}$ . What is the value of  $k$  at  $60^\circ\text{C}$  if (a)  $E_a = 75.5\text{ kJ/mol}$ ; (b)  $E_a = 125\text{ kJ/mol}$ ?

- 14.56 Understanding the high-temperature behavior of nitrogen oxides is essential for controlling pollution generated in automobile engines. The decomposition of nitric oxide ( $\text{NO}$ ) to  $\text{N}_2$  and  $\text{O}_2$  is second order with a rate constant of  $0.0796\text{ M}^{-1}\text{ s}^{-1}$  at  $737^\circ\text{C}$  and  $0.0815\text{ M}^{-1}\text{ s}^{-1}$  at  $947^\circ\text{C}$ . Calculate the activation energy for the reaction.

- 14.57 The rate of the reaction

was measured at several temperatures, and the following data were collected:

Temperature ( $^\circ\text{C}$ )	$k (\text{M}^{-1}\text{ s}^{-1})$
15	0.0521
25	0.101
35	0.184
45	0.332

Using these data, graph  $\ln k$  versus  $1/T$ . Using your graph, determine the value of  $E_a$ .

- 14.58 The temperature dependence of the rate constant for the reaction is tabulated as follows:

Temperature (K)	$k (\text{M}^{-1}\text{ s}^{-1})$
600	0.028
650	0.22
700	1.3
750	6.0
800	23

Calculate  $E_a$  and  $A$ .

- [14.59] The activation energy of a certain reaction is  $65.7\text{ kJ/mol}$ . How many times faster will the reaction occur at  $50^\circ\text{C}$  than at  $0^\circ\text{C}$ ?

- [14.60] The following is a quote from an article in the August 18, 1998, issue of *The New York Times* about the breakdown of cellulose and starch: "A drop of 18 degrees Fahrenheit [from  $77^\circ\text{F}$  to  $59^\circ\text{F}$ ] lowers the reaction rate six times; a 36-degree drop [from  $77^\circ\text{F}$  to  $41^\circ\text{F}$ ] produces a fortyfold decrease in the rate." (a) Calculate activation energies for the breakdown process based on the two estimates of the effect of temperature on rate. Are the values consistent? (b) Assuming the value of  $E_a$  calculated from the 36-degree drop and that the rate of breakdown is first order with a half-life at  $25^\circ\text{C}$  of 2.7 years, calculate the half-life for breakdown at a temperature of  $-15^\circ\text{C}$ .

## Reaction Mechanisms

14.61 (a) What is meant by the term *elementary reaction*? (b) What is the difference between a *unimolecular* and a *bimolecular elementary reaction*? (c) What is a *reaction mechanism*?

14.62 (a) What is meant by the term *molecularity*? (b) Why are termolecular elementary reactions so rare? (c) What is an *intermediate* in a mechanism?

14.63 What is the molecularity of each of the following elementary reactions? Write the rate law for each.

14.64 What is the molecularity of each of the following elementary reactions? Write the rate law for each.

14.65 (a) Based on the following reaction profile, how many intermediates are formed in the reaction  $\text{A} \rightarrow \text{D}$ ? (b) How many transition states are there? (c) Which step is the fastest? (d) Is the reaction  $\text{A} \rightarrow \text{D}$  exothermic or endothermic?

14.66 Consider the following energy profile.

(a) How many elementary reactions are in the reaction mechanism? (b) How many intermediates are formed in the reaction? (c) Which step is rate limiting? (d) Is the overall reaction exothermic or endothermic?

14.67 The following mechanism has been proposed for the gas-phase reaction of  $\text{H}_2$  with  $\text{ICl}$ :

(a) Write the balanced equation for the overall reaction. (b) Identify any intermediates in the mechanism. (c) Write rate laws for each elementary reaction in the mechanism. (d) If the first step is slow and the second one is fast, what rate law do you expect to be observed for the overall reaction?

14.68 The decomposition of hydrogen peroxide is catalyzed by iodide ion. The catalyzed reaction is thought to proceed by a two-step mechanism:

(a) Write the rate law for each of the elementary reactions of the mechanism. (b) Write the chemical equation for the overall process. (c) Identify the intermediate, if any, in the mechanism. (d) Assuming that the first step of the mechanism is rate determining, predict the rate law for the overall process.

14.69 The reaction  $2 \text{NO}(\text{g}) + \text{Cl}_2(\text{g}) \rightarrow 2 \text{NOCl}(\text{g})$  obeys the rate law,  $\text{rate} = k[\text{NO}]^2[\text{Cl}_2]$ . The following mechanism has been proposed for this reaction:

(a) What would the rate law be if the first step were rate determining? (b) Based on the observed rate law, what can we conclude about the relative rates of the two steps?

14.70 You have studied the gas-phase oxidation of  $\text{HBr}$  by  $\text{O}_2$ :

You find the reaction to be first order with respect to  $\text{HBr}$  and first order with respect to  $\text{O}_2$ . You propose the following mechanism:

(a) Indicate how the elementary reactions add to give the overall reaction. (*Hint*: You will need to multiply the coefficients of one of the equations by 2.) (b) Based on the rate law, which step is rate determining? (c) What are the intermediates in this mechanism? (d) If you are unable to detect  $\text{HOBr}$  or  $\text{HOOBr}$  among the products, does this disprove your mechanism?

## Catalysis

- 14.71** (a) What part of the energy profile of a reaction is affected by a catalyst? (b) What is the difference between a homogeneous and a heterogeneous catalyst?
- 14.72** (a) Most heterogeneous catalysts of importance are extremely finely divided solid materials. Why is particle size important? (b) What role does adsorption play in the action of a heterogeneous catalyst?
- 14.73** The oxidation of  $\text{SO}_2$  to  $\text{SO}_3$  is catalyzed by  $\text{NO}_2$ . Thereafter proceeds as follows:

- (a) Show that the two reactions can be summed to give the overall oxidation of  $\text{SO}_2$  by  $\text{O}_2$  to give  $\text{SO}_3$ . (*Hint*: The top reaction must be multiplied by a factor so the  $\text{NO}$  and  $\text{NO}_2$  cancel out.) (b) Why do we consider  $\text{NO}_2$  a catalyst and not an intermediate in this reaction? (c) Is this an example of homogeneous catalysis or heterogeneous catalysis?
- 14.74**  $\text{NO}$  catalyzes the decomposition of  $\text{N}_2\text{O}$ , possibly by the following mechanism:

- (a) What is the chemical equation for the overall reaction? Show how the two steps can be added to give the overall equation. (b) Why is  $\text{NO}$  considered a catalyst and not an intermediate? (c) If experiments show that during the decomposition of  $\text{N}_2\text{O}$ ,  $\text{NO}_2$  does not accumulate in measurable quantities, does this rule out the proposed mechanism? If you think not, suggest what might be going on.
- 14.75** Many metallic catalysts, particularly the precious-metal ones, are often deposited as very thin films on a substance of high surface area per unit mass, such as alumina ( $\text{Al}_2\text{O}_3$ ) or silica ( $\text{SiO}_2$ ). (a) Why is this an effective way of utilizing the catalyst material? (b) How does the surface area affect the rate of reaction?

- 14.76** (a) If you were going to build a system to check the effectiveness of automobile catalytic converters on cars, what substances would you want to look for in the car exhaust? (b) Automobile catalytic converters have to work at high temperatures, as hot exhaust gases stream through them. In what ways could this be an advantage? In what ways a disadvantage? (c) Why is the rate of flow of exhaust gases over a catalytic converter important?

- 14.77** When  $\text{D}_2$  reacts with ethylene ( $\text{C}_2\text{H}_4$ ) in the presence of a finely divided catalyst, ethane with two deuteriums,  $\text{CH}_2\text{D}-\text{CH}_2\text{D}$ , is formed. (Deuterium,  $\text{D}$ , is an isotope of hydrogen of mass 2.) Very little ethane forms in which two deuteriums are bound to one carbon (for example,  $\text{CH}_3-\text{CHD}_2$ ). Use the sequence of steps involved in the reaction to explain why this is so.
- 14.78** Heterogeneous catalysts that perform hydrogenation reactions, as illustrated in Figure 14.21, are subject to poisoning, which shuts down their catalytic ability. Compounds of sulfur are often poisons. Suggest a mechanism by which such compounds might act as poisons.

- 14.79** (a) Explain the importance of enzymes in biological systems. (b) What chemical transformations are catalyzed (i) by the enzyme catalase, (ii) by nitrogenase?
- 14.80** There are literally thousands of enzymes at work in complex living systems such as human beings. What properties of the enzymes give rise to their ability to distinguish one substrate from another?

- [14.81]** The activation energy of an uncatalyzed reaction is 95 kJ/mol. The addition of a catalyst lowers the activation energy to 55 kJ/mol. Assuming that the collision factor remains the same, by what factor will the catalyst increase the rate of the reaction at (a) 25 °C, (b) 125 °C?
- [14.82]** Suppose that a certain biologically important reaction is quite slow at physiological temperature (37 °C) in the absence of a catalyst. Assuming that the collision factor remains the same, by how much must an enzyme lower the activation energy of the reaction in order to achieve a  $1 \times 10^5$ -fold increase in the reaction rate?

## ADDITIONAL EXERCISES

- 14.83** Explain why rate laws generally cannot be written from balanced equations. Under what circumstance is the rate law related directly to the balanced equation for a reaction?
- 14.84** Hydrogen sulfide ( $\text{H}_2\text{S}$ ) is a common and troublesome pollutant in industrial wastewaters. One way to remove  $\text{H}_2\text{S}$  is to treat the water with chlorine, in which case the following reaction occurs:

The rate of this reaction is first order in each reactant. The rate constant for the disappearance of  $\text{H}_2\text{S}$  at 28 °C is  $3.5 \times 10^{-2} \text{ M}^{-1} \text{ s}^{-1}$ . If at a given time the concentration of  $\text{H}_2\text{S}$  is  $2.0 \times 10^{-4} \text{ M}$  and that of  $\text{Cl}_2$  is 0.025  $\text{M}$ , what is the rate of formation of  $\text{Cl}^-$ ?

- 14.85** The reaction  $2\text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{NO}_2(\text{g})$  is second order in  $\text{NO}$  and first order in  $\text{O}_2$ . When  $[\text{NO}] = 0.040 \text{ M}$  and  $[\text{O}_2] = 0.035 \text{ M}$ , the observed rate of disappearance of  $\text{NO}$  is  $9.3 \times 10^{-5} \text{ M/s}$ . (a) What is the rate of disappearance of  $\text{O}_2$  at this moment? (b) What is the value of the rate constant? (c) What are the units of the rate constant? (d) What would happen to the rate if the concentration of  $\text{NO}$  were increased by a factor of 1.8?

- 14.86** Consider the following reaction between mercury(II) chloride and oxalate ion:

The initial rate of this reaction was determined for several concentrations of  $\text{HgCl}_2$  and  $\text{C}_2\text{O}_4^{2-}$ , and the

following rate data were obtained for the rate of disappearance of  $C_2O_4^{2-}$ :

Experiment	$[HgCl_2] (M)$	$[C_2O_4^{2-}] (M)$	Rate (M/s)
1	0.164	0.15	$3.2 \times 10^{-5}$
2	0.164	0.45	$2.9 \times 10^{-4}$
3	0.082	0.45	$1.4 \times 10^{-4}$
4	0.246	0.15	$4.8 \times 10^{-5}$

(a) What is the rate law for this reaction? (b) What is the value of the rate constant? (c) What is the reaction rate when the concentration of  $HgCl_2$  is 0.100 M and that of  $(C_2O_4^{2-})$  is 0.25 M, if the temperature is the same as that used to obtain the data shown?

- 14.87 The reaction  $2NO_2 \longrightarrow 2NO + O_2$  has the rate constant  $k = 0.63 M^{-1} s^{-1}$ . Based on the units for  $k$ , is the reaction first or second order in  $NO_2$ ? If the initial concentration of  $NO_2$  is 0.100 M, how would you determine how long it would take for the concentration to decrease to 0.025 M?
- 14.88 Consider two reactions. Reaction (1) has a constant half-life, whereas reaction (2) has a half-life that gets longer as the reaction proceeds. What can you conclude about the rate laws of these reactions from these observations?
- 14.89 (a) The reaction  $H_2O_2(aq) \longrightarrow H_2O(l) + \frac{1}{2} O_2(g)$ , is first order. Near room temperature, the rate constant equals  $7.0 \times 10^{-4} s^{-1}$ . Calculate the half-life at this temperature. (b) At 415 °C,  $(CH_2)_2O$  decomposes in the gas phase,  $(CH_2)_2O(g) \longrightarrow CH_4(g) + CO(g)$ . If the reaction is first order with a half-life of 56.3 min at this temperature, calculate the rate constant in  $s^{-1}$ .
- 14.90 Americium-241 is used in smoke detectors. It has a rate constant for radioactive decay of  $k = 1.6 \times 10^{-3} yr^{-1}$ . By contrast, iodine-125, which is used to test for thyroid functioning, has a rate constant for radioactive decay of  $k = 0.011 day^{-1}$ . (a) What are the half-lives of these two isotopes? (b) Which one decays at a faster rate? (c) How much of a 1.00-mg sample of either isotope remains after three half-lives?
- 14.91 Urea ( $NH_2CONH_2$ ) is the end product in protein metabolism in animals. The decomposition of urea in 0.1 M HCl occurs according to the reaction

The reaction is first order in urea and first order overall. When  $[NH_2CONH_2] = 0.200 M$ , the rate at 61.05 °C is  $8.56 \times 10^{-5} M/s$ . (a) What is the value for the rate constant,  $k$ ? (b) What is the concentration of urea in this solution after  $4.00 \times 10^3 s$  if the starting concentration is 0.500 M? (c) What is the half-life for this reaction at 61.05 °C?

- 14.92 The rate of a first-order reaction is followed by spectroscopy, monitoring the absorption of a colored reactant. The reaction occurs in a 1.00-cm sample cell, and the only colored species in the reaction has a molar absorptivity constant of  $5.60 \times 10^3 cm^{-1} M^{-1}$ . (a) Calculate the initial concentration of the colored reactant if the absorbance is 0.605 at the beginning of the reaction. (b) The absorbance falls to 0.250 within 30.0 min. Calculate the

rate constant in units of  $s^{-1}$ . (c) Calculate the half-life of the reaction. (d) How long does it take for the absorbance to fall to 0.100?

- 14.93 Cyclopentadiene ( $C_5H_6$ ) reacts with itself to form dicyclopentadiene ( $C_{10}H_{12}$ ). A 0.0400 M solution of  $C_5H_6$  was monitored as a function of time as the reaction  $2C_5H_6 \longrightarrow C_{10}H_{12}$  proceeded. The following data were collected:

Time (s)	$[C_5H_6] (M)$
0.0	0.0400
50.0	0.0300
100.0	0.0240
150.0	0.0200
200.0	0.0174

Plot  $[C_5H_6]$  versus time,  $\ln [C_5H_6]$  versus time, and  $1/[C_5H_6]$  versus time. What is the order of the reaction? What is the value of the rate constant?

- 14.94 (a) Two reactions have identical values for  $E_a$ . Does this ensure that they will have the same rate constant if run at the same temperature? Explain. (b) Two similar reactions have the same rate constant at 25 °C, but at 35 °C one of the reactions has a higher rate constant than the other. Account for these observations.
- 14.95 The first-order rate constant for reaction of a particular organic compound with water varies with temperature as follows:

Temperature (K)	Rate Constant ( $s^{-1}$ )
300	$3.2 \times 10^{-11}$
320	$1.0 \times 10^{-9}$
340	$3.0 \times 10^{-8}$
355	$2.4 \times 10^{-7}$

From these data, calculate the activation energy in units of kJ/mol.

- 14.96 The following mechanism has been proposed for the reaction of NO with  $H_2$  to form  $N_2O$  and  $H_2O$ :

- (a) Show that the elementary reactions of the proposed mechanism add to provide a balanced equation for the reaction. (b) Write a rate law for each elementary reaction in the mechanism. (c) Identify any intermediates in the mechanism. (d) The observed rate law is  $rate = k[NO]^2[H_2]$ . If the proposed mechanism is correct, what can we conclude about the relative speeds of the first and second reactions?

- 14.97 Ozone in the upper atmosphere can be destroyed by the following two-step mechanism:

- (a) What is the overall equation for this process? (b) What is the catalyst in the reaction? How do you know? (c) What is the intermediate in the reaction? How do you distinguish it from the catalyst?

**14.98** Using Figure 14.20 as your basis, draw the energy profile for the bromide ion-catalyzed decomposition of hydrogen peroxide. (a) Label the curve with the activation energies for reactions [14.30] and [14.31]. (b) Notice from Figure 14.19(b) that when  $\text{Br}^-(aq)$  is added initially,  $\text{Br}_2$  accumulates to some extent during the reaction. What does this tell us about the relative rates of reactions [14.30] and [14.31]?

**[14.99]** The following mechanism has been proposed for the gas-phase reaction of chloroform ( $\text{CHCl}_3$ ) and chlorine:

(a) What is the overall reaction? (b) What are the intermediates in the mechanism? (c) What is the molecularity of each of the elementary reactions? (d) What is the rate-determining step? (e) What is the rate law predicted by this mechanism? (*Hint:* The overall reaction order is not an integer.)

**[14.100]** In a hydrocarbon solution, the gold compound  $(\text{CH}_3)_3\text{AuPH}_3$  decomposes into ethane ( $\text{C}_2\text{H}_6$ ) and a different gold compound,  $(\text{CH}_3)\text{AuPH}_3$ . The following mechanism has been proposed for the decomposition of  $(\text{CH}_3)_3\text{AuPH}_3$ :

(a) What is the overall reaction? (b) What are the intermediates in the mechanism? (c) What is the molecularity

of each of the elementary steps? (d) What is the rate-determining step? (e) What is the rate law predicted by this mechanism? (f) What would be the effect on the reaction rate of adding  $\text{PH}_3$  to the solution of  $(\text{CH}_3)_3\text{AuPH}_3$ ?

**14.101** One of the many remarkable enzymes in the human body is carbonic anhydrase, which catalyzes the interconversion of carbonic acid with carbon dioxide and water. If it were not for this enzyme, the body could not rid itself rapidly enough of the  $\text{CO}_2$  accumulated by cell metabolism. The enzyme catalyzes the dehydration (release to air) of up to  $10^7$   $\text{CO}_2$  molecules per second. Which components of this description correspond to the terms *enzyme*, *substrate*, and *turnover number*?

**14.102** Enzymes are often described as following the two-step mechanism:

Where E = enzyme, S = substrate, and P = product. If an enzyme follows this mechanism, what rate law is expected for the reaction?

**14.103** The enzyme *invertase* catalyzes the conversion of sucrose, a disaccharide, to invert sugar, a mixture of glucose and fructose. When the concentration of invertase is  $4.2 \times 10^{-7}$  M and the concentration of sucrose is 0.0077 M, invert sugar is formed at the rate of  $1.5 \times 10^{-4}$  M/s. When the sucrose concentration is doubled, the rate of formation of invert sugar is doubled also. (a) Assuming that the enzyme-substrate model is operative, is the fraction of enzyme tied up as a complex large or small? Explain. (b) Addition of inositol, another sugar, decreases the rate of formation of invert sugar. Suggest a mechanism by which this occurs.

## INTEGRATIVE EXERCISES

**14.104** Dinitrogen pentoxide ( $\text{N}_2\text{O}_5$ ) decomposes in chloroform as a solvent to yield  $\text{NO}_2$  and  $\text{O}_2$ . The decomposition is first order with a rate constant at  $45^\circ\text{C}$  of  $1.0 \times 10^{-5} \text{ s}^{-1}$ . Calculate the partial pressure of  $\text{O}_2$  produced from 1.00 L of 0.600 M  $\text{N}_2\text{O}_5$  solution at  $45^\circ\text{C}$  over a period of 20.0 h if the gas is collected in a 10.0-L container. (Assume that the products do not dissolve in chloroform.)

**[14.105]** The reaction between ethyl iodide and hydroxide ion in ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) solution,  $\text{C}_2\text{H}_5\text{I}(alc) + \text{OH}^-(alc) \longrightarrow \text{C}_2\text{H}_5\text{OH}(l) + \text{I}^-(alc)$ , has an activation energy of 86.8 kJ/mol and a frequency factor of  $2.10 \times 10^{11} \text{ M}^{-1} \text{ s}^{-1}$ . (a) Predict the rate constant for the reaction at  $35^\circ\text{C}$ . (b) A solution of KOH in ethanol is made up by dissolving 0.335 g KOH in ethanol to form 250.0 mL of solution. Similarly, 1.453 g of  $\text{C}_2\text{H}_5\text{I}$  is dissolved in ethanol to form 250.0 mL of solution. Equal volumes of the two solutions are mixed. Assuming the reaction is first order in each reactant, what is the initial rate at  $35^\circ\text{C}$ ? (c) Which reagent in the reaction is limiting, assuming the reaction proceeds to completion?

**14.106** Zinc metal dissolves in hydrochloric acid according to the reaction

Suppose you are asked to study the kinetics of this reaction by monitoring the rate of production of  $\text{H}_2(g)$ .

(a) By using a reaction flask, a manometer, and any other common laboratory equipment, design an experimental apparatus that would allow you to monitor the partial pressure of  $\text{H}_2(g)$  produced as a function of time. (b) Explain how you would use the apparatus to determine the rate law of the reaction. (c) Explain how you would use the apparatus to determine the reaction order for  $[\text{H}^+]$  for the reaction. (d) How could you use the apparatus to determine the activation energy of the reaction? (e) Explain how you would use the apparatus to determine the effects of changing the form of  $\text{Zn}(s)$  from metal strips to granules.

**14.107** The gas-phase reaction of NO with  $\text{F}_2$  to form NOF and F has an activation energy of  $E_a = 6.3 \text{ kJ/mol}$  and a

frequency factor of  $A = 6.0 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ . The reaction is believed to be bimolecular:

(a) Calculate the rate constant at 100 °C. (b) Draw the Lewis structures for the NO and the NOF molecules, given that the chemical formula for NOF is misleading because the nitrogen atom is actually the central atom in the molecule. (c) Predict the structure for the NOF molecule. (d) Draw a possible transition state for the formation of NOF, using dashed lines to indicate the weak bonds that are beginning to form. (e) Suggest a reason for the low activation energy for the reaction.

**14.108** The mechanism for the oxidation of HBr by  $\text{O}_2$  to form  $2 \text{H}_2\text{O}$  and  $\text{Br}_2$  is shown in Exercise 14.70. (a) Calculate the overall standard enthalpy change for the reaction process. (b) HBr does not react with  $\text{O}_2$  at a measurable rate at room temperature under ordinary conditions. What can you infer from this about the magnitude of the activation energy for the rate-determining step? (c) Draw a plausible Lewis structure for the intermediate  $\text{HOOBr}$ . To what familiar compound of hydrogen and oxygen does it appear similar?

**14.109** Enzymes, the catalysts of biological systems, are high molecular weight protein materials. The active site of the enzyme is formed by the three-dimensional arrangement of the protein in solution. When heated in solution, proteins undergo denaturation, a process in which the three-dimensional structure of the protein unravels or at least partly does so. The accompanying graph shows the variation with temperature of the activity of a typical enzyme. The activity increases with temperature to a point above the usual operating region for the enzyme, then declines rapidly with further temperature increases. What role does denaturation play in determining the shape of this curve? How does your explanation fit in with the lock-and-key model of enzyme action?

**[14.110]** Metals often form several cations with different charges. Cerium, for example, forms  $\text{Ce}^{3+}$  and  $\text{Ce}^{4+}$  ions, and thallium forms  $\text{Tl}^+$  and  $\text{Tl}^{3+}$  ions. Cerium and thallium ions react as follows:

This reaction is very slow and is thought to occur in a single elementary step. The reaction is catalyzed by the

addition of  $\text{Mn}^{2+}(\text{aq})$ , according to the following mechanism:

(a) Write the rate law for the uncatalyzed reaction. (b) What is unusual about the uncatalyzed reaction? Why might it be a slow reaction? (c) The rate for the catalyzed reaction is first order in  $[\text{Ce}^{4+}]$  and first order in  $[\text{Mn}^{2+}]$ . Based on this rate law, which of the steps in the catalyzed mechanism is rate determining? (d) Use the available oxidation states of Mn to comment on its special suitability to catalyze this reaction.

**[14.111]** The rates of many atmospheric reactions are accelerated by the absorption of light by one of the reactants. For example, consider the reaction between methane and chlorine to produce methyl chloride and hydrogen chloride:

This reaction is very slow in the absence of light. However,  $\text{Cl}_2(\text{g})$  can absorb light to form Cl atoms:

Once the Cl atoms are generated, they can catalyze the reaction of  $\text{CH}_4$  and  $\text{Cl}_2$ , according to the following proposed mechanism:

The enthalpy changes and activation energies for these two reactions are tabulated as follows:

Reaction	$\Delta H_{\text{ran}}^\circ$ (kJ/mol)	$E_a$ (kJ/mol)
3	+4	17
4	-109	4

(a) By using the bond enthalpy for  $\text{Cl}_2$  (Table 8.4), determine the longest wavelength of light that is energetic enough to cause reaction 2 to occur. In which portion of the electromagnetic spectrum is this light found? (b) By using the data tabulated here, sketch a quantitative energy profile for the catalyzed reaction represented by reactions 3 and 4. (c) By using bond enthalpies, estimate where the reactants,  $\text{CH}_4(\text{g}) + \text{Cl}_2(\text{g})$ , should be placed on your diagram in part (b). Use this result to estimate the value of  $E_a$  for the reaction  $\text{CH}_4(\text{g}) + \text{Cl}_2(\text{g}) \longrightarrow \text{CH}_3(\text{g}) + \text{HCl}(\text{g}) + \text{Cl}(\text{g})$ . (d) The species  $\text{Cl}(\text{g})$  and  $\text{CH}_3(\text{g})$  in reactions 3 and 4 are radicals, that is, atoms or molecules with unpaired electrons. Draw a Lewis structure of  $\text{CH}_3$ , and verify that it is a radical. (e) The sequence of reactions 3 and 4 comprise a radical chain mechanism. Why do you think this is called a "chain reaction"? Propose a reaction that will terminate the chain reaction.

CHAPTER  
15

# CHEMICAL EQUILIBRIUM

TRAFFIC ENTERING AND LEAVING San Francisco over the Golden Gate Bridge in the early morning.

## WHAT'S AHEAD

---

### 15.1 The Concept of Equilibrium

We begin by examining the concept of equilibrium.

### 15.2 The Equilibrium Constant

We then define the *equilibrium constant* and learn how to write *equilibrium-constant expressions* for homogeneous reactions.

### 15.3 Interpreting and Working with Equilibrium Constants

We also learn how to interpret the magnitude of an equilibrium constant and how to determine the way in which its value is affected when the chemical equation is reversed or changed in some other fashion.

### 15.4 Heterogeneous Equilibria

We then learn how to write equilibrium-constant expressions for heterogeneous reactions.

### 15.5 Calculating Equilibrium Constants

We will see that the value of an equilibrium constant can be calculated using equilibrium concentrations of reactants and products.

### 15.6 Applications of Equilibrium Constants

We will also see that equilibrium constants can be used to predict the equilibrium concentrations of reactants and products and to determine the direction in which a reaction mixture must proceed to achieve equilibrium.

### 15.7 Le Châtelier's Principle

We conclude the chapter with a discussion of *Le Châtelier's principle*, which predicts how a system at equilibrium responds to changes in concentration, volume, pressure, and temperature.

**TO BE IN EQUILIBRIUM IS TO BE IN A STATE OF BALANCE.** A tug of war in which the two sides are pulling with equal force so that the rope does not move is an example of a *static* equilibrium, one in which an object is at rest. Equilibria can also be *dynamic*, as illustrated in the

chapter-opening photograph, which shows cars traveling in both directions over a bridge that serves as an entranceway to a city. If the rate at which cars leave the city equals the rate at which they enter, the two opposing processes are in balance, and the net number of cars in the city is constant.

We have already encountered several instances of dynamic equilibrium.

For example, the vapor above a liquid is in equilibrium with the liquid phase. ∞ (Section 11.5) The rate at which molecules escape from the liquid into the gas phase equals the rate at which molecules in the gas phase strike the surface and become part of the liquid. Similarly, in a saturated solution of sodium chloride the solid sodium chloride is in equilibrium with the ions dispersed in water. ∞ (Section 13.2) The rate at which ions leave the solid surface equals the rate at which other ions are removed from the liquid to become part of the solid. Both of these examples involve a pair of opposing processes. At equilibrium these opposing processes are occurring at the same rate.

In this chapter we will consider yet another type of dynamic equilibrium, one involving chemical reactions. **Chemical equilibrium** occurs when opposing reactions are proceeding at equal rates: The rate at which the products are formed from the reactants equals the rate at which the reactants are formed from the products. As a result, concentrations cease to change, making the reaction appear to be stopped. How fast a reaction reaches equilibrium is a matter of kinetics.

Chemical equilibria are involved in a great many natural phenomena, and they play important roles in many industrial processes. In this and the next two chapters, we will explore chemical equilibrium in some detail. Here we will learn how to express the equilibrium position of a reaction in quantitative terms. We will also study the factors that determine the relative concentrations of reactants and products in equilibrium mixtures.

## 15.1 THE CONCEPT OF EQUILIBRIUM

Let's examine a simple reaction to see how it reaches an *equilibrium state*—a mixture of reactants and products whose concentrations no longer change with time. We begin with  $\text{N}_2\text{O}_4$ , a colorless substance that dissociates to form  $\text{NO}_2$ , which is brown. Figure 15.1 shows a sample of frozen  $\text{N}_2\text{O}_4$  inside a sealed tube resting in a beaker. Because the chemical reaction occurs in a closed system, the reaction will eventually reach equilibrium.

The solid  $\text{N}_2\text{O}_4$  vaporizes as it is warmed above its boiling point (21.2 °C), and the gas turns progressively darker as the colorless  $\text{N}_2\text{O}_4$  gas dissociates into brown  $\text{NO}_2$  gas (Figure 15.1). Eventually, even though there is still  $\text{N}_2\text{O}_4$  in the tube, the color stops getting darker because the system reaches equilibrium. We are left with an *equilibrium mixture* of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  in which the concentrations of the gases no longer change as time passes.

The equilibrium mixture results because the reaction is *reversible*.  $\text{N}_2\text{O}_4$  can react to form  $\text{NO}_2$ , and  $\text{NO}_2$  can react to form  $\text{N}_2\text{O}_4$ . This situation is represented by writing the equation for the reaction with two half arrows pointing in both directions:  $\rightleftharpoons$  (Section 4.1)

We can analyze this equilibrium using our knowledge of kinetics. Let's call the decomposition of  $\text{N}_2\text{O}_4$  to form  $\text{NO}_2$  the forward reaction and the reaction of  $\text{NO}_2$  to re-form  $\text{N}_2\text{O}_4$  the reverse reaction. In this case both the forward reaction and the reverse reaction are elementary reactions. As we learned in Section 14.6, the rate laws for elementary reactions can be written from their chemical equations:

where  $k_f$  and  $k_r$  are the rate constants for the forward and reverse reactions, respectively. At equilibrium the rate at which products are produced from reactants equals the rate at which reactants are produced from products:

$$\underset{\text{Forward reaction}}{k_f[\text{N}_2\text{O}_4]} = \underset{\text{Reverse reaction}}{k_r[\text{NO}_2]^2} \quad [15.4]$$

Rearranging this equation gives

$$\frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{k_f}{k_r} = \text{a constant} \quad [15.5]$$

As shown in Equation 15.5, the quotient of two constants, such as  $k_f$  and  $k_r$ , is itself a constant. Thus, at equilibrium the ratio of the concentration terms involving  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  equals a constant. (We will consider this constant, called the *equilibrium constant*, in Section 15.2.) It makes no difference whether we start with  $\text{N}_2\text{O}_4$  or with  $\text{NO}_2$ , or even with some mixture of the two. At equilibrium the ratio equals a specific value. Thus, there is an important constraint on the proportions of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  at equilibrium.

▲ **Figure 15.1** The  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$  equilibrium.

Once equilibrium is established, the concentrations of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  no longer change, as shown in Figure 15.2(a) ▼. If the composition of the equilibrium mixture remains constant with time, it does not mean, however, that  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  stop reacting. On the contrary, the equilibrium is dynamic—some  $\text{N}_2\text{O}_4$  is still converting to  $\text{NO}_2$ , and some  $\text{NO}_2$  is still converting to  $\text{N}_2\text{O}_4$ . At equilibrium, however, the two processes occur at the same rate, as shown in Figure 15.2(b).

◀ **Figure 15.2** Achieving chemical equilibrium for  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ . (a) The concentration of  $\text{N}_2\text{O}_4$  decreases while the concentration of  $\text{NO}_2$  increases during the course of the reaction. Equilibrium is indicated when the concentrations no longer change with time. (b) The rate of disappearance of  $\text{N}_2\text{O}_4$  decreases with time as the concentration of  $\text{N}_2\text{O}_4$  decreases. At the same time, the rate of formation of  $\text{NO}_2$  also decreases with time. Equilibrium occurs when these two rates are equal.

We learn several important lessons about equilibrium from this example:

- At equilibrium, the concentrations of reactants and products no longer change with time.
- For equilibrium to occur, neither reactants nor products can escape from the system.
- At equilibrium a particular ratio of concentration terms equals a constant.

We will examine the last of these facts in the next section.

### GIVE IT SOME THOUGHT

(a) Which quantities are equal in a dynamic equilibrium? (b) If the rate constant for the forward reaction in Equation 15.1 is larger than the rate constant for the reverse reaction, will the constant in Equation 15.5 be greater than 1 or smaller than 1?

## 15.2 THE EQUILIBRIUM CONSTANT

Opposing reactions naturally lead to an equilibrium, regardless of how complicated the reaction might be and regardless of the nature of the kinetic processes for the forward and reverse reactions. Consider the synthesis of ammonia from nitrogen and hydrogen:

This reaction is the basis for the **Haber process**, which, in the presence of a catalyst, combines  $\text{N}_2$  and  $\text{H}_2$  at a pressure of several hundred atmospheres and a temperature of several hundred degrees Celsius. The two gases react to form ammonia under these conditions, but in a closed system the reaction does not lead to complete consumption of the  $\text{N}_2$  and  $\text{H}_2$ . Rather, at some point the reaction appears to stop, with all three components of the reaction mixture present at the same time.

The manner in which the concentrations of  $\text{H}_2$ ,  $\text{N}_2$ , and  $\text{NH}_3$  vary with time is shown in Figure 15.3(a) ▼. Notice that an equilibrium mixture is obtained regardless of whether we begin with  $\text{N}_2$  and  $\text{H}_2$  or only with  $\text{NH}_3$ . *The equilibrium condition can be reached from either direction.*

### GIVE IT SOME THOUGHT

How do we know when equilibrium has been reached in a chemical reaction?

Earlier, we saw that when the reaction  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$  reaches equilibrium, a ratio based on the equilibrium concentrations of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  has a constant value (Equation 15.5). A similar relationship governs the concentrations of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  at equilibrium. If we were to systematically change the relative amounts of the three gases in the starting mixture and then analyze each equilibrium mixture, we could determine the relationship among the equilibrium concentrations.

► **Figure 15.3 Concentration changes approaching equilibrium.**

(a) Equilibrium for the reaction  $\text{N}_2 + 3 \text{H}_2 \rightleftharpoons 2 \text{NH}_3$  is approached beginning with  $\text{H}_2$  and  $\text{N}_2$  present in the ratio 3 : 1 and no  $\text{NH}_3$  present.  
(b) Equilibrium for the same reaction is approached beginning with only  $\text{NH}_3$  in the reaction vessel.

## Chemistry Put to Work THE HABER PROCESS

We presented a “Chemistry and Life” box in Section 14.7 that discussed *nitrogen fixation*, the processes that convert  $N_2$  gas into ammonia, which can then be incorporated into living organisms. We learned that the enzyme nitrogenase is responsible for generating most of the fixed nitrogen essential for plant growth. However, the quantity of food required to feed the ever-increasing human population far exceeds that provided by nitrogen-fixing plants, so human agriculture requires substantial amounts of ammonia-based fertilizers that can be applied directly to croplands. Thus, of all the chemical reactions that humans have learned to carry out and control for their own purposes, the synthesis of ammonia from hydrogen and atmospheric nitrogen is one of the most important.

In 1912 the German chemist Fritz Haber (1868–1934) developed a process for synthesizing ammonia directly from nitrogen and hydrogen (Figure 15.4▼). The process is sometimes called the *Haber-Bosch process* to also honor Karl Bosch, the engineer who developed the equipment for the industrial production of ammonia. The engineering needed to implement the Haber process requires the use of temperatures and pressures (approximately 500 °C and 200 atm) that were difficult to achieve at that time.

The Haber process provides a historically interesting example of the complex impact of chemistry on our lives. At the start of World War I, in 1914, Germany depended on nitrate deposits in Chile for the nitrogen-containing compounds needed to manufacture explosives. During the war the Allied naval

▲ **Figure 15.4 The Haber process.** Used to convert  $N_2(g)$  and  $H_2(g)$  to  $NH_3(g)$ , this process, although exothermic, requires breaking the very strong triple bond in  $N_2$ .

▲ **Figure 15.5 Liquid ammonia used as fertilizer.** Ammonia, produced by the Haber process, can be added directly to the soil as a fertilizer. Agricultural use is the largest single application of manufactured  $NH_3$ .

blockade of South America cut off this supply. However, by fixing nitrogen from air, Germany was able to continue to produce explosives. Experts have estimated that World War I would have ended before 1918 had it not been for the Haber process.

From these unhappy beginnings as a major factor in international warfare, the Haber process has become the world’s principal source of fixed nitrogen. The same process that prolonged World War I has enabled the manufacture of fertilizers that have increased crop yields, thereby saving millions of people from starvation. About 40 billion pounds of ammonia are manufactured annually in the United States, mostly by the Haber process. The ammonia can be applied directly to the soil as fertilizer (Figure 15.5▲). It can also be converted into ammonium salts—for example, ammonium sulfate,  $(NH_4)_2SO_4$ , and ammonium hydrogen phosphate,  $(NH_4)_2HPO_4$ —which, in turn, are used as fertilizers.

Haber was a patriotic German who gave enthusiastic support to his nation’s war effort. He served as chief of Germany’s Chemical Warfare Service during World War I and developed the use of chlorine as a poison-gas weapon. Consequently, the decision to award him the Nobel Prize for chemistry in 1918 was the subject of considerable controversy and criticism. The ultimate irony, however, came in 1933 when Haber was expelled from Germany because he was Jewish.

*Related Exercises:* 15.38 and 15.64

Chemists carried out studies of this kind on other chemical systems in the nineteenth century, before Haber’s work. In 1864, Cato Maximilian Guldberg (1836–1902) and Peter Waage (1833–1900) postulated their **law of mass action**, which expresses, for any reaction, the relationship between the concentrations of the reactants and products present at equilibrium. Suppose we have the following general equilibrium equation:

where A, B, D, and E are the chemical species involved and  $a$ ,  $b$ ,  $d$ , and  $e$  are their coefficients in the balanced chemical equation. According to the law of mass action, the equilibrium condition is expressed by the expression

$$K_c = \frac{[D]^d[E]^e}{[A]^a[B]^b} \quad [15.8]$$

← products  
← reactants

We call this relationship the **equilibrium-constant expression** (or merely the equilibrium expression) for the reaction. The constant  $K_c$ , which we call the **equilibrium constant**, is the numerical value obtained when we substitute equilibrium concentrations into the equilibrium-constant expression. The subscript  $c$  on the  $K$  indicates that concentrations expressed in molarity are used to evaluate the constant.

In general, the numerator of the equilibrium-constant expression is the product of the concentrations of all substances on the product side of the equilibrium equation, each raised to a power equal to its coefficient in the balanced equation. The denominator is similarly derived from the reactant side of the equilibrium equation. (Remember, the convention is to write the substances on the *product* side in the *numerator* and the substances on the *reactant* side in the *denominator*.) Thus, for the Haber process,  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ , the equilibrium-constant expression is

$$K_c = \frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3} \quad [15.9]$$

Note that once we know the balanced chemical equation for an equilibrium, we can write the equilibrium-constant expression even if we do not know the reaction mechanism. *The equilibrium-constant expression depends only on the stoichiometry of the reaction, not on its mechanism.*

The value of the equilibrium constant at any given temperature does not depend on the initial amounts of reactants and products. It also does not matter whether other substances are present, as long as they do not react with a reactant or a product. The value of the equilibrium constant depends only on the particular reaction and on the temperature.

### ■ SAMPLE EXERCISE 15.1 | Writing Equilibrium-Constant Expressions

Write the equilibrium expression for  $K_c$  for the following reactions:

- (a)  $2 \text{O}_3(\text{g}) \rightleftharpoons 3 \text{O}_2(\text{g})$   
 (b)  $2 \text{NO}(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2 \text{NOCl}(\text{g})$   
 (c)  $\text{Ag}^+(\text{aq}) + 2 \text{NH}_3(\text{aq}) \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+(\text{aq})$

#### SOLUTION

**Analyze:** We are given three equations and are asked to write an equilibrium-constant expression for each.

**Plan:** Using the law of mass action, we write each expression as a quotient having the product concentration terms in the numerator and the reactant concentration terms in the denominator. Each concentration term is raised to the power of its coefficient in the balanced chemical equation.

**Solve:** (a)  $K_c = \frac{[\text{O}_2]^3}{[\text{O}_3]^2}$ , (b)  $K_c = \frac{[\text{NOCl}]^2}{[\text{NO}]^2[\text{Cl}_2]}$ , (c)  $K_c = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2}$

#### ■ PRACTICE EXERCISE

Write the equilibrium-constant expression  $K_c$  for (a)  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$ , (b)  $\text{Cd}^{2+}(\text{aq}) + 4 \text{Br}^-(\text{aq}) \rightleftharpoons \text{CdBr}_4^{2-}(\text{aq})$

**Answers:** (a)  $K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]}$ ; (b)  $K_c = \frac{[\text{CdBr}_4^{2-}]}{[\text{Cd}^{2+}][\text{Br}^-]^4}$

### Evaluating $K_c$

We can illustrate how the law of mass action was discovered empirically and demonstrate that the equilibrium constant is independent of starting concentrations by examining a series of experiments involving dinitrogen tetroxide and nitrogen dioxide:

**TABLE 15.1** Initial and Equilibrium Concentrations of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  in the Gas Phase at  $100^\circ\text{C}$ 

Experiment	Initial $[\text{N}_2\text{O}_4]$ (M)	Initial $[\text{NO}_2]$ (M)	Equilibrium $[\text{N}_2\text{O}_4]$ (M)	Equilibrium $[\text{NO}_2]$ (M)	$K_c$
1	0.0	0.0200	0.00140	0.0172	0.211
2	0.0	0.0300	0.00280	0.0243	0.211
3	0.0	0.0400	0.00452	0.0310	0.213
4	0.0200	0.0	0.00452	0.0310	0.213

We start with several sealed tubes containing different concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ . The tubes are kept at  $100^\circ\text{C}$  until equilibrium is reached. We then analyze the mixtures and determine the equilibrium concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ , as shown in Table 15.1  $\blacktriangle$ .

To evaluate the equilibrium constant,  $K_c$ , we insert the equilibrium concentrations into the equilibrium-constant expression. For example, using the Experiment 1 data,  $[\text{NO}_2] = 0.0172\text{ M}$  and  $[\text{N}_2\text{O}_4] = 0.00140\text{ M}$ , we find

$$K_c = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{[0.0172]^2}{0.00140} = 0.211$$

Proceeding in the same way, the values of  $K_c$  for the other samples were calculated, as listed in Table 15.1. Note that the value for  $K_c$  is constant ( $K_c = 0.212$ , within the limits of experimental error) even though the initial concentrations vary. Furthermore, the results of Experiment 4 show that equilibrium can be achieved beginning with  $\text{N}_2\text{O}_4$  rather than with  $\text{NO}_2$ . That is, equilibrium can be approached from either direction. Figure 15.6  $\blacktriangleright$  shows how both Experiments 3 and 4 result in the same equilibrium mixture even though one begins with  $0.0400\text{ M NO}_2$  and the other with  $0.0200\text{ M N}_2\text{O}_4$ .

Notice that no units are given for the values of  $K_c$  either in Table 15.1 or in our calculation using the Experiment 1 data. It is common practice to write equilibrium constants without units for reasons that we address later in this section.

$\blacktriangle$  **Figure 15.6** Concentration changes approaching equilibrium. As seen in Table 15.1, the same equilibrium mixture is produced starting with either  $0.0400\text{ M NO}_2$  (Experiment 3) or  $0.0200\text{ M N}_2\text{O}_4$  (Experiment 4).

### GIVE IT SOME THOUGHT

How does the value of  $K_c$  in Equation 15.10 depend on the starting concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ ?

### Equilibrium Constants in Terms of Pressure, $K_p$

When the reactants and products in a chemical reaction are gases, we can formulate the equilibrium-constant expression in terms of partial pressures instead of molar concentrations. When partial pressures in atmospheres are used in the equilibrium-constant expression, we can denote the equilibrium constant as  $K_p$  (where the subscript  $p$  stands for pressure). For the general reaction in Equation 15.7, the expression for  $K_p$  is

$$K_p = \frac{(P_D)^d(P_E)^e}{(P_A)^a(P_B)^b} \quad [15.11]$$

where  $P_A$  is the partial pressure of A in atmospheres, and so forth. For example, for  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2\text{NO}_2(\text{g})$  we have

$$K_p = \frac{(P_{\text{NO}_2})^2}{P_{\text{N}_2\text{O}_4}}$$

### GIVE IT SOME THOUGHT

What do the symbols  $K_c$  and  $K_p$  represent?

For a given reaction, the numerical value of  $K_c$  is generally different from the numerical value of  $K_p$ . We must therefore take care to indicate, via a subscript  $c$  or  $p$ , which of these equilibrium constants we are using. It is possible, however, to calculate one from the other using the ideal-gas equation (Section 10.4) to convert between concentration (in molarity,  $M$ ) and pressure (in atm):

$$PV = nRT, \text{ so } P = \frac{n}{V}RT \quad [15.12]$$

The usual units for  $n/V$  are mol/L, which equals molarity,  $M$ . For substance A we therefore see that

$$P_A = \frac{n_A}{V}RT = [A]RT \quad [15.13]$$

When we substitute Equation 15.13 and like expressions for the other gaseous components of the reaction into the expression for  $K_p$  (Equation 15.11), we obtain a general expression relating  $K_p$  and  $K_c$ .

$$K_p = K_c(RT)^{\Delta n} \quad [15.14]$$

The quantity  $\Delta n$  is the change in the number of moles of gas in the chemical equation for the reaction. It equals the sum of the coefficients of the gaseous products minus the sum of the coefficients of the gaseous reactants:

$$\Delta n = (\text{moles of gaseous product}) - (\text{moles of gaseous reactant}) \quad [15.15]$$

For example, in the reaction  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ , there are two moles of the product  $\text{NO}_2$  (the coefficient in the balanced equation) and one mole of the reactant  $\text{N}_2\text{O}_4$ . Therefore,  $\Delta n = 2 - 1 = 1$ , and  $K_p = K_c(RT)$  for this reaction. From Equation 15.14, we see that  $K_p = K_c$  only when the same number of moles of gas appears on both sides of the balanced chemical equation, which means that  $\Delta n = 0$ .

### SAMPLE EXERCISE 15.2 | Converting between $K_c$ and $K_p$

In the synthesis of ammonia from nitrogen and hydrogen,

$K_c = 9.60$  at  $300^\circ\text{C}$ . Calculate  $K_p$  for this reaction at this temperature.

#### SOLUTION

**Analyze:** We are given  $K_c$  for a reaction and asked to calculate  $K_p$ .

**Plan:** The relationship between  $K_c$  and  $K_p$  is given by Equation 15.14. To apply that equation, we must determine  $\Delta n$  by comparing the number of moles of product with the number of moles of reactants (Equation 15.15).

**Solve:** There are two moles of gaseous products ( $2 \text{NH}_3$ ) and four moles of gaseous reactants ( $1 \text{N}_2 + 3 \text{H}_2$ ). Therefore,  $\Delta n = 2 - 4 = -2$ . (Remember that  $\Delta$  functions are always based on products minus reactants.) The temperature,  $T$ , is  $273 + 300 = 573 \text{ K}$ . The value for the ideal-gas constant,  $R$ , is  $0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K}$ . Using  $K_c = 9.60$ , we therefore have

$$K_p = K_c(RT)^{\Delta n} = (9.60)(0.0821 \times 573)^{-2} = \frac{(9.60)}{(0.0821 \times 573)^2} = 4.34 \times 10^{-3}$$

#### PRACTICE EXERCISE

For the equilibrium  $2 \text{SO}_3(\text{g}) \rightleftharpoons 2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g})$ ,  $K_c$  is  $4.08 \times 10^{-3}$  at  $1000 \text{ K}$ . Calculate the value for  $K_p$ .

**Answer:** 0.335

## Equilibrium Constants and Units

You may wonder why equilibrium constants are reported without units. The equilibrium constant is related to the kinetics of a reaction as well as to the thermodynamics of the process. (We will explore this latter connection in Chapter 19.) Equilibrium constants derived from thermodynamic measurements are defined in terms of *activities* rather than concentrations or partial pressures.

The activity of any substance in an *ideal* mixture is the ratio of the concentration or pressure of the substance to a reference concentration (1 *M*) or a reference pressure (1 atm). For example, if the concentration of a substance in an equilibrium mixture is 0.010 *M*, its activity is 0.010 *M*/1 *M* = 0.010. The units of such ratios always cancel, and consequently, activities have no units. Furthermore, the numerical value of the activity equals the concentration. For pure solids and pure liquids, the situation is even simpler because the activities then merely equal 1 (again with no units).

In real systems, activities are also ratios that have no units. Even though these activities may not be exactly numerically equal to concentrations, we will ignore the differences. All we need to know at this point is that activities have no units. As a result, the *thermodynamic equilibrium constant* derived from them also has no units. It is therefore common practice to write all types of equilibrium constants without units as well, a practice that we adhere to in this text.

### GIVE IT SOME THOUGHT

If the concentration of  $\text{N}_2\text{O}_4$  in an equilibrium mixture is 0.00140 *M*, what is its activity? (Assume the solution is ideal.)

## 15.3 INTERPRETING AND WORKING WITH EQUILIBRIUM CONSTANTS

In this section we explore two important ideas. Before doing calculations with equilibrium constants, it is valuable to understand what the magnitude of an equilibrium constant can tell us about the relative concentrations of reactants and products in an equilibrium mixture. It is also useful to consider how the magnitude of any equilibrium constant depends on how the chemical equation is expressed.

### The Magnitude of Equilibrium Constants

Equilibrium constants can vary from very large to very small. The magnitude of the constant provides us with important information about the composition of an equilibrium mixture. For example, consider the reaction of carbon monoxide gas and chlorine gas at 100 °C to form phosgene ( $\text{COCl}_2$ ), a toxic gas used in the manufacture of certain polymers and insecticides:

For the equilibrium constant to be so large, the numerator of the equilibrium-constant expression must be much larger than the denominator. Thus, the equilibrium concentration of  $\text{COCl}_2$  must be much greater than that of  $\text{CO}$  or  $\text{Cl}_2$ , and in fact this is just what we find experimentally. We say that this equilibrium *lies to the right* (that is, toward the product side). Likewise, a very small equilibrium constant indicates that the equilibrium mixture contains mostly reactants.

(a)  $K \gg 1$ (b)  $K \ll 1$ 

**▲ Figure 15.7  $K$  and the composition of the equilibrium mixture.** The equilibrium expression has products in the numerator and reactants in the denominator. (a) When  $K \gg 1$ , there are more products than reactants at equilibrium, and the equilibrium is said to lie to the right. (b) When  $K \ll 1$ , there are more reactants than products at equilibrium, and the equilibrium is said to lie to the left.

We then say that the equilibrium *lies to the left*. In general,

If  $K \gg 1$  (that is, large  $K$ ): Equilibrium lies to the right; products predominate.

If  $K \ll 1$  (that is, small  $K$ ): Equilibrium lies to the left; reactants predominate.

These situations are summarized in Figure 15.7 ◀. Remember, opposing rates, not concentrations, are equal at equilibrium. Thus, equilibrium constants for different reactions can span a very wide range.

### SAMPLE EXERCISE 15.3 Interpreting the Magnitude of an Equilibrium Constant

The following diagrams represent three different systems at equilibrium, all in the same size containers. (a) Without doing any calculations, rank the three systems in order of increasing equilibrium constant,  $K_c$ . (b) If the volume of the containers is 1.0 L and each sphere represents 0.10 mol, calculate  $K_c$  for each system.

### SOLUTION

**Analyze:** We are first asked to judge the relative magnitudes of three equilibrium constants and then to calculate them.

**Plan:** (a) The more product that is present at equilibrium, relative to the reactant, the greater the equilibrium constant. (b) The equilibrium constant is given by the concentrations of products over reactants.

**Solve:**

(a) Each box contains 10 spheres. The amount of product in each varies as follows: (i) 6, (ii) 1, (iii) 8. Thus, the equilibrium constant varies in the order (ii) < (i) < (iii).

(b) In (i) we have 0.60 mol/L reactant and 0.40 mol/L product, giving  $K_c = 0.60/0.40 = 1.5$ . (You will get the same result by merely dividing the number of spheres of each kind: 6 spheres/4 spheres = 1.5.) In (ii) we have 0.10 mol/L product and 0.90 mol/L reactant, giving  $K_c = 0.10/0.90 = 0.11$  (or 1 sphere/9 spheres = 0.11). In (iii) we have 0.80 mol/L product and 0.20 mol/L reactant, giving  $K_c = 0.80/0.20 = 4.0$  (or 8 spheres/2 spheres = 4.0). These calculations verify the order in (a).

**Comment:** Imagine that there was a drawing, like those above, that represents a reaction with a very small or very large value of  $K_c$ . For example, what would the drawing look like if  $K_c = 1 \times 10^{-5}$ ? In that case there would need to be 100,000 reactant molecules for every 1 product molecule. But then, that would be impractical to draw.

### PRACTICE EXERCISE

For the reaction  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$ ,  $K_p = 794$  at 298 K and  $K_p = 54$  at 700 K. Is the formation of HI favored more at the higher or lower temperature?

**Answer:** The formation of product, HI, is favored at the lower temperature because  $K_p$  is larger at the lower temperature.

## The Direction of the Chemical Equation and $K$

Because an equilibrium can be approached from either direction, the direction in which we write the chemical equation for an equilibrium is arbitrary. For example, we have seen that we can represent the  $\text{N}_2\text{O}_4 - \text{NO}_2$  equilibrium as

We could equally well consider this same equilibrium in terms of the reverse reaction:

The equilibrium expression is then

$$K_c = \frac{[\text{N}_2\text{O}_4]}{[\text{NO}_2]^2} = \frac{1}{0.212} = 4.72 \quad (\text{at } 100^\circ\text{C}) \quad [15.17]$$

Equation 15.17 is just the reciprocal of the equilibrium-constant expression in Equation 15.16. *The equilibrium-constant expression for a reaction written in one direction is the reciprocal of the one for the reaction written in the reverse direction.* Consequently, the numerical value of the equilibrium constant for the reaction written in one direction is the reciprocal of that for the reverse reaction. Both expressions are equally valid, but it is meaningless to say that the equilibrium constant for the equilibrium between  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  is 0.212 or 4.72 unless we indicate how the equilibrium reaction is written and specify the temperature.

### SAMPLE EXERCISE 15.4 | Evaluating an Equilibrium Constant When an Equation Is Reversed

The equilibrium constant for the reaction of  $\text{N}_2$  with  $\text{O}_2$  to form  $\text{NO}$  equals  $K_c = 1 \times 10^{-30}$  at  $25^\circ\text{C}$ :

Using this information, write the equilibrium constant expression and calculate the equilibrium constant for the following reaction:

#### SOLUTION

**Analyze:** We are asked to write the equilibrium-constant expression for a reaction and to determine the value of  $K_c$  given the chemical equation and equilibrium constant for the reverse reaction.

**Plan:** The equilibrium-constant expression is a quotient of products over reactants, each raised to a power equal to its coefficient in the balanced equation. The value of the equilibrium constant is the reciprocal of that for the reverse reaction.

#### Solve:

Writing products over reactants, we have

$$K_c = \frac{[\text{N}_2][\text{O}_2]}{[\text{NO}]^2}$$

Both the equilibrium-constant expression and the numerical value of the equilibrium constant are the reciprocals of those for the formation of  $\text{NO}$  from  $\text{N}_2$  and  $\text{O}_2$ :

$$K_c = \frac{[\text{N}_2][\text{O}_2]}{[\text{NO}]^2} = \frac{1}{1 \times 10^{-30}} = 1 \times 10^{30}$$

**Comment:** Regardless of the way we express the equilibrium among  $\text{NO}$ ,  $\text{N}_2$ , and  $\text{O}_2$ , at  $25^\circ\text{C}$  it lies on the side that favors  $\text{N}_2$  and  $\text{O}_2$ . Thus, the equilibrium mixture will contain mostly  $\text{N}_2$  and  $\text{O}_2$ , with very little  $\text{NO}$  present.

#### PRACTICE EXERCISE

For the formation of  $\text{NH}_3$  from  $\text{N}_2$  and  $\text{H}_2$ ,  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ ,  $K_p = 4.34 \times 10^{-3}$  at  $300^\circ\text{C}$ . What is the value of  $K_p$  for the reverse reaction?

**Answer:**  $2.30 \times 10^2$

## Relating Chemical Equations and Equilibrium Constants

Just as the equilibrium constants of forward and reverse reactions are reciprocals of each other, the equilibrium constants of reactions associated in other ways are also related. For example, if we were to multiply our original  $\text{N}_2\text{O}_4 - \text{NO}_2$  equilibrium by 2, we would have

The equilibrium-constant expression,  $K_c$ , for this equation is

$$K_c = \frac{[\text{NO}_2]^4}{[\text{N}_2\text{O}_4]^2}$$

which is simply the square of the equilibrium-constant expression for the original equation, given in Equation 15.10. Because the new equilibrium-constant expression equals the original expression squared, the new equilibrium constant equals the original constant squared: in this case  $0.212^2 = 0.0449$  (at  $100^\circ\text{C}$ ).

**GIVE IT SOME THOUGHT**

How does the magnitude of the equilibrium constant  $K_p$  for the reaction  $2 \text{HI}(g) \rightleftharpoons \text{H}_2(g) + \text{I}_2(g)$  change if the equilibrium is written  $6 \text{HI}(g) \rightleftharpoons 3 \text{H}_2(g) + 3 \text{I}_2(g)$ ?

Sometimes, as in problems that utilize Hess's law (Section 5.6), we must use equations made up of two or more steps in the overall process. We obtain the net equation by adding the individual equations and canceling identical terms. Consider the following two reactions, their equilibrium-constant expressions, and their equilibrium constants at 100 °C:

The net sum of these two equations is

and the equilibrium-constant expression for the net equation is the product of the expressions for the individual steps:

$$K_c = \frac{[\text{NO}]^2[\text{BrCl}]^2}{[\text{NOBr}]^2[\text{Cl}_2]} = \frac{[\text{NO}]^2[\text{Br}_2]}{[\text{NOBr}]^2} \times \frac{[\text{BrCl}]^2}{[\text{Br}_2][\text{Cl}_2]}$$

Because the equilibrium-constant expression for the net equation is the product of two equilibrium-constant expressions, the equilibrium constant for the net equation is the product of the two individual equilibrium constants:  $K_c = 0.014 \times 7.2 = 0.10$ .

To summarize:

1. The equilibrium constant of a reaction in the *reverse* direction is the *inverse* of the equilibrium constant of the reaction in the forward direction.
2. The equilibrium constant of a reaction that has been *multiplied* by a number is the equilibrium constant raised to a *power* equal to that number.
3. The equilibrium constant for a net reaction made up of *two or more steps* is the *product* of the equilibrium constants for the individual steps.

**SAMPLE EXERCISE 15.5** | Combining Equilibrium Expressions

Given the following information,

determine the value of  $K_c$  for the reaction

**SOLUTION**

**Analyze:** We are given two equilibrium equations and the corresponding equilibrium constants and are asked to determine the equilibrium constant for a third equation, which is related to the first two.

**Plan:** We cannot simply add the first two equations to get the third. Instead, we need to determine how to manipulate the equations to come up with the steps that will add to give us the desired equation.

**Solve:** If we multiply the first equation by 2 and make the corresponding change to its equilibrium constant (raising to the power 2), we get

Reversing the second equation and again making the corresponding change to its equilibrium constant (taking the reciprocal) gives

Now we have two equations that sum to give the net equation, and we can multiply the individual  $K_c$  values to get the desired equilibrium constant.

### ■ PRACTICE EXERCISE

Given that, at 700 K,  $K_p = 54.0$  for the reaction  $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2 \text{HI}(g)$  and  $K_p = 1.04 \times 10^{-4}$  for the reaction  $\text{N}_2(g) + 3 \text{H}_2(g) \rightleftharpoons 2 \text{NH}_3(g)$ , determine the value of  $K_p$  for the reaction  $2 \text{NH}_3(g) + 3 \text{I}_2(g) \rightleftharpoons 6 \text{HI}(g) + \text{N}_2(g)$  at 700 K.

*Answer:*  $\frac{(54.0)^3}{1.04 \times 10^{-4}} = 1.51 \times 10^9$

## 15.4 HETEROGENEOUS EQUILIBRIA

Many equilibria, such as the hydrogen-nitrogen-ammonia system, involve substances all in the same phase. Such equilibria are called **homogeneous equilibria**. In other cases the substances in equilibrium are in different phases, giving rise to **heterogeneous equilibria**. As an example, consider the equilibrium that occurs when solid lead(II) chloride ( $\text{PbCl}_2$ ) dissolves in water to form a saturated solution:

This system consists of a solid in equilibrium with two aqueous species. If we write the equilibrium-constant expression for this process, we encounter a problem we have not encountered previously: How do we express the concentration of a solid substance? Although it is possible to express the concentration of a solid in terms of moles per unit volume, it is unnecessary to do so in writing equilibrium-constant expressions. *Whenever a pure solid or a pure liquid is involved in a heterogeneous equilibrium, its concentration is not included in the equilibrium-constant expression for the reaction.* Thus, the equilibrium-constant expression for Equation 15.18 is

$$K_c = [\text{Pb}^{2+}][\text{Cl}^-]^2 \quad [15.19]$$

Even though  $\text{PbCl}_2(s)$  does not appear in the equilibrium-constant expression, it must be present for equilibrium to occur.

The fact that pure solids and pure liquids are excluded from equilibrium-constant expressions can be explained in two ways. First, the concentration of a pure solid or liquid has a constant value. If the mass of a solid is doubled, its volume also doubles. Thus, its concentration, which relates to the ratio of mass to volume, stays the same. Because equilibrium-constant expressions include terms only for reactants and products whose concentrations can change during a chemical reaction, the concentrations of pure solids and pure liquids are omitted.

The omission of pure solids and liquids from equilibrium-constant expressions can also be rationalized in a second way. Recall from the last section that what is substituted into a thermodynamic equilibrium expression is the activity of each substance, which is a ratio of the concentration to a reference value. For a pure substance, the reference value is the concentration of the pure substance itself, so that the activity of any pure solid or liquid is always simply 1.

### GIVE IT SOME THOUGHT

Write the equilibrium-constant expression for the evaporation of water,  $\text{H}_2\text{O}(l) \rightleftharpoons \text{H}_2\text{O}(g)$ , in terms of partial pressures,  $K_p$ .

► **Figure 15.8 A heterogeneous equilibrium.** The equilibrium involving  $\text{CaCO}_3$ ,  $\text{CaO}$ , and  $\text{CO}_2$  is a heterogeneous equilibrium. The equilibrium pressure of  $\text{CO}_2$  is the same in the two bell jars as long as the systems are at the same temperature, even though the relative amounts of pure  $\text{CaCO}_3$  and  $\text{CaO}$  differ greatly. The equilibrium-constant expression for the reaction is  $K_p = P_{\text{CO}_2}$ .

As a further example of a heterogeneous reaction, consider the decomposition of calcium carbonate:

Omitting the concentrations of solids from the equilibrium-constant expression gives

$$K_c = [\text{CO}_2] \quad \text{and} \quad K_p = P_{\text{CO}_2}$$

These equations tell us that at a given temperature, an equilibrium among  $\text{CaCO}_3$ ,  $\text{CaO}$ , and  $\text{CO}_2$  will always lead to the same partial pressure of  $\text{CO}_2$  as long as all three components are present. As shown in Figure 15.8, we would have the same pressure of  $\text{CO}_2$  regardless of the relative amounts of  $\text{CaO}$  and  $\text{CaCO}_3$ .

### SAMPLE EXERCISE 15.6 | Writing Equilibrium-Constant Expressions for Heterogeneous Reactions

Write the equilibrium-constant expression for  $K_c$  for each of the following reactions:

- (a)  $\text{CO}_2(\text{g}) + \text{H}_2(\text{g}) \rightleftharpoons \text{CO}(\text{g}) + \text{H}_2\text{O}(\text{l})$   
 (b)  $\text{SnO}_2(\text{s}) + 2 \text{CO}(\text{g}) \rightleftharpoons \text{Sn}(\text{s}) + 2 \text{CO}_2(\text{g})$

#### SOLUTION

**Analyze:** We are given two chemical equations, both for heterogeneous equilibria, and asked to write the corresponding equilibrium-constant expressions.

**Plan:** We use the law of mass action, remembering to omit any pure solids, pure liquids, and solvents from the expressions.

**Solve:**

(a) The equilibrium-constant expression is

$$K_c = \frac{[\text{CO}]}{[\text{CO}_2][\text{H}_2]}$$

Because  $\text{H}_2\text{O}$  appears in the reaction as a pure liquid, its concentration does not appear in the equilibrium-constant expression.

(b) The equilibrium-constant expression is

$$K_c = \frac{[\text{CO}_2]^2}{[\text{CO}]^2}$$

Because  $\text{SnO}_2$  and  $\text{Sn}$  are both pure solids, their concentrations do not appear in the equilibrium-constant expression.

### PRACTICE EXERCISE

Write the following equilibrium-constant expressions:

- (a)  $K_c$  for  $\text{Cr}(\text{s}) + 3 \text{Ag}^+(\text{aq}) \rightleftharpoons \text{Cr}^{3+}(\text{aq}) + 3 \text{Ag}(\text{s})$   
 (b)  $K_p$  for  $3 \text{Fe}(\text{s}) + 4 \text{H}_2\text{O}(\text{g}) \rightleftharpoons \text{Fe}_3\text{O}_4(\text{s}) + 4 \text{H}_2(\text{g})$

**Answers:** (a)  $K_c = \frac{[\text{Cr}^{3+}]}{[\text{Ag}^+]^3}$ , (b)  $K_p = \frac{(P_{\text{H}_2})^4}{(P_{\text{H}_2\text{O}})^4}$

**SAMPLE EXERCISE 15.7 | Analyzing a Heterogeneous Equilibrium**

Each of the following mixtures was placed in a closed container and allowed to stand. Which is capable of attaining the equilibrium  $\text{CaCO}_3(s) \rightleftharpoons \text{CaO}(s) + \text{CO}_2(g)$ : (a) pure  $\text{CaCO}_3$ , (b)  $\text{CaO}$  and a  $\text{CO}_2$  pressure greater than the value of  $K_p$ , (c) some  $\text{CaCO}_3$  and a  $\text{CO}_2$  pressure greater than the value of  $K_p$ , (d)  $\text{CaCO}_3$  and  $\text{CaO}$ ?

**SOLUTION**

**Analyze:** We are asked which of several combinations of species can establish an equilibrium between calcium carbonate and its decomposition products, calcium oxide and carbon dioxide.

**Plan:** For equilibrium to be achieved, it must be possible for both the forward process and the reverse process to occur. For the forward process to occur, there must be some calcium carbonate present. For the reverse process to occur, there must be both calcium oxide and carbon dioxide. In both cases, either the necessary compounds may be present initially, or they may be formed by reaction of the other species.

**Solve:** Equilibrium can be reached in all cases except (c) as long as sufficient quantities of solids are present. (a)  $\text{CaCO}_3$  simply decomposes, forming  $\text{CaO}(s)$  and  $\text{CO}_2(g)$  until the equilibrium pressure of  $\text{CO}_2$  is attained. There must be enough  $\text{CaCO}_3$ , however, to allow the  $\text{CO}_2$  pressure to reach equilibrium. (b)  $\text{CO}_2$  continues to combine with  $\text{CaO}$  until the partial pressure of the  $\text{CO}_2$  decreases to the equilibrium value. (c) There is no  $\text{CaO}$  present, so equilibrium cannot be attained because there is no way the  $\text{CO}_2$  pressure can decrease to its equilibrium value (which would require some of the  $\text{CO}_2$  to react with  $\text{CaO}$ ). (d) The situation is essentially the same as in (a):  $\text{CaCO}_3$  decomposes until equilibrium is attained. The presence of  $\text{CaO}$  initially makes no difference.

**PRACTICE EXERCISE**

When added to  $\text{Fe}_3\text{O}_4(s)$  in a closed container, which one of the following substances— $\text{H}_2(g)$ ,  $\text{H}_2\text{O}(g)$ ,  $\text{O}_2(g)$ —will allow equilibrium to be established in the reaction  $3 \text{Fe}(s) + 4 \text{H}_2\text{O}(g) \rightleftharpoons \text{Fe}_3\text{O}_4(s) + 4 \text{H}_2(g)$ ?

**Answer:** only  $\text{H}_2(g)$

When a solvent is involved as a reactant or product in an equilibrium, its concentration is also excluded from the equilibrium-constant expression, provided the concentrations of reactants and products are low, so that the solvent is essentially a pure substance. Applying this guideline to an equilibrium involving water as a solvent,

gives an equilibrium-constant expression in which  $[\text{H}_2\text{O}]$  is excluded:

$$K_c = \frac{[\text{OH}^-][\text{HCO}_3^-]}{[\text{CO}_3^{2-}]} \quad [15.21]$$

**GIVE IT SOME THOUGHT**

Write the equilibrium-constant expression for the following reaction:  $\text{NH}_3(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NH}_4^+(aq) + \text{OH}^-(aq)$

**15.5 CALCULATING EQUILIBRIUM CONSTANTS**

One of the first tasks confronting Haber when he approached the problem of ammonia synthesis was finding the magnitude of the equilibrium constant for the synthesis of  $\text{NH}_3$  at various temperatures. If the value of  $K$  for Equation 15.6 was very small, the amount of  $\text{NH}_3$  in an equilibrium mixture would be small relative to the amounts of  $\text{N}_2$  and  $\text{H}_2$ . That is, if the equilibrium lies too far to the left, it would be impossible to develop a satisfactory synthesis process for ammonia.

Haber and his coworkers therefore evaluated the equilibrium constants for this reaction at various temperatures. The method they employed is analogous to that described in constructing Table 15.1: They started with various mixtures of  $N_2$ ,  $H_2$ , and  $NH_3$ , allowed the mixtures to achieve equilibrium at a specific temperature, and measured the concentrations of all three gases at equilibrium. Because the equilibrium concentrations of all products and reactants were known, the equilibrium constant could be calculated directly from the equilibrium-constant expression.

### ■ SAMPLE EXERCISE 15.8 Calculating $K$ When All Equilibrium Concentrations Are Known

A mixture of hydrogen and nitrogen in a reaction vessel is allowed to attain equilibrium at  $472^\circ\text{C}$ . The equilibrium mixture of gases was analyzed and found to contain 7.38 atm  $H_2$ , 2.46 atm  $N_2$ , and 0.166 atm  $NH_3$ . From these data, calculate the equilibrium constant  $K_p$  for the reaction

#### SOLUTION

**Analyze:** We are given a balanced equation and equilibrium partial pressures and are asked to calculate the value of the equilibrium constant.

**Plan:** Using the balanced equation, we write the equilibrium-constant expression. We then substitute the equilibrium partial pressures into the expression and solve for  $K_p$ .

**Solve:**

$$K_p = \frac{(P_{NH_3})^2}{P_{N_2}(P_{H_2})^3} = \frac{(0.166)^2}{(2.46)(7.38)^3} = 2.79 \times 10^{-5}$$

#### ■ PRACTICE EXERCISE

An aqueous solution of acetic acid is found to have the following equilibrium concentrations at  $25^\circ\text{C}$ :  $[HC_2H_3O_2] = 1.65 \times 10^{-2} M$ ;  $[H^+] = 5.44 \times 10^{-4} M$ ; and  $[C_2H_3O_2^-] = 5.44 \times 10^{-4} M$ . Calculate the equilibrium constant  $K_c$  for the ionization of acetic acid at  $25^\circ\text{C}$ . The reaction is

*Answer:*  $1.79 \times 10^{-5}$

We often do not know the equilibrium concentrations of all chemical species in an equilibrium mixture. If we know the equilibrium concentration of at least one species, however, we can generally use the stoichiometry of the reaction to deduce the equilibrium concentrations of the others. The following steps outline the procedure we use to do this:

1. Tabulate all the known initial and equilibrium concentrations of the species that appear in the equilibrium-constant expression.
2. For those species for which both the initial and equilibrium concentrations are known, calculate the change in concentration that occurs as the system reaches equilibrium.
3. Use the stoichiometry of the reaction (that is, use the coefficients in the balanced chemical equation) to calculate the changes in concentration for all the other species in the equilibrium.
4. From the initial concentrations and the changes in concentration, calculate the equilibrium concentrations. These are then used to evaluate the equilibrium constant.

**SAMPLE EXERCISE 15.9** | Calculating  $K$  from Initial and Equilibrium Concentrations

A closed system initially containing  $1.000 \times 10^{-3} M$   $H_2$  and  $2.000 \times 10^{-3} M$   $I_2$  at  $448^\circ C$  is allowed to reach equilibrium. Analysis of the equilibrium mixture shows that the concentration of  $HI$  is  $1.87 \times 10^{-3} M$ . Calculate  $K_c$  at  $448^\circ C$  for the reaction taking place, which is

**SOLUTION**

**Analyze:** We are given the initial concentrations of  $H_2$  and  $I_2$  and the equilibrium concentration of  $HI$ . We are asked to calculate the equilibrium constant  $K_c$  for  $H_2(g) + I_2(g) \rightleftharpoons 2 HI(g)$ .

**Plan:** We construct a table to find equilibrium concentrations of all species and then use the equilibrium concentrations to calculate the equilibrium constant.

**Solve:** First, we tabulate the initial and equilibrium concentrations of as many species as we can. We also provide space in our table for listing the changes in concentrations. As shown, it is convenient to use the chemical equation as the heading for the table.

	$H_2(g)$	+	$I_2(g)$	$\rightleftharpoons$	$2 HI(g)$
Initial	$1.000 \times 10^{-3} M$		$2.000 \times 10^{-3} M$		$0 M$
Change					
Equilibrium					$1.87 \times 10^{-3} M$

Second, we calculate the change in concentration of  $HI$ , which is the difference between the equilibrium values and the initial values:

$$\text{Change in } [HI] = 1.87 \times 10^{-3} M - 0 = 1.87 \times 10^{-3} M$$

Third, we use the coefficients in the balanced equation to relate the change in  $[HI]$  to the changes in  $[H_2]$  and  $[I_2]$ :

$$\left(1.87 \times 10^{-3} \frac{\text{mol HI}}{L}\right) \left(\frac{1 \text{ mol } H_2}{2 \text{ mol HI}}\right) = 0.935 \times 10^{-3} \frac{\text{mol } H_2}{L}$$

$$\left(1.87 \times 10^{-3} \frac{\text{mol HI}}{L}\right) \left(\frac{1 \text{ mol } I_2}{2 \text{ mol HI}}\right) = 0.935 \times 10^{-3} \frac{\text{mol } I_2}{L}$$

Fourth, we calculate the equilibrium concentrations of  $H_2$  and  $I_2$ , using the initial concentrations and the changes. The equilibrium concentration equals the initial concentration minus that consumed:

$$[H_2] = 1.000 \times 10^{-3} M - 0.935 \times 10^{-3} M = 0.065 \times 10^{-3} M$$

$$[I_2] = 2.000 \times 10^{-3} M - 0.935 \times 10^{-3} M = 1.065 \times 10^{-3} M$$

The completed table now looks like this (with equilibrium concentrations in blue for emphasis):

	$H_2(g)$	+	$I_2(g)$	$\rightleftharpoons$	$2 HI(g)$
Initial	$1.000 \times 10^{-3} M$		$2.000 \times 10^{-3} M$		$0 M$
Change	$-0.935 \times 10^{-3} M$		$-0.935 \times 10^{-3} M$		$+1.87 \times 10^{-3} M$
Equilibrium	$0.065 \times 10^{-3} M$		$1.065 \times 10^{-3} M$		$1.87 \times 10^{-3} M$

Notice that the entries for the changes are negative when a reactant is consumed and positive when a product is formed.

Finally, now that we know the equilibrium concentration of each reactant and product, we can use the equilibrium-constant expression to calculate the equilibrium constant.

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = \frac{(1.87 \times 10^{-3})^2}{(0.065 \times 10^{-3})(1.065 \times 10^{-3})} = 51$$

**Comment:** The same method can be applied to gaseous equilibrium problems to calculate  $K_p$ , in which case partial pressures are used as table entries in place of molar concentrations.

**PRACTICE EXERCISE**

Sulfur trioxide decomposes at high temperature in a sealed container:  $2 SO_3(g) \rightleftharpoons 2 SO_2(g) + O_2(g)$ . Initially, the vessel is charged at  $1000 K$  with  $SO_3(g)$  at a partial pressure of  $0.500 \text{ atm}$ . At equilibrium the  $SO_3$  partial pressure is  $0.200 \text{ atm}$ . Calculate the value of  $K_p$  at  $1000 K$ .

**Answer:** 0.338

## 15.6 APPLICATIONS OF EQUILIBRIUM CONSTANTS

We have seen that the magnitude of  $K$  indicates the extent to which a reaction will proceed. If  $K$  is very large, the equilibrium mixture will contain mostly substances on the product side of the equation. (That is, the reaction will tend to proceed far to the right.) If  $K$  is very small (that is, much less than 1), the equilibrium mixture will contain mainly reactants. The equilibrium constant also allows us to (1) predict the direction in which a reaction mixture will proceed to achieve equilibrium and (2) calculate the concentrations of reactants and products when equilibrium has been reached.

### Predicting the Direction of Reaction

For the formation of  $\text{NH}_3$  from  $\text{N}_2$  and  $\text{H}_2$  (Equation 15.6),  $K_c = 0.105$  at  $472^\circ\text{C}$ . Suppose we place a mixture of 2.00 mol of  $\text{H}_2$ , 1.00 mol of  $\text{N}_2$ , and 2.00 mol of  $\text{NH}_3$  in a 1.00-L container at  $472^\circ\text{C}$ . How will the mixture react to reach equilibrium? Will  $\text{N}_2$  and  $\text{H}_2$  react to form more  $\text{NH}_3$ , or will  $\text{NH}_3$  decompose to form  $\text{N}_2$  and  $\text{H}_2$ ?

To answer this question, we can substitute the starting concentrations of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  into the equilibrium-constant expression and compare its value to the equilibrium constant:

$$\frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3} = \frac{(2.00)^2}{(1.00)(2.00)^3} = 0.500 \quad \text{whereas} \quad K_c = 0.105$$

To reach equilibrium, the quotient  $[\text{NH}_3]^2/[\text{N}_2][\text{H}_2]^3$  will need to decrease from the starting value of 0.500 to the equilibrium value of 0.105. Because the system is closed, this change can happen only if the concentration of  $\text{NH}_3$  decreases and the concentrations of  $\text{N}_2$  and  $\text{H}_2$  increase. Thus, the reaction proceeds toward equilibrium by forming  $\text{N}_2$  and  $\text{H}_2$  from  $\text{NH}_3$ ; that is, the reaction proceeds from right to left.

The approach we have illustrated can be formalized by defining a quantity called the reaction quotient. The **reaction quotient**,  $Q$ , is a number obtained by substituting reactant and product concentrations or partial pressures at any point during a reaction into an equilibrium-constant expression. Therefore, for the general reaction

the reaction quotient is defined as

$$Q_c = \frac{[\text{D}]^d[\text{E}]^e}{[\text{A}]^a[\text{B}]^b} \quad [15.22]$$

(A related quantity  $Q_p$  can be written for any reaction that involves gases by using partial pressures instead of concentrations.)

Although we use the equilibrium-constant expression to calculate the reaction quotient, the concentrations that we use are not restricted to the equilibrium state. Thus, in our earlier example, when we substituted the starting concentrations into the equilibrium-constant expression, we obtained  $Q_c = 0.500$  whereas  $K_c = 0.105$ . The equilibrium constant has only one value at each temperature. The reaction quotient, however, varies as the reaction proceeds.

To determine the direction in which a reaction will proceed to achieve equilibrium, we compare the values of  $Q_c$  and  $K_c$  or  $Q_p$  and  $K_p$ . Three possible situations arise:

- $Q = K$ : The reaction quotient will equal the equilibrium constant only if the system is already at equilibrium.
- $Q > K$ : The concentration of products is too large and that of reactants too small. Thus, substances on the right side of the chemical equation will react to form substances on the left; the reaction moves from right to left in approaching equilibrium.

◀ **Figure 15.9 Predicting the direction of a reaction by comparing  $Q$  and  $K$ .** The relative magnitudes of the reaction quotient  $Q$  and the equilibrium constant  $K$  indicate how the reaction mixture changes as it moves toward equilibrium. If  $Q$  is smaller than  $K$ , the reaction proceeds from left to right until  $Q = K$ . When  $Q = K$ , the reaction is at equilibrium and has no tendency to change. If  $Q$  is larger than  $K$ , the reaction proceeds from right to left until  $Q = K$ .

- $Q < K$ : The concentration of products is too small and that of reactants too large. Thus, the reaction will achieve equilibrium by forming more products; it moves from left to right.

These relationships are summarized in Figure 15.9 ▲.

### SAMPLE EXERCISE 15.10 | Predicting the Direction of Approach to Equilibrium

At 448 °C the equilibrium constant  $K_c$  for the reaction

is 50.5. Predict in which direction the reaction will proceed to reach equilibrium at 448 °C if we start with  $2.0 \times 10^{-2}$  mol of HI,  $1.0 \times 10^{-2}$  mol of  $\text{H}_2$ , and  $3.0 \times 10^{-2}$  mol of  $\text{I}_2$  in a 2.00-L container.

#### SOLUTION

**Analyze:** We are given a volume and initial molar amounts of the species in a reaction and asked to determine in which direction the reaction must proceed to achieve equilibrium.

**Plan:** We can determine the starting concentration of each species in the reaction mixture. We can then substitute the starting concentrations into the equilibrium-constant expression to calculate the reaction quotient,  $Q_c$ . Comparing the magnitudes of the equilibrium constant, which is given, and the reaction quotient will tell us in which direction the reaction will proceed.

**Solve:** The initial concentrations are  $[\text{HI}] = 2.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 1.0 \times 10^{-2} \text{ M}$

$$[\text{H}_2] = 1.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 5.0 \times 10^{-3} \text{ M}$$

$$[\text{I}_2] = 3.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 1.5 \times 10^{-2} \text{ M}$$

The reaction quotient is therefore

$$Q_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.0 \times 10^{-2})^2}{(5.0 \times 10^{-3})(1.5 \times 10^{-2})} = 1.3$$

Because  $Q_c < K_c$ , the concentration of HI must increase and the concentrations of  $\text{H}_2$  and  $\text{I}_2$  must decrease to reach equilibrium; the reaction will proceed from left to right as it moves toward equilibrium.

#### PRACTICE EXERCISE

At 1000 K the value of  $K_p$  for the reaction  $2 \text{SO}_3(\text{g}) \rightleftharpoons 2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g})$  is 0.338. Calculate the value for  $Q_p$ , and predict the direction in which the reaction will proceed toward equilibrium if the initial partial pressures are  $P_{\text{SO}_3} = 0.16 \text{ atm}$ ;  $P_{\text{SO}_2} = 0.41 \text{ atm}$ ;  $P_{\text{O}_2} = 2.5 \text{ atm}$ .

**Answer:**  $Q_p = 16$ ;  $Q_p > K_p$ , and so the reaction will proceed from right to left, forming more  $\text{SO}_3$ .

## Calculating Equilibrium Concentrations

Chemists frequently need to calculate the amounts of reactants and products present at equilibrium. Our approach in solving problems of this type is similar to the one we used for evaluating equilibrium constants: We tabulate the initial concentrations or partial pressures, the changes therein, and the final equilibrium concentrations or partial pressures. Usually we end up using the equilibrium-constant expression to derive an equation that must be solved for an unknown quantity, as demonstrated in Sample Exercise 15.11.

**SAMPLE EXERCISE 15.11** | Calculating Equilibrium Concentrations

For the Haber process,  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ ,  $K_p = 1.45 \times 10^{-5}$  at  $500^\circ\text{C}$ . In an equilibrium mixture of the three gases at  $500^\circ\text{C}$ , the partial pressure of  $\text{H}_2$  is  $0.928 \text{ atm}$  and that of  $\text{N}_2$  is  $0.432 \text{ atm}$ . What is the partial pressure of  $\text{NH}_3$  in this equilibrium mixture?

**SOLUTION**

**Analyze:** We are given an equilibrium constant,  $K_p$ , and the equilibrium partial pressures of two of the three substances in the equation ( $\text{N}_2$  and  $\text{H}_2$ ), and we are asked to calculate the equilibrium partial pressure for the third substance ( $\text{NH}_3$ ).

**Plan:** We can set  $K_p$  equal to the equilibrium-constant expression and substitute in the partial pressures that we know. Then we can solve for the only unknown in the equation.

**Solve:** We tabulate the equilibrium pressures as follows:

Because we do not know the equilibrium pressure of  $\text{NH}_3$ , we represent it with a variable,  $x$ . At equilibrium the pressures must satisfy the equilibrium-constant expression:

$$K_p = \frac{(P_{\text{NH}_3})^2}{P_{\text{N}_2}(P_{\text{H}_2})^3} = \frac{x^2}{(0.432)(0.928)^3} = 1.45 \times 10^{-5}$$

We now rearrange the equation to solve for  $x$ :

$$\begin{aligned} x^2 &= (1.45 \times 10^{-5})(0.432)(0.928)^3 = 5.01 \times 10^{-6} \\ x &= \sqrt{5.01 \times 10^{-6}} = 2.24 \times 10^{-3} \text{ atm} = P_{\text{NH}_3} \end{aligned}$$

**Comment:** We can always check our answer by using it to recalculate the value of the equilibrium constant:

$$K_p = \frac{(2.24 \times 10^{-3})^2}{(0.432)(0.928)^3} = 1.45 \times 10^{-5}$$

**PRACTICE EXERCISE**

At  $500 \text{ K}$  the reaction  $\text{PCl}_5(\text{g}) \rightleftharpoons \text{PCl}_3(\text{g}) + \text{Cl}_2(\text{g})$  has  $K_p = 0.497$ . In an equilibrium mixture at  $500 \text{ K}$ , the partial pressure of  $\text{PCl}_5$  is  $0.860 \text{ atm}$  and that of  $\text{PCl}_3$  is  $0.350 \text{ atm}$ . What is the partial pressure of  $\text{Cl}_2$  in the equilibrium mixture?

**Answer:**  $1.22 \text{ atm}$

In many situations we will know the value of the equilibrium constant and the initial amounts of all species. We must then solve for the equilibrium amounts. Solving this type of problem usually entails treating the change in concentration as a variable. The stoichiometry of the reaction gives us the relationship between the changes in the amounts of all the reactants and products, as illustrated in Sample Exercise 15.12.

**SAMPLE EXERCISE 15.12** | Calculating Equilibrium Concentrations from Initial Concentrations

A  $1.000\text{-L}$  flask is filled with  $1.000 \text{ mol}$  of  $\text{H}_2$  and  $2.000 \text{ mol}$  of  $\text{I}_2$  at  $448^\circ\text{C}$ . The value of the equilibrium constant  $K_c$  for the reaction

at  $448^\circ\text{C}$  is  $50.5$ . What are the equilibrium concentrations of  $\text{H}_2$ ,  $\text{I}_2$ , and  $\text{HI}$  in moles per liter?

**SOLUTION**

**Analyze:** We are given the volume of a container, an equilibrium constant, and starting amounts of reactants in the container and are asked to calculate the equilibrium concentrations of all species.

**Plan:** In this case we are not given any of the equilibrium concentrations. We must develop some relationships that relate the initial concentrations to those at equilibrium. The procedure is similar in many regards to that outlined in Sample Exercise 15.9, where we calculated an equilibrium constant using initial concentrations.

**Solve:** First, we note the initial concentrations of  $\text{H}_2$  and  $\text{I}_2$  in the  $1.000\text{-L}$  flask:

$$[\text{H}_2] = 1.000 \text{ M} \quad \text{and} \quad [\text{I}_2] = 2.000 \text{ M}$$

Second, we construct a table in which we tabulate the initial concentrations:

	$\text{H}_2(\text{g})$	+	$\text{I}_2(\text{g})$	$\rightleftharpoons$	$2 \text{HI}(\text{g})$
Initial	$1.000 \text{ M}$		$2.000 \text{ M}$		$0 \text{ M}$
Change					
Equilibrium					

Third, we use the stoichiometry of the reaction to determine the changes in concentration that occur as the reaction proceeds to equilibrium. The concentrations of  $\text{H}_2$  and  $\text{I}_2$  will decrease as equilibrium is established and that of HI will increase. Let's represent the change in concentration of  $\text{H}_2$  by the variable  $x$ . The balanced chemical equation tells us the relationship between the changes in the concentrations of the three gases:

For each  $x$  mol of  $\text{H}_2$  that reacts,  $x$  mol of  $\text{I}_2$  are consumed and  $2x$  mol of HI are produced:

$$\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$$

Initial	1.000 M	2.000 M	0 M
Change	$-x$	$-x$	$+2x$
Equilibrium			

Fourth, we use the initial concentrations and the changes in concentrations, as dictated by stoichiometry, to express the equilibrium concentrations. With all our entries, our table now looks like this:

$$\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$$

Initial	1.000 M	2.000 M	0 M
Change	$-x$	$-x$	$+2x$
Equilibrium	$(1.000 - x) \text{ M}$	$(2.000 - x) \text{ M}$	$2x \text{ M}$

Fifth, we substitute the equilibrium concentrations into the equilibrium-constant expression and solve for the unknown,  $x$ :

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(2x)^2}{(1.000 - x)(2.000 - x)} = 50.5$$

If you have an equation-solving calculator, you can solve this equation directly for  $x$ . If not, expand this expression to obtain a quadratic equation in  $x$ :

$$4x^2 = 50.5(x^2 - 3.000x + 2.000)$$

$$46.5x^2 - 151.5x + 101.0 = 0$$

Solving the quadratic equation (Appendix A.3) leads to two solutions for  $x$ :

$$x = \frac{-(-151.5) \pm \sqrt{1(-151.5)^2 - 4(46.5)(101.0)}}{2(46.5)} = 2.323 \text{ or } 0.935$$

When we substitute  $x = 2.323$  into the expressions for the equilibrium concentrations, we find *negative* concentrations of  $\text{H}_2$  and  $\text{I}_2$ . Because a negative concentration is not chemically meaningful, we reject this solution. We then use  $x = 0.935$  to find the equilibrium concentrations:

$$[\text{H}_2] = 1.000 - x = 0.065 \text{ M}$$

$$[\text{I}_2] = 2.000 - x = 1.065 \text{ M}$$

$$[\text{HI}] = 2x = 1.87 \text{ M}$$

**Check:** We can check our solution by putting these numbers into the equilibrium-constant expression to assure that we correctly calculate the equilibrium constant:

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.87)^2}{(0.065)(1.065)} = 51$$

**Comment:** Whenever you use a quadratic equation to solve an equilibrium problem, one of the solutions will not be chemically meaningful and should be rejected.

### ■ PRACTICE EXERCISE

For the equilibrium  $\text{PCl}_5(\text{g}) \rightleftharpoons \text{PCl}_3(\text{g}) + \text{Cl}_2(\text{g})$ , the equilibrium constant  $K_p$  has the value 0.497 at 500 K. A gas cylinder at 500 K is charged with  $\text{PCl}_5(\text{g})$  at an initial pressure of 1.66 atm. What are the equilibrium pressures of  $\text{PCl}_5$ ,  $\text{PCl}_3$ , and  $\text{Cl}_2$  at this temperature?

**Answer:**  $P_{\text{PCl}_5} = 0.967 \text{ atm}$ ;  $P_{\text{PCl}_3} = P_{\text{Cl}_2} = 0.693 \text{ atm}$

▲ **Figure 15.10** Effect of temperature and pressure on the percentage of  $\text{NH}_3$  in an equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$ . Each mixture was produced by starting with a 3:1 molar mixture of  $\text{H}_2$  and  $\text{N}_2$ . The yield of  $\text{NH}_3$  is greatest at the lowest temperature and at the highest pressure.

## 15.7 LE CHÂTELIER'S PRINCIPLE

When Haber developed his process for making ammonia from  $\text{N}_2$  and  $\text{H}_2$ , he sought the factors that might be varied to increase the yield of  $\text{NH}_3$ . Using the values of the equilibrium constant at various temperatures, he calculated the equilibrium amounts of  $\text{NH}_3$  formed under a variety of conditions. Some of Haber's results are shown in Figure 15.10 ◀. Notice that the percent of  $\text{NH}_3$  present at equilibrium decreases with increasing temperature and increases with increasing pressure. We can understand these effects in terms of a principle first put forward by Henri-Louis Le Châtelier\* (1850–1936), a French industrial chemist. **Le Châtelier's principle** can be stated as follows: *If a system at equilibrium is disturbed*

*by a change in temperature, pressure, or the concentration of one of the components, the system will shift its equilibrium position so as to counteract the effect of the disturbance.*

In this section we will use Le Châtelier's principle to make qualitative predictions about how a system at equilibrium responds to various changes in external conditions. We will consider three ways that a chemical equilibrium can be disturbed: (1) adding or removing a reactant or product, (2) changing the pressure by changing the volume, and (3) changing the temperature.

### Change in Reactant or Product Concentrations

A system at equilibrium is in a dynamic state of balance. When the conditions of the equilibrium are altered, the equilibrium shifts until a new state of balance is attained. Le Châtelier's principle states that the shift will be in the direction that minimizes or reduces the effect of the change. Therefore, *if a chemical system is at equilibrium and we increase the concentration of a substance (either a reactant or a product), the system reacts to consume some of the substance. Conversely, if we decrease the concentration of a substance, the system reacts to produce some of the substance.*

As an example, consider an equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$ :

Adding  $\text{H}_2$  would cause the system to shift so as to reduce the newly increased concentration of  $\text{H}_2$ . This change can occur only by consuming  $\text{H}_2$  and simultaneously consuming  $\text{N}_2$  to form more  $\text{NH}_3$ . This situation is illustrated in Figure 15.11 ◀. Adding more  $\text{N}_2$  to the equilibrium mixture would likewise cause the direction of the reaction to shift toward forming more  $\text{NH}_3$ . Removing  $\text{NH}_3$  would also cause a shift toward producing more  $\text{NH}_3$ , whereas *adding*  $\text{NH}_3$  to the system at equilibrium would cause the concentrations to shift in the direction that reduces the newly increased  $\text{NH}_3$  concentration. Some of the added ammonia would decompose to form  $\text{N}_2$  and  $\text{H}_2$ .

In the Haber reaction, therefore, removing  $\text{NH}_3$  from an equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  causes the reaction to shift from left to right to form more  $\text{NH}_3$ . If the  $\text{NH}_3$  can be removed continuously, the yield of  $\text{NH}_3$  can be increased dramatically. In the industrial production of ammonia, the  $\text{NH}_3$  is continuously

▲ **Figure 15.11** Effect of adding  $\text{H}_2$  to an equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$ . When  $\text{H}_2$  is added, a portion of the  $\text{H}_2$  reacts with  $\text{N}_2$  to form  $\text{NH}_3$ , thereby establishing a new equilibrium position that has the same equilibrium constant. The results shown are in accordance with Le Châtelier's principle.

\*Pronounced "le-SHOT-lee-ay."

◀ **Figure 15.12 Schematic diagram summarizing the industrial production of ammonia.** Incoming  $\text{N}_2$  and  $\text{H}_2$  gases are heated to approximately  $500\text{ }^\circ\text{C}$  and passed over a catalyst. The resultant gas mixture is allowed to expand and cool, causing  $\text{NH}_3$  to liquefy. Unreacted  $\text{N}_2$  and  $\text{H}_2$  gases are recycled.

removed by selectively liquefying it; the boiling point of  $\text{NH}_3$  ( $-33\text{ }^\circ\text{C}$ ) is much higher than that of  $\text{N}_2$  ( $-196\text{ }^\circ\text{C}$ ) and  $\text{H}_2$  ( $-253\text{ }^\circ\text{C}$ ). The liquid  $\text{NH}_3$  is removed, and the  $\text{N}_2$  and  $\text{H}_2$  are recycled to form more  $\text{NH}_3$ , as diagrammed in Figure 15.12▲. By continuously removing the product, the reaction is driven essentially to completion.

### GIVE IT SOME THOUGHT

What happens to the equilibrium  $2\text{NO}(g) + \text{O}_2(g) \rightleftharpoons 2\text{NO}_2(g)$  if (a)  $\text{O}_2$  is added to the system, (b)  $\text{NO}$  is removed?

### Effects of Volume and Pressure Changes

If a system is at equilibrium and its volume is decreased, thereby increasing its total pressure, Le Châtelier's principle indicates that the system will respond by shifting its equilibrium position to reduce the pressure. A system can reduce its pressure by reducing the total number of gas molecules (fewer molecules of gas exert a lower pressure). Thus, at constant temperature, *reducing the volume of a gaseous equilibrium mixture causes the system to shift in the direction that reduces the number of moles of gas.* Conversely, increasing the volume causes a shift in the direction that produces more gas molecules.

For example, let's again consider the equilibrium  $\text{N}_2\text{O}_4(g) \rightleftharpoons 2\text{NO}_2(g)$ . What happens if the total pressure of an equilibrium mixture is increased by decreasing the volume as shown in the sequential photos in Figure 15.13▼? According to Le Châtelier's principle, we expect the equilibrium to shift to the side that reduces the total number of moles of gas, which is the reactant side in this case. (Notice the coefficients in the chemical equation; 1 mol of  $\text{N}_2\text{O}_4$  appears on the reactant side and 2 mol  $\text{NO}_2$  appears on the product side.) We therefore expect the equilibrium to shift to the left, so that  $\text{NO}_2$  is

### LE CHÂTELIER'S PRINCIPLE

If a system at equilibrium is disturbed by a change in temperature, pressure, or the concentration of one of the components, the system will shift its equilibrium position so as to counteract the effect of the disturbance.

The equilibrium shown is  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ .

▲ **Figure 15.13** Effect of pressure on an equilibrium. (The equilibrium shown is  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ .)

converted into  $\text{N}_2\text{O}_4$  as equilibrium is reestablished. In Figure 15.13, compressing the gas mixture initially causes the color to darken as the concentration of  $\text{NO}_2$  increases. The color then fades as equilibrium is reestablished. The color fades because the pressure increase causes the equilibrium to shift in favor of colorless  $\text{N}_2\text{O}_4$ .

#### GIVE IT SOME THOUGHT

What happens to the equilibrium  $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2 \text{SO}_3(\text{g})$  if the volume of the system is increased?

For the reaction  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ , four molecules of reactant are consumed for every two molecules of product produced. Consequently, an increase in pressure (decrease in volume) causes a shift toward the side with fewer gas molecules, which leads to the formation of more  $\text{NH}_3$ , as indicated in Figure 15.10. In the case of the reaction  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$ , the number of molecules of gaseous products (two) equals the number of molecules of gaseous reactants; therefore, changing the pressure will not influence the position of the equilibrium.

Keep in mind that pressure-volume changes do *not* change the value of  $K$  as long as the temperature remains constant. Rather, they change the partial pressures of the gaseous substances. In Sample Exercise 15.8 we calculated  $K_p$  for an equilibrium mixture at 472 °C that contained 7.38 atm  $H_2$ , 2.46 atm  $N_2$ , and 0.166 atm  $NH_3$ . The value of  $K_p$  is  $2.79 \times 10^{-5}$ . Consider what happens when we suddenly reduce the volume of the system by one-half. If there were no shift in equilibrium, this volume change would cause the partial pressures of all substances to double, giving  $P_{H_2} = 14.76$  atm,  $P_{N_2} = 4.92$  atm, and  $P_{NH_3} = 0.332$  atm. The reaction quotient would then no longer equal the equilibrium constant.

$$Q_p = \frac{(P_{NH_3})^2}{P_{N_2}(P_{H_2})^3} = \frac{(0.332)^2}{(4.92)(14.76)^3} = 6.97 \times 10^{-6} \neq K_p$$

Because  $Q_p < K_p$ , the system is no longer at equilibrium. Equilibrium will be reestablished by increasing  $P_{NH_3}$  and decreasing  $P_{N_2}$  and  $P_{H_2}$  until  $Q_p = K_p = 2.79 \times 10^{-5}$ . Therefore, the equilibrium shifts to the right as Le Châtelier's principle predicts.

It is possible to change the total pressure of the system without changing its volume. For example, pressure increases if additional amounts of any of the reacting components are added to the system. We have already seen how to deal with a change in concentration of a reactant or product. The total pressure within the reaction vessel might also be increased by adding a gas that is not involved in the equilibrium. For example, argon might be added to the ammonia equilibrium system. The argon would not alter the partial pressures of any of the reacting components and therefore would not cause a shift in equilibrium.

## Effect of Temperature Changes

Changes in concentrations or partial pressures cause shifts in equilibrium without changing the value of the equilibrium constant. In contrast, almost every equilibrium constant changes in value as the temperature changes. For example, consider the equilibrium established when cobalt(II) chloride ( $CoCl_2$ ) is dissolved in hydrochloric acid,  $HCl(aq)$ :

The formation of  $CoCl_4^{2-}$  from  $Co(H_2O)_6^{2+}$  is an endothermic process. We will discuss the significance of this enthalpy change shortly. Because  $Co(H_2O)_6^{2+}$  is pink and  $CoCl_4^{2-}$  is blue, the position of this equilibrium is readily apparent from the color of the solution. Figure 15.14(left) ▼ shows a room-temperature solution of  $CoCl_2$  in  $HCl(aq)$ . Both  $Co(H_2O)_6^{2+}$  and  $CoCl_4^{2-}$  are present in significant amounts in the solution; the violet color results from the presence of both the pink and blue ions. When the solution is heated [Figure 15.14(middle)], it becomes intensely blue in color, indicating that the equilibrium has shifted to form more  $CoCl_4^{2-}$ . Cooling the solution, as in Figure 15.14(right), leads to a pink solution, indicating that the equilibrium has shifted to produce more  $Co(H_2O)_6^{2+}$ . How can we explain the dependence of this equilibrium on temperature?

We can deduce the rules for the temperature dependence of the equilibrium constant by applying Le Châtelier's principle. A simple way to do this is to treat heat as if it were a chemical reagent. In an *endothermic* (heat-absorbing) reaction we can consider heat as a *reactant*, whereas in an *exothermic* (heat-releasing) reaction we can consider heat as a *product*.

When the temperature of a system at equilibrium is increased, the system reacts as if we added a reactant to an endothermic reaction or a product to an exothermic reaction. The equilibrium shifts in the direction that consumes the excess reactant (or product), namely heat.

## EFFECT OF TEMPERATURE CHANGES

Almost every equilibrium constant changes in value as the temperature changes. In an endothermic reaction, such as the one shown, heat is absorbed as reactants are converted to products. Increasing the temperature causes the equilibrium to shift to the right and  $K$  to increase. Lowering the temperature shifts the equilibrium in the direction that produces heat, to the left, decreasing  $K$ .

▲ **Figure 15.14 Temperature and equilibrium.** (The reaction shown is  $\text{Co}(\text{H}_2\text{O})_6^{2+}(\text{aq}) + 4 \text{Cl}^{-}(\text{aq}) \rightleftharpoons \text{CoCl}_4^{2-}(\text{aq}) + 6 \text{H}_2\text{O}(\text{l})$ .)

## GIVE IT SOME THOUGHT

Use Le Châtelier's principle to explain why the equilibrium vapor pressure of a liquid increases with increasing temperature.

In an endothermic reaction, such as Equation 15.23, heat is absorbed as reactants are converted to products. Thus, increasing the temperature causes the equilibrium to shift to the right, in the direction of products, and  $K$  increases. For Equation 15.23, increasing the temperature leads to the formation of more  $\text{CoCl}_4^{2-}$ , as observed in Figure 15.14(b).

In an exothermic reaction the opposite occurs. Heat is absorbed as products are converted to reactants; therefore the equilibrium shifts to the left and  $K$  decreases. We can summarize these results as follows:

*Endothermic:* Increasing  $T$  results in an increase in  $K$ .

*Exothermic:* Increasing  $T$  results in a decrease in  $K$ .

Cooling a reaction has the opposite effect. As we lower the temperature, the equilibrium shifts to the side that produces heat. Thus, cooling an endothermic reaction shifts the equilibrium to the left, decreasing  $K$ . We observed this effect in Figure 15.14(c). Cooling an exothermic reaction shifts the equilibrium to the right, increasing  $K$ .

### SAMPLE EXERCISE 15.13 | Using Le Châtelier's Principle to Predict Shifts in Equilibrium

Consider the equilibrium

In which direction will the equilibrium shift when (a)  $\text{N}_2\text{O}_4$  is added, (b)  $\text{NO}_2$  is removed, (c) the total pressure is increased by addition of  $\text{N}_2(\text{g})$ , (d) the volume is increased, (e) the temperature is decreased?

#### SOLUTION

**Analyze:** We are given a series of changes to be made to a system at equilibrium and are asked to predict what effect each change will have on the position of the equilibrium.

**Plan:** Le Châtelier's principle can be used to determine the effects of each of these changes.

#### Solve:

(a) The system will adjust to decrease the concentration of the added  $\text{N}_2\text{O}_4$ , so the equilibrium shifts to the right, in the direction of products.

(b) The system will adjust to the removal of  $\text{NO}_2$  by shifting to the side that produces more  $\text{NO}_2$ ; thus, the equilibrium shifts to the right.

(c) Adding  $\text{N}_2$  will increase the total pressure of the system, but  $\text{N}_2$  is not involved in the reaction. The partial pressures of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  are therefore unchanged, and there is no shift in the position of the equilibrium.

(d) If the volume is increased, the system will shift in the direction that occupies a larger volume (more gas molecules); thus, the equilibrium shifts to the right. (This is the opposite of the effect observed in Figure 15.13, where the volume was decreased.)

(e) The reaction is endothermic, so we can imagine heat as a reagent on the reactant side of the equation. Decreasing the temperature will shift the equilibrium in the direction that produces heat, so the equilibrium shifts to the left, toward the formation of more  $\text{N}_2\text{O}_4$ . Note that only this last change also affects the value of the equilibrium constant,  $K$ .

### PRACTICE EXERCISE

For the reaction

in which direction will the equilibrium shift when (a)  $\text{Cl}_2(\text{g})$  is removed, (b) the temperature is decreased, (c) the volume of the reaction system is increased, (d)  $\text{PCl}_3(\text{g})$  is added?

**Answers:** (a) right, (b) left, (c) right, (d) left

### SAMPLE EXERCISE 15.14 | Predicting the Effect of Temperature on $K$

(a) Using the standard heat of formation data in Appendix C, determine the standard enthalpy change for the reaction

(b) Determine how the equilibrium constant for this reaction should change with temperature.

#### SOLUTION

**Analyze:** We are asked to determine the standard enthalpy change of a reaction and how the equilibrium constant for the reaction varies with temperature.

**Plan:** (a) We can use standard enthalpies of formation to calculate  $\Delta H^\circ$  for the reaction. (b) We can then use Le Châtelier's principle to determine what effect temperature will have on the equilibrium constant.

**TABLE 15.2** Variation in  $K_p$  for the Equilibrium  $\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3$  as a Function of Temperature

Temperature (°C)	$K_p$
300	$4.34 \times 10^{-3}$
400	$1.64 \times 10^{-4}$
450	$4.51 \times 10^{-5}$
500	$1.45 \times 10^{-5}$
550	$5.38 \times 10^{-6}$
600	$2.25 \times 10^{-6}$

**Solve:**

(a) Recall that the standard enthalpy change for a reaction is given by the sum of the standard molar enthalpies of formation of the products, each multiplied by its coefficient in the balanced chemical equation, less the same quantities for the reactants. At 25 °C,  $\Delta H_f^\circ$  for  $\text{NH}_3(\text{g})$  is  $-46.19 \text{ kJ/mol}$ . The  $\Delta H_f^\circ$  values for  $\text{H}_2(\text{g})$  and  $\text{N}_2(\text{g})$  are zero by definition because the enthalpies of formation of the elements in their normal states at 25 °C are defined as zero (Section 5.7). Because 2 mol of  $\text{NH}_3$  is formed, the total enthalpy change is

$$(2 \text{ mol})(-46.19 \text{ kJ/mol}) - 0 = -92.38 \text{ kJ}$$

(b) Because the reaction in the forward direction is exothermic, we can consider heat a product of the reaction. An increase in temperature causes the reaction to shift in the direction of less  $\text{NH}_3$  and more  $\text{N}_2$  and  $\text{H}_2$ . This effect is seen in the values for  $K_p$  presented in Table 15.2. Notice that  $K_p$  changes markedly with changes in temperature and that it is larger at lower temperatures.

**Comment:** The fact that  $K_p$  for the formation of  $\text{NH}_3$  from  $\text{N}_2$  and  $\text{H}_2$  decreases with increasing temperature is a matter of great practical importance. To form  $\text{NH}_3$  at a reasonable rate requires higher temperatures. At higher temperatures, however, the equilibrium constant is smaller, and so the percentage conversion to  $\text{NH}_3$  is smaller. To compensate for this, higher pressures are needed because high pressure favors  $\text{NH}_3$  formation.

**PRACTICE EXERCISE**

Using the thermodynamic data in Appendix C, determine the enthalpy change for the reaction

Use this result to determine how the equilibrium constant for the reaction should change with temperature.

**Answer:**  $\Delta H^\circ = 508.3 \text{ kJ}$ ; the equilibrium constant will increase with increasing temperature

**▲ Figure 15.15** Effect of a catalyst on equilibrium. At equilibrium for the hypothetical reaction  $\text{A} \rightleftharpoons \text{B}$ , the forward reaction rate,  $r_f$ , equals the reverse reaction rate,  $r_r$ . The violet curve represents the path over the transition state in the absence of a catalyst. A catalyst lowers the energy of the transition state, as shown by the green curve. Thus, the activation energy is lowered for both the forward and the reverse reactions. As a result, the rates of forward and reverse reactions in the catalyzed reaction are increased.

**The Effect of Catalysts**

What happens if we add a catalyst to a chemical system that is at equilibrium? As shown in Figure 15.15, a catalyst lowers the activation barrier between the reactants and products. The activation energy of the forward reaction is lowered to the same extent as that for the reverse reaction. The catalyst thereby increases the rates of both the forward and reverse reactions. As a result, a catalyst increases the rate at which equilibrium is achieved, but it does not change the composition of the equilibrium mixture. The value of the equilibrium constant for a reaction is not affected by the presence of a catalyst.

The rate at which a reaction approaches equilibrium is an important practical consideration. As an example, let's again consider the synthesis of ammonia from  $\text{N}_2$  and  $\text{H}_2$ . In designing a process for ammonia synthesis, Haber had to deal with a rapid decrease in the equilibrium constant with increasing temperature, as shown in

Table 15.2. At temperatures sufficiently high to give a satisfactory reaction rate, the amount of ammonia formed was too small. The solution to this dilemma was to develop a catalyst that would produce a reasonably rapid approach to equilibrium at a sufficiently low temperature, so that the equilibrium constant was still reasonably large. The development of a suitable catalyst thus became the focus of Haber's research efforts.

After trying different substances to see which would be most effective, Haber finally settled on iron mixed with metal oxides. Variants of the original catalyst formulations are still used. These catalysts make it possible to obtain a reasonably rapid approach to equilibrium at temperatures around 400 °C to 500 °C and with gas pressures of 200 to 600 atm. The high pressures are needed to obtain a satisfactory degree of conversion at equilibrium. You can see from

Figure 15.10 that if an improved catalyst could be found—one that would lead to sufficiently rapid reaction at temperatures lower than 400 °C to 500 °C—it would be possible to obtain the same degree of equilibrium conversion at much lower pressures. This would result in great savings in the cost of equipment for ammonia synthesis. In view of the growing need for nitrogen as fertilizer, the fixation of nitrogen is a process of ever-increasing importance.

### GIVE IT SOME THOUGHT

Does the addition of a catalyst have any effect on the position of an equilibrium?

#### SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

At temperatures near 800 °C, steam passed over hot coke (a form of carbon obtained from coal) reacts to form CO and H<sub>2</sub>:

The mixture of gases that results is an important industrial fuel called *water gas*. (a) At 800 °C the equilibrium constant for this reaction is  $K_p = 14.1$ . What are the equilibrium partial pressures of H<sub>2</sub>O, CO, and H<sub>2</sub> in the equilibrium mixture at this temperature if we start with solid carbon and 0.100 mol of H<sub>2</sub>O in a 1.00-L vessel? (b) What is the minimum amount of carbon required to achieve equilibrium under these conditions? (c) What is the total pressure in the vessel at equilibrium? (d) At 25 °C the value of  $K_p$  for this reaction is  $1.7 \times 10^{-21}$ . Is the reaction exothermic or endothermic? (e) To produce the maximum amount of CO and H<sub>2</sub> at equilibrium, should the pressure of the system be increased or decreased?

#### SOLUTION

(a) To determine the equilibrium partial pressures, we use the ideal gas equation, first determining the starting partial pressure of hydrogen.

$$P_{\text{H}_2\text{O}} = \frac{n_{\text{H}_2\text{O}}RT}{V} = \frac{(0.100 \text{ mol})(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(1073 \text{ K})}{1.00 \text{ L}} = 8.81 \text{ atm}$$

We then construct a table of starting partial pressures and their changes as equilibrium is achieved:

Initial		8.81 atm	0 atm	0 atm
Change		-x	+x	+x
Equilibrium		8.81 - x atm	x atm	x atm

There are no entries in the table under C(s) because the reactant, being a solid, does not appear in the equilibrium-constant expression. Substituting the equilibrium partial pressures of the other species into the equilibrium-constant expression for the reaction gives

$$K_p = \frac{P_{\text{CO}}P_{\text{H}_2}}{P_{\text{H}_2\text{O}}} = \frac{(x)(x)}{(8.81 - x)} = 14.1$$

Multiplying through by the denominator gives a quadratic equation in  $x$ :

$$x^2 = (14.1)(8.81 - x)$$

$$x^2 + 14.1x - 124.22 = 0$$

Solving this equation for  $x$  using the quadratic formula yields  $x = 6.14$  atm. Hence, the equilibrium partial pressures are  $P_{\text{CO}} = x = 6.14$  atm,  $P_{\text{H}_2} = x = 6.14$  atm, and  $P_{\text{H}_2\text{O}} = (8.81 - x) = 2.67$  atm.

(b) Part (a) shows that  $x = 6.14$  atm of H<sub>2</sub>O must react for the system to achieve equilibrium. We can use the ideal-gas equation to convert this partial pressure into a mole amount.

$$n = \frac{PV}{RT} = \frac{(6.14 \text{ atm})(1.00 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(1073 \text{ K})} = 0.0697 \text{ mol}$$

Thus, 0.0697 mol of  $\text{H}_2\text{O}$  and the same amount of C must react to achieve equilibrium. As a result, there must be at least 0.0697 mol of C (0.836 g C) present among the reactants at the start of the reaction.

(c) The total pressure in the vessel at equilibrium is simply the sum of the equilibrium partial pressures:

$$P_{\text{total}} = P_{\text{H}_2\text{O}} + P_{\text{CO}} + P_{\text{H}_2} = 2.67 \text{ atm} + 6.14 \text{ atm} + 6.14 \text{ atm} = 14.95 \text{ atm}$$

(d) In discussing Le Châtelier's principle, we saw that endothermic reactions exhibit an increase in  $K_p$  with increasing temperature. Because the equilibrium constant for this reaction increases as temperature increases, the reaction must be endothermic. From the enthalpies of formation given in Appendix C, we can verify our prediction by calculating the enthalpy change for the reaction,  $\Delta H^\circ = \Delta H_f^\circ(\text{CO}) + \Delta H_f^\circ(\text{H}_2) - \Delta H_f^\circ(\text{C}) - \Delta H_f^\circ(\text{H}_2\text{O}) = +131.3 \text{ kJ}$ . The positive sign for  $\Delta H^\circ$  indicates that the reaction is endothermic.

(e) According to Le Châtelier's principle, a decrease in the pressure causes a gaseous equilibrium to shift toward the side of the equation with the greater number of moles of gas. In this case there are two moles of gas on the product side and only one on the reactant side. Therefore, the pressure should be reduced to maximize the yield of the CO and  $\text{H}_2$ .

## Chemistry Put to Work

### CONTROLLING NITRIC OXIDE EMISSIONS

The formation of NO from  $\text{N}_2$  and  $\text{O}_2$  provides another interesting example of the practical importance of changes in the equilibrium constant and reaction rate with temperature. The equilibrium equation and the standard enthalpy change for the reaction are

The reaction is endothermic; that is, heat is absorbed when NO is formed from the elements. By applying Le Châtelier's principle, we deduce that an increase in temperature will shift the equilibrium in the direction of more NO. The equilibrium constant  $K_p$  for formation of 1 mol of NO from the elements at 300 K is only about  $10^{-15}$ . In contrast, at a much higher temperature of about 2400 K the equilibrium constant is  $10^{13}$  times as large, about 0.05. The manner in which  $K_p$  for Equation 15.24 varies with temperature is shown in Figure 15.16.

This graph helps to explain why NO is a pollution problem. In the cylinder of a modern high-compression auto engine, the temperatures during the fuel-burning part of the cycle may be approximately 2400 K. Also, there is a fairly large excess of air in the cylinder. These conditions favor the formation of some NO. After the combustion, however, the gases are quickly cooled. As the temperature drops, the equilibrium in Equation 15.24 shifts strongly to the left (that is, in the direction of  $\text{N}_2$  and  $\text{O}_2$ ). The lower temperatures also mean that the rate of the reaction is decreased, however, so the NO formed at high temperatures is essentially "frozen" in that form as the gas cools.

The gases exhausting from the cylinder are still quite hot, perhaps 1200 K. At this temperature, as shown in Figure 15.16, the equilibrium constant for formation of NO is much smaller. However, the rate of conversion of NO to  $\text{N}_2$  and  $\text{O}_2$  is too slow to permit much loss of NO before the gases are cooled still further.

As discussed in the "Chemistry Put to Work" box in Section 14.7, one of the goals of automotive catalytic converters is to achieve the rapid conversion of NO to  $\text{N}_2$  and  $\text{O}_2$  at the temperature of the exhaust gas. Some catalysts for this reaction have been developed that are reasonably effective under the grueling conditions found in automotive exhaust systems. Nevertheless, scientists and engineers are continually searching for new materials that provide even more effective catalysis of the decomposition of nitrogen oxides.

**▲ Figure 15.16 Equilibrium and temperature.** The graph shows how the equilibrium constant for the reaction  $\frac{1}{2} \text{N}_2(\text{g}) + \frac{1}{2} \text{O}_2(\text{g}) \rightleftharpoons \text{NO}(\text{g})$  varies as a function of temperature. The equilibrium constant increases with increasing temperature because the reaction is endothermic. It is necessary to use a log scale for  $K_p$  because the values vary over such a large range.

# CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Introduction and Section 15.1** A chemical reaction can achieve a state in which the forward and reverse processes are occurring at the same rate. This condition is called **chemical equilibrium**, and it results in the formation of an equilibrium mixture of the reactants and products of the reaction. The composition of an equilibrium mixture does not change with time.

**Section 15.2** An equilibrium that is used throughout this chapter is the reaction  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ . This reaction is the basis of the **Haber process** for the production of ammonia. The relationship between the concentrations of the reactants and products of a system at equilibrium is given by the **law of mass action**. For an equilibrium equation of the form  $a \text{A} + b \text{B} \rightleftharpoons d \text{D} + e \text{E}$ , the **equilibrium-constant expression** is written as

$$K_c = \frac{[\text{D}]^d[\text{E}]^e}{[\text{A}]^a[\text{B}]^b}$$

where  $K_c$  is a constant called the **equilibrium constant**. When the equilibrium system of interest consists of gases, it is often convenient to express the concentrations of reactants and products in terms of gas pressures:

$$K_p = \frac{(P_D)^d(P_E)^e}{(P_A)^a(P_B)^b}$$

$K_c$  and  $K_p$  are related by the expression  $K_p = K_c(RT)^{\Delta n}$ .

**Section 15.3** The value of the equilibrium constant changes with temperature. A large value of  $K_c$  indicates that the equilibrium mixture contains more products than reactants and therefore lies toward the product side of the equation. A small value for the equilibrium constant means that the equilibrium mixture contains less products than reactants and therefore lies toward the reactant side. The equilibrium-constant expression and the equilibrium constant of the reverse of a reaction are the reciprocals of those of the forward reaction. If a reaction is the sum of two or more reactions, its equilibrium constant will be the product of the equilibrium constants for the individual reactions.

**Section 15.4** Equilibria for which all substances are in the same phase are called **homogeneous equilibria**; in **heterogeneous equilibria** two or more phases are present. The concentrations of pure solids and liquids are left out of the equilibrium-constant expression for a heterogeneous equilibrium.

**Section 15.5** If the concentrations of all species in an equilibrium are known, the equilibrium-constant expression can be used to calculate the value of the equilibrium constant. The changes in the concentrations of reactants and products on the way to achieving equilibrium are governed by the stoichiometry of the reaction.

**Section 15.6** The **reaction quotient**,  $Q$ , is found by substituting reactant and product concentrations or partial pressures at any point during a reaction into the equilibrium-constant expression. If the system is at equilibrium,  $Q = K$ . If  $Q \neq K$ , however, the system is not at equilibrium. When  $Q < K$ , the reaction will move toward equilibrium by forming more products (the reaction moves from left to right); when  $Q > K$ , the reaction will proceed from right to left. Knowing the value of  $K$  makes it possible to calculate the equilibrium amounts of reactants and products, often by the solution of an equation in which the unknown is the change in a partial pressure or concentration.

**Section 15.7** **Le Châtelier's principle** states that if a system at equilibrium is disturbed, the equilibrium will shift to minimize the disturbing influence. By this principle, if a reactant or product is added to a system at equilibrium, the equilibrium will shift to consume the added substance. The effects of removing reactants or products and of changing the pressure or volume of a reaction can be similarly deduced. For example, if the volume of the system is reduced, the equilibrium will shift in the direction that decreased the number of gas molecules. The enthalpy change for a reaction indicates how an increase in temperature affects the equilibrium: For an endothermic reaction, an increase in temperature shifts the equilibrium to the right; for an exothermic reaction, a temperature increase shifts the equilibrium to the left. Catalysts affect the speed at which equilibrium is reached but do not affect the magnitude of  $K$ .

## KEY SKILLS

- Understand what is meant by chemical equilibrium and how it relates to reaction rates.
- Write the equilibrium-constant expression for any reaction.
- Relate  $K_c$  and  $K_p$ .
- Relate the magnitude of an equilibrium constant to the relative amounts of reactants and products present in an equilibrium mixture.
- Manipulate the equilibrium constant to reflect changes in the chemical equation.

- Write the equilibrium-constant expression for a heterogeneous reaction.
- Calculate an equilibrium constant from concentration measurements.
- Predict the direction of a reaction given the equilibrium constant and the concentrations of reactants and products.
- Calculate equilibrium concentrations given the equilibrium constant and all but one equilibrium concentration.
- Calculate equilibrium concentrations given the equilibrium constant and the starting concentrations.
- Understand how changing the concentrations, volume, or temperature of a system at equilibrium affects the equilibrium position.

## KEY EQUATIONS

$$K_c = \frac{[D]^d[E]^e}{[A]^a[B]^b} \quad [15.8]$$

The equilibrium-constant expression for a general reaction of the type  $aA + bB \rightleftharpoons dD + eE$ ; the concentrations are equilibrium concentrations only

$$K_p = \frac{(P_D)^d(P_E)^e}{(P_A)^a(P_B)^b} \quad [15.11]$$

The equilibrium-constant expression in terms of equilibrium partial pressures

$$K_p = K_c(RT)^{\Delta n} \quad [15.14]$$

Relating the equilibrium constant based on pressures to the equilibrium constant based on concentration

$$Q_c = \frac{[D]^d[E]^e}{[A]^a[B]^b} \quad [15.22]$$

The reaction quotient. The concentrations are for any time during a reaction. If the concentrations are equilibrium concentrations, then  $Q_c = K_c$ .

## VISUALIZING CONCEPTS

- 15.1** (a) Based on the following energy profile, predict whether  $k_f > k_r$  or  $k_f < k_r$ . (b) Using Equation 15.5, predict whether the equilibrium constant for the process is greater than 1 or less than 1. [Section 15.1]

- 15.2** The following diagrams represent a hypothetical reaction  $A \rightarrow B$ , with A represented by red spheres and B represented by blue spheres. The sequence from left to right represents the system as time passes. Do the diagrams indicate that the system reaches an equilibrium state? Explain. [Sections 15.1 and 15.2]

- 15.3** The following diagram represents an equilibrium mixture produced for a reaction of the type  $A + X \rightleftharpoons AX$ . If the volume is 1 L, is  $K$  greater or smaller than 1? [Section 15.2]

- 15.4** The following diagram represents a reaction shown going to completion. (a) Letting A = red spheres and B = blue spheres, write a balanced equation for the reaction. (b) Write the equilibrium-constant expression for the reaction. (c) Assuming that all of the molecules are in the gas phase, calculate  $\Delta n$ , the change in the number of gas molecules that accompanies the reaction. (d) How can you calculate  $K_p$  if you know  $K_c$  at a particular temperature? [Section 15.2]

- 15.5 Ethene ( $C_2H_4$ ) reacts with halogens ( $X_2$ ) by the following reaction:

The following figures represent the concentrations at equilibrium at the same temperature when  $X_2$  is  $Cl_2$  (green),  $Br_2$  (brown), and  $I_2$  (purple). List the equilibria from smallest to largest equilibrium constant. [Section 15.3]

(a) (b)

(c)

- 15.6 The reaction  $A_2 + B_2 \rightleftharpoons 2 AB$  has an equilibrium constant  $K_c = 1.5$ . The following diagrams represent reaction mixtures containing  $A_2$  molecules (red),  $B_2$  molecules (blue), and  $AB$  molecules (red and blue). (a) Which reaction mixture is at equilibrium? (b) For those mixtures that are not at equilibrium, how will the reaction proceed to reach equilibrium? [Sections 15.5 and 15.6]

(i) (ii) (iii)

- 15.7 The reaction  $A_2(g) + B(g) \rightleftharpoons A(g) + AB(g)$  has an equilibrium constant of  $K_p = 2$ . The accompanying diagram shows a mixture containing  $A$  atoms (red),  $A_2$  molecules, and  $AB$  molecules (red and blue). How many  $B$  atoms should be added to the diagram to illustrate an equilibrium mixture? [Section 15.6]

- 15.8 The following diagram represents the equilibrium state for the reaction  $A_2(g) + 2 B(g) \rightleftharpoons 2 AB(g)$ . (a) Assuming the volume is 1 L, calculate the equilibrium constant,  $K_c$ , for the reaction. (b) If the volume of the equilibrium mixture is decreased, will the number of  $AB$  molecules increase or decrease? [Sections 15.5 and 15.7]

- 15.9 The following diagrams represent equilibrium mixtures for the reaction  $A_2 + B \rightleftharpoons A + AB$  at (1) 300 K and (2) 500 K. The  $A$  atoms are red, and the  $B$  atoms are blue. Is the reaction exothermic or endothermic? [Section 15.7]

(a) (b)

- 15.10 The following graph represents the yield of the compound  $AB$  at equilibrium in the reaction  $A(g) + B(g) \rightarrow AB(g)$ .

- (a) Is this reaction exothermic or endothermic? (b) Is  $P = x$  greater or smaller than  $P = y$ ? [Section 15.7]

## EXERCISES

## Equilibrium; The Equilibrium Constant

**15.11** Suppose that the gas-phase reactions  $A \longrightarrow B$  and  $B \longrightarrow A$  are both elementary processes with rate constants of  $3.8 \times 10^{-2} \text{ s}^{-1}$  and  $3.1 \times 10^{-1} \text{ s}^{-1}$ , respectively. (a) What is the value of the equilibrium constant for the equilibrium  $A(g) \rightleftharpoons B(g)$ ? (b) Which is greater at equilibrium, the partial pressure of A or the partial pressure of B? Explain.

**15.12** Consider the reaction  $A + B \rightleftharpoons C + D$ . Assume that both the forward reaction and the reverse reaction are elementary processes and that the value of the equilibrium constant is very large. (a) Which species predominate at equilibrium, reactants or products? (b) Which reaction has the larger rate constant, the forward or the reverse? Explain.

**15.13** Write the expression for  $K_c$  for the following reactions. In each case indicate whether the reaction is homogeneous or heterogeneous.

- (a)  $3 \text{NO}(g) \rightleftharpoons \text{N}_2\text{O}(g) + \text{NO}_2(g)$   
 (b)  $\text{CH}_4(g) + 2 \text{H}_2\text{S}(g) \rightleftharpoons \text{CS}_2(g) + 4 \text{H}_2(g)$   
 (c)  $\text{Ni}(\text{CO})_4(g) \rightleftharpoons \text{Ni}(s) + 4 \text{CO}(g)$   
 (d)  $\text{HF}(aq) \rightleftharpoons \text{H}^+(aq) + \text{F}^-(aq)$   
 (e)  $2 \text{Ag}(s) + \text{Zn}^{2+}(aq) \rightleftharpoons 2 \text{Ag}^+(aq) + \text{Zn}(s)$

**15.14** Write the expressions for  $K_c$  for the following reactions. In each case indicate whether the reaction is homogeneous or heterogeneous.

- (a)  $2 \text{O}_3(g) \rightleftharpoons 3 \text{O}_2(g)$   
 (b)  $\text{Ti}(s) + 2 \text{Cl}_2(g) \rightleftharpoons \text{TiCl}_4(l)$   
 (c)  $2 \text{C}_2\text{H}_4(g) + 2 \text{H}_2\text{O}(g) \rightleftharpoons 2 \text{C}_2\text{H}_6(g) + \text{O}_2(g)$   
 (d)  $\text{C}(s) + 2 \text{H}_2(g) \rightleftharpoons \text{CH}_4(g)$   
 (e)  $4 \text{HCl}(aq) + \text{O}_2(g) \rightleftharpoons 2 \text{H}_2\text{O}(l) + 2 \text{Cl}_2(g)$

**15.15** When the following reactions come to equilibrium, does the equilibrium mixture contain mostly reactants or mostly products?

- (a)  $\text{N}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{NO}(g)$ ;  $K_c = 1.5 \times 10^{-10}$   
 (b)  $2 \text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{SO}_3(g)$ ;  $K_p = 2.5 \times 10^9$

**15.16** Which of the following reactions lies to the right, favoring the formation of products, and which lies to the left, favoring formation of reactants?

- (a)  $2 \text{NO}(g) + \text{O}_2(g) \rightleftharpoons 2 \text{NO}_2(g)$ ;  $K_p = 5.0 \times 10^{12}$   
 (b)  $2 \text{HBr}(g) \rightleftharpoons \text{H}_2(g) + \text{Br}_2(g)$ ;  $K_c = 5.8 \times 10^{-18}$

**15.17** If  $K_c = 0.042$  for  $\text{PCl}_3(g) + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$  at 500 K, what is the value of  $K_p$  for this reaction at this temperature?

**15.18** Calculate  $K_c$  at 303 K for  $\text{SO}_2(g) + \text{Cl}_2(g) \rightleftharpoons \text{SO}_2\text{Cl}_2(g)$  if  $K_p = 34.5$  at this temperature.

**15.19** The equilibrium constant for the reaction

is  $K_c = 1.3 \times 10^{-2}$  at 1000 K. (a) Calculate  $K_c$  for  $2 \text{NOBr}(g) \rightleftharpoons 2 \text{NO}(g) + \text{Br}_2(g)$ . (b) At this temperature does the equilibrium favor NO and  $\text{Br}_2$ , or does it favor NOBr?

**15.20** Consider the following equilibrium:

(a) Calculate  $K_p$ . (b) Does the equilibrium mixture contain mostly  $\text{H}_2$  and  $\text{S}_2$  or mostly  $\text{H}_2\text{S}$ ?

**15.21** At 1000 K,  $K_p = 1.85$  for the reaction

(a) What is the value of  $K_p$  for the reaction  $\text{SO}_3(g) \rightleftharpoons \text{SO}_2(g) + \frac{1}{2} \text{O}_2(g)$ ? (b) What is the value of  $K_p$  for the reaction  $2 \text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{SO}_3(g)$ ? (c) What is the value of  $K_c$  for the reaction in part (b)?

**15.22** Consider the following equilibrium, for which  $K_p = 0.0752$  at 480 °C:

(a) What is the value of  $K_p$  for the reaction  $4 \text{HCl}(g) + \text{O}_2(g) \rightleftharpoons 2 \text{Cl}_2(g) + 2 \text{H}_2\text{O}(g)$ ? (b) What is the value of  $K_p$  for the reaction  $\text{Cl}_2(g) + \text{H}_2\text{O}(g) \rightleftharpoons 2 \text{HCl}(g) + \frac{1}{2} \text{O}_2(g)$ ? (c) What is the value of  $K_c$  for the reaction in part (b)?

**15.23** The following equilibria were attained at 823 K:

Based on these equilibria, calculate the equilibrium constant for  $\text{H}_2(g) + \text{CO}_2(g) \rightleftharpoons \text{CO}(g) + \text{H}_2\text{O}(g)$  at 823 K.

**15.24** Consider the equilibrium

Calculate the equilibrium constant  $K_p$  for this reaction, given the following information (at 298 K):

**15.25** Mercury(I) oxide decomposes into elemental mercury and elemental oxygen:  $2 \text{Hg}_2\text{O}(s) \rightleftharpoons 4 \text{Hg}(l) + \text{O}_2(g)$

(a) Write the equilibrium-constant expression for this reaction in terms of partial pressures. (b) Explain why we normally exclude pure solids and liquids from equilibrium-constant expressions.

**15.26** Consider the equilibrium  $\text{Na}_2\text{O}(s) + \text{SO}_2(g) \rightleftharpoons \text{Na}_2\text{SO}_3(s)$ . (a) Write the equilibrium-constant expression for this reaction in terms of partial pressures. (b) Why doesn't the concentration of  $\text{Na}_2\text{O}$  appear in the equilibrium-constant expression?

## Calculating Equilibrium Constants

**15.27** Gaseous hydrogen iodide is placed in a closed container at 425 °C, where it partially decomposes to hydrogen and iodine:  $2 \text{HI}(g) \rightleftharpoons \text{H}_2(g) + \text{I}_2(g)$ . At equilibrium it is

found that  $[\text{HI}] = 3.53 \times 10^{-3} \text{ M}$ ,  $[\text{H}_2] = 4.79 \times 10^{-4} \text{ M}$ , and  $[\text{I}_2] = 4.79 \times 10^{-4} \text{ M}$ . What is the value of  $K_c$  at this temperature?

- 15.28** Methanol ( $\text{CH}_3\text{OH}$ ) is produced commercially by the catalyzed reaction of carbon monoxide and hydrogen:  $\text{CO}(g) + 2 \text{H}_2(g) \rightleftharpoons \text{CH}_3\text{OH}(g)$ . An equilibrium mixture in a 2.00-L vessel is found to contain 0.0406 mol  $\text{CH}_3\text{OH}$ , 0.170 mol  $\text{CO}$ , and 0.302 mol  $\text{H}_2$  at 500 K. Calculate  $K_c$  at this temperature.
- 15.29** The equilibrium  $2 \text{NO}(g) + \text{Cl}_2(g) \rightleftharpoons 2 \text{NOCl}(g)$  is established at 500 K. An equilibrium mixture of the three gases has partial pressures of 0.095 atm, 0.171 atm, and 0.28 atm for  $\text{NO}$ ,  $\text{Cl}_2$ , and  $\text{NOCl}$ , respectively. Calculate  $K_p$  for this reaction at 500 K.
- 15.30** Phosphorus trichloride gas and chlorine gas react to form phosphorus pentachloride gas:  $\text{PCl}_3 + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$ . A gas vessel is charged with a mixture of  $\text{PCl}_3(g)$  and  $\text{Cl}_2(g)$ , which is allowed to equilibrate at 450 K. At equilibrium the partial pressures of the three gases are  $P_{\text{PCl}_3} = 0.124$  atm,  $P_{\text{Cl}_2} = 0.157$  atm, and  $P_{\text{PCl}_5} = 1.30$  atm. (a) What is the value of  $K_p$  at this temperature? (b) Does the equilibrium favor reactants or products?
- 15.31** A mixture of 0.10 mol of  $\text{NO}$ , 0.050 mol of  $\text{H}_2$ , and 0.10 mol of  $\text{H}_2\text{O}$  is placed in a 1.0-L vessel at 300 K. The following equilibrium is established:
- $$2 \text{NO}(g) + 2 \text{H}_2(g) \rightleftharpoons \text{N}_2(g) + 2 \text{H}_2\text{O}(g)$$
- At equilibrium  $[\text{NO}] = 0.062 \text{ M}$ . (a) Calculate the equilibrium concentrations of  $\text{H}_2$ ,  $\text{N}_2$ , and  $\text{H}_2\text{O}$ . (b) Calculate  $K_c$ .
- 15.32** A mixture of 1.374 g of  $\text{H}_2$  and 70.31 g of  $\text{Br}_2$  is heated in a 2.00-L vessel at 700 K. These substances react as follows:
- $$\text{H}_2(g) + \text{Br}_2(g) \rightleftharpoons 2 \text{HBr}(g)$$
- At equilibrium the vessel is found to contain 0.566 g of  $\text{H}_2$ . (a) Calculate the equilibrium concentrations of  $\text{H}_2$ ,  $\text{Br}_2$ , and  $\text{HBr}$ . (b) Calculate  $K_c$ .
- 15.33** A mixture of 0.2000 mol of  $\text{CO}_2$ , 0.1000 mol of  $\text{H}_2$ , and 0.1600 mol of  $\text{H}_2\text{O}$  is placed in a 2.00-L vessel. The following equilibrium is established at 500 K:
- $$\text{CO}_2(g) + \text{H}_2(g) \rightleftharpoons \text{CO}(g) + \text{H}_2\text{O}(g)$$
- (a) Calculate the initial partial pressures of  $\text{CO}_2$ ,  $\text{H}_2$ , and  $\text{H}_2\text{O}$ . (b) At equilibrium  $P_{\text{H}_2\text{O}} = 3.51$  atm. Calculate the equilibrium partial pressures of  $\text{CO}_2$ ,  $\text{H}_2$ , and  $\text{CO}$ . (c) Calculate  $K_p$  for the reaction.
- 15.34** A flask is charged with 1.500 atm of  $\text{N}_2\text{O}_4(g)$  and 1.00 atm  $\text{NO}_2(g)$  at 25 °C, and the following equilibrium is achieved:
- $$\text{N}_2\text{O}_4(g) \rightleftharpoons 2 \text{NO}_2(g)$$
- After equilibrium is reached, the partial pressure of  $\text{NO}_2$  is 0.512 atm. (a) What is the equilibrium partial pressure of  $\text{N}_2\text{O}_4$ ? (b) Calculate the value of  $K_p$  for the reaction.

## Applications of Equilibrium Constants

- 15.35** (a) How does a reaction quotient differ from an equilibrium constant? (b) If  $Q_c < K_c$ , in which direction will a reaction proceed in order to reach equilibrium? (c) What condition must be satisfied so that  $Q_c = K_c$ ?
- 15.36** (a) How is a reaction quotient used to determine whether a system is at equilibrium? (b) If  $Q_c > K_c$ , how must the reaction proceed to reach equilibrium? (c) At the start of a certain reaction, only reactants are present; no products have been formed. What is the value of  $Q_c$  at this point in the reaction?
- 15.37** At 100 °C the equilibrium constant for the reaction  $\text{COCl}_2(g) \rightleftharpoons \text{CO}(g) + \text{Cl}_2(g)$  has the value  $K_c = 2.19 \times 10^{-10}$ . Are the following mixtures of  $\text{COCl}_2$ ,  $\text{CO}$ , and  $\text{Cl}_2$  at 100 °C at equilibrium? If not, indicate the direction that the reaction must proceed to achieve equilibrium. (a)  $[\text{COCl}_2] = 2.00 \times 10^{-3} \text{ M}$ ,  $[\text{CO}] = 3.3 \times 10^{-6} \text{ M}$ ,  $[\text{Cl}_2] = 6.62 \times 10^{-6} \text{ M}$ ; (b)  $[\text{COCl}_2] = 4.50 \times 10^{-2} \text{ M}$ ,  $[\text{CO}] = 1.1 \times 10^{-7} \text{ M}$ ,  $[\text{Cl}_2] = 2.25 \times 10^{-6} \text{ M}$ ; (c)  $[\text{COCl}_2] = 0.0100 \text{ M}$ ,  $[\text{CO}] = [\text{Cl}_2] = 1.48 \times 10^{-6} \text{ M}$
- 15.38** As shown in Table 15.2,  $K_p$  for the equilibrium
- $$\text{N}_2(g) + 3 \text{H}_2(g) \rightleftharpoons 2 \text{NH}_3(g)$$
- is  $4.51 \times 10^{-5}$  at 450 °C. For each of the mixtures listed here, indicate whether the mixture is at equilibrium at 450 °C. If it is not at equilibrium, indicate the direction (toward product or toward reactants) in which the mixture must shift to achieve equilibrium.
- (a) 98 atm  $\text{NH}_3$ , 45 atm  $\text{N}_2$ , 55 atm  $\text{H}_2$   
 (b) 57 atm  $\text{NH}_3$ , 143 atm  $\text{N}_2$ , no  $\text{H}_2$   
 (c) 13 atm  $\text{NH}_3$ , 27 atm  $\text{N}_2$ , 82 atm  $\text{H}_2$
- 15.39** At 100 °C,  $K_c = 0.078$  for the reaction
- $$\text{SO}_2\text{Cl}_2(g) \rightleftharpoons \text{SO}_2(g) + \text{Cl}_2(g)$$
- In an equilibrium mixture of the three gases, the concentrations of  $\text{SO}_2\text{Cl}_2$  and  $\text{SO}_2$  are 0.108 M and 0.052 M, respectively. What is the partial pressure of  $\text{Cl}_2$  in the equilibrium mixture?
- 15.40** At 900 K the following reaction has  $K_p = 0.345$ :
- $$2 \text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{SO}_3(g)$$
- In an equilibrium mixture the partial pressures of  $\text{SO}_2$  and  $\text{O}_2$  are 0.135 atm and 0.455 atm, respectively. What is the equilibrium partial pressure of  $\text{SO}_3$  in the mixture?
- 15.41** (a) At 1285 °C the equilibrium constant for the reaction  $\text{Br}_2(g) \rightleftharpoons 2 \text{Br}(g)$  is  $K_c = 1.04 \times 10^{-3}$ . A 0.200-L vessel containing an equilibrium mixture of the gases has 0.245 g  $\text{Br}_2(g)$  in it. What is the mass of  $\text{Br}(g)$  in the vessel? (b) For the reaction  $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2 \text{HI}(g)$ ,  $K_c = 55.3$  at 700 K. In a 2.00-L flask containing an equilibrium mixture of the three gases, there are 0.056 g  $\text{H}_2$  and 4.36 g  $\text{I}_2$ . What is the mass of  $\text{HI}$  in the flask?
- 15.42** (a) At 800 K the equilibrium constant for  $\text{I}_2(g) \rightleftharpoons 2 \text{I}(g)$  is  $K_c = 3.1 \times 10^{-5}$ . If an equilibrium mixture in a 10.0-L vessel contains  $2.67 \times 10^{-2}$  g of  $\text{I}(g)$ , how many grams of  $\text{I}_2$  are in the mixture? (b) For  $2 \text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{SO}_3(g)$ ,  $K_p = 30 \times 10^4$  at 700 K. In a 2.00-L vessel the equilibrium mixture contains 1.17 g of  $\text{SO}_3$  and 0.105 g of  $\text{O}_2$ . How many grams of  $\text{SO}_2$  are in the vessel?

- 15.43 At 2000 °C the equilibrium constant for the reaction

is  $K_c = 2.4 \times 10^3$ . If the initial concentration of NO is 0.200 M, what are the equilibrium concentrations of NO,  $\text{N}_2$ , and  $\text{O}_2$ ?

- 15.44 For the equilibrium

at 400 K,  $K_c = 7.0$ . If 0.25 mol of  $\text{Br}_2$  and 0.25 mol of  $\text{Cl}_2$  are introduced into a 1.0-L container at 400 K, what will be the equilibrium concentrations of  $\text{Br}_2$ ,  $\text{Cl}_2$ , and  $\text{BrCl}$ ?

- 15.45 At 373 K,  $K_p = 0.416$  for the equilibrium

If the pressures of  $\text{NOBr}(g)$  and  $\text{NO}(g)$  are equal, what is the equilibrium pressure of  $\text{Br}_2(g)$ ?

- 15.46 At 218 °C,  $K_c = 1.2 \times 10^{-4}$  for the equilibrium

Calculate the equilibrium concentrations of  $\text{NH}_3$  and  $\text{H}_2\text{S}$  if a sample of solid  $\text{NH}_4\text{HS}$  is placed in a closed vessel and decomposes until equilibrium is reached.

- 15.47 Consider the reaction

At 25 °C the equilibrium constant is  $K_c = 2.4 \times 10^{-5}$  for this reaction. (a) If excess  $\text{CaSO}_4(s)$  is mixed with water at 25 °C to produce a saturated solution of  $\text{CaSO}_4$ , what are the equilibrium concentrations of  $\text{Ca}^{2+}$  and  $\text{SO}_4^{2-}$ ? (b) If the resulting solution has a volume of 3.0 L, what is the minimum mass of  $\text{CaSO}_4(s)$  needed to achieve equilibrium?

- 15.48 At 80 °C,  $K_c = 1.87 \times 10^{-3}$  for the reaction

(a) Calculate the equilibrium concentrations of  $\text{PH}_3$  and  $\text{BCl}_3$  if a solid sample of  $\text{PH}_3\text{BCl}_3$  is placed in a closed vessel and decomposes until equilibrium is reached. (b) If the flask has a volume of 0.500 L, what is the minimum mass of  $\text{PH}_3\text{BCl}_3(s)$  that must be added to the flask to achieve equilibrium?

- 15.49 For the reaction  $\text{I}_2 + \text{Br}_2(g) \rightleftharpoons 2 \text{IBr}(g)$ ,  $K_c = 280$  at 150 °C. Suppose that 0.500 mol  $\text{IBr}$  in a 1.00-L flask is allowed to reach equilibrium at 150 °C. What are the equilibrium concentrations of  $\text{IBr}$ ,  $\text{I}_2$ , and  $\text{Br}_2$ ?

- 15.50 At 25 °C the reaction

has an equilibrium constant  $K_c = 7.1 \times 10^{-4}$ . What are the equilibrium concentrations of  $\text{Ca}^{2+}$  and  $\text{CrO}_4^{2-}$  in a saturated solution of  $\text{CaCrO}_4$ ?

## Le Châtelier's Principle

- 15.51 Consider the following equilibrium, for which  $\Delta H < 0$

How will each of the following changes affect an equilibrium mixture of the three gases? (a)  $\text{O}_2(g)$  is added to the system; (b) the reaction mixture is heated; (c) the volume of the reaction vessel is doubled; (d) a catalyst is added to the mixture; (e) the total pressure of the system is increased by adding a noble gas; (f)  $\text{SO}_3(g)$  is removed from the system.

- 15.52 Consider  $4 \text{NH}_3(g) + 5 \text{O}_2(g) \rightleftharpoons 4 \text{NO}(g) + 6 \text{H}_2\text{O}(g)$ ,  $\Delta H = -904.4 \text{ kJ}$ . How does each of the following changes affect the yield of NO at equilibrium? Answer increase, decrease, or no change: (a) increase  $[\text{NH}_3]$ ; (b) increase  $[\text{H}_2\text{O}]$ ; (c) decrease  $[\text{O}_2]$ ; (d) decrease the volume of the container in which the reaction occurs; (e) add a catalyst; (f) increase temperature.

- 15.53 How do the following changes affect the value of the equilibrium constant for a gas-phase exothermic reaction: (a) removal of a reactant or product, (b) decrease in the volume, (c) decrease in the temperature, (d) addition of a catalyst?

- 15.54 For a certain gas-phase reaction, the fraction of products in an equilibrium mixture is increased by increasing the temperature and increasing the volume of the reaction vessel. (a) What can you conclude about the reaction from the influence of temperature on the equilibrium? (b) What can you conclude from the influence of increasing the volume?

- 15.55 Consider the following equilibrium between oxides of nitrogen

- (a) Use data in Appendix C to calculate  $\Delta H^\circ$  for this reaction. (b) Will the equilibrium constant for the reaction increase or decrease with increasing temperature? Explain. (c) At constant temperature would a change in the volume of the container affect the fraction of products in the equilibrium mixture?
- 15.56 Methanol ( $\text{CH}_3\text{OH}$ ) can be made by the reaction of CO with  $\text{H}_2$ :
- $$\text{CO}(g) + 2 \text{H}_2(g) \rightleftharpoons \text{CH}_3\text{OH}(g)$$
- (a) Use thermochemical data in Appendix C to calculate  $\Delta H^\circ$  for this reaction. (b) To maximize the equilibrium yield of methanol, would you use a high or low temperature? (c) To maximize the equilibrium yield of methanol, would you use a high or low pressure?

## ADDITIONAL EXERCISES

- 15.57 Both the forward reaction and the reverse reaction in the following equilibrium are believed to be elementary steps:

At 25 °C the rate constants for the forward and reverse reactions are  $1.4 \times 10^{-28} \text{ M}^{-1} \text{ s}^{-1}$  and  $9.3 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$ , respectively. (a) What is the value for the equilibrium constant at 25 °C? (b) Are reactants or products more plentiful at equilibrium?

- 15.58 If  $K_c = 1$  for the equilibrium  $2A(g) \rightleftharpoons B(g)$ , what is the relationship between  $[A]$  and  $[B]$  at equilibrium?
- 15.59 A mixture of  $CH_4$  and  $H_2O$  is passed over a nickel catalyst at 1000 K. The emerging gas is collected in a 5.00-L flask and is found to contain 8.62 g of CO, 2.60 g of  $H_2$ , 43.0 g of  $CH_4$ , and 48.4 g of  $H_2O$ . Assuming that equilibrium has been reached, calculate  $K_c$  and  $K_p$  for the reaction.
- 15.60 When 2.00 mol of  $SO_2Cl_2$  is placed in a 2.00-L flask at 303 K, 56% of the  $SO_2Cl_2$  decomposes to  $SO_2$  and  $Cl_2$ :
- $$SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g)$$
- Calculate  $K_c$  for this reaction at this temperature.
- 15.61 A mixture of  $H_2$ , S, and  $H_2S$  is held in a 1.0-L vessel at 90 °C until the following equilibrium is reached:
- $$H_2(g) + S(s) \rightleftharpoons H_2S(g)$$
- At equilibrium the mixture contains 0.46 g of  $H_2S$  and 0.40 g  $H_2$ . (a) Write the equilibrium-constant expression for this reaction. (b) What is the value of  $K_c$  for the reaction at this temperature? (c) Why can we ignore the amount of S when doing the calculation in part (b)?
- 15.62 A sample of nitrosyl bromide (NOBr) decomposes according to the equation
- $$2NOBr(g) \rightleftharpoons 2NO(g) + Br_2(g)$$
- An equilibrium mixture in a 5.00-L vessel at 100 °C contains 3.22 g of NOBr, 3.08 g of NO, and 4.19 g of  $Br_2$ . (a) Calculate  $K_c$ . (b) What is the total pressure exerted by the mixture of gases?
- 15.63 Consider the hypothetical reaction  $A(g) \rightleftharpoons 2B(g)$ . A flask is charged with 0.75 atm of pure A, after which it is allowed to reach equilibrium at 0 °C. At equilibrium the partial pressure of A is 0.36 atm. (a) What is the total pressure in the flask at equilibrium? (b) What is the value of  $K_p$ ?
- 15.64 As shown in Table 15.2, the equilibrium constant for the reaction  $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$  is  $K_p = 4.34 \times 10^{-3}$  at 300 °C. Pure  $NH_3$  is placed in a 1.00-L flask and allowed to reach equilibrium at this temperature. There are 1.05 g  $NH_3$  in the equilibrium mixture. (a) What are the masses of  $N_2$  and  $H_2$  in the equilibrium mixture? (b) What was the initial mass of ammonia placed in the vessel? (c) What is the total pressure in the vessel?
- 15.65 For the equilibrium
- $$2IBr(g) \rightleftharpoons I_2(g) + Br_2(g)$$
- $K_p = 8.5 \times 10^{-3}$  at 150 °C. If 0.025 atm of IBr is placed in a 2.0-L container, what is the partial pressure of this substance after equilibrium is reached?
- 15.66 For the equilibrium
- $$PH_3BCl_3(s) \rightleftharpoons PH_3(g) + BCl_3(g)$$
- $K_p = 0.052$  at 60 °C. (a) Calculate  $K_c$ . (b) Some solid  $PH_3BCl_3$  is added to a closed 0.500-L vessel at 60 °C; the vessel is then charged with 0.0128 mol of  $BCl_3(g)$ . What is the equilibrium concentration of  $PH_3$ ?
- [15.67] Solid  $NH_4HS$  is introduced into an evacuated flask at 24 °C. The following reaction takes place:
- $$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$$
- At equilibrium the total pressure (for  $NH_3$  and  $H_2S$  taken together) is 0.614 atm. What is  $K_p$  for this equilibrium at 24 °C?
- [15.68] A 0.831-g sample of  $SO_3$  is placed in a 1.00-L container and heated to 1100 K. The  $SO_3$  decomposes to  $SO_2$  and  $O_2$ .
- $$2SO_3(g) \rightleftharpoons 2SO_2(g) + O_2(g)$$
- At equilibrium the total pressure in the container is 1.300 atm. Find the values of  $K_p$  and  $K_c$  for this reaction at 1100 K.
- 15.69 Nitric oxide (NO) reacts readily with chlorine gas as follows:
- $$2NO(g) + Cl_2(g) \rightleftharpoons 2NOCl(g)$$
- At 700 K the equilibrium constant  $K_p$  for this reaction is 0.26. Predict the behavior of each of the following mixtures at this temperature: (a)  $P_{NO} = 0.15$  atm,  $P_{Cl_2} = 0.31$  atm, and  $P_{NOCl} = 0.11$  atm; (b)  $P_{NO} = 0.12$  atm,  $P_{Cl_2} = 0.10$  atm, and  $P_{NOCl} = 0.050$  atm; (c)  $P_{NO} = 0.15$  atm,  $P_{Cl_2} = 0.20$  atm, and  $P_{NOCl} = 5.10 \times 10^{-3}$  atm.
- 15.70 At 900 °C,  $K_c = 0.0108$  for the reaction
- $$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$
- A mixture of  $CaCO_3$ , CaO, and  $CO_2$  is placed in a 10.0-L vessel at 900 °C. For the following mixtures, will the amount of  $CaCO_3$  increase, decrease, or remain the same as the system approaches equilibrium? (a) 15.0 g  $CaCO_3$ , 15.0 g CaO, and 4.25 g  $CO_2$  (b) 25.0 g  $CaCO_3$ , 25.0 g CaO, and 5.66 g  $CO_2$  (c) 30.5 g  $CaCO_3$ , 25.5 g CaO, and 6.48 g  $CO_2$ .
- 15.71 When 1.50 mol  $CO_2$  and 1.50 mol  $H_2$  are placed in a 0.750-L container at 395 °C, the following equilibrium is achieved:  $CO_2(g) + H_2(g) \rightleftharpoons CO(g) + H_2O(g)$ . If  $K_c = 0.802$ , what are the concentrations of each substance in the equilibrium mixture?
- 15.72 The equilibrium constant  $K_c$  for  $C(s) + CO_2(g) \rightleftharpoons 2CO(g)$  is 1.9 at 1000 K and 0.133 at 298 K. (a) If excess C is allowed to react with 25.0 g of  $CO_2$  in a 3.00-L vessel at 1000 K, how many grams of  $CO_2$  are produced? (b) How many grams of C are consumed? (c) If a smaller vessel is used for the reaction, will the yield of CO be greater or smaller? (d) If the reaction is endothermic, how does increasing the temperature affect the equilibrium constant?
- 15.73 NiO is to be reduced to nickel metal in an industrial process by use of the reaction
- $$NiO(s) + CO(g) \rightleftharpoons Ni(s) + CO_2(g)$$
- At 1600 K the equilibrium constant for the reaction is  $K_p = 6.0 \times 10^2$ . If a CO pressure of 150 torr is to be employed in the furnace and total pressure never exceeds 760 torr, will reduction occur?
- [15.74] At 700 K the equilibrium constant for the reaction
- $$CCl_4(g) \rightleftharpoons C(s) + 2Cl_2(g)$$
- is  $K_p = 0.76$ . A flask is charged with 2.00 atm of  $CCl_4$ , which then reaches equilibrium at 700 K. (a) What fraction of the  $CCl_4$  is converted into C and  $Cl_2$ ? (b) What are the partial pressures of  $CCl_4$  and  $Cl_2$  at equilibrium?
- [15.75] The reaction  $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$  has  $K_p = 0.0870$  at 300 °C. A flask is charged with 0.50 atm  $PCl_3$ , 0.50 atm  $Cl_2$ , and 0.20 atm  $PCl_5$  at this temperature. (a) Use the reaction quotient to determine the direction the reaction must proceed to reach equilibrium. (b) Calculate the equilibrium partial pressures of the gases. (c) What effect will increasing the volume of the system have on the mole fraction of  $Cl_2$  in the equilibrium mixture? (d) The reaction is exothermic. What effect will increasing the temperature of the system have on the mole fraction of  $Cl_2$  in the equilibrium mixture?

- [15.76]** An equilibrium mixture of  $\text{H}_2$ ,  $\text{I}_2$ , and  $\text{HI}$  at  $458^\circ\text{C}$  contains  $0.112\text{ mol H}_2$ ,  $0.112\text{ mol I}_2$ , and  $0.775\text{ mol HI}$  in a  $5.00\text{-L}$  vessel. What are the equilibrium partial pressures when equilibrium is reestablished following the addition of  $0.100\text{ mol of HI}$ ?
- [15.77]** Consider the hypothetical reaction  $\text{A(g)} + 2\text{B(g)} \rightleftharpoons 2\text{C(g)}$ , for which  $K_c = 0.25$  at some temperature. A  $1.00\text{-L}$  reaction vessel is loaded with  $1.00\text{ mol}$  of compound  $\text{C}$ , which is allowed to reach equilibrium. Let the variable  $x$  represent the number of  $\text{mol/L}$  of compound  $\text{A}$  present at equilibrium. (a) In terms of  $x$ , what are the equilibrium concentrations of compounds  $\text{B}$  and  $\text{C}$ ? (b) What limits must be placed on the value of  $x$  so that all concentrations are positive? (c) By putting the equilibrium concentrations (in terms of  $x$ ) into the equilibrium-constant expression, derive an equation that can be solved for  $x$ . (d) The equation from part (c) is a cubic equation (one that has the form  $ax^3 + bx^2 + cx + d = 0$ ). In general, cubic equations cannot be solved in closed form. However, you can estimate the solution by plotting the cubic equation in the allowed range of  $x$  that you specified in part (b). The point at which the cubic

equation crosses the  $x$ -axis is the solution. (e) From the plot in part (d), estimate the equilibrium concentrations of  $\text{A}$ ,  $\text{B}$ , and  $\text{C}$ . (*Hint:* You can check the accuracy of your answer by substituting these concentrations into the equilibrium expression.)

- 15.78** At  $1200\text{ K}$ , the approximate temperature of automobile exhaust gases (Figure 15.16),  $K_p$  for the reaction

is about  $1 \times 10^{-13}$ . Assuming that the exhaust gas (total pressure  $1\text{ atm}$ ) contains  $0.2\%$   $\text{CO}$ ,  $12\%$   $\text{CO}_2$ , and  $3\%$   $\text{O}_2$  by volume, is the system at equilibrium with respect to the above reaction? Based on your conclusion, would the  $\text{CO}$  concentration in the exhaust be decreased or increased by a catalyst that speeds up the reaction above?

- 15.79** Suppose that you worked at the U.S. Patent Office and a patent application came across your desk claiming that a newly developed catalyst was much superior to the Haber catalyst for ammonia synthesis because the catalyst led to much greater equilibrium conversion of  $\text{N}_2$  and  $\text{H}_2$  into  $\text{NH}_3$  than the Haber catalyst under the same conditions. What would be your response?

## INTEGRATIVE EXERCISES

- 15.80** Consider the equilibrium  $\text{IO}_4^-(\text{aq}) + 2\text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}_4\text{IO}_6^-(\text{aq})$ ,  $K_c = 3.5 \times 10^{-2}$ . If you start with  $20.0\text{ mL}$  of a  $0.905\text{ M}$  solution of  $\text{NaIO}_4$ , and then dilute it with water to  $250.0\text{ mL}$ , what is the concentration of  $\text{H}_4\text{IO}_6^-$  at equilibrium?
- 15.81** Consider the following equilibria in aqueous solution:
- $\text{Na(s)} + \text{Ag}^+(\text{aq}) \rightleftharpoons \text{Na}^+(\text{aq}) + \text{Ag(s)}$
  - $3\text{Hg(l)} + 2\text{Al}^{3+}(\text{aq}) \rightleftharpoons 3\text{Hg}^{2+}(\text{aq}) + 2\text{Al(s)}$
  - $\text{Zn(s)} + 2\text{H}^+(\text{aq}) \rightleftharpoons \text{Zn}^{2+}(\text{aq}) + \text{H}_2(\text{g})$
- (a) For each reaction, write the equilibrium-constant expression for  $K_c$ . (b) Using information provided in Table 4.5, predict whether  $K_c$  is large ( $K_c \gg 1$ ) or small ( $K_c \ll 1$ ). Explain your reasoning. (c) At  $25^\circ\text{C}$  the reaction  $\text{Cd(s)} + \text{Fe}^{2+}(\text{aq}) \rightleftharpoons \text{Cd}^{2+}(\text{aq}) + \text{Fe(s)}$  has  $K_c = 6 \times 10^{-2}$ . If  $\text{Cd}$  were added to Table 4.5, would you expect it to be above or below iron? Explain.
- 15.82** Silver chloride,  $\text{AgCl(s)}$ , is an insoluble strong electrolyte. (a) Write the equation for the dissolution of  $\text{AgCl(s)}$  in  $\text{H}_2\text{O(l)}$  (b) Write the expression for  $K_c$  for the reaction in part (a). (c) Based on the thermochemical data in Appendix C and Le Châtelier's principle, predict whether the solubility of  $\text{AgCl}$  in  $\text{H}_2\text{O}$  increases or decreases with increasing temperature.
- 15.83** The hypothetical reaction  $\text{A} + \text{B} \rightleftharpoons \text{C}$  occurs in the forward direction in a single step. The energy profile of the reaction is shown in the drawing. (a) Is the forward or reverse reaction faster at equilibrium? (b) Would you expect the equilibrium to favor reactants or products? (c) In general, how would a catalyst affect the energy profile

shown? (d) How would a catalyst affect the ratio of the rate constants for the forward and reverse reactions? (e) How would you expect the equilibrium constant of the reaction to change with increasing temperature?

- [15.84]** Consider the equilibrium  $\text{A} \rightleftharpoons \text{B}$  in which both the forward and reverse reactions are elementary (single-step) reactions. Assume that the only effect of a catalyst on the reaction is to lower the activation energies of the forward and reverse reactions, as shown in Figure 15.15. Using the Arrhenius equation (Section 14.5), prove that the equilibrium constant is the same for the catalyzed reaction as for the uncatalyzed one.
- [15.85]** At  $25^\circ\text{C}$  the reaction

has  $K_p = 0.120$ . A  $5.00\text{-L}$  flask is charged with  $0.300\text{ g}$  of pure  $\text{H}_2\text{S(g)}$  at  $25^\circ\text{C}$ . Solid  $\text{NH}_4\text{HS}$  is then added until there is excess unreacted solid remaining. (a) What is the initial pressure of  $\text{H}_2\text{S(g)}$  in the flask? (b) Why does no reaction occur until  $\text{NH}_4\text{HS}$  is added? (c) What are the partial pressures of  $\text{NH}_3$  and  $\text{H}_2\text{S}$  at equilibrium? (d) What is the mole fraction of  $\text{H}_2\text{S}$  in the gas mixture at equilibrium? (e) What is the minimum mass, in grams, of  $\text{NH}_4\text{HS}$  that must be added to the flask to achieve equilibrium?

- [15.86] Write the equilibrium-constant expression for the equilibrium

The table included below shows the relative mole percentages of  $\text{CO}_2(g)$  and  $\text{CO}(g)$  at a total pressure of 1 atm for several temperatures. Calculate the value of  $K_p$  at each temperature. Is the reaction exothermic or endothermic? Explain.

Temperature (°C)	$\text{CO}_2$ (mol %)	$\text{CO}$ (mol %)
850	6.23	93.77
950	1.32	98.68
1050	0.37	99.63
1200	0.06	99.94

- 15.87 In Section 11.5 we defined the vapor pressure of a liquid in terms of an equilibrium. (a) Write the equation representing the equilibrium between liquid water and water vapor, and the corresponding expression for  $K_p$ . (b) By using data in Appendix B, give the value of  $K_p$  for this reaction at 30 °C. (c) What is the value of  $K_p$  for any liquid in equilibrium with its vapor at the normal boiling point of the liquid?

- [15.88] Polyvinyl chloride (PVC) is one of the most commercially important polymers (Table 12.5). PVC is made by addition polymerization of vinyl chloride ( $\text{C}_2\text{H}_3\text{Cl}$ ). Vinyl chloride is synthesized from ethylene ( $\text{C}_2\text{H}_4$ ) in a two-step process involving the following equilibria:

The product of Equilibrium 1 is 1,2-dichloroethane, a compound in which one Cl atom is bonded to each C atom. (a) Draw Lewis structures for  $\text{C}_2\text{H}_4\text{Cl}_2$  and  $\text{C}_2\text{H}_3\text{Cl}$ . What are the C—C bond orders in these two compounds? (b) Use average bond enthalpies (Table 8.4) to estimate the enthalpy changes in the two equilibria. (c) How would the yield of  $\text{C}_2\text{H}_4\text{Cl}_2$  in Equilibrium 1 vary with temperature and volume? (d) How would the yield of  $\text{C}_2\text{H}_3\text{Cl}$  in Equilibrium 2 vary with temperature and volume? (e) Look up the normal boiling points of 1,2-dichloroethane and vinyl chloride in a sourcebook, such as the *CRC Handbook of Chemistry and Physics*. Based on these data, propose a reactor design (analogous to Figure 15.12) that could be used to maximize the amount of  $\text{C}_2\text{H}_3\text{Cl}$  produced by using the two equilibria.

grapefruit, and tangerines).

## WHAT'S AHEAD

---

### 16.1 Acids and Bases: A Brief Review

We start by reviewing the *Arrhenius* definitions of acid and base.

### 16.2 Brønsted–Lowry Acids and Bases

We then learn the more general *Brønsted–Lowry* definitions for acid and base. A Brønsted–Lowry acid is a *proton donor* and a Brønsted–Lowry base is a *proton acceptor*. Two species that differ by the presence or absence of a proton are known as a *conjugate acid–base pair*.

### 16.3 The Autoionization of Water

We will see that the *autoionization* of water produces small concentrations of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  ions. The *equilibrium constant* for autoionization,  $K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$ , defines the relationship between  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  concentrations in aqueous solutions.

### 16.4 The pH Scale

We will use the pH scale ( $\text{pH} = -\log[\text{H}^+]$ ) to describe the acidity or basicity of an aqueous solution. Neutral solutions have a  $\text{pH} = 7$ , acidic solutions have  $\text{pH}$  below 7, and basic solutions have  $\text{pH}$  above 7.

### 16.5 Strong Acids and Bases

We categorize acids and bases as being either strong or weak electrolytes. *Strong* acids and bases are strong electrolytes, ionizing or dissociating completely in aqueous solution. *Weak* acids and bases are weak electrolytes and therefore ionize only partially.

### 16.6 Weak Acids

We learn that the ionization of a weak acid in water is an equilibrium process with an equilibrium constant  $K_a$  that can be used to calculate the  $\text{pH}$  of a weak acid solution.

### 16.7 Weak Bases

We learn that the ionization of a weak base in water is an equilibrium process with equilibrium constant  $K_b$  that can be used to calculate the  $\text{pH}$  of a weak base solution.

### 16.8 Relationship between $K_a$ and $K_b$

We will see that a relationship exists between the  $K_a$  and  $K_b$  of any conjugate *acid–base* pair:  $K_a \times K_b = K_w$ . Thus, the stronger an acid, the weaker its conjugate base.

### 16.9 Acid–Base Properties of Salt Solutions

We will explore the fact that the ions of a soluble ionic compound (a salt) can serve as Brønsted–Lowry acids or bases.

### 16.10 Acid–Base Behavior and Chemical Structure

We continue by exploring the relationship between chemical structure and acid–base behavior.

### 16.11 Lewis Acids and Bases

Finally, we learn the *Lewis* definitions of acid and base. A Lewis acid is an *electron-pair acceptor*, and a Lewis base is an *electron-pair donor*.

**WHAT IS THE SOUREST FOOD YOU'VE EVER TASTED?** Citrus fruit, such as the lemons shown in the chapter-opening photograph?

Sour cherries? Rhubarb? The sour taste of foods is due primarily to the presence of acids. Citric acid ( $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$ ), malic acid ( $\text{H}_2\text{C}_4\text{H}_4\text{O}_5$ ), oxalic acid ( $\text{H}_2\text{C}_2\text{O}_4$ ), and ascorbic

acid, also known as vitamin C ( $\text{HC}_6\text{H}_7\text{O}_6$ ), are present in many fruits as well as in certain vegetables, such as rhubarb and tomatoes.

Acids and bases are important in numerous chemical processes that occur around us—from industrial processes to biological ones, from reactions in the laboratory to those in our environment. The time required for a metal object immersed in water to corrode, the ability of an aquatic environment to support fish and plant life, the fate of pollutants washed out of the air by rain, and even the rates of reactions that maintain our lives all critically depend upon the acidity or basicity of solutions. Indeed, an enormous amount of chemistry can be understood in terms of acid–base reactions.

We have encountered acids and bases many times in earlier discussions. For example, a portion of Chapter 4 focused on their reactions. But what makes a substance behave as an acid or as a base? In this chapter we reexamine acids and bases, taking a closer look at how they are identified and characterized. In doing so, we will consider their behavior both in terms of their structure and bonding and in terms of the chemical equilibria in which they participate.

## 16.1 ACIDS AND BASES: A BRIEF REVIEW

From the earliest days of experimental chemistry, scientists have recognized acids and bases by their characteristic properties. Acids have a sour taste and cause certain dyes to change color (for example, litmus turns red on contact with acids). Indeed, the word *acid* comes from the Latin word *acidus*, meaning sour or tart. Bases, in contrast, have a bitter taste and feel slippery (soap is a good example). The word *base* comes from an old English meaning of the word, which is “to bring low.” (We still use the word *debase* in this sense, meaning to lower the value of something.) When bases are added to acids, they lower the amount of acid. Indeed, when acids and bases are mixed in certain proportions, their characteristic properties disappear altogether.  $\infty$  (Section 4.3)

Historically, chemists have sought to relate the properties of acids and bases to their compositions and molecular structures. By 1830 it was evident that all acids contain hydrogen but not all hydrogen-containing substances are acids. During the 1880s, the Swedish chemist Svante Arrhenius (1859–1927) linked acid behavior with the presence of  $H^+$  ions and base behavior with the presence of  $OH^-$  ions in aqueous solution.

Arrhenius defined acids as substances that produce  $H^+$  ions in water and bases as substances that produce  $OH^-$  ions in water. Indeed, the properties of aqueous solutions of acids, such as sour taste, are due to  $H^+(aq)$ , whereas the properties of aqueous solutions of bases are due to  $OH^-(aq)$ . Over time the Arrhenius concept of acids and bases came to be stated in the following way:

- An *acid* is a substance that, when dissolved in water, increases the concentration of  $H^+$  ions.
- A *base* is a substance that, when dissolved in water, increases the concentration of  $OH^-$  ions.

Hydrogen chloride is an Arrhenius acid. Hydrogen chloride gas is highly soluble in water because of its chemical reaction with water, which produces hydrated  $H^+$  and  $Cl^-$  ions:

The aqueous solution of HCl is known as hydrochloric acid. Concentrated hydrochloric acid is about 37% HCl by mass and is 12 M in HCl. Sodium hydroxide, on the other hand, is an Arrhenius base. Because NaOH is an ionic compound, it dissociates into  $Na^+$  and  $OH^-$  ions when it dissolves in water, thereby releasing  $OH^-$  ions into the solution.

### GIVE IT SOME THOUGHT

What two ions are central to the Arrhenius definitions of acids and bases?

## 16.2 BRØNSTED–LOWRY ACIDS AND BASES

The Arrhenius concept of acids and bases, while useful, has limitations. For one thing, it is restricted to aqueous solutions. In 1923 the Danish chemist Johannes Brønsted (1879–1947) and the English chemist Thomas Lowry (1874–1936) independently proposed a more general definition of acids and bases. Their concept is based on the fact that *acid–base reactions involve the transfer of  $H^+$  ions from one substance to another.*

## The H<sup>+</sup> Ion in Water

In Equation 16.1 hydrogen chloride is shown ionizing in water to form H<sup>+</sup>(aq). An H<sup>+</sup> ion is simply a proton with no surrounding valence electron. This small, positively charged particle interacts strongly with the nonbonding electron pairs of water molecules to form hydrated hydrogen ions. For example, the interaction of a proton with one water molecule forms the **hydronium ion**, H<sub>3</sub>O<sup>+</sup>(aq):

The formation of hydronium ions is one of the complex features of the interaction of the H<sup>+</sup> ion with liquid water. In fact, the H<sub>3</sub>O<sup>+</sup> ion can form hydrogen bonds to additional H<sub>2</sub>O molecules to generate larger clusters of hydrated hydrogen ions, such as H<sub>5</sub>O<sub>2</sub><sup>+</sup> and H<sub>9</sub>O<sub>4</sub><sup>+</sup> (Figure 16.1).

Chemists use H<sup>+</sup>(aq) and H<sub>3</sub>O<sup>+</sup>(aq) interchangeably to represent the same thing—namely the hydrated proton that is responsible for the characteristic properties of aqueous solutions of acids. We often use the H<sup>+</sup>(aq) ion for simplicity and convenience, as we did in Equation 16.1. The H<sub>3</sub>O<sup>+</sup>(aq) ion, however, more closely represents reality.

## Proton-Transfer Reactions

When we closely examine the reaction that occurs when HCl dissolves in water, we find that the HCl molecule actually transfers an H<sup>+</sup> ion (a proton) to a water molecule as depicted in Figure 16.2. Thus, we can represent the reaction as occurring between an HCl molecule and a water molecule to form hydronium and chloride ions:

The polar H<sub>2</sub>O molecule promotes the ionization of acids in water solution by accepting a proton to form H<sub>3</sub>O<sup>+</sup>.

Brønsted and Lowry proposed definitions of acids and bases in terms of their ability to transfer protons:

- An *acid* is a substance (molecule or ion) that donates a proton to another substance.
- A *base* is a substance that accepts a proton.

Thus, when HCl dissolves in water (Equation 16.3), HCl acts as a **Brønsted–Lowry acid** (it donates a proton to H<sub>2</sub>O), and H<sub>2</sub>O acts as a **Brønsted–Lowry base** (it accepts a proton from HCl).

Because the emphasis in the Brønsted–Lowry concept is on proton transfer, the concept also applies to reactions that do not occur in aqueous solution. In the reaction between HCl and NH<sub>3</sub>, for example, a proton is transferred from the acid HCl to the base NH<sub>3</sub>:

This reaction can occur in the gas phase. The hazy film that forms on the windows of general chemistry laboratories and on glassware in the lab is largely solid NH<sub>4</sub>Cl formed by the gas-phase reaction of HCl and NH<sub>3</sub> (Figure 16.3).

▲ **Figure 16.1** Hydrated hydronium ions. Lewis structures and molecular models for H<sub>3</sub>O<sub>2</sub><sup>+</sup> and H<sub>9</sub>O<sub>4</sub><sup>+</sup>. There is good experimental evidence for the existence of both these species.

▲ **Figure 16.2** A proton-transfer reaction. When a proton is transferred from HCl to H<sub>2</sub>O, HCl acts as the Brønsted–Lowry acid and H<sub>2</sub>O acts as the Brønsted–Lowry base.

▲ **Figure 16.3** A gas-phase acid–base reaction. The  $\text{HCl}(g)$  escaping from concentrated hydrochloric acid and the  $\text{NH}_3(g)$  escaping from aqueous ammonia (here labeled ammonium hydroxide) combine to form a white fog of  $\text{NH}_4\text{Cl}(s)$ .

Let's consider another example that compares the relationship between the Arrhenius definitions and the Brønsted–Lowry definitions of acids and bases— an aqueous solution of ammonia, in which the following equilibrium occurs:

Ammonia is an Arrhenius base because adding it to water leads to an increase in the concentration of  $\text{OH}^-(aq)$ . It is a Brønsted–Lowry base because it accepts a proton from  $\text{H}_2\text{O}$ . The  $\text{H}_2\text{O}$  molecule in Equation 16.5 acts as a Brønsted–Lowry acid because it donates a proton to the  $\text{NH}_3$  molecule.

An acid and a base always work together to transfer a proton. In other words, a substance can function as an acid only if another substance simultaneously behaves as a base. To be a Brønsted–Lowry acid, a molecule or ion must have a hydrogen atom that it can lose as an  $\text{H}^+$  ion. To be a Brønsted–Lowry base, a molecule or ion must have a nonbonding pair of electrons that it can use to bind the  $\text{H}^+$  ion.

Some substances can act as an acid in one reaction and as a base in another. For example,  $\text{H}_2\text{O}$  is a Brønsted–Lowry base in its reaction with  $\text{HCl}$  (Equation 16.3) and a Brønsted–Lowry acid in its reaction with  $\text{NH}_3$  (Equation 16.5). A substance that is capable of acting as either an acid or a base is called **amphiprotic**. An amphiprotic substance acts as a base when combined with something more strongly acidic than itself and as an acid when combined with something more strongly basic than itself.

### GIVE IT SOME THOUGHT

In the forward reaction, which substance acts as the Brønsted–Lowry base:

## Conjugate Acid–Base Pairs

In any acid–base equilibrium both the forward reaction (to the right) and the reverse reaction (to the left) involve proton transfers. For example, consider the reaction of an acid, which we will denote  $\text{HX}$ , with water:

In the forward reaction  $\text{HX}$  donates a proton to  $\text{H}_2\text{O}$ . Therefore,  $\text{HX}$  is the Brønsted–Lowry acid, and  $\text{H}_2\text{O}$  is the Brønsted–Lowry base. In the reverse reaction the  $\text{H}_3\text{O}^+$  ion donates a proton to the  $\text{X}^-$  ion, so  $\text{H}_3\text{O}^+$  is the acid and  $\text{X}^-$  is the base. When the acid  $\text{HX}$  donates a proton, it leaves behind a substance,  $\text{X}^-$ , which can act as a base. Likewise, when  $\text{H}_2\text{O}$  acts as a base, it generates  $\text{H}_3\text{O}^+$ , which can act as an acid.

An acid and a base such as  $\text{HX}$  and  $\text{X}^-$  that differ only in the presence or absence of a proton are called a **conjugate acid–base pair**.<sup>\*</sup> Every acid has a **conjugate base**, formed by removing a proton from the acid. For example,  $\text{OH}^-$  is the conjugate base of  $\text{H}_2\text{O}$ , and  $\text{X}^-$  is the conjugate base of  $\text{HX}$ . Similarly, every base has associated with it a **conjugate acid**, formed by adding a proton to the base. Thus,  $\text{H}_3\text{O}^+$  is the conjugate acid of  $\text{H}_2\text{O}$ , and  $\text{HX}$  is the conjugate acid of  $\text{X}^-$ .

In any acid–base (proton-transfer) reaction we can identify two sets of conjugate acid–base pairs. For example, consider the reaction between nitrous acid ( $\text{HNO}_2$ ) and water:

<sup>\*</sup>The word conjugate means “joined together as a pair.”

Likewise, for the reaction between  $\text{NH}_3$  and  $\text{H}_2\text{O}$  (Equation 16.5), we have

### SAMPLE EXERCISE 16.1 | Identifying Conjugate Acids and Bases

(a) What is the conjugate base of each of the following acids:  $\text{HClO}_4$ ,  $\text{H}_2\text{S}$ ,  $\text{PH}_4^+$ ,  $\text{HCO}_3^-$ ? (b) What is the conjugate acid of each of the following bases:  $\text{CN}^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{H}_2\text{O}$ ,  $\text{HCO}_3^-$ ?

#### SOLUTION

**Analyze:** We are asked to give the conjugate base for each of a series of species and to give the conjugate acid for each of another series of species.

**Plan:** The conjugate base of a substance is simply the parent substance minus one proton, and the conjugate acid of a substance is the parent substance plus one proton.

**Solve:** (a)  $\text{HClO}_4$  less one proton ( $\text{H}^+$ ) is  $\text{ClO}_4^-$ . The other conjugate bases are  $\text{HS}^-$ ,  $\text{PH}_3$ , and  $\text{CO}_3^{2-}$ . (b)  $\text{CN}^-$  plus one proton ( $\text{H}^+$ ) is  $\text{HCN}$ . The other conjugate acids are  $\text{HSO}_4^-$ ,  $\text{H}_3\text{O}^+$ , and  $\text{H}_2\text{CO}_3$ .

Notice that the hydrogen carbonate ion ( $\text{HCO}_3^-$ ) is amphiprotic. It can act as either an acid or a base.

#### PRACTICE EXERCISE

Write the formula for the conjugate acid of each of the following:  $\text{HSO}_3^-$ ,  $\text{F}^-$ ,  $\text{PO}_4^{3-}$ ,  $\text{CO}$ .

**Answers:**  $\text{H}_2\text{SO}_3$ ,  $\text{HF}$ ,  $\text{HPO}_4^{2-}$ ,  $\text{HCO}^+$

### SAMPLE EXERCISE 16.2 | Writing Equations for Proton-Transfer Reactions

The hydrogen sulfite ion ( $\text{HSO}_3^-$ ) is amphiprotic. (a) Write an equation for the reaction of  $\text{HSO}_3^-$  with water, in which the ion acts as an acid. (b) Write an equation for the reaction of  $\text{HSO}_3^-$  with water, in which the ion acts as a base. In both cases identify the conjugate acid–base pairs.

#### SOLUTION

**Analyze and Plan:** We are asked to write two equations representing reactions between  $\text{HSO}_3^-$  and water, one in which  $\text{HSO}_3^-$  should donate a proton to water, thereby acting as a Brønsted–Lowry acid, and one in which  $\text{HSO}_3^-$  should accept a proton from water, thereby acting as a base. We are also asked to identify the conjugate pairs in each equation.

#### Solve:

The conjugate pairs in this equation are  $\text{HSO}_3^-$  (acid) and  $\text{SO}_3^{2-}$  (conjugate base); and  $\text{H}_2\text{O}$  (base) and  $\text{H}_3\text{O}^+$  (conjugate acid).

The conjugate pairs in this equation are  $\text{H}_2\text{O}$  (acid) and  $\text{OH}^-$  (conjugate base), and  $\text{HSO}_3^-$  (base) and  $\text{H}_2\text{SO}_3$  (conjugate acid).

#### PRACTICE EXERCISE

When lithium oxide ( $\text{Li}_2\text{O}$ ) is dissolved in water, the solution turns basic from the reaction of the oxide ion ( $\text{O}^{2-}$ ) with water. Write the reaction that occurs, and identify the conjugate acid–base pairs.

**Answer:**  $\text{O}^{2-}(aq) + \text{H}_2\text{O}(l) \longrightarrow \text{OH}^-(aq) + \text{OH}^-(aq)$ .  $\text{OH}^-$  is the conjugate acid of the base  $\text{O}^{2-}$ .  $\text{OH}^-$  is also the conjugate base of the acid  $\text{H}_2\text{O}$ .

## Relative Strengths of Acids and Bases

Some acids are better proton donors than others; likewise, some bases are better proton acceptors than others. If we arrange acids in order of their ability to donate a proton, we find that the more easily a substance gives up a proton, the less easily its conjugate base accepts a proton. Similarly, the more easily a base accepts a proton, the less easily its conjugate acid gives up a proton. In other words, *the stronger an acid, the weaker is its conjugate base; the stronger a base, the weaker is its conjugate acid*. Thus, if we know something about the strength of an acid (its ability to donate protons), we also know something about the strength of its conjugate base (its ability to accept protons).

The inverse relationship between the strengths of acids and the strengths of their conjugate bases is illustrated in Figure 16.4. Here we have grouped acids and bases into three broad categories based on their behavior in water.

1. A *strong acid* completely transfers its protons to water, leaving no undissociated molecules in solution.  $\rightleftharpoons$  (Section 4.3) Its conjugate base has a negligible tendency to be protonated (to abstract protons) in aqueous solution.
2. A *weak acid* only partially dissociates in aqueous solution and therefore exists in the solution as a mixture of acid molecules and their constituent ions. The conjugate base of a weak acid shows a slight ability to remove protons from water. (*The conjugate base of a weak acid is a weak base.*)
3. A substance with *negligible acidity*, such as  $\text{CH}_4$ , contains hydrogen but does not demonstrate any acidic behavior in water. Its conjugate base is a strong base, reacting completely with water, abstracting protons to form  $\text{OH}^-$  ions.

		ACID	BASE			
100% ionized in $\text{H}_2\text{O}$	Strong	HCl	$\text{Cl}^-$	Negligible	Base strength increases	
		$\text{H}_2\text{SO}_4$	$\text{HSO}_4^-$			
		$\text{HNO}_3$	$\text{NO}_3^-$			
	Weak	$\text{H}_3\text{O}^+(aq)$	$\text{H}_2\text{O}$			Weak
		$\text{HSO}_4^-$	$\text{SO}_4^{2-}$			
		$\text{H}_3\text{PO}_4$	$\text{H}_2\text{PO}_4^-$			
		HF	$\text{F}^-$			
		$\text{CH}_3\text{COOH}$	$\text{CH}_3\text{COO}^-$			
		$\text{H}_2\text{CO}_3$	$\text{HCO}_3^-$			
		$\text{H}_2\text{S}$	$\text{HS}^-$			
		$\text{H}_2\text{PO}_4^-$	$\text{HPO}_4^{2-}$			
		$\text{NH}_4^+$	$\text{NH}_3$			
		$\text{HCO}_3^-$	$\text{CO}_3^{2-}$			
		$\text{HPO}_4^{2-}$	$\text{PO}_4^{3-}$			
		Negligible	$\text{H}_2\text{O}$			
$\text{OH}^-$	$\text{O}^{2-}$					
$\text{H}_2$	$\text{H}^-$					
		$\text{CH}_4$	$\text{CH}_3^-$		100% protonated in $\text{H}_2\text{O}$	

Acid strength increases (upward arrow on left)  
Base strength increases (downward arrow on right)

▲ **Figure 16.4** Relative strengths of some conjugate acid–base pairs. The two members of each pair are listed opposite each other in the two columns. The acids decrease in strength from top to bottom, whereas their conjugate bases increase in strength from top to bottom.

## GIVE IT SOME THOUGHT

Using the three categories above, specify the strength of  $\text{HNO}_3$  and the strength of its conjugate base,  $\text{NO}_3^-$ .

We can think of proton-transfer reactions as being governed by the relative abilities of two bases to abstract protons. For example, consider the proton transfer that occurs when an acid  $\text{HX}$  dissolves in water:

If  $\text{H}_2\text{O}$  (the base in the forward reaction) is a stronger base than  $\text{X}^-$  (the conjugate base of  $\text{HX}$ ), then  $\text{H}_2\text{O}$  will abstract the proton from  $\text{HX}$  to produce  $\text{H}_3\text{O}^+$  and  $\text{X}^-$ . As a result, the equilibrium will lie to the right. This describes the behavior of a strong acid in water. For example, when  $\text{HCl}$  dissolves in water, the solution consists almost entirely of  $\text{H}_3\text{O}^+$  and  $\text{Cl}^-$  ions with a negligible concentration of  $\text{HCl}$  molecules.

$\text{H}_2\text{O}$  is a stronger base than  $\text{Cl}^-$  (Figure 16.4), so  $\text{H}_2\text{O}$  acquires the proton to become the hydronium ion.

When  $X^-$  is a stronger base than  $H_2O$ , the equilibrium will lie to the left. This situation occurs when  $HX$  is a weak acid. For example, an aqueous solution of acetic acid ( $CH_3COOH$ ) consists mainly of  $CH_3COOH$  molecules with only a relatively few  $H_3O^+$  and  $CH_3COO^-$  ions.

$CH_3COO^-$  is a stronger base than  $H_2O$  (Figure 16.4) and therefore abstracts the proton from  $H_3O^+$ .

From these examples, we conclude that *in every acid–base reaction the position of the equilibrium favors transfer of the proton from the stronger acid to the stronger base to form the weaker acid and the weaker base*. As a result, the equilibrium mixture contains more of the weaker acid and weaker base and less of the stronger acid and stronger base.

### SAMPLE EXERCISE 16.3 Predicting the Position of a Proton-Transfer Equilibrium

For the following proton-transfer reaction, use Figure 16.4 to predict whether the equilibrium lies predominantly to the left (that is,  $K_c < 1$ ) or to the right ( $K_c > 1$ ):

#### SOLUTION

**Analyze:** We are asked to predict whether the equilibrium shown lies to the right, favoring products, or to the left, favoring reactants.

**Plan:** This is a proton-transfer reaction, and the position of the equilibrium will favor the proton going to the stronger of two bases. The two bases in the equation are  $CO_3^{2-}$ , the base in the forward reaction as written, and  $SO_4^{2-}$ , the conjugate base of  $HSO_4^-$ . We can find the relative positions of these two bases in Figure 16.4 to determine which is the stronger base.

**Solve:**  $CO_3^{2-}$  appears lower in the right-hand column in Figure 16.4 and is therefore a stronger base than  $SO_4^{2-}$ .  $CO_3^{2-}$ , therefore, will get the proton preferentially to become  $HCO_3^-$ , while  $SO_4^{2-}$  will remain mostly unprotonated. The resulting equilibrium will lie to the right, favoring products (that is,  $K_c > 1$ ).

**Comment:** Of the two acids in the equation,  $HSO_4^-$  and  $HCO_3^-$ , the stronger one gives up a proton more readily while the weaker one tends to retain its proton. Thus, the equilibrium favors the direction in which the proton moves from the stronger acid and becomes bonded to the stronger base.

### PRACTICE EXERCISE

For each of the following reactions, use Figure 16.4 to predict whether the equilibrium lies predominantly to the left or to the right:

**Answers:** (a) left, (b) right

## 16.3 THE AUTOIONIZATION OF WATER

One of the most important chemical properties of water is its ability to act as either a Brønsted acid or a Brønsted base, depending on the circumstances. In the presence of an acid, water acts as a proton acceptor; in the presence of a base, water acts as a proton donor. In fact, one water molecule can donate a proton to another water molecule:

We call this process the **autoionization** of water. No individual molecule remains ionized for long; the reactions are extremely rapid in both directions.

At room temperature only about two out of every  $10^9$  molecules are ionized at any given instant. Thus, pure water consists almost entirely of  $\text{H}_2\text{O}$  molecules and is an extremely poor conductor of electricity. Nevertheless, the autoionization of water is very important, as we will soon see.

### The Ion Product of Water

Because the autoionization of water (Equation 16.12) is an equilibrium process, we can write the following equilibrium-constant expression for it:

$$K_c = [\text{H}_3\text{O}^+][\text{OH}^-] \quad [16.13]$$

The term  $[\text{H}_2\text{O}]$  is excluded from the equilibrium-constant expression because we exclude the concentrations of pure solids and liquids.  $\infty$  (Section 15.4) Because this equilibrium-constant expression refers specifically to the autoionization of water, we use the symbol  $K_w$  to denote the equilibrium constant, which we call the **ion-product constant** for water. At  $25^\circ\text{C}$ ,  $K_w$  equals  $1.0 \times 10^{-14}$ . Thus, we have

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \quad (\text{at } 25^\circ\text{C}) \quad [16.14]$$

Because we use  $\text{H}^+(\text{aq})$  and  $\text{H}_3\text{O}^+(\text{aq})$  interchangeably to represent the hydrated proton, the autoionization reaction for water can also be written as

Likewise, the expression for  $K_w$  can be written in terms of either  $\text{H}_3\text{O}^+$  or  $\text{H}^+$ , and  $K_w$  has the same value in either case:

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14} \quad (\text{at } 25^\circ\text{C}) \quad [16.16]$$

This equilibrium-constant expression and the value of  $K_w$  at  $25^\circ\text{C}$  are extremely important, and you should commit them to memory.

What makes Equation 16.16 particularly useful is that it is applicable to pure water and to any aqueous solution. Although the equilibrium between  $\text{H}^+(\text{aq})$  and  $\text{OH}^-(\text{aq})$  as well as other ionic equilibria are affected somewhat by the presence of additional ions in solution, it is customary to ignore these ionic effects except in work requiring exceptional accuracy. Thus, Equation 16.16 is taken to be valid for any dilute aqueous solution, and it can be used to calculate either  $[\text{H}^+]$  (if  $[\text{OH}^-]$  is known) or  $[\text{OH}^-]$  (if  $[\text{H}^+]$  is known).

A solution in which  $[\text{H}^+] = [\text{OH}^-]$  is said to be *neutral*. In most solutions  $\text{H}^+$  and  $\text{OH}^-$  concentrations are not equal. As the concentration of one of these ions increases, the concentration of the other must decrease, so that the product of their concentrations equals  $1.0 \times 10^{-14}$ . In acidic solutions  $[\text{H}^+]$  exceeds  $[\text{OH}^-]$ . In basic solutions  $[\text{OH}^-]$  exceeds  $[\text{H}^+]$ .

#### SAMPLE EXERCISE 16.4 | Calculating $[\text{H}^+]$ for Pure Water

Calculate the values of  $[\text{H}^+]$  and  $[\text{OH}^-]$  in a neutral solution at  $25^\circ\text{C}$ .

#### SOLUTION

**Analyze:** We are asked to determine the concentrations of  $\text{H}^+$  and  $\text{OH}^-$  ions in a neutral solution at  $25^\circ\text{C}$ .

**Plan:** We will use Equation 16.16 and the fact that, by definition,  $[\text{H}^+] = [\text{OH}^-]$  in a neutral solution.

**Solve:** We will represent the concentration of  $[\text{H}^+]$  and  $[\text{OH}^-]$  in neutral solution with  $x$ . This gives

$$\begin{aligned} [\text{H}^+][\text{OH}^-] &= (x)(x) = 1.0 \times 10^{-14} \\ x^2 &= 1.0 \times 10^{-14} \\ x &= 1.0 \times 10^{-7} \text{ M} = [\text{H}^+] = [\text{OH}^-] \end{aligned}$$

In an acid solution  $[\text{H}^+]$  is greater than  $1.0 \times 10^{-7} \text{ M}$ ; in a basic solution  $[\text{H}^+]$  is less than  $1.0 \times 10^{-7} \text{ M}$ .

**PRACTICE EXERCISE**

Indicate whether solutions with each of the following ion concentrations are neutral, acidic, or basic: (a)  $[H^+] = 4 \times 10^{-9} M$ ; (b)  $[OH^-] = 1 \times 10^{-7} M$ ; (c)  $[OH^-] = 7 \times 10^{-13} M$ .

**Answers:** (a) basic, (b) neutral, (c) acidic

**SAMPLE EXERCISE 16.5** | Calculating  $[H^+]$  from  $[OH^-]$ 

Calculate the concentration of  $H^+(aq)$  in (a) a solution in which  $[OH^-]$  is 0.010 M, (b) a solution in which  $[OH^-]$  is  $1.8 \times 10^{-9} M$ .  
*Note:* In this problem and all that follow, we assume, unless stated otherwise, that the temperature is 25 °C.

**SOLUTION**

**Analyze:** We are asked to calculate the hydronium ion concentration in an aqueous solution where the hydroxide concentration is known.

**Plan:** We can use the equilibrium-constant expression for the autoionization of water and the value of  $K_w$  to solve for each unknown concentration.

**Solve:**

(a) Using Equation 16.16, we have:  $[H^+][OH^-] = 1.0 \times 10^{-14}$

$$[H^+] = \frac{(1.0 \times 10^{-14})}{[OH^-]} = \frac{1.0 \times 10^{-14}}{0.010} = 1.0 \times 10^{-12} M$$

This solution is basic because

$$[OH^-] > [H^+]$$

(b) In this instance

$$[H^+] = \frac{(1.0 \times 10^{-14})}{[OH^-]} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-9}} = 5.6 \times 10^{-6} M$$

This solution is acidic because

$$[H^+] > [OH^-]$$

**PRACTICE EXERCISE**

Calculate the concentration of  $OH^-(aq)$  in a solution in which (a)  $[H^+] = 2 \times 10^{-6} M$ ; (b)  $[H^+] = [OH^-]$ ; (c)  $[H^+] = 100 \times [OH^-]$ .  
**Answers:** (a)  $5 \times 10^{-9} M$ , (b)  $1.0 \times 10^{-7} M$ , (c)  $1.0 \times 10^{-8} M$

## 16.4 THE pH SCALE

The molar concentration of  $H^+(aq)$  in an aqueous solution is usually very small. For convenience, we therefore usually express  $[H^+]$  in terms of **pH**, which is the negative logarithm in base 10 of  $[H^+]$ .\*

$$pH = -\log[H^+] \quad [16.17]$$

If you need to review the use of logs, see Appendix A.

We can use Equation 16.17 to calculate the pH of a neutral solution at 25 °C (that is, one in which  $[H^+] = 1.0 \times 10^{-7} M$ ):

$$pH = -\log(1.0 \times 10^{-7}) = -(-7.00) = 7.00$$

The pH of a neutral solution is 7.00 at 25 °C. Notice that the pH is reported with two decimal places. We do so because only the numbers to the right of the decimal point are the significant figures in a logarithm. Because our original value for the concentration ( $1.0 \times 10^{-7} M$ ) has two significant figures, the corresponding pH has two decimal places (7.00).

What happens to the pH of a solution as we make the solution acidic? An acidic solution is one in which  $[H^+] > 1.0 \times 10^{-7} M$ . Because of the negative sign in Equation 16.17, the pH decreases as  $[H^+]$  increases. For example, the pH of an acidic solution in which  $[H^+] = 1.0 \times 10^{-3} M$  is

$$pH = -\log(1.0 \times 10^{-3}) = -(-3.00) = 3.00$$

At 25 °C the pH of an acidic solution is less than 7.00.

\*Because  $[H^+]$  and  $[H_3O^+]$  are used interchangeably, you might see pH defined as  $-\log[H_3O^+]$ .

**TABLE 16.1** Relationships among  $[H^+]$ ,  $[OH^-]$ , and pH at 25 °C

Solution Type	$[H^+]$ (M)	$[OH^-]$ (M)	pH Value
Acidic	$>1.0 \times 10^{-7}$	$<1.0 \times 10^{-7}$	$<7.00$
Neutral	$=1.0 \times 10^{-7}$	$=1.0 \times 10^{-7}$	$=7.00$
Basic	$<1.0 \times 10^{-7}$	$>1.0 \times 10^{-7}$	$>7.00$

We can also calculate the pH of a basic solution, one in which  $[OH^-] > 1.0 \times 10^{-7}$  M. Suppose  $[OH^-] = 2.0 \times 10^{-3}$  M. We can use Equation 16.16 to calculate  $[H^+]$  for this solution, and Equation 16.17 to calculate the pH:

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{2.0 \times 10^{-3}} = 5.0 \times 10^{-12} \text{ M}$$

$$\text{pH} = -\log(5.0 \times 10^{-12}) = 11.30$$

At 25 °C the pH of a basic solution is greater than 7.00. The relationships among  $[H^+]$ ,  $[OH^-]$ , and pH are summarized in Table 16.1 and in Figure 16.5.

The pH values characteristic of several familiar solutions are shown in Figure 16.5. Notice that a change in  $[H^+]$  by a factor of 10 causes the pH to change by 1. Thus, a solution of pH 6 has 10 times the concentration of  $H^+(aq)$  as a solution of pH 7.

### GIVE IT SOME THOUGHT

(a) What is the significance of pH = 7? (b) How does the pH change as  $OH^-$  is added to the solution?

You might think that when  $[H^+]$  is very small, as it is for some of the examples shown in Figure 16.5, it would be unimportant. Nothing is further from the truth. If  $[H^+]$  is part of a kinetic rate law, then changing its concentration will

► **Figure 16.5**  $H^+$  concentrations and pH values of some common substances at 25 °C. The pH of a solution can be estimated using the benchmark concentrations of  $H^+$  and  $OH^-$  corresponding to whole-number pH values.

	$[H^+]$ (M)	pH	pOH	$[OH^-]$ (M)
	$1 (1 \times 10^{-0})$	0.0	14.0	$1 \times 10^{-14}$
	$1 \times 10^{-1}$	1.0	13.0	$1 \times 10^{-13}$
Gastric juice	$1 \times 10^{-2}$	2.0	12.0	$1 \times 10^{-12}$
Lemon juice	$1 \times 10^{-3}$	3.0	11.0	$1 \times 10^{-11}$
Cola, vinegar	$1 \times 10^{-4}$	4.0	10.0	$1 \times 10^{-10}$
Wine	$1 \times 10^{-5}$	5.0	9.0	$1 \times 10^{-9}$
Tomatoes	$1 \times 10^{-6}$	6.0	8.0	$1 \times 10^{-8}$
Banana	$1 \times 10^{-7}$	7.0	7.0	$1 \times 10^{-7}$
Black coffee	$1 \times 10^{-8}$	8.0	6.0	$1 \times 10^{-6}$
Rain	$1 \times 10^{-9}$	9.0	5.0	$1 \times 10^{-5}$
Saliva	$1 \times 10^{-10}$	10.0	4.0	$1 \times 10^{-4}$
Milk	$1 \times 10^{-11}$	11.0	3.0	$1 \times 10^{-3}$
Human blood, tears	$1 \times 10^{-12}$	12.0	2.0	$1 \times 10^{-2}$
Egg white, seawater	$1 \times 10^{-13}$	13.0	1.0	$1 \times 10^{-1}$
Baking soda	$1 \times 10^{-14}$	14.0	0.0	$1 (1 \times 10^{-0})$
Borax				
Milk of magnesia				
Lime water				
Household ammonia				
Household bleach				
NaOH, 0.1 M				

change the rate.  $\infty$  (Section 14.3) Thus, if the rate law is first order in  $[H^+]$  doubling its concentration will double the rate even if the change is merely from  $1 \times 10^{-7} M$  to  $2 \times 10^{-7} M$ . In biological systems many reactions involve proton transfers and have rates that depend on  $[H^+]$ . Because the speeds of these reactions are crucial, the pH of biological fluids must be maintained within narrow limits. For example, human blood has a normal pH range of 7.35 to 7.45. Illness and even death can result if the pH varies much from this narrow range.

### SAMPLE EXERCISE 16.6 | Calculating pH from $[H^+]$

Calculate the pH values for the two solutions described in Sample Exercise 16.5.

#### SOLUTION

**Analyze:** We are asked to determine the pH of aqueous solutions for which we have already calculated  $[H^+]$ .

**Plan:** We can calculate pH using its defining equation, Equation 16.17.

**Solve:**

(a) In the first instance we found  $[H^+]$  to be  $1.0 \times 10^{-12} M$ .

$$\text{pH} = -\log(1.0 \times 10^{-12}) = -(-12.00) = 12.00$$

Because  $1.0 \times 10^{-12}$  has two significant figures, the pH has two decimal places, 12.00. (b) For the second solution,  $[H^+] = 5.6 \times 10^{-6} M$ . Before performing the calculation, it is helpful to estimate the pH. To do so, we note that  $[H^+]$  lies between  $1 \times 10^{-6}$  and  $1 \times 10^{-5}$ .

$$1 \times 10^{-6} < 5.6 \times 10^{-6} < 1 \times 10^{-5}$$

Thus, we expect the pH to lie between 6.0 and 5.0. We use Equation 16.17 to calculate the pH.

$$\text{pH} = -\log(5.6 \times 10^{-6}) = 5.25$$

**Check:** After calculating a pH, it is useful to compare it to your prior estimate. In this case the pH, as we predicted, falls between 6 and 5. Had the calculated pH and the estimate not agreed, we should have reconsidered our calculation or estimate or both.

#### PRACTICE EXERCISE

(a) In a sample of lemon juice  $[H^+]$  is  $3.8 \times 10^{-4} M$ . What is the pH? (b) A commonly available window-cleaning solution has  $[OH^-] = 1.9 \times 10^{-6} M$ . What is the pH?

**Answers:** (a) 3.42, (b)  $[H^+] = 5.3 \times 10^{-9} M$ , so pH = 8.28

### SAMPLE EXERCISE 16.7 | Calculating $[H^+]$ from pH

A sample of freshly pressed apple juice has a pH of 3.76. Calculate  $[H^+]$ .

#### SOLUTION

**Analyze:** We need to calculate  $[H^+]$  from pH.

**Plan:** We will use Equation 16.17,  $\text{pH} = -\log[H^+]$ , for the calculation.

**Solve:** From Equation 16.17, we have

$$\text{pH} = -\log[H^+] = 3.76$$

Thus,

$$\log[H^+] = -3.76$$

To find  $[H^+]$ , we need to determine the *antilog* of  $-3.76$ . Scientific calculators have an antilog function (sometimes labeled  $\text{INV log}$  or  $10^x$ ) that allows us to perform the calculation:

$$[H^+] = \text{antilog}(-3.76) = 10^{-3.76} = 1.7 \times 10^{-4} M$$

**Comment:** Consult the user's manual for your calculator to find out how to perform the antilog operation. The number of significant figures in  $[H^+]$  is two because the number of decimal places in the pH is two.

**Check:** Because the pH is between 3.0 and 4.0, we know that  $[H^+]$  will be between  $1 \times 10^{-3}$  and  $1 \times 10^{-4} M$ . Our calculated  $[H^+]$  falls within this estimated range.

#### PRACTICE EXERCISE

A solution formed by dissolving an antacid tablet has a pH of 9.18. Calculate  $[H^+]$ .

**Answer:**  $[H^+] = 6.6 \times 10^{-10} M$

### pOH and Other “p” Scales

The negative log is also a convenient way of expressing the magnitudes of small quantities. We use the convention that the negative log of a quantity is labeled “p” (quantity). Thus, we can express the concentration of  $\text{OH}^-$  as pOH:

$$\text{pOH} = -\log[\text{OH}^-] \quad [16.18]$$

Likewise,  $\text{p}K_w$  equals  $-\log K_w$ .

By taking the negative log of both sides of Equation 16.16,

$$-\log[\text{H}^+] + (-\log[\text{OH}^-]) = -\log K_w \quad [16.19]$$

we obtain the following useful expression:

$$\text{pH} + \text{pOH} = 14.00 \quad (\text{at } 25^\circ\text{C}) \quad [16.20]$$

We will see in Section 16.8 that p scales are also useful when working with other equilibrium constants.

#### GIVE IT SOME THOUGHT

If the pOH for a solution is 3.00, what is the pH of the solution? Is the solution acidic or basic?

### Measuring pH

The pH of a solution can be measured quickly and accurately with a *pH meter* (Figure 16.6 ◀). A complete understanding of how this important device works requires a knowledge of electrochemistry, a subject we take up in Chapter 20. In brief, a pH meter consists of a pair of electrodes connected to a meter capable of measuring small voltages, on the order of millivolts. A voltage, which varies with the pH, is generated when the electrodes are placed in a solution. This voltage is read by the meter, which is calibrated to give pH.

The electrodes used with pH meters come in many shapes and sizes, depending on their intended use. Electrodes have even been developed that are so small that they can be inserted into single living cells to monitor the pH of the cell medium. Pocket-size pH meters are also available for use in environmental studies, in monitoring industrial effluents, and in agricultural work.

Although less precise, acid–base indicators can be used to measure pH. An acid–base indicator is a colored substance that itself can exist in either an acid or a base form. The two forms have different colors. Thus, the indicator turns one color in an acid and another color in a base. If you know the pH at which the indicator turns from one form to the other, you can determine whether a solution has a higher or lower pH than this value. Litmus, for example, changes color in the vicinity of pH 7. The color change, however, is not very sharp. Red litmus indicates a pH of about 5 or lower, and blue litmus indicates a pH of about 8 or higher.

Some of the more common indicators are listed in Figure 16.7 ▶. Methyl orange, for example, changes color over the pH interval from 3.1 to 4.4. Below pH 3.1 it is in the acid form, which is red. In the interval between 3.1 and 4.4, it is gradually converted to its basic form, which has a yellow color. By pH 4.4 the conversion is complete, and the solution is yellow. Paper tape that is impregnated with several indicators and comes complete with a comparator color scale is widely used for approximate determinations of pH.

▲ **Figure 16.6** A digital pH meter. The device is a millivoltmeter, and the electrodes immersed in the solution being tested produce a voltage that depends on the pH of the solution.

#### GIVE IT SOME THOUGHT

If phenolphthalein turns pink when added to a solution, what can we conclude about the pH of the solution?

▲ **Figure 16.7 Some common acid-base indicators.** The pH ranges for the color changes of some common acid-base indicators. Most indicators have a useful range of about 2 pH units.

## 16.5 STRONG ACIDS AND BASES

The chemistry of an aqueous solution often depends critically on the pH of the solution. It is therefore important to examine how the pH of solutions relates to the concentrations of acids and bases. The simplest cases are those involving strong acids and strong bases. Strong acids and bases are *strong electrolytes*, existing in aqueous solution entirely as ions. There are relatively few common strong acids and bases, and we listed these substances in Table 4.2.

### Strong Acids

The seven most common strong acids include six monoprotic acids (HCl, HBr, HI, HNO<sub>3</sub>, HClO<sub>3</sub>, and HClO<sub>4</sub>), and one diprotic acid (H<sub>2</sub>SO<sub>4</sub>). Nitric acid (HNO<sub>3</sub>) exemplifies the behavior of the monoprotic strong acids. For all practical purposes, an aqueous solution of HNO<sub>3</sub> consists entirely of H<sub>3</sub>O<sup>+</sup> and NO<sub>3</sub><sup>-</sup> ions.

We have not used equilibrium arrows for Equation 16.21 because the reaction lies entirely to the right, the side with the ions. ⇌ (Section 4.1) As noted in Section 16.3, we use H<sub>3</sub>O<sup>+</sup>(aq) and H<sup>+</sup>(aq) interchangeably to represent the hydrated proton in water. Thus, we often simplify the equations for the ionization reactions of acids as follows:

In an aqueous solution of a strong acid, the acid is normally the only significant source of H<sup>+</sup> ions.\* As a result, calculating the pH of a solution of a strong monoprotic acid is straightforward because [H<sup>+</sup>] equals the original concentration of acid. In a 0.20 M solution of HNO<sub>3</sub>(aq), for example, [H<sup>+</sup>] = [NO<sub>3</sub><sup>-</sup>] = 0.20 M. The situation with the diprotic acid H<sub>2</sub>SO<sub>4</sub> is more complex, as we will see in Section 16.6.

\*If the concentration of the acid is 10<sup>-6</sup> M or less, we also need to consider H<sup>+</sup> ions that result from the autoionization of H<sub>2</sub>O. Normally, the concentration of H<sup>+</sup> from H<sub>2</sub>O is so small that it can be neglected.

**SAMPLE EXERCISE 16.8** | Calculating the pH of a Strong Acid

What is the pH of a 0.040 M solution of  $\text{HClO}_4$ ?

**SOLUTION**

**Analyze and Plan:** Because  $\text{HClO}_4$  is a strong acid, it is completely ionized, giving  $[\text{H}^+] = [\text{ClO}_4^-] = 0.040 \text{ M}$ .

**Solve:** The pH of the solution is given by

$$\text{pH} = -\log(0.040) = 1.40.$$

**Check:** Because  $[\text{H}^+]$  lies between  $1 \times 10^{-2}$  and  $1 \times 10^{-1}$ , the pH will be between 2.0 and 1.0. Our calculated pH falls within the estimated range. Furthermore, because the concentration has two significant figures, the pH has two decimal places.

**PRACTICE EXERCISE**

An aqueous solution of  $\text{HNO}_3$  has a pH of 2.34. What is the concentration of the acid?

*Answer:* 0.0046 M

**Strong Bases**

There are relatively few common strong bases. The most common soluble strong bases are the ionic hydroxides of the alkali metals (group 1A) and the heavier alkaline earth metals (group 2A), such as  $\text{NaOH}$ ,  $\text{KOH}$ , and  $\text{Ca(OH)}_2$ . These compounds completely dissociate into ions in aqueous solution. Thus, a solution labeled 0.30 M  $\text{NaOH}$  consists of 0.30 M  $\text{Na}^+(aq)$  and 0.30 M  $\text{OH}^-(aq)$ ; there is essentially no undissociated  $\text{NaOH}$ .

**SAMPLE EXERCISE 16.9** | Calculating the pH of a Strong Base

What is the pH of (a) a 0.028 M solution of  $\text{NaOH}$ , (b) a 0.0011 M solution of  $\text{Ca(OH)}_2$ ?

**SOLUTION**

**Analyze:** We are asked to calculate the pH of two solutions of strong bases.

**Plan:** We can calculate each pH by either of two equivalent methods. First, we could use Equation 16.16 to calculate  $[\text{H}^+]$  and then use Equation 16.17 to calculate the pH. Alternatively, we could use  $[\text{OH}^-]$  to calculate pOH and then use Equation 16.20 to calculate the pH.

**Solve:**

(a)  $\text{NaOH}$  dissociates in water to give one  $\text{OH}^-$  ion per formula unit. Therefore, the  $\text{OH}^-$  concentration for the solution in (a) equals the stated concentration of  $\text{NaOH}$ , namely 0.028 M.

*Method 1:*

$$[\text{H}^+] = \frac{1.0 \times 10^{-14}}{0.028} = 3.57 \times 10^{-13} \text{ M} \quad \text{pH} = -\log(3.57 \times 10^{-13}) = 12.45$$

*Method 2:*

$$\text{pOH} = -\log(0.028) = 1.55 \quad \text{pH} = 14.00 - \text{pOH} = 12.45$$

(b)  $\text{Ca(OH)}_2$  is a strong base that dissociates in water to give two  $\text{OH}^-$  ions per formula unit. Thus, the concentration of  $\text{OH}^-(aq)$  for the solution in part (b) is  $2 \times (0.0011 \text{ M}) = 0.0022 \text{ M}$ .

*Method 1:*

$$[\text{H}^+] = \frac{1.0 \times 10^{-14}}{0.0022} = 4.55 \times 10^{-12} \text{ M} \quad \text{pH} = -\log(4.55 \times 10^{-12}) = 11.34$$

*Method 2:*

$$\text{pOH} = -\log(0.0022) = 2.66 \quad \text{pH} = 14.00 - \text{pOH} = 11.34$$

**PRACTICE EXERCISE**

What is the concentration of a solution of (a)  $\text{KOH}$  for which the pH is 11.89; (b)  $\text{Ca(OH)}_2$  for which the pH is 11.68?

*Answers:* (a)  $7.8 \times 10^{-3} \text{ M}$ , (b)  $2.4 \times 10^{-3} \text{ M}$

Although all the hydroxides of the alkali metals (group 1A) are strong electrolytes, LiOH, RbOH, and CsOH are not commonly encountered in the laboratory. The hydroxides of the heavier alkaline earth metals,  $\text{Ca}(\text{OH})_2$ ,  $\text{Sr}(\text{OH})_2$ , and  $\text{Ba}(\text{OH})_2$ , are also strong electrolytes. They have limited solubilities, however, so they are used only when high solubility is not critical.

Strongly basic solutions are also created by certain substances that react with water to form  $\text{OH}^-$  (aq). The most common of these contain the oxide ion. Ionic metal oxides, especially  $\text{Na}_2\text{O}$  and  $\text{CaO}$ , are often used in industry when a strong base is needed. The  $\text{O}^{2-}$  reacts with water to form  $\text{OH}^-$ , leaving virtually no  $\text{O}^{2-}$  remaining in the solution:

Thus, a solution formed by dissolving 0.010 mol of  $\text{Na}_2\text{O}(\text{s})$  in enough water to form 1.0 L of solution will have  $[\text{OH}^-] = 0.020 \text{ M}$  and a pH of 12.30.

### GIVE IT SOME THOUGHT

The  $\text{CH}_3^-$  ion is the conjugate base of  $\text{CH}_4$ , and  $\text{CH}_4$  shows no evidence of being an acid in water. What happens when  $\text{CH}_3^-$  is added to water?

## 16.6 WEAK ACIDS

Most acidic substances are weak acids and are therefore only partially ionized in aqueous solution. We can use the equilibrium constant for the ionization reaction to express the extent to which a weak acid ionizes. If we represent a general weak acid as HA, we can write the equation for its ionization reaction in either of the following ways, depending on whether the hydrated proton is represented as  $\text{H}_3\text{O}^+(\text{aq})$  or  $\text{H}^+(\text{aq})$ :

or

Because  $\text{H}_2\text{O}$  is the solvent, it is omitted from the equilibrium-constant expression.  $\rightleftharpoons$  (Section 15.4) Thus, we can write the equilibrium-constant expression as either

$$K_c = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \quad \text{or} \quad K_c = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]}$$

As we did for the ion-product constant for the autoionization of water, we change the subscript on this equilibrium constant to indicate the type of equation to which it corresponds.

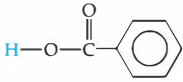

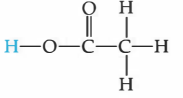

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \quad \text{or} \quad K_a = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]} \quad [16.25]$$

The subscript  $a$  on  $K_a$  denotes that it is an equilibrium constant for the ionization of an acid, so  $K_a$  is called the **acid-dissociation constant**.

Table 16.2  $\blacktriangledown$  shows the names, structures, and  $K_a$  values for several weak acids. Appendix D provides a more complete list. Many weak acids are organic compounds composed entirely of carbon, hydrogen, and oxygen. These compounds usually contain some hydrogen atoms bonded to carbon atoms and some bonded to oxygen atoms. In almost all cases the hydrogen atoms bonded to carbon do not ionize in water; instead, the acidic behavior of these compounds is due to the hydrogen atoms attached to oxygen atoms.

The magnitude of  $K_a$  indicates the tendency of the acid to ionize in water: *The larger the value of  $K_a$ , the stronger the acid.* Hydrofluoric acid (HF), for example, is the strongest acid listed in Table 16.2, and phenol ( $\text{HOC}_6\text{H}_5$ ) is the weakest. Notice that  $K_a$  is typically less than  $10^{-3}$ .

TABLE 16.2 ■ Some Weak Acids in Water at 25 °C

Acid	Structural Formula*	Conjugate Base	Equilibrium Reaction	$K_a$
Hydrofluoric (HF)	$\text{H}-\text{F}$	$\text{F}^-$	$\text{HF}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{F}^-(aq)$	$6.8 \times 10^{-4}$
Nitrous ( $\text{HNO}_2$ )	$\text{H}-\text{O}-\text{N}=\text{O}$	$\text{NO}_2^-$	$\text{HNO}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{NO}_2^-(aq)$	$4.5 \times 10^{-4}$
Benzoic ( $\text{C}_6\text{H}_5\text{COOH}$ )		$\text{C}_6\text{H}_5\text{COO}^-$	$\text{C}_6\text{H}_5\text{COOH}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{C}_6\text{H}_5\text{COO}^-(aq)$	$6.3 \times 10^{-5}$
Acetic ( $\text{CH}_3\text{COOH}$ )		$\text{CH}_3\text{COO}^-$	$\text{CH}_3\text{COOH}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{CH}_3\text{COO}^-(aq)$	$1.8 \times 10^{-5}$
Hypochlorous ( $\text{HClO}$ )	$\text{H}-\text{O}-\text{Cl}$	$\text{ClO}^-$	$\text{HClO}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{ClO}^-(aq)$	$3.0 \times 10^{-8}$
Hydrocyanic ( $\text{HCN}$ )	$\text{H}-\text{C}\equiv\text{N}$	$\text{CN}^-$	$\text{HCN}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{CN}^-(aq)$	$4.9 \times 10^{-10}$
Phenol ( $\text{HOC}_6\text{H}_5$ )		$\text{C}_6\text{H}_5\text{O}^-$	$\text{HOC}_6\text{H}_5(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{C}_6\text{H}_5\text{O}^-(aq)$	$1.3 \times 10^{-10}$

\*The proton that ionizes is shown in blue.

### Calculating $K_a$ from pH

In order to calculate either the  $K_a$  value for a weak acid or the pH of its solutions, we will use many of the skills for solving equilibrium problems that we developed in Section 15.5. In many cases the small magnitude of  $K_a$  allows us to use approximations to simplify the problem. In doing these calculations, it is important to realize that proton-transfer reactions are generally very rapid. As a result, the measured or calculated pH for a weak acid always represents an equilibrium condition.

#### SAMPLE EXERCISE 16.10 | Calculating $K_a$ from Measured pH

A student prepared a 0.10 M solution of formic acid ( $\text{HCOOH}$ ) and measured its pH. The pH at 25 °C was found to be 2.38. Calculate  $K_a$  for formic acid at this temperature.

#### SOLUTION

**Analyze:** We are given the molar concentration of an aqueous solution of weak acid and the pH of the solution, and we are asked to determine the value of  $K_a$  for the acid.

**Plan:** Although we are dealing specifically with the ionization of a weak acid, this problem is very similar to the equilibrium problems we encountered in Chapter 15. We can solve this problem using the method first outlined in Sample Exercise 15.9, starting with the chemical reaction and a tabulation of initial and equilibrium concentrations.

**Solve:** The first step in solving any equilibrium problem is to write the equation for the equilibrium reaction. The ionization of formic acid can be written as follows:

The equilibrium-constant expression is

$$K_a = \frac{[\text{H}^+][\text{HCOO}^-]}{[\text{HCOOH}]}$$

From the measured pH, we can calculate  $[\text{H}^+]$ :

$$\text{pH} = -\log[\text{H}^+] = 2.38$$

$$\log[\text{H}^+] = -2.38$$

$$[\text{H}^+] = 10^{-2.38} = 4.2 \times 10^{-3} \text{ M}$$

We can do a little accounting to determine the concentrations of the species involved in the equilibrium. We imagine that the solution is initially  $0.10\text{ M}$  in  $\text{HCOOH}$  molecules. We then consider the ionization of the acid into  $\text{H}^+$  and  $\text{HCOO}^-$ . For each  $\text{HCOOH}$  molecule that ionizes, one  $\text{H}^+$  ion and one  $\text{HCOO}^-$  ion are produced in solution. Because the pH measurement indicates that  $[\text{H}^+] = 4.2 \times 10^{-3}\text{ M}$  at equilibrium, we can construct the following table:

$$\text{HCOOH}(aq) \rightleftharpoons \text{H}^+(aq) + \text{HCOO}^-(aq)$$

Initial	$0.10\text{ M}$	$0$	$0$
Change	$-4.2 \times 10^{-3}\text{ M}$	$+4.2 \times 10^{-3}\text{ M}$	$+4.2 \times 10^{-3}\text{ M}$
Equilibrium	$(0.10 - 4.2 \times 10^{-3})\text{ M}$	$4.2 \times 10^{-3}\text{ M}$	$4.2 \times 10^{-3}\text{ M}$

Notice that we have neglected the very small concentration of  $\text{H}^+(aq)$  that is due to the autoionization of  $\text{H}_2\text{O}$ . Notice also that the amount of  $\text{HCOOH}$  that ionizes is very small compared with the initial concentration of the acid. To the number of significant figures we are using, the subtraction yields  $0.10\text{ M}$ :

$$(0.10 - 4.2 \times 10^{-3})\text{ M} \approx 0.10\text{ M}$$

We can now insert the equilibrium concentrations into the expression for  $K_a$ :

$$K_a = \frac{(4.2 \times 10^{-3})(4.2 \times 10^{-3})}{0.10} = 1.8 \times 10^{-4}$$

**Check:** The magnitude of our answer is reasonable because  $K_a$  for a weak acid is usually between  $10^{-3}$  and  $10^{-10}$ .

### PRACTICE EXERCISE

Niacin, one of the B vitamins, has the following molecular structure:

A  $0.020\text{ M}$  solution of niacin has a pH of 3.26. What is the acid-dissociation constant,  $K_a$ , for niacin?

**Answers:**  $1.5 \times 10^{-5}$

## Percent Ionization

We have seen that the magnitude of  $K_a$  indicates the strength of a weak acid. Another measure of acid strength is **percent ionization**, which is defined as

$$\text{Percent ionization} = \frac{\text{concentration ionized}}{\text{original concentration}} \times 100\% \quad [16.26]$$

The stronger the acid, the greater is the percent ionization.

For any acid, the concentration of acid that undergoes ionization equals the concentration of  $\text{H}^+(aq)$  that forms, assuming that the autoionization of water is negligible. Thus, the percent ionization for an acid  $\text{HA}$  is also given by

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HA}]_{\text{initial}}} \times 100\% \quad [16.27]$$

For example, a  $0.035\text{ M}$  solution of  $\text{HNO}_2$  contains  $3.7 \times 10^{-3}\text{ M}$   $\text{H}^+(aq)$ . Thus, the percent ionization is

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HNO}_2]_{\text{initial}}} \times 100\% = \frac{3.7 \times 10^{-3}\text{ M}}{0.035\text{ M}} \times 100\% = 11\%$$

**SAMPLE EXERCISE 16.11** | Calculating Percent Ionization

A 0.10 M solution of formic acid (HCOOH) contains  $4.2 \times 10^{-3} M$   $H^+(aq)$ . Calculate the percentage of the acid that is ionized.

**SOLUTION**

**Analyze:** We are given the molar concentration of an aqueous solution of weak acid and the equilibrium concentration of  $H^+(aq)$  and asked to determine the percent ionization of the acid.

**Plan:** The percent ionization is given by Equation 16.27.

**Solve:**

$$\text{Percent ionization} = \frac{[H^+]_{\text{equilibrium}}}{[HCOOH]_{\text{initial}}} \times 100\% = \frac{4.2 \times 10^{-3} M}{0.10 M} \times 100\% = 4.2\%$$

**PRACTICE EXERCISE**

A 0.020 M solution of niacin has a pH of 3.26. Calculate the percent ionization of the niacin.

*Answer:* 2.7%

Using  $K_a$  to Calculate pH

Knowing the value of  $K_a$  and the initial concentration of the weak acid, we can calculate the concentration of  $H^+(aq)$  in a solution of a weak acid. Let's calculate the pH of a 0.30 M solution of acetic acid ( $CH_3COOH$ ), the weak acid responsible for the characteristic odor and acidity of vinegar, at 25 °C.

Our *first* step is to write the ionization equilibrium for acetic acid:

Notice that the hydrogen that ionizes is the one attached to an oxygen atom.

The *second* step is to write the equilibrium-constant expression and the value for the equilibrium constant. From Table 16.2, we have  $K_a = 1.8 \times 10^{-5}$ . Thus, we can write the following:

$$K_a = \frac{[H^+][CH_3COO^-]}{[CH_3COOH]} = 1.8 \times 10^{-5} \quad [16.29]$$

As the *third* step, we need to express the concentrations that are involved in the equilibrium reaction. This can be done with a little accounting, as described in Sample Exercise 16.10. Because we want to find the equilibrium value for  $[H^+]$ , let's call this quantity  $x$ . The concentration of acetic acid before any of it ionizes is 0.30 M. The chemical equation tells us that for each molecule of  $CH_3COOH$  that ionizes, one  $H^+(aq)$  and one  $CH_3COO^-(aq)$  are formed. Consequently, if  $x$  moles per liter of  $H^+(aq)$  form at equilibrium,  $x$  moles per liter of  $CH_3COO^-(aq)$  must also form, and  $x$  moles per liter of  $CH_3COOH$  must be ionized. This gives rise to the following table with the equilibrium concentrations shown on the last line:

Initial	0.30 M	0	0
Change	$-x M$	$+x M$	$+x M$
Equilibrium	$(0.30 - x) M$	$x M$	$x M$

As the *fourth* step of the problem, we need to substitute the equilibrium concentrations into the equilibrium-constant expression. The substitutions give the following equation:

$$K_a = \frac{[H^+][CH_3COO^-]}{[CH_3COOH]} = \frac{(x)(x)}{0.30 - x} = 1.8 \times 10^{-5} \quad [16.30]$$

This expression leads to a quadratic equation in  $x$ , which we can solve by using an equation-solving calculator or by using the quadratic formula. We can also simplify the problem, however, by noting that the value of  $K_a$  is quite small. As a result, we anticipate that the equilibrium will lie far to the left and that  $x$  will be very small compared to the initial concentration of acetic acid. Thus, we will *assume* that  $x$  is negligible compared to 0.30, so that  $0.30 - x$  is essentially equal to 0.30.

$$0.30 - x \approx 0.30$$

As we will see, we can (and should!) check the validity of this assumption when we finish the problem. By using this assumption, Equation 16.30 now becomes

$$K_a = \frac{x^2}{0.30} = 1.8 \times 10^{-5}$$

Solving for  $x$ , we have

$$x^2 = (0.30)(1.8 \times 10^{-5}) = 5.4 \times 10^{-6}$$

$$x = \sqrt{5.4 \times 10^{-6}} = 2.3 \times 10^{-3}$$

$$[\text{H}^+] = x = 2.3 \times 10^{-3} \text{ M}$$

$$\text{pH} = -\log(2.3 \times 10^{-3}) = 2.64$$

We should now go back and check the validity of our simplifying assumption that  $0.30 - x \approx 0.30$ . The value of  $x$  we determined is so small that, for this number of significant figures, the assumption is entirely valid. We are thus satisfied that the assumption was a reasonable one to make. Because  $x$  represents the moles per liter of acetic acid that ionize, we see that, in this particular case, less than 1% of the acetic acid molecules ionize:

$$\text{Percent ionization of } \text{CH}_3\text{COOH} = \frac{0.0023 \text{ M}}{0.30 \text{ M}} \times 100\% = 0.77\%$$

As a general rule, if the quantity  $x$  is more than about 5% of the initial value, it is better to use the quadratic formula. You should always check the validity of any simplifying assumptions after you have finished solving a problem.

### GIVE IT SOME THOUGHT

Why can we generally assume that the equilibrium concentration of a weak acid equals its initial concentration?

Finally, we can compare the pH value of this weak acid to a solution of a strong acid of the same concentration. The pH of the 0.30 M solution of acetic acid is 2.64. By comparison, the pH of a 0.30 M solution of a strong acid such as HCl is  $-\log(0.30) = 0.52$ . As expected, the pH of a solution of a weak acid is higher than that of a solution of a strong acid of the same molarity.

#### SAMPLE EXERCISE 16.12 | Using $K_a$ to Calculate pH

Calculate the pH of a 0.20 M solution of HCN. (Refer to Table 16.2 or Appendix D for the value of  $K_a$ .)

#### SOLUTION

**Analyze:** We are given the molarity of a weak acid and are asked for the pH. From Table 16.2,  $K_a$  for HCN is  $4.9 \times 10^{-10}$ .

**Plan:** We proceed as in the example just worked in the text, writing the chemical equation and constructing a table of initial and equilibrium concentrations in which the equilibrium concentration of  $\text{H}^+$  is our unknown.

**Solve:** Writing both the chemical equation for the ionization reaction that forms  $\text{H}^+(\text{aq})$  and the equilibrium-constant ( $K_a$ ) expression for the reaction:

$$K_a = \frac{[\text{H}^+][\text{CN}^-]}{[\text{HCN}]} = 4.9 \times 10^{-10}$$

Next, we tabulate the concentration of the species involved in the equilibrium reaction, letting  $x = [\text{H}^+]$  at equilibrium:

	$\text{HCN}(aq)$	$\rightleftharpoons$	$\text{H}^+(aq)$	+	$\text{CN}^-(aq)$
Initial	0.20 M		0		0
Change	$-x$ M		$+x$ M		$+x$ M
Equilibrium	$(0.20 - x)$ M		$x$ M		$x$ M

Substituting the equilibrium concentrations from the table into the equilibrium-constant expression yields

$$K_a = \frac{(x)(x)}{0.20 - x} = 4.9 \times 10^{-10}$$

We next make the simplifying approximation that  $x$ , the amount of acid that dissociates, is small compared with the initial concentration of acid; that is,

$$0.20 - x \approx 0.20$$

Thus,

$$\frac{x^2}{0.20} = 4.9 \times 10^{-10}$$

Solving for  $x$ , we have

$$x^2 = (0.20)(4.9 \times 10^{-10}) = 9.98 \times 10^{-11}$$

$$x = \sqrt{9.98 \times 10^{-11}} = 9.9 \times 10^{-6} \text{ M} = [\text{H}^+]$$

A concentration of  $9.9 \times 10^{-6}$  M is much smaller than 5% of 0.20, the initial HCN concentration. Our simplifying approximation is therefore appropriate. We now calculate the pH of the solution:

$$\text{pH} = -\log[\text{H}^+] = -\log(9.9 \times 10^{-6}) = 5.00$$

### PRACTICE EXERCISE

The  $K_a$  for niacin (Practice Exercise 16.10) is  $1.5 \times 10^{-5}$ . What is the pH of a 0.010 M solution of niacin?

**Answer:** 3.41

The properties of the acid solution that relate directly to the concentration of  $\text{H}^+(aq)$ , such as electrical conductivity and rate of reaction with an active metal, are much less evident for a solution of a weak acid than for a solution of a strong acid of the same concentration. Figure 16.8  $\blacktriangledown$  presents an experiment that demonstrates this difference by comparing the behavior of 1 M  $\text{CH}_3\text{COOH}$  and 1 M HCl. The 1 M  $\text{CH}_3\text{COOH}$  contains only 0.004 M  $\text{H}^+(aq)$ , whereas the 1 M HCl solution contains 1 M  $\text{H}^+(aq)$ . As a result, the rate of reaction with the metal is much faster for the solution of HCl.

As the concentration of a weak acid increases, the equilibrium concentration of  $\text{H}^+(aq)$  increases, as expected. However, as shown in Figure 16.9  $\blacktriangleright$ , the percent ionization decreases as the concentration increases. Thus, the concentration of  $\text{H}^+(aq)$  is not directly proportional to the concentration of the weak acid. For example, doubling the concentration of a weak acid does not double the concentration of  $\text{H}^+(aq)$ . This lack of proportionality between the concentration of a weak acid and the concentration of  $\text{H}^+(aq)$  is demonstrated in Sample Exercise 16.13.

**► Figure 16.8 Reaction rates for weak and strong acids.** (a) The flask on the left contains 1 M  $\text{CH}_3\text{COOH}$ ; the one on the right contains 1 M HCl. Each balloon contains the same amount of magnesium metal. (b) When the Mg metal is dropped into the acid,  $\text{H}_2$  gas is formed. The rate of  $\text{H}_2$  formation is higher for the 1 M HCl solution on the right as evidenced by more gas in the balloon. Eventually, the same amount of  $\text{H}_2$  forms in both cases.

(a)

(b)

◀ **Figure 16.9** The effect of concentration on ionization of a weak acid. The percent ionization of a weak acid decreases with increasing concentration. The data shown are for acetic acid.

### SAMPLE EXERCISE 16.13 | Using $K_a$ to Calculate Percent Ionization

Calculate the percentage of HF molecules ionized in (a) a 0.10 M HF solution, (b) a 0.010 M HF solution.

#### SOLUTION

**Analyze:** We are asked to calculate the percent ionization of two HF solutions of different concentration. From Appendix D, we find  $K_a = 6.8 \times 10^{-4}$ .

**Plan:** We approach this problem as we would previous equilibrium problems. We begin by writing the chemical equation for the equilibrium and tabulating the known and unknown concentrations of all species. We then substitute the equilibrium concentrations into the equilibrium-constant expression and solve for the unknown concentration, that of  $H^+$ .

#### Solve:

(a) The equilibrium reaction and equilibrium concentrations are as follows:

	HF(aq)	$\rightleftharpoons$	$H^+(aq)$	+	$F^-(aq)$
Initial	0.10 M		0		0
Change	$-x$ M		$+x$ M		$+x$ M
Equilibrium	$(0.10 - x)$ M		$x$ M		$x$ M

The equilibrium-constant expression is

$$K_a = \frac{[H^+][F^-]}{[HF]} = \frac{(x)(x)}{0.10 - x} = 6.8 \times 10^{-4}$$

When we try solving this equation using the approximation  $0.10 - x = 0.10$  (that is, by neglecting the concentration of acid that ionizes in comparison with the initial concentration), we obtain

$$x = 8.2 \times 10^{-3} \text{ M}$$

Because this value is greater than 5% of 0.10 M, we should work the problem without the approximation, using an equation-solving calculator or the quadratic formula. Rearranging our equation and writing it in standard quadratic form, we have

$$\begin{aligned} x^2 &= (0.10 - x)(6.8 \times 10^{-4}) \\ &= 6.8 \times 10^{-5} - (6.8 \times 10^{-4})x \\ x^2 + (6.8 \times 10^{-4})x - 6.8 \times 10^{-5} &= 0 \end{aligned}$$

This equation can be solved using the standard quadratic formula.

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Substituting the appropriate numbers gives

$$\begin{aligned} x &= \frac{-6.8 \times 10^{-4} \pm \sqrt{(6.8 \times 10^{-4})^2 + 4(6.8 \times 10^{-5})}}{2} \\ &= \frac{-6.8 \times 10^{-4} \pm 1.6 \times 10^{-2}}{2} \end{aligned}$$

Of the two solutions, only the one that gives a positive value for  $x$  is chemically reasonable. Thus,

$$x = [\text{H}^+] = [\text{F}^-] = 7.9 \times 10^{-3} \text{ M}$$

From our result, we can calculate the percent of molecules ionized:

$$\begin{aligned} \text{Percent ionization of HF} &= \frac{\text{concentration ionized}}{\text{original concentration}} \times 100\% \\ &= \frac{7.9 \times 10^{-3} \text{ M}}{0.10 \text{ M}} \times 100\% = 7.9\% \end{aligned}$$

(b) Proceeding similarly for the 0.010 M solution, we have

$$\frac{x^2}{0.010 - x} = 6.8 \times 10^{-4}$$

Solving the resultant quadratic expression, we obtain

$$x = [\text{H}^+] = [\text{F}^-] = 2.3 \times 10^{-3} \text{ M}$$

The percentage of molecules ionized is

$$\frac{0.0023 \text{ M}}{0.010 \text{ M}} \times 100\% = 23\%$$

**Comment:** Notice that if we do not use the quadratic formula to solve the problem properly, we calculate 8.2% ionization for (a) and 26% ionization for (b). Notice also that in diluting the solution by a factor of 10, the percentage of molecules ionized increases by a factor of 3. This result is in accord with what we see in Figure 16.9. It is also what we would expect from Le Châtelier's principle.  $\rightleftharpoons$  (Section 15.7) There are more "particles" or reaction components on the right side of the equation than on the left. Dilution causes the reaction to shift in the direction of the larger number of particles because this counters the effect of the decreasing concentration of particles.

### PRACTICE EXERCISE

In Practice Exercise 16.11, we found that the percent ionization of niacin ( $K_a = 1.5 \times 10^{-5}$ ) in a 0.020 M solution is 2.7%. Calculate the percentage of niacin molecules ionized in a solution that is (a) 0.010 M, (b)  $1.0 \times 10^{-3}$  M.

**Answers:** (a) 3.9%, (b) 12%

## Polyprotic Acids

Many acids have more than one ionizable H atom. These acids are known as **polyprotic acids**. For example, each of the H atoms in sulfurous acid ( $\text{H}_2\text{SO}_3$ ) can ionize in successive steps:

The acid-dissociation constants for these equilibria are labeled  $K_{a1}$  and  $K_{a2}$ . The numbers on the constants refer to the particular proton of the acid that is ionizing. Thus,  $K_{a2}$  always refers to the equilibrium involving removal of the second proton of a polyprotic acid.

In the preceding example  $K_{a2}$  is much smaller than  $K_{a1}$ . Because of electrostatic attractions, we would expect a positively charged proton to be lost more readily from the neutral  $\text{H}_2\text{SO}_3$  molecule than from the negatively charged  $\text{HSO}_3^-$  ion. This observation is general: *It is always easier to remove the first proton from a polyprotic acid than to remove the second.* Similarly, for an acid with three ionizable protons, it is easier to remove the second proton than the third. Thus, the  $K_a$  values become successively smaller as successive protons are removed.

### GIVE IT SOME THOUGHT

What is meant by the symbol  $K_{a3}$  for  $\text{H}_3\text{PO}_4$ ?

The acid-dissociation constants for a few common polyprotic acids are listed in Table 16.3. Appendix D provides a more complete list. The structures for ascorbic and citric acids are shown in the margin. Notice that the  $K_a$  values for successive losses of protons from these acids usually differ by a factor of at least  $10^3$ . Notice also that the value of  $K_{a1}$  for sulfuric acid is listed simply as "large."

TABLE 16.3 Acid-Dissociation Constants of Some Common Polyprotic Acids

Name	Formula	$K_{a1}$	$K_{a2}$	$K_{a3}$
Ascorbic	$\text{H}_2\text{C}_6\text{H}_6\text{O}_6$	$8.0 \times 10^{-5}$	$1.6 \times 10^{-12}$	
Carbonic	$\text{H}_2\text{CO}_3$	$4.3 \times 10^{-7}$	$5.6 \times 10^{-11}$	
Citric	$\text{H}_3\text{C}_6\text{H}_5\text{O}_7$	$7.4 \times 10^{-4}$	$1.7 \times 10^{-5}$	$4.0 \times 10^{-7}$
Oxalic	$\text{H}_2\text{C}_2\text{O}_4$	$5.9 \times 10^{-2}$	$6.4 \times 10^{-5}$	
Phosphoric	$\text{H}_3\text{PO}_4$	$7.5 \times 10^{-3}$	$6.2 \times 10^{-8}$	$4.2 \times 10^{-13}$
Sulfurous	$\text{H}_2\text{SO}_3$	$1.7 \times 10^{-2}$	$6.4 \times 10^{-8}$	
Sulfuric	$\text{H}_2\text{SO}_4$	Large	$1.2 \times 10^{-2}$	
Tartaric	$\text{H}_2\text{C}_4\text{H}_4\text{O}_6$	$1.0 \times 10^{-3}$	$4.6 \times 10^{-5}$	

Sulfuric acid is a strong acid with respect to the removal of the first proton. Thus, the reaction for the first ionization step lies completely to the right:

$\text{HSO}_4^-$ , on the other hand, is a weak acid for which  $K_{a2} = 1.2 \times 10^{-2}$ .

Because  $K_{a1}$  is so much larger than subsequent dissociation constants for these polyprotic acids, most of the  $\text{H}^+(aq)$  in the solution comes from the first ionization reaction. As long as successive  $K_a$  values differ by a factor of  $10^3$  or more, it is possible to obtain a satisfactory estimate of the pH of polyprotic acid solutions by treating them as if they were monoprotic acids, considering only  $K_{a1}$ .

### SAMPLE EXERCISE 16.14 | Calculating the pH of a Polyprotic Acid Solution

The solubility of  $\text{CO}_2$  in pure water at  $25^\circ\text{C}$  and 0.1 atm pressure is  $0.0037\text{ M}$ . The common practice is to assume that all of the dissolved  $\text{CO}_2$  is in the form of carbonic acid ( $\text{H}_2\text{CO}_3$ ), which is produced by reaction between the  $\text{CO}_2$  and  $\text{H}_2\text{O}$ :

What is the pH of a  $0.0037\text{ M}$  solution of  $\text{H}_2\text{CO}_3$ ?

#### SOLUTION

**Analyze:** We are asked to determine the pH of a  $0.0037\text{ M}$  solution of a polyprotic acid.

**Plan:**  $\text{H}_2\text{CO}_3$  is a diprotic acid; the two acid-dissociation constants,  $K_{a1}$  and  $K_{a2}$  (Table 16.3), differ by more than a factor of  $10^3$ . Consequently, the pH can be determined by considering only  $K_{a1}$ , thereby treating the acid as if it were a monoprotic acid.

**Solve:** Proceeding as in Sample Exercises 16.12 and 16.13, we can write the equilibrium reaction and equilibrium concentrations as follows:

	$\text{H}_2\text{CO}_3(aq)$	$\rightleftharpoons$	$\text{H}^+(aq)$	+	$\text{HCO}_3^-(aq)$
Initial	$0.0037\text{ M}$		0		0
Change	$-x\text{ M}$		$+x\text{ M}$		$+x\text{ M}$
Equilibrium	$(0.0037 - x)\text{ M}$		$x\text{ M}$		$x\text{ M}$

The equilibrium-constant expression is as follows:

$$K_{a1} = \frac{[\text{H}^+][\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} = \frac{(x)(x)}{0.0037 - x} = 4.3 \times 10^{-7}$$

Solving this equation using an equation-solving calculator, we get

$$x = 4.0 \times 10^{-5}\text{ M}$$

Alternatively, because  $K_{a1}$  is small, we can make the simplifying approximation that  $x$  is small, so that

$$0.0037 - x \approx 0.0037$$

Thus,

$$\frac{(x)(x)}{0.0037} = 4.3 \times 10^{-7}$$

Solving for  $x$ , we have

$$x^2 = (0.0037)(4.3 \times 10^{-7}) = 1.6 \times 10^{-9}$$

$$x = [\text{H}^+] = [\text{HCO}_3^-] = \sqrt{1.6 \times 10^{-9}} = 4.0 \times 10^{-5}\text{ M}$$

The small value of  $x$  indicates that our simplifying assumption was justified. The pH is therefore

$$\text{pH} = -\log[\text{H}^+] = -\log(4.0 \times 10^{-5}) = 4.40$$

**Comment:** If we were asked to solve for  $[\text{CO}_3^{2-}]$ , we would need to use  $K_{a2}$ . Let's illustrate that calculation. Using the values of  $[\text{HCO}_3^-]$  and  $[\text{H}^+]$  calculated above, and setting  $[\text{CO}_3^{2-}] = y$ , we have the following initial and equilibrium concentration values:

Initial	$4.0 \times 10^{-5} M$	$4.0 \times 10^{-5} M$	0
Change	$-y M$	$+y M$	$+y M$
Equilibrium	$(4.0 \times 10^{-5} - y) M$	$(4.0 \times 10^{-5} + y) M$	$y M$

Assuming that  $y$  is small compared to  $4.0 \times 10^{-5}$ , we have

$$K_{a2} = \frac{[\text{H}^+][\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} = \frac{(4.0 \times 10^{-5})(y)}{4.0 \times 10^{-5}} = 5.6 \times 10^{-11}$$

$$y = 5.6 \times 10^{-11} M = [\text{CO}_3^{2-}]$$

The value calculated for  $y$  is indeed very small compared to  $4.0 \times 10^{-5}$ , showing that our assumption was justified. It also shows that the ionization of  $\text{HCO}_3^-$  is negligible compared to that of  $\text{H}_2\text{CO}_3$ , as far as production of  $\text{H}^+$  is concerned. However, it is the *only* source of  $\text{CO}_3^{2-}$ , which has a very low concentration in the solution. Our calculations thus tell us that in a solution of carbon dioxide in water, most of the  $\text{CO}_2$  is in the form of  $\text{CO}_2$  or  $\text{H}_2\text{CO}_3$ , a small fraction ionizes to form  $\text{H}^+$  and  $\text{HCO}_3^-$ , and an even smaller fraction ionizes to give  $\text{CO}_3^{2-}$ . Notice also that  $[\text{CO}_3^{2-}]$  is numerically equal to  $K_{a2}$ .

### ■ PRACTICE EXERCISE

(a) Calculate the pH of a 0.020 M solution of oxalic acid ( $\text{H}_2\text{C}_2\text{O}_4$ ). (See Table 16.3 for  $K_{a1}$  and  $K_{a2}$ .) (b) Calculate the concentration of oxalate ion,  $[\text{C}_2\text{O}_4^{2-}]$ , in this solution.

**Answers:** (a) pH = 1.80, (b)  $[\text{C}_2\text{O}_4^{2-}] = 6.4 \times 10^{-5} M$

## 16.7 WEAK BASES

Many substances behave as weak bases in water. Weak bases react with water, abstracting protons from  $\text{H}_2\text{O}$ , thereby forming the conjugate acid of the base and  $\text{OH}^-$  ions.

The equilibrium-constant expression for this reaction can be written as

$$K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]} \quad [16.34]$$

Water is the solvent, so it is omitted from the equilibrium-constant expression. The most commonly encountered weak base is ammonia.

As with  $K_w$  and  $K_a$ , the subscript "b" denotes that this equilibrium constant refers to a particular type of reaction, namely the ionization of a weak base in water. The constant  $K_b$  is called the **base-dissociation constant**. The constant  $K_b$  always refers to the equilibrium in which a base reacts with  $\text{H}_2\text{O}$  to form the corresponding conjugate acid and  $\text{OH}^-$ .

Table 16.4 lists the names, formulas, Lewis structures, equilibrium reactions, and values of  $K_b$  for several weak bases in water. Appendix D includes a more extensive list. These bases contain one or more lone pairs of electrons because a lone pair is necessary to form the bond with  $\text{H}^+$ . Notice that in the neutral molecules in Table 16.4, the lone pairs are on nitrogen atoms. The other bases listed are anions derived from weak acids.

TABLE 16.4 ■ Some Weak Bases and Their Aqueous Solution Equilibria

Base	Lewis Structure	Conjugate Acid	Equilibrium Reaction	$K_b$
Ammonia (NH <sub>3</sub> )		NH <sub>4</sub> <sup>+</sup>	NH <sub>3</sub> + H <sub>2</sub> O ⇌ NH <sub>4</sub> <sup>+</sup> + OH <sup>-</sup>	1.8 × 10 <sup>-5</sup>
Pyridine (C <sub>5</sub> H <sub>5</sub> N)		C <sub>5</sub> H <sub>5</sub> NH <sup>+</sup>	C <sub>5</sub> H <sub>5</sub> N + H <sub>2</sub> O ⇌ C <sub>5</sub> H <sub>5</sub> NH <sup>+</sup> + OH <sup>-</sup>	1.7 × 10 <sup>-9</sup>
Hydroxylamine (H <sub>2</sub> NOH)		H <sub>3</sub> NOH <sup>+</sup>	H <sub>2</sub> NOH + H <sub>2</sub> O ⇌ H <sub>3</sub> NOH <sup>+</sup> + OH <sup>-</sup>	1.1 × 10 <sup>-8</sup>
Methylamine (NH <sub>2</sub> CH <sub>3</sub> )		NH <sub>3</sub> CH <sub>3</sub> <sup>+</sup>	NH <sub>2</sub> CH <sub>3</sub> + H <sub>2</sub> O ⇌ NH <sub>3</sub> CH <sub>3</sub> <sup>+</sup> + OH <sup>-</sup>	4.4 × 10 <sup>-4</sup>
Hydrosulfide ion (HS <sup>-</sup> )		H <sub>2</sub> S	HS <sup>-</sup> + H <sub>2</sub> O ⇌ H <sub>2</sub> S + OH <sup>-</sup>	1.8 × 10 <sup>-7</sup>
Carbonate ion (CO <sub>3</sub> <sup>2-</sup> )		HCO <sub>3</sub> <sup>-</sup>	CO <sub>3</sub> <sup>2-</sup> + H <sub>2</sub> O ⇌ HCO <sub>3</sub> <sup>-</sup> + OH <sup>-</sup>	1.8 × 10 <sup>-4</sup>
Hypochlorite ion (ClO <sup>-</sup> )		HClO	ClO <sup>-</sup> + H <sub>2</sub> O ⇌ HClO + OH <sup>-</sup>	3.3 × 10 <sup>-7</sup>

**SAMPLE EXERCISE 16.15** | Using  $K_b$  to Calculate OH<sup>-</sup>

Calculate the concentration of OH<sup>-</sup> in a 0.15 M solution of NH<sub>3</sub>.

**SOLUTION**

**Analyze:** We are given the concentration of a weak base and are asked to determine the concentration of OH<sup>-</sup>.

**Plan:** We will use essentially the same procedure here as used in solving problems involving the ionization of weak acids; that is, we write the chemical equation and tabulate initial and equilibrium concentrations.

**Solve:** We first write the ionization reaction and the corresponding equilibrium-constant ( $K_b$ ) expression:

We then tabulate the equilibrium concentrations involved in the equilibrium:

	NH <sub>3</sub> (aq)	+ H <sub>2</sub> O(l)	⇌	NH <sub>4</sub> <sup>+</sup> (aq)	+ OH <sup>-</sup> (aq)
Initial	0.15 M	—		0	0
Change	-x M	—		+x M	+x M
Equilibrium	(0.15 - x) M	—		x M	x M

(We ignore the concentration of H<sub>2</sub>O because it is not involved in the equilibrium-constant expression.) Inserting these quantities into the equilibrium-constant expression gives the following:

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = \frac{(x)(x)}{0.15 - x} = 1.8 \times 10^{-5}$$

Because  $K_b$  is small, we can neglect the small amount of NH<sub>3</sub> that reacts with water, as compared to the total NH<sub>3</sub> concentration; that is, we can neglect  $x$  relative to 0.15 M. Then we have

$$\frac{x^2}{0.15} = 1.8 \times 10^{-5}$$

$$x^2 = (0.15)(1.8 \times 10^{-5}) = 2.7 \times 10^{-6}$$

$$x = [\text{NH}_4^+] = [\text{OH}^-] = \sqrt{2.7 \times 10^{-6}} = 1.6 \times 10^{-3} \text{ M}$$

**Check:** The value obtained for  $x$  is only about 1% of the  $\text{NH}_3$  concentration, 0.15  $M$ . Therefore, neglecting  $x$  relative to 0.15 was justified.

**Comment:** You may be asked to find the pH of a solution of a weak base. Once you have found  $[\text{OH}^-]$ , you can proceed as in Sample Exercise 16.9, where we calculated the pH of a strong base. In the present sample exercise, we have seen that the 0.15  $M$  solution of  $\text{NH}_3$  contains  $[\text{OH}^-] = 1.6 \times 10^{-3} M$ . Thus,  $\text{pOH} = -\log(1.6 \times 10^{-3}) = 2.80$ , and  $\text{pH} = 14.00 - 2.80 = 11.20$ . The pH of the solution is above 7 because we are dealing with a solution of a base.

### PRACTICE EXERCISE

Which of the following compounds should produce the highest pH as a 0.05  $M$  solution: pyridine, methylamine, or nitrous acid? **Answer:** methylamine (because it has the largest  $K_b$  value of the two amine bases in the list)

## Types of Weak Bases

How can we recognize from a chemical formula whether a molecule or ion is able to behave as a weak base? Weak bases fall into two general categories. The first category contains neutral substances that have an atom with a nonbonding pair of electrons that can serve as a proton acceptor. Most of these bases, including all of the uncharged bases listed in Table 16.4, contain a nitrogen atom. These substances include ammonia and a related class of compounds called amines. In organic amines, one or more of the  $\text{N}-\text{H}$  bonds in  $\text{NH}_3$  is replaced with a bond between  $\text{N}$  and  $\text{C}$ . Thus, the replacement of one  $\text{N}-\text{H}$  bond in  $\text{NH}_3$  with a  $\text{N}-\text{CH}_3$  bond gives methylamine,  $\text{NH}_2\text{CH}_3$  (usually written  $\text{CH}_3\text{NH}_2$ ). Like  $\text{NH}_3$ , amines can abstract a proton from a water molecule by forming an additional  $\text{N}-\text{H}$  bond, as shown here for methylamine:

The chemical formula for the conjugate acid of methylamine is usually written  $\text{CH}_3\text{NH}_3^+$ .

The second general category of weak bases consists of the anions of weak acids. In an aqueous solution of sodium hypochlorite ( $\text{NaClO}$ ), for example,  $\text{NaClO}$  dissociates to give  $\text{Na}^+$  and  $\text{ClO}^-$  ions. The  $\text{Na}^+$  ion is always a spectator ion in acid–base reactions.  $\rightleftharpoons$  (Section 4.3) The  $\text{ClO}^-$  ion, however, is the conjugate base of a weak acid, hypochlorous acid. Consequently, the  $\text{ClO}^-$  ion acts as a weak base in water:

### SAMPLE EXERCISE 16.16 | Using pH to Determine the Concentration of a Salt

A solution made by adding solid sodium hypochlorite ( $\text{NaClO}$ ) to enough water to make 2.00 L of solution has a pH of 10.50. Using the information in Equation 16.37, calculate the number of moles of  $\text{NaClO}$  that were added to the water.

#### SOLUTION

**Analyze:** We are given the pH of a 2.00-L solution of  $\text{NaClO}$  and must calculate the number of moles of  $\text{NaClO}$  needed to raise the pH to 10.50.  $\text{NaClO}$  is an ionic compound consisting of  $\text{Na}^+$  and  $\text{ClO}^-$  ions. As such, it is a strong electrolyte that completely dissociates in solution into  $\text{Na}^+$ , which is a spectator ion, and  $\text{ClO}^-$  ion, which is a weak base with  $K_b = 3.3 \times 10^{-7}$  (Equation 16.37).

**Plan:** From the pH, we can determine the equilibrium concentration of  $\text{OH}^-$ . We can then construct a table of initial and equilibrium concentrations in which the initial concentration of  $\text{ClO}^-$  is our unknown. We can calculate  $[\text{ClO}^-]$  using the equilibrium-constant expression,  $K_b$ .

**Solve:** We can calculate  $[\text{OH}^-]$  by using either Equation 16.16 or Equation 16.20; we will use the latter method here:

$$\begin{aligned} \text{pOH} &= 14.00 - \text{pH} = 14.00 - 10.50 = 3.50 \\ [\text{OH}^-] &= 10^{-3.50} = 3.2 \times 10^{-4} M \end{aligned}$$

This concentration is high enough that we can assume that Equation 16.37 is the only source of  $\text{OH}^-$ ; that is, we can neglect any  $\text{OH}^-$  produced by the autoionization of  $\text{H}_2\text{O}$ . We now assume a value of  $x$  for the initial concentration of  $\text{ClO}^-$  and solve the equilibrium problem in the usual way.

We now use the expression for the base-dissociation constant to solve for  $x$ :

Thus

$$\text{ClO}^-(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HClO}(aq) + \text{OH}^-(aq)$$

Initial	$x \text{ M}$	—	0	0
Change	$-3.2 \times 10^{-4} \text{ M}$	—	$+3.2 \times 10^{-4} \text{ M}$	$+3.2 \times 10^{-4} \text{ M}$
Equilibrium	$(x - 3.2 \times 10^{-4}) \text{ M}$	—	$3.2 \times 10^{-4} \text{ M}$	$3.2 \times 10^{-4} \text{ M}$

$$K_b = \frac{[\text{HClO}][\text{OH}^-]}{[\text{ClO}^-]} = \frac{(3.2 \times 10^{-4})^2}{x - 3.2 \times 10^{-4}} = 3.3 \times 10^{-7}$$

$$x = \frac{(3.2 \times 10^{-4})^2}{3.3 \times 10^{-7}} + (3.2 \times 10^{-4}) = 0.31 \text{ M}$$

We say that the solution is 0.31 M in NaClO even though some of the  $\text{ClO}^-$  ions have reacted with water. Because the solution is 0.31 M in NaClO and the total volume of solution is 2.00 L, 0.62 mol of NaClO is the amount of the salt that was added to the water.

### ■ PRACTICE EXERCISE

A solution of  $\text{NH}_3$  in water has a pH of 11.17. What is the molarity of the solution?

*Answer:* 0.12 M

## 16.8 RELATIONSHIP BETWEEN $K_a$ AND $K_b$

We have seen in a qualitative way that the stronger acids have the weaker conjugate bases. To see if we can find a corresponding *quantitative* relationship, let's consider the  $\text{NH}_4^+$  and  $\text{NH}_3$  conjugate acid–base pair. Each of these species reacts with water:

Each of these equilibria is expressed by a characteristic dissociation constant:

$$K_a = \frac{[\text{NH}_3][\text{H}^+]}{[\text{NH}_4^+]}$$

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$$

When Equations 16.38 and 16.39 are added together, the  $\text{NH}_4^+$  and  $\text{NH}_3$  species cancel and we are left with just the autoionization of water.

Recall that when two equations are added to give a third, the equilibrium constant associated with the third equation equals the product of the equilibrium constants for the two equations added together.  $\rightleftharpoons$  (Section 15.3)

Applying this rule to our present example, when we multiply  $K_a$  and  $K_b$ , we obtain the following:

$$\begin{aligned} K_a \times K_b &= \left( \frac{[\text{NH}_3][\text{H}^+]}{[\text{NH}_4^+]} \right) \left( \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} \right) \\ &= [\text{H}^+][\text{OH}^-] = K_w \end{aligned}$$

TABLE 16.5 ■ Some Conjugate Acid–Base Pairs

Acid	$K_a$	Base	$K_b$
HNO <sub>3</sub>	(Strong acid)	NO <sub>3</sub> <sup>−</sup>	(Negligible basicity)
HF	$6.8 \times 10^{-4}$	F <sup>−</sup>	$1.5 \times 10^{-11}$
HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub>	$1.8 \times 10^{-5}$	C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> <sup>−</sup>	$5.6 \times 10^{-10}$
H <sub>2</sub> CO <sub>3</sub>	$4.3 \times 10^{-7}$	HCO <sub>3</sub> <sup>−</sup>	$2.3 \times 10^{-8}$
NH <sub>4</sub> <sup>+</sup>	$5.6 \times 10^{-10}$	NH <sub>3</sub>	$1.8 \times 10^{-5}$
HCO <sub>3</sub> <sup>−</sup>	$5.6 \times 10^{-11}$	CO <sub>3</sub> <sup>2−</sup>	$1.8 \times 10^{-4}$
OH <sup>−</sup>	(Negligible acidity)	O <sup>2−</sup>	(Strong base)

Thus, the result of multiplying  $K_a$  times  $K_b$  is just the ion-product constant for water,  $K_w$  (Equation 16.16). We expect this result because adding Equations 16.38 and 16.39 gave us the autoionization equilibrium for water, for which the equilibrium constant is  $K_w$ .

This relationship is so important that it should receive special attention: *The product of the acid-dissociation constant for an acid and the base-dissociation constant for its conjugate base equals the ion-product constant for water.*

$$K_a \times K_b = K_w \quad [16.40]$$

As the strength of an acid increases (larger  $K_a$ ), the strength of its conjugate base must decrease (smaller  $K_b$ ) so that the product  $K_a \times K_b$  equals  $1.0 \times 10^{-14}$  at 25 °C. The  $K_a$  and  $K_b$  data in Table 16.5 ▲ demonstrate this relationship. Remember, this important relationship applies *only* to conjugate acid–base pairs.

## Chemistry Put to Work

### AMINES AND AMINE HYDROCHLORIDES

Many amines with low molecular weights have unpleasant “fishy” odors. Amines and NH<sub>3</sub> are produced by the anaerobic (absence of O<sub>2</sub>) decomposition of dead animal or plant matter. Two such amines with very disagreeable odors are H<sub>2</sub>N(CH<sub>2</sub>)<sub>4</sub>NH<sub>2</sub>, known as *putrescine*, and H<sub>2</sub>N(CH<sub>2</sub>)<sub>5</sub>NH<sub>2</sub>, known as *cadaverine*.

Many drugs, including quinine, codeine, caffeine, and amphetamine (Benzedrine<sup>®</sup>), are amines. Like other amines, these substances are weak bases; the amine nitrogen is readily protonated upon treatment with an acid. The resulting products are called *acid salts*. If we use A as the abbreviation for an amine, the acid salt formed by reaction with hydrochloric acid can be written as AH<sup>+</sup>Cl<sup>−</sup>. It can also be written as A·HCl and referred to as a hydrochloride. Amphetamine hydrochloride, for example, is the acid salt formed by treating amphetamine with HCl:

Such acid salts are much less volatile, more stable, and generally more water soluble than the corresponding neutral amines. Many drugs that are amines are sold and administered as acid salts. Some examples of over-the-counter medications that contain amine hydrochlorides as active ingredients are shown in Figure 16.10 ▼.

*Related Exercises: 16.77, 16.78, 16.108, 16.119, and 16.127*

▲ **Figure 16.10** Some over-the-counter medications in which an amine hydrochloride is a major active ingredient.

By using Equation 16.40, we can calculate  $K_b$  for any weak base if we know  $K_a$  for its conjugate acid. Similarly, we can calculate  $K_a$  for a weak acid if we know  $K_b$  for its conjugate base. As a practical consequence, ionization constants are often listed for only one member of a conjugate acid–base pair. For example, Appendix D does not contain  $K_b$  values for the anions of weak acids because they can be readily calculated from the tabulated  $K_a$  values for their conjugate acids.

If you look up the values for acid- or base-dissociation constants in a chemistry handbook, you may find them expressed as  $pK_a$  or  $pK_b$  (that is, as  $-\log K_a$  or  $-\log K_b$ ).  $\rightleftharpoons$  (Section 16.4) Equation 16.40 can be written in terms of  $pK_a$  and  $pK_b$  by taking the negative log of both sides:

$$pK_a + pK_b = pK_w = 14.00 \quad \text{at } 25^\circ\text{C} \quad [16.41]$$

### SAMPLE EXERCISE 16.17 | Calculating $K_a$ or $K_b$ for a Conjugate Acid–Base Pair

Calculate (a) the base-dissociation constant,  $K_b$ , for the fluoride ion ( $F^-$ ); (b) the acid-dissociation constant,  $K_a$ , for the ammonium ion ( $NH_4^+$ ).

#### SOLUTION

**Analyze:** We are asked to determine dissociation constants for  $F^-$ , the conjugate base of HF, and  $NH_4^+$ , the conjugate acid of  $NH_3$ .

**Plan:** Although neither  $F^-$  nor  $NH_4^+$  appears in the tables, we can find the tabulated values for ionization constants for HF and  $NH_3$ , and use the relationship between  $K_a$  and  $K_b$  to calculate the ionization constants for each of the conjugates.

#### Solve:

(a)  $K_a$  for the weak acid, HF, is given in Table 16.2 and Appendix D as  $K_a = 6.8 \times 10^{-4}$ . We can use Equation 16.40 to calculate  $K_b$  for the conjugate base,  $F^-$ :

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{6.8 \times 10^{-4}} = 1.5 \times 10^{-11}$$

(b)  $K_b$  for  $NH_3$  is listed in Table 16.4 and in Appendix D as  $K_b = 1.8 \times 10^{-5}$ . Using Equation 16.40, we can calculate  $K_a$  for the conjugate acid,  $NH_4^+$ :

$$K_a = \frac{K_w}{K_b} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

### PRACTICE EXERCISE

(a) Which of the following anions has the largest base-dissociation constant:  $NO_2^-$ ,  $PO_4^{3-}$ , or  $N_3^-$ ? (b) The base quinoline has the following structure:

Its conjugate acid is listed in handbooks as having a  $pK_a$  of 4.90. What is the base-dissociation constant for quinoline?

**Answers:** (a)  $PO_4^{3-}$  ( $K_b = 2.4 \times 10^{-2}$ ), (b)  $7.9 \times 10^{-10}$

## 16.9 ACID–BASE PROPERTIES OF SALT SOLUTIONS

Even before you began this chapter, you were undoubtedly aware of many substances that are acidic, such as  $HNO_3$ ,  $HCl$ , and  $H_2SO_4$ , and others that are basic, such as  $NaOH$  and  $NH_3$ . However, our recent discussions have indicated that ions can also exhibit acidic or basic properties. For example, we calculated  $K_a$  for  $NH_4^+$  and  $K_b$  for  $F^-$  in Sample Exercise 16.17. Such behavior implies that salt solutions can be acidic or basic. Before proceeding with further discussions of acids and bases, let's examine the way dissolved salts can affect pH.

Because nearly all salts are strong electrolytes, we can assume that when salts dissolve in water, they are completely dissociated. Consequently, the acid–base properties of salt solutions are due to the behavior of their constituent cations and anions. Many ions are able to react with water to generate  $\text{H}^+(\text{aq})$  or  $\text{OH}^-(\text{aq})$ . This type of reaction is often called **hydrolysis**. The pH of an aqueous salt solution can be predicted qualitatively by considering the ions of which the salt is composed.

### An Anion’s Ability to React with Water

In general, an anion,  $\text{X}^-$ , in solution can be considered the conjugate base of an acid. For example,  $\text{Cl}^-$  is the conjugate base of  $\text{HCl}$ , and  $\text{CH}_3\text{COO}^-$  is the conjugate base of  $\text{CH}_3\text{COOH}$ . Whether an anion reacts with water to produce hydroxide depends upon the strength of the acid to which it is conjugate. To identify the acid and assess its strength, we can simply add a proton to the anion’s formula:

If the acid determined in this way is one of the strong acids listed at the beginning of Section 16.5, then the anion in question will have a negligible tendency to abstract protons from water.  $\rightleftharpoons$  (Section 16.2) Consequently, the anion  $\text{X}^-$  will not affect the pH of the solution. The presence of  $\text{Cl}^-$  in an aqueous solution, for example, does not result in the production of any  $\text{OH}^-$  and does not affect the pH. Thus,  $\text{Cl}^-$  is always a spectator in acid–base chemistry.

Conversely, if  $\text{HX}$  is *not* one of the seven strong acids, then it is a weak acid. In this case the conjugate base  $\text{X}^-$  is a weak base. This anion will therefore react to a small extent with water to produce the weak acid and hydroxide ions:

The  $\text{OH}^-$  ion generated in this way increases the pH of the solution, making it basic. Acetate ion ( $\text{CH}_3\text{COO}^-$ ), for example, being the conjugate base of a weak acid, reacts with water to produce acetic acid and hydroxide ions, thereby increasing the pH of the solution.\*

### GIVE IT SOME THOUGHT

What effect will each of the following ions have on the pH of a solution:  $\text{NO}_3^-$  and  $\text{CO}_3^{2-}$ ?

Anions that still have ionizable protons, such as  $\text{HSO}_3^-$ , are amphiprotic.  $\rightleftharpoons$  (Section 16.2) They can act as either acids or bases. Their behavior toward water will be determined by the relative magnitudes of  $K_a$  and  $K_b$  for the ion, as shown in Sample Exercise 16.19. If  $K_a > K_b$ , the ion will cause the solution to be acidic. If  $K_b > K_a$ , the solution will be basic.

### A Cation’s Ability to React with Water

Polyatomic cations whose formulas contain one or more protons can be considered the conjugate acids of weak bases.  $\text{NH}_4^+$ , for example, is the conjugate acid of the weak base  $\text{NH}_3$ . Thus,  $\text{NH}_4^+$  is a weak acid and will donate a proton to water, producing hydronium ions and thereby lowering the pH:

\*These rules apply to what are called *normal salts*. These salts contain no ionizable protons on the anion. The pH of an acid salt (such as  $\text{NaHCO}_3$  or  $\text{NaH}_2\text{PO}_4$ ) is affected by the hydrolysis of the anion and by its acid dissociation, as shown in Sample Exercise 16.19.

Most metal ions can also react with water to decrease the pH of an aqueous solution. The mechanism by which metal ions produce acidic solutions is described in Section 16.11. However, ions of alkali metals and of the heavier alkaline earth metals do not react with water and therefore do not affect pH. Note that these exceptions are the cations found in the strong bases. ∞ (Section 16.5)

### GIVE IT SOME THOUGHT

Which of the following cations has no effect on the pH of a solution:  $K^+$ ,  $Fe^{2+}$ , or  $Al^{3+}$ ?

### Combined Effect of Cation and Anion in Solution

If an aqueous salt solution contains an anion that does not react with water and a cation that does not react with water, we expect the pH to be neutral. If the solution contains an anion that reacts with water to produce hydroxide and a cation that does not react with water, we expect the pH to be basic. If the solution contains a cation that reacts with water to produce hydronium and an anion that does not react with water, we expect the pH to be acidic. Finally, a solution may contain an anion and a cation *both* capable of reacting with water. In this case both hydroxide and hydronium will be produced. Whether the solution is basic, neutral, or acidic will depend upon the relative abilities of the ions to react with water.

To summarize:

1. An anion that is the conjugate base of a strong acid, for example,  $Br^-$ , will not affect the pH of a solution. (It will be a spectator ion in acid–base chemistry.)
2. An anion that is the conjugate base of a weak acid, for example,  $CN^-$ , will cause an increase in pH.
3. A cation that is the conjugate acid of a weak base, for example,  $CH_3NH_3^+$ , will cause a decrease in pH.
4. The cations of group 1A and heavier members of group 2A ( $Ca^{2+}$ ,  $Sr^{2+}$ , and  $Ba^{2+}$ ) will not affect pH. These are the cations of the strong Arrhenius bases. (They will be spectator ions in acid–base chemistry.)
5. Other metal ions will cause a decrease in pH.
6. When a solution contains both the conjugate base of a weak acid and the conjugate acid of a weak base, the ion with the larger equilibrium constant,  $K_a$  or  $K_b$ , will have the greater influence on the pH.

Figure 16.11 ▼ demonstrates the influence of several salts on pH.

◀ **Figure 16.11** Salt solutions can be neutral, acidic, or basic. These three solutions contain the acid–base indicator bromthymol blue. (a) The  $NaCl$  solution is neutral ( $pH = 7.0$ ); (b) the  $NH_4Cl$  solution is acidic ( $pH = 3.5$ ); (c) the  $NaClO$  solution is basic ( $pH = 9.5$ ).

**SAMPLE EXERCISE 16.18** | Determining Whether Salt Solutions Are Acidic, Basic, or Neutral

Determine whether aqueous solutions of each of the following salts will be acidic, basic, or neutral: (a)  $\text{Ba}(\text{CH}_3\text{COO})_2$ , (b)  $\text{NH}_4\text{Cl}$ , (c)  $\text{CH}_3\text{NH}_3\text{Br}$ , (d)  $\text{KNO}_3$ , (e)  $\text{Al}(\text{ClO}_4)_3$ .

**SOLUTION**

**Analyze:** We are given the chemical formulas of five ionic compounds (salts) and asked whether their aqueous solutions will be acidic, basic, or neutral.

**Plan:** We can determine whether a solution of a salt is acidic, basic, or neutral by identifying the ions in solution and by assessing how each ion will affect the pH.

**Solve:**

(a) This solution contains barium ions and acetate ions. The cation,  $\text{Ba}^{2+}$ , is an ion of one of the heavy alkaline earth metals and will therefore not affect the pH (summary point 4). The anion,  $\text{CH}_3\text{COO}^-$ , is the conjugate base of the weak acid  $\text{CH}_3\text{COOH}$  and will hydrolyze to produce  $\text{OH}^-$  ions, thereby making the solution basic (summary point 2).

(b) This solution contains  $\text{NH}_4^+$  and  $\text{Cl}^-$  ions.  $\text{NH}_4^+$  is the conjugate acid of a weak base ( $\text{NH}_3$ ) and is therefore acidic (summary point 3).  $\text{Cl}^-$  is the conjugate base of a strong acid ( $\text{HCl}$ ) and therefore has no influence on the pH of the solution (summary point 1). Because the solution contains an ion that is acidic ( $\text{NH}_4^+$ ) and one that has no influence on pH ( $\text{Cl}^-$ ), the solution of  $\text{NH}_4\text{Cl}$  will be acidic.

(c) This solution contains  $\text{CH}_3\text{NH}_3^+$  and  $\text{Br}^-$  ions.  $\text{CH}_3\text{NH}_3^+$  is the conjugate acid of a weak base ( $\text{CH}_3\text{NH}_2$ , an amine) and is therefore acidic (summary point 3).  $\text{Br}^-$  is the conjugate base of a strong acid ( $\text{HBr}$ ) and is therefore pH-neutral (summary point 1). Because the solution contains one ion that is acidic and one that is neutral, the solution of  $\text{CH}_3\text{NH}_3\text{Br}$  will be acidic.

(d) This solution contains the  $\text{K}^+$  ion, which is a cation of group 1A, and the  $\text{NO}_3^-$  ion, which is the conjugate base of the strong acid  $\text{HNO}_3$ . Neither of the ions will react with water to any appreciable extent (summary points 1 and 4), making the solution neutral.

(e) This solution contains  $\text{Al}^{3+}$  and  $\text{ClO}_4^-$  ions. Cations, such as  $\text{Al}^{3+}$ , that are not in groups 1A or 2A are acidic (summary point 5). The  $\text{ClO}_4^-$  ion is the conjugate base of a strong acid ( $\text{HClO}_4$ ) and therefore does not affect pH (summary point 1). Thus, the solution of  $\text{Al}(\text{ClO}_4)_3$  will be acidic.

**PRACTICE EXERCISE**

In each of the following, indicate which salt in each of the following pairs will form the more acidic (or less basic) 0.010 M solution: (a)  $\text{NaNO}_3$ , or  $\text{Fe}(\text{NO}_3)_3$ ; (b)  $\text{KBr}$ , or  $\text{KBrO}_3$ ; (c)  $\text{CH}_3\text{NH}_3\text{Cl}$ , or  $\text{BaCl}_2$ ; (d)  $\text{NH}_4\text{NO}_2$ , or  $\text{NH}_4\text{NO}_3$ .

**Answers:** (a)  $\text{Fe}(\text{NO}_3)_3$ , (b)  $\text{KBr}$ , (c)  $\text{CH}_3\text{NH}_3\text{Cl}$ , (d)  $\text{NH}_4\text{NO}_3$

**SAMPLE EXERCISE 16.19** | Predicting Whether the Solution of an Amphiprotic Anion Is Acidic or Basic

Predict whether the salt  $\text{Na}_2\text{HPO}_4$  will form an acidic solution or a basic solution on dissolving in water.

**SOLUTION**

**Analyze:** We are asked to predict whether a solution of  $\text{Na}_2\text{HPO}_4$  will be acidic or basic. This substance is an ionic compound composed of  $\text{Na}^+$  and  $\text{HPO}_4^{2-}$  ions.

**Plan:** We need to evaluate each ion, predicting whether each is acidic or basic. Because  $\text{Na}^+$  is a cation of group 1A, we know that it has no influence on pH. It is merely a spectator ion in acid–base chemistry. Thus, our analysis of whether the solution is acidic or basic must focus on the behavior of the  $\text{HPO}_4^{2-}$  ion. We need to consider the fact that  $\text{HPO}_4^{2-}$  can act as either an acid or a base.

The reaction with the larger equilibrium constant will determine whether the solution is acidic or basic.

**Solve:** The value of  $K_a$  for Equation 16.45, as shown in Table 16.3, is  $4.2 \times 10^{-13}$ . We must calculate the value of  $K_b$  for Equation 16.46 from the value of  $K_a$  for its conjugate acid,  $\text{H}_2\text{PO}_4^-$ . We make use of the relationship shown in Equation 16.40.

$$K_a \times K_b = K_w$$

We want to know  $K_b$  for the base  $\text{HPO}_4^{2-}$ , knowing the value of  $K_a$  for the conjugate acid  $\text{H}_2\text{PO}_4^-$ :

$$K_b(\text{HPO}_4^{2-}) \times K_a(\text{H}_2\text{PO}_4^-) = K_w = 1.0 \times 10^{-14}$$

Because  $K_a$  for  $\text{H}_2\text{PO}_4^-$  is  $6.2 \times 10^{-8}$  (Table 16.3), we calculate  $K_b$  for  $\text{HPO}_4^{2-}$  to be  $1.6 \times 10^{-7}$ . This is more than  $10^2$  times larger than  $K_a$  for  $\text{HPO}_4^{2-}$ ; thus, the reaction shown in Equation 16.46 predominates over that in Equation 16.45, and the solution will be basic.

### ■ PRACTICE EXERCISE

Predict whether the dipotassium salt of citric acid ( $\text{K}_2\text{HC}_6\text{H}_5\text{O}_7$ ) will form an acidic or basic solution in water (see Table 16.3 for data).

*Answer:* acidic

## 16.10 ACID–BASE BEHAVIOR AND CHEMICAL STRUCTURE

When a substance is dissolved in water, it may behave as an acid, behave as a base, or exhibit no acid–base properties. How does the chemical structure of a substance determine which of these behaviors is exhibited by the substance? For example, why do some substances that contain OH groups behave as bases, releasing  $\text{OH}^-$  ions into solution, whereas others behave as acids, ionizing to release  $\text{H}^+$  ions? Why are some acids stronger than others? In this section we will discuss briefly the effects of chemical structure on acid–base behavior.

### Factors That Affect Acid Strength

A molecule containing H will transfer a proton only if the  $\text{H—X}$  bond is polarized in the following way:

In ionic hydrides, such as NaH, the reverse is true; the H atom possesses a negative charge and behaves as a proton acceptor. Essentially nonpolar  $\text{H—X}$  bonds, such as the  $\text{H—C}$  bond in  $\text{CH}_4$ , produce neither acidic nor basic aqueous solutions.

A second factor that helps determine whether a molecule containing an  $\text{H—X}$  bond will donate a proton is the strength of the bond. Very strong bonds are less easily dissociated than weaker ones. This factor is important, for example, in the case of the hydrogen halides. The  $\text{H—F}$  bond is the most polar  $\text{H—X}$  bond. You therefore might expect that HF would be a very strong acid if the first factor were all that mattered. However, HF has the highest bond strength among the hydrogen halides, as seen in Table 8.4. As a result, HF is a weak acid, whereas all the other hydrogen halides are strong acids in water.

A third factor that affects the ease with which a hydrogen atom ionizes from HX is the stability of the conjugate base,  $\text{X}^-$ . In general, the greater the stability of the conjugate base, the stronger is the acid. The strength of an acid is often a combination of all three factors: (1) the polarity of the  $\text{H—X}$  bond, (2) the strength of the  $\text{H—X}$  bond, and (3) the stability of the conjugate base,  $\text{X}^-$ .

### Binary Acids

In general, the  $\text{H—X}$  bond strength is the most important factor determining acid strength among the binary acids (those containing hydrogen and just one other element) in which X is in the same *group* in the periodic table. The strength of an  $\text{H—X}$  bond tends to decrease as the element X increases in size. As a result, the bond strength decreases and the acidity increases down a group. Thus, HCl is a stronger acid than HF, and  $\text{H}_2\text{S}$  is a stronger acid than  $\text{H}_2\text{O}$ .

	GROUP			
	4A	5A	6A	7A
Period 2	CH <sub>4</sub> No acid or base properties	NH <sub>3</sub> Weak base	H <sub>2</sub> O ---	HF Weak acid

▲ **Figure 16.12 Trends in acid–base properties of binary hydrides.** The acidity of the binary compounds of hydrogen and nonmetals increases moving left to right across a period and moving top to bottom down a group.

Bond strengths change less moving across a row in the periodic table than they do down a group. As a result, bond polarity is the major factor determining acidity for binary acids in the same *row*. Thus, acidity increases as the electronegativity of the element X increases, as it generally does moving from left to right in a row. For example, the acidity of the second-row elements varies in the following order: CH<sub>4</sub> < NH<sub>3</sub> << H<sub>2</sub>O < HF. Because the C–H bond is essentially nonpolar, CH<sub>4</sub> shows no tendency to form H<sup>+</sup> and CH<sub>3</sub><sup>−</sup> ions. Although the N–H bond is polar, NH<sub>3</sub> has a nonbonding pair of electrons on the nitrogen atom that dominates its chemistry, so NH<sub>3</sub> acts as a base rather than as an acid. The periodic trends in the acid strengths of binary compounds of hydrogen and the nonmetals of periods 2 and 3 are summarized in Figure 16.12 ▲.

### GIVE IT SOME THOUGHT

What is the major factor determining the increase in acidity of binary acids going down a column of the periodic table? What is the major factor going across a period?

### Oxyacids

Many common acids, such as sulfuric acid, contain one or more O–H bonds:

Acids in which OH groups and possibly additional oxygen atoms are bound to a central atom are called **oxyacids**. The OH group is also present in bases. What factors determine whether an OH group will behave as a base or as an acid?

Let's consider an OH group bound to some atom Y, which might in turn have other groups attached to it:

At one extreme, Y might be a metal, such as Na, K, or Mg. Because of their low electronegativities, the pair of electrons shared between Y and O is completely transferred to oxygen, and an ionic compound containing OH<sup>−</sup> is formed. Such compounds are therefore sources of OH<sup>−</sup> ions and behave as bases.

◀ **Figure 16.13** The acidity of oxyacids increases with increasing electronegativity of the central atom. As the electronegativity of the atom attached to an OH group increases, the ease with which the hydrogen ion is released increases. The drift of electron density toward the electronegative atom further polarizes the O—H bond, which favors ionization. In addition, the electronegative atom will help stabilize the conjugate base, which also leads to a stronger acid. Because Cl is more electronegative than I, HClO is a stronger acid than HIO.

When Y is a nonmetal, the bond to O is covalent and the substance does not readily lose  $\text{OH}^-$ . Instead, these compounds are either acidic or neutral. Generally, as the electronegativity of Y increases, so will the acidity of the substance. This happens for two reasons: First, as electron density is drawn toward Y, the O—H bond becomes weaker and more polar, thereby favoring loss of  $\text{H}^+$  (Figure 16.13▲). Second, because the conjugate base is usually an anion, its stability generally increases as the electronegativity of Y increases.

Many oxyacids contain additional oxygen atoms bonded to the central atom Y. The additional electronegative oxygen atoms pull electron density from the O—H bond, further increasing its polarity. Increasing the number of oxygen atoms also helps stabilize the conjugate base by increasing its ability to “spread out” its negative charge. Thus, the strength of an acid will increase as additional electronegative atoms bond to the central atom Y.

We can summarize these ideas as two simple rules that relate the acid strength of oxyacids to the electronegativity of Y and to the number of groups attached to Y.

1. For oxyacids that have the same number of OH groups and the same number of O atoms, acid strength increases with increasing electronegativity of the central atom Y. For example, the strength of the hypohalous acids, which have the structure  $\text{H—O—Y}$ , increases as the electronegativity of Y increases (Table 16.6▶).
2. For oxyacids that have the same central atom Y, acid strength increases as the number of oxygen atoms attached to Y increases. For example, the strength of the oxyacids of chlorine steadily increases from hypochlorous acid (HClO) to perchloric acid ( $\text{HClO}_4$ ):

Because the oxidation number of the central atom increases as the number of attached O atoms increases, this correlation can be stated in an equivalent way: In a series of oxyacids, the acidity increases as the oxidation number of the central atom increases.

**TABLE 16.6** ■ Electronegativity Values (EN) of Y and Acid-Dissociation Constants

Acid	EN of Y	$K_a$
HClO	3.0	$3.0 \times 10^{-8}$
HBrO	2.8	$2.5 \times 10^{-9}$
HIO	2.5	$2.3 \times 10^{-11}$

**SAMPLE EXERCISE 16.20** Predicting Relative Acidities from Composition and Structure

Arrange the compounds in each of the following series in order of increasing acid strength: (a)  $\text{AsH}_3$ ,  $\text{HI}$ ,  $\text{NaH}$ ,  $\text{H}_2\text{O}$ ; (b)  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{SeO}_3$ ,  $\text{H}_2\text{SeO}_4$ .

**SOLUTION**

**Analyze:** We are asked to arrange two sets of compounds in order from weakest acid to strongest acid. In (a), the substances are binary compounds containing H, whereas in (b) the substances are oxyacids.

**Plan:** For the binary compounds in part (a), we will consider the electronegativities of As, I, Na, and O relative to H. A higher electronegativity will cause the H to have a higher partial positive charge, causing the compound to be more acidic. For the oxyacids in part (b), we will consider both the relative electronegativities of the central atom (S and Se) and the number of oxygen atoms bonded to the central atom.

**Solve:**

(a) Because Na is on the left side of the periodic table, we know that it has a very low electronegativity. As a result, the hydrogen in  $\text{NaH}$  carries a negative charge. Thus  $\text{NaH}$  should be the least acidic (most basic) compound on the list. Because arsenic is less electronegative than oxygen, we might expect that  $\text{AsH}_3$  would be a weak base toward water. We would make the same prediction by an extension of the trends shown in Figure 16.12. Further, we expect that the binary hydrogen compounds of the halogens, as the most electronegative element in each period, will be acidic relative to water. In fact,  $\text{HI}$  is one of the strong acids in water. Thus the order of increasing acidity is  $\text{NaH} < \text{AsH}_3 < \text{H}_2\text{O} < \text{HI}$ .

(b) The acids  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SeO}_4$  have the same number of O atoms and OH groups. In such cases, the acid strength increases with increasing electronegativity of the central atom. Because S is more electronegative than Se, we predict that  $\text{H}_2\text{SO}_4$  is more acidic than  $\text{H}_2\text{SeO}_4$ . Next, we can compare  $\text{H}_2\text{SeO}_4$  and  $\text{H}_2\text{SeO}_3$ . For acids with the same central atom, the acidity increases as the number of oxygen atoms bonded to the central atom increases. Thus,  $\text{H}_2\text{SeO}_4$  should be a stronger acid than  $\text{H}_2\text{SeO}_3$ . Thus, we predict the order of increasing acidity to be  $\text{H}_2\text{SeO}_3 < \text{H}_2\text{SeO}_4 < \text{H}_2\text{SO}_4$ .

**PRACTICE EXERCISE**

In each of the following pairs choose the compound that leads to the more acidic (or less basic) solution: (a)  $\text{HBr}$ ,  $\text{HF}$ ; (b)  $\text{PH}_3$ ,  $\text{H}_2\text{S}$ ; (c)  $\text{HNO}_2$ ,  $\text{HNO}_3$ ; (d)  $\text{H}_2\text{SO}_3$ ,  $\text{H}_2\text{SeO}_3$ .  
**Answers:** (a)  $\text{HBr}$ , (b)  $\text{H}_2\text{S}$ , (c)  $\text{HNO}_3$ , (d)  $\text{H}_2\text{SO}_3$

## Carboxylic Acids

Another large group of acids is illustrated by acetic acid:

The portion of the structure shown in blue is called the *carboxyl group*, which is often written as  $\text{COOH}$ . Thus, the chemical formula of acetic acid is written as  $\text{CH}_3\text{COOH}$ , where only the hydrogen atom in the carboxyl group can be ionized. Acids that contain a carboxyl group are called **carboxylic acids**, and they form the largest category of organic acids. Formic acid and benzoic acid, whose structures are drawn below, are further examples of this large and important category of acids.

Acetic acid ( $\text{CH}_3\text{COOH}$ ) is a weak acid ( $K_a = 1.8 \times 10^{-5}$ ). Two factors contribute to the acidic behavior of carboxylic acids. First, the additional oxygen atom attached to the carbon of the carboxyl group draws electron density from the  $\text{O}-\text{H}$  bond, increasing its polarity and helping to stabilize the conjugate base.

## Chemistry and Life

## THE AMPHIPROTIC BEHAVIOR OF AMINO ACIDS

**A**mino acids are the building blocks of proteins. The general structure of amino acids is shown here, where different amino acids have different R groups attached to the central carbon atom:

For example, in *glycine*, which is the simplest amino acid, R is a hydrogen atom, whereas in *alanine*, R is a CH<sub>3</sub> group.

Amino acids contain a carboxyl group and can therefore serve as acids. They also contain an NH<sub>2</sub> group, characteristic of amines (Section 16.7), and thus they can also act as bases. Amino acids, therefore, are amphiprotic. For glycine, we might expect that the acid and the base reactions with water would be as follows:

The pH of a solution of glycine in water is about 6.0, indicating that it is a slightly stronger acid than a base.

The acid-base chemistry of amino acids is somewhat more complicated than shown in Equations 16.47 and 16.48, however. Because the COOH can act as an acid and the NH<sub>2</sub> group can act as a base, amino acids undergo a “self-contained” Brønsted-Lowry acid-base reaction in which the proton of the carboxyl group is transferred to the basic nitrogen atom:

Although the form of the amino acid on the right side of Equation 16.49 is electrically neutral overall, it has a positively charged end and a negatively charged end. A molecule of this type is called a *zwitterion* (German for “hybrid ion”).

Do amino acids exhibit any properties indicating that they behave as zwitterions? If so, they should behave similar to ionic substances.  $\square$  (Section 8.2) Crystalline amino acids (Figure 16.14  $\blacktriangledown$ ) have relatively high melting points, usually above 200 °C, which is characteristic of ionic solids. Amino acids are far more soluble in water than in nonpolar solvents. In addition, the dipole moments of amino acids are large, consistent with a large separation of charge in the molecule. Thus, the ability of amino acids to act simultaneously as acids and bases has important effects on their properties.

**Related Exercise:** 16.119

**▲ Figure 16.14 Lysine.** One of the amino acids found in proteins, lysine is available as a dietary supplement. The L on the label refers to a specific arrangement of atoms that is found in naturally occurring amino acids. Molecules with the L arrangement are mirror images of molecules with the D arrangement, much like our left hand is a mirror image of our right hand.

Second, the conjugate base of a carboxylic acid (a *carboxylate anion*) can exhibit resonance (Section 8.6), which contributes further to the stability of the anion by spreading the negative charge over several atoms:

## GIVE IT SOME THOUGHT

What group of atoms is present in all carboxylic acids?

## 16.11 LEWIS ACIDS AND BASES

For a substance to be a proton acceptor (a Brønsted–Lowry base), it must have an unshared pair of electrons for binding the proton.  $\text{NH}_3$ , for example, acts as a proton acceptor. Using Lewis structures, we can write the reaction between  $\text{H}^+$  and  $\text{NH}_3$  as follows:

G. N. Lewis was the first to notice this aspect of acid–base reactions. He proposed a definition of acid and base that emphasizes the shared electron pair: A **Lewis acid** is an electron-pair acceptor, and a **Lewis base** is an electron-pair donor.

Every base that we have discussed thus far—whether it be  $\text{OH}^-$ ,  $\text{H}_2\text{O}$ , an amine, or an anion—is an electron-pair donor. Everything that is a base in the Brønsted–Lowry sense (a proton acceptor) is also a base in the Lewis sense (an electron-pair donor). In the Lewis theory, however, a base can donate its electron pair to something other than  $\text{H}^+$ . The Lewis definition therefore greatly increases the number of species that can be considered acids;  $\text{H}^+$  is a Lewis acid, but not the only one. For example, consider the reaction between  $\text{NH}_3$  and  $\text{BF}_3$ . This reaction occurs because  $\text{BF}_3$  has a vacant orbital in its valence shell.  $\infty$  (Section 8.7) It therefore acts as an electron-pair acceptor (a Lewis acid) toward  $\text{NH}_3$ , which donates the electron pair. The curved arrow shows the donation of a pair of electrons from N to B to form a covalent bond:

## GIVE IT SOME THOUGHT

What feature must any molecule or ion have to act as a Lewis base?

Our emphasis throughout this chapter has been on water as the solvent and on the proton as the source of acidic properties. In such cases we find the Brønsted–Lowry definition of acids and bases to be the most useful. In fact, when we speak of a substance as being acidic or basic, we are usually thinking of aqueous solutions and using these terms in the Arrhenius or Brønsted–Lowry sense. The advantage of the Lewis theory is that it allows us to treat a wider variety of reactions, including those that do not involve proton transfer, as acid–base reactions. To avoid confusion, a substance such as  $\text{BF}_3$  is rarely called an acid unless it is clear from the context that we are using the term in the sense of the Lewis definition. Instead, substances that function as electron-pair acceptors are referred to explicitly as “Lewis acids.”

Lewis acids include molecules that, like  $\text{BF}_3$ , have an incomplete octet of electrons. In addition, many simple cations can function as Lewis acids. For example,  $\text{Fe}^{3+}$  interacts strongly with cyanide ions to form the ferricyanide ion,  $[\text{Fe}(\text{CN})_6]^{3-}$ .

The  $\text{Fe}^{3+}$  ion has vacant orbitals that accept the electron pairs donated by the cyanide ions; we will learn more in Chapter 24 about just which orbitals are used by the  $\text{Fe}^{3+}$  ion. The metal ion is highly charged, too, which contributes to the interaction with  $\text{CN}^-$  ions.

Some compounds with multiple bonds can behave as Lewis acids. For example, the reaction of carbon dioxide with water to form carbonic acid ( $\text{H}_2\text{CO}_3$ ) can be pictured as an attack by a water molecule on  $\text{CO}_2$ , in which the water acts as an electron-pair donor and the  $\text{CO}_2$  as an electron-pair acceptor, as shown in the margin. The electron pair of one of the carbon–oxygen double bonds is moved onto the oxygen, leaving a vacant orbital on the carbon that can act as an electron-pair acceptor. We have shown the shift of these electrons with arrows. After forming the initial acid–base product, a proton moves from one oxygen to another, thereby forming carbonic acid. A similar kind of Lewis acid–base reaction takes place when any oxide of a nonmetal dissolves in water to form an acidic solution.

### Hydrolysis of Metal Ions

As we have already seen, most metal ions behave as acids in aqueous solution.  $\rightleftharpoons$  (Section 16.9) For example, an aqueous solution of  $\text{Fe}(\text{NO}_3)_3$  is quite acidic. An aqueous solution of  $\text{ZnCl}_2$  is also acidic, though to a lesser extent. The Lewis concept helps explain the interactions between metal ions and water molecules that give rise to this acidic behavior.

Because metal ions are positively charged, they attract the unshared electron pairs of water molecules. It is primarily this interaction, referred to as *hydration*, that causes salts to dissolve in water.  $\rightleftharpoons$  (Section 13.1) The process of hydration can be thought of as a Lewis acid–base interaction in which the metal ion acts as a Lewis acid and the water molecules as Lewis bases. When a water molecule interacts with the positively charged metal ion, electron density is drawn from the oxygen, as illustrated in Figure 16.15  $\blacktriangleright$ . This flow of electron density causes the O—H bond to become more polarized; as a result, water molecules bound to the metal ion are more acidic than those in the bulk solvent.

The hydrated  $\text{Fe}^{3+}$  ion,  $\text{Fe}(\text{H}_2\text{O})_6^{3+}$ , which we usually represent simply as  $\text{Fe}^{3+}(\text{aq})$ , acts as a source of protons:

The acid-dissociation constant for this hydrolysis reaction has the value  $K_a = 2 \times 10^{-3}$ , so  $\text{Fe}^{3+}(\text{aq})$  is a fairly strong acid. Acid-dissociation constants for hydrolysis reactions generally increase with increasing charge and decreasing radius of the ion (Figure 16.15). Thus, the  $\text{Cu}^{2+}$  ion, which has a smaller charge and a larger radius than  $\text{Fe}^{3+}$ , forms less acidic solutions than  $\text{Fe}^{3+}$ : The  $K_a$  for  $\text{Cu}^{2+}(\text{aq})$  is  $1 \times 10^{-8}$ . The acid hydrolysis of a number of salts of metal ions is demonstrated in Figure 16.16  $\blacktriangledown$ . Note that the  $\text{Na}^+$  ion, which is large and has only a 1+ charge (and which we have previously identified as the cation of a strong base), exhibits no acid hydrolysis and yields a neutral solution.

$\blacktriangle$  **Figure 16.15** The acidity of a hydrated cation depends on cation charge and size. The interaction between a water molecule and a cation is much stronger when the cation is a smaller ion of higher charge. The pull of electron density toward the cation weakens the polar O—H bond of the water molecule and allows the transfer of a  $\text{H}^+$  ion to a nearby water molecule. As a result, hydrated cations tend to be acidic, with their acidities increasing with increasing charge and decreasing size.

$\blacktriangledown$  **Figure 16.16** Effect of cations on the pH of a solution. The pH values of 1.0 M solutions of a series of nitrate salts are estimated using acid–base indicators.

## GIVE IT SOME THOUGHT

Which of the following cations will be most acidic and why:  $\text{Ca}^{2+}$ ,  $\text{Fe}^{2+}$ ,  $\text{Fe}^{3+}$ ?

## SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

Phosphorous acid ( $\text{H}_3\text{PO}_3$ ) has the following Lewis structure.

(a) Explain why  $\text{H}_3\text{PO}_3$  is diprotic and not triprotic. (b) A 25.0-mL sample of a solution of  $\text{H}_3\text{PO}_3$  is titrated with 0.102 M NaOH. It requires 233 mL of NaOH to neutralize both acidic protons. What is the molarity of the  $\text{H}_3\text{PO}_3$  solution? (c) The original solution from part (b) has a pH of 1.59. Calculate the percent ionization and  $K_{a1}$  for  $\text{H}_3\text{PO}_3$ , assuming that  $K_{a1} \gg K_{a2}$ . (d) How does the osmotic pressure of a 0.050 M solution of HCl compare qualitatively with that of a 0.050 M solution of  $\text{H}_3\text{PO}_3$ ? Explain.

## SOLUTION

We will use what we have learned about molecular structure and its impact on acidic behavior to answer part (a). We will then use stoichiometry and the relationship between pH and  $[\text{H}^+]$  to answer parts (b) and (c). Finally, we will consider acid strength in order to compare the colligative properties of the two solutions in part (d).

(a) Acids have polar H—X bonds. From Figure 8.6 we see that the electronegativity of H is 2.1 and that of P is also 2.1. Because the two elements have the same electronegativity, the H—P bond is nonpolar.  $\leftarrow$  (Section 8.4) Thus, this H cannot be acidic. The other two H atoms, however, are bonded to O, which has an electronegativity of 3.5. The H—O bonds are therefore polar, with H having a partial positive charge. These two H atoms are consequently acidic.

(b) The chemical equation for the neutralization reaction is

From the definition of molarity,  $M = \text{mol/L}$ , we see that moles =  $M \times L$ .  $\leftarrow$  (Section 4.5) Thus, the number of moles of NaOH added to the solution is  $(0.0233 \text{ L})(0.102 \text{ mol/L}) = 2.38 \times 10^{-3} \text{ mol NaOH}$ . The balanced equation indicates that 2 mol of NaOH is consumed for each mole of  $\text{H}_3\text{PO}_3$ . Thus, the number of moles of  $\text{H}_3\text{PO}_3$  in the sample is

$$(2.38 \times 10^{-3} \text{ mol NaOH}) \left( \frac{1 \text{ mol H}_3\text{PO}_3}{2 \text{ mol NaOH}} \right) = 1.19 \times 10^{-3} \text{ mol H}_3\text{PO}_3$$

The concentration of the  $\text{H}_3\text{PO}_3$  solution, therefore, equals  $(1.19 \times 10^{-3} \text{ mol}) / (0.0250 \text{ L}) = 0.0476 \text{ M}$ .

(c) From the pH of the solution, 1.59, we can calculate  $[\text{H}^+]$  at equilibrium.

$$[\text{H}^+] = \text{antilog}(-1.59) = 10^{-1.59} = 0.026 \text{ M (two significant figures)}$$

Because  $K_{a1} \gg K_{a2}$ , the vast majority of the ions in solution are from the first ionization step of the acid.

Because one  $\text{H}_2\text{PO}_3^-$  ion forms for each  $\text{H}^+$  ion formed, the equilibrium concentrations of  $\text{H}^+$  and  $\text{H}_2\text{PO}_3^-$  are equal:  $[\text{H}^+] = [\text{H}_2\text{PO}_3^-] = 0.026 \text{ M}$ . The equilibrium concentration of  $\text{H}_3\text{PO}_3$  equals the initial concentration minus the amount that ionizes to form  $\text{H}^+$  and  $\text{H}_2\text{PO}_3^-$ :  $[\text{H}_3\text{PO}_3] = 0.0476 \text{ M} - 0.026 \text{ M} = 0.022 \text{ M}$  (two significant figures). These results can be tabulated as follows:

	$\text{H}_3\text{PO}_3(aq)$	$\rightleftharpoons$	$\text{H}^+(aq)$	+	$\text{H}_2\text{PO}_3^-(aq)$
Initial	0.0476 M		0		0
Change	-0.026 M		+0.026 M		+0.026 M
Equilibrium	0.022 M		0.026 M		0.026 M

The percent ionization is

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{H}_3\text{PO}_3]_{\text{initial}}} \times 100\% = \frac{0.026 \text{ M}}{0.0476 \text{ M}} \times 100\% = 55\%$$

The first acid-dissociation constant is

$$K_{a1} = \frac{[\text{H}^+][\text{H}_2\text{PO}_3^-]}{[\text{H}_3\text{PO}_3]} = \frac{(0.026)(0.026)}{0.022} = 0.031$$

(d) Osmotic pressure is a colligative property and depends on the total concentration of particles in solution.  $\hookrightarrow$  (Section 13.5) Because HCl is a strong acid, a 0.050 M solution will contain 0.050 M  $\text{H}^+(aq)$  and 0.050 M  $\text{Cl}^-(aq)$ , or a total of 0.100 mol/L of particles. Because  $\text{H}_3\text{PO}_3$  is a weak acid, it ionizes to a lesser extent than HCl, and, hence, there are fewer particles in the  $\text{H}_3\text{PO}_3$  solution. As a result, the  $\text{H}_3\text{PO}_3$  solution will have the lower osmotic pressure.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Section 16.1** Acids and bases were first recognized by the properties of their aqueous solutions. For example, acids turn litmus red, whereas bases turn litmus blue. Arrhenius recognized that the properties of acidic solutions are due to  $\text{H}^+(aq)$  ions and those of basic solutions are due to  $\text{OH}^-(aq)$  ions.

**Section 16.2** The Brønsted–Lowry concept of acids and bases is more general than the Arrhenius concept and emphasizes the transfer of a proton ( $\text{H}^+$ ) from an acid to a base. The  $\text{H}^+$  ion, which is merely a proton with no surrounding valence electrons, is strongly bound to water. For this reason, the **hydronium ion**,  $\text{H}_3\text{O}^+(aq)$ , is often used to represent the predominant form of  $\text{H}^+$  in water instead of the simpler  $\text{H}^+(aq)$ .

A **Brønsted–Lowry acid** is a substance that donates a proton to another substance; a **Brønsted–Lowry base** is a substance that accepts a proton from another substance. Water is an **amphiprotic** substance, one that can function as either a Brønsted–Lowry acid or base, depending on the substance with which it reacts.

The **conjugate base** of a Brønsted–Lowry acid is the species that remains when a proton is removed from the acid. The **conjugate acid** of a Brønsted–Lowry base is the species formed by adding a proton to the base. Together, an acid and its conjugate base (or a base and its conjugate acid) are called a **conjugate acid–base pair**.

The acid–base strengths of conjugate acid–base pairs are related: The stronger an acid, the weaker is its conjugate base; the weaker an acid, the stronger is its conjugate base. In every acid–base reaction, the position of the equilibrium favors the transfer of the proton from the stronger acid to the stronger base.

**Section 16.3** Water ionizes to a slight degree, forming  $\text{H}^+(aq)$  and  $\text{OH}^-(aq)$ . The extent of this **autoionization** is expressed by the **ion-product constant** for water:

$K_w = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$  (25 °C). This relationship describes both pure water and aqueous solutions. The  $K_w$  expression indicates that the product of  $[\text{H}^+]$  and  $[\text{OH}^-]$  is a constant. Thus, as  $[\text{H}^+]$  increases,  $[\text{OH}^-]$  decreases. Acidic solutions are those that contain more  $\text{H}^+(aq)$  than  $\text{OH}^-(aq)$ ; basic solutions contain more  $\text{OH}^-(aq)$  than  $\text{H}^+(aq)$ .

**Section 16.4** The concentration of  $\text{H}^+(aq)$  can be expressed in terms of **pH**:  $\text{pH} = -\log[\text{H}^+]$ . At 25 °C the pH of a neutral solution is 7.00, whereas the pH of an acidic solution is below 7.00, and the pH of a basic solution is above 7.00. The **pX** notation is also used to represent the negative log of other small quantities, as in pOH and  $\text{p}K_w$ . The pH of a solution can be measured using a pH meter, or it can be estimated using acid–base indicators.

**Section 16.5** Strong acids are strong electrolytes, ionizing completely in aqueous solution. The common strong acids are HCl, HBr, HI,  $\text{HNO}_3$ ,  $\text{HClO}_3$ ,  $\text{HClO}_4$ , and  $\text{H}_2\text{SO}_4$ . The conjugate bases of strong acids have negligible basicity.

Common strong bases are the ionic hydroxides of alkali metals and the heavy alkaline earth metals. The cations of these metals have negligible acidity.

**Section 16.6** Weak acids are weak electrolytes; only some of the molecules exist in solution in ionized form. The extent of ionization is expressed by the **acid-dissociation constant**,  $K_a$ , which is the equilibrium constant for the reaction  $\text{HA}(aq) \rightleftharpoons \text{H}^+(aq) + \text{A}^-(aq)$ , which can also be written  $\text{HA}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{A}^-(aq)$ . The larger the value of  $K_a$ , the stronger is the acid. For solutions of the same concentration, a stronger acid also has a larger **percent ionization**. The concentration of a weak acid and its  $K_a$  value can be used to calculate the pH of a solution.

**Polyprotic acids**, such as  $\text{H}_2\text{SO}_3$ , have more than one ionizable proton. These acids have acid-dissociation constants that decrease in magnitude in the order

$K_{a1} > K_{a2} > K_{a3}$ . Because nearly all the  $H^+(aq)$  in a polyprotic acid solution comes from the first dissociation step, the pH can usually be estimated satisfactorily by considering only  $K_{a1}$ .

**Sections 16.7 and 16.8** Weak bases include  $NH_3$ , amines, and the anions of weak acids. The extent to which a weak base reacts with water to generate the corresponding conjugate acid and  $OH^-$  is measured by the **base-dissociation constant**,  $K_b$ . This is the equilibrium constant for the reaction  $B(aq) + H_2O(l) \rightleftharpoons HB^+(aq) + OH^-(aq)$ , where B is the base.

The relationship between the strength of an acid and the strength of its conjugate base is expressed quantitatively by the equation  $K_a \times K_b = K_w$ , where  $K_a$  and  $K_b$  are dissociation constants for conjugate acid–base pairs.

**Section 16.9** The acid–base properties of salts can be ascribed to the behavior of their respective cations and anions. The reaction of ions with water, with a resultant change in pH, is called **hydrolysis**. The cations of the alkali metals and the alkaline earth metals and the anions of strong acids do not undergo hydrolysis. They are always spectator ions in acid–base chemistry.

**Section 16.10** The tendency of a substance to show acidic or basic characteristics in water can be correlated with its chemical structure. Acid character requires the presence of a highly polar  $H-X$  bond. Acidity is also favored when the  $H-X$  bond is weak and when the  $X^-$  ion is very stable.

For **oxyacids** with the same number of OH groups and the same number of O atoms, acid strength increases with increasing electronegativity of the central atom. For oxyacids with the same central atom, acid strength increases as the number of oxygen atoms attached to the central atom increases. The structures of **carboxylic acids**, which are organic acids containing the COOH group, also help us to understand their acidity.

**Section 16.11** The Lewis concept of acids and bases emphasizes the shared electron pair rather than the proton. A **Lewis acid** is an electron-pair acceptor, and a **Lewis base** is an electron-pair donor. The Lewis concept is more general than the Brønsted–Lowry concept because it can apply to cases in which the acid is some substance other than  $H^+$ . The Lewis concept helps to explain why many hydrated metal cations form acidic aqueous solutions. The acidity of these cations generally increases as their charge increases and as the size of the metal ion decreases.

## KEY SKILLS

- Understand the nature of the hydrated proton, represented as either  $H^+(aq)$  or  $H_3O^+(aq)$ .
- Define and identify Arrhenius acids and bases.
- Define and identify Brønsted–Lowry acids and bases, and identify conjugate acid–base pairs.
- Relate the strength of an acid to the strength of its conjugate base.
- Understand how the equilibrium position of a proton transfer reaction relates the strengths of the acids and bases involved.
- Describe the autoionization of water and understand how  $[H_3O^+]$  and  $[OH^-]$  are related.
- Calculate the pH of a solution given  $[H_3O^+]$  or  $[OH^-]$ .
- Calculate the pH of a strong acid or strong base given its concentration.
- Calculate  $K_a$  or  $K_b$  for a weak acid or weak base given its concentration and the pH of the solution.
- Calculate the pH of a weak acid or weak base or its percent ionization given its concentration and  $K_a$  or  $K_b$ .
- Calculate  $K_b$  for a weak base given  $K_a$  of its conjugate acid, and similarly calculate  $K_a$  from  $K_b$ .
- Predict whether an aqueous solution of a salt will be acidic, basic, or neutral.
- Predict the relative strength of a series of acids from their molecular structures.
- Define and identify Lewis acids and bases.

## KEY EQUATIONS

- $K_w = [H_3O^+][OH^-] = [H^+][OH^-] = 1.0 \times 10^{-14}$  [16.16] The ion product of water at 25 °C
- $pH = -\log[H^+]$  [16.17] Definition of pH
- $pOH = -\log[OH^-]$  [16.18] Definition of pOH

- $\text{pH} + \text{pOH} = 14.00$  [16.20]
- $K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$  or  $K_a = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]}$  [16.25]
- Percent ionization =  $\frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HA}]_{\text{initial}}} \times 100\%$  [16.27]
- $K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]}$  [16.34]
- $K_a \times K_b = K_w$  [16.40]

Relationship between pH and pOH

The acid dissociation constant for a weak acid, HA

Percent ionization of a weak acid

The base dissociation constant for a weak base, B

The relationship between the acid and base dissociation constants of a conjugate acid–base pair

## VISUALIZING CONCEPTS

- 16.1** (a) Identify the Brønsted–Lowry acid and the Brønsted–Lowry base in the following reaction:

(b) Identify the Lewis acid and the Lewis base in the reaction. [Sections 16.2 and 16.11]

- 16.2** The following diagrams represent aqueous solutions of two monoprotic acids, HA (A = X or Y). The water molecules have been omitted for clarity. (a) Which is the stronger acid, HX or HY? (b) Which is the stronger base, X<sup>−</sup> or Y<sup>−</sup>? (c) If you mix equal concentrations of HX and NaY, will the equilibrium

lie mostly to the right ( $K_c > 1$ ) or to the left ( $K_c < 1$ )? [Section 16.2]

- 16.3** The following diagrams represent aqueous solutions of three acids, HX, HY, and HZ. The water molecules have been omitted for clarity, and the hydrated proton is represented as a simple sphere rather than as a hydronium ion. (a) Which of the acids is a strong acid? Explain.

- (b) Which acid would have the smallest acid-dissociation constant,  $K_a$ ? (c) Which solution would have the highest pH? [Sections 16.5 and 16.6]

- 16.4** In which of the following cases is the approximation that the equilibrium concentration of  $\text{H}^+(\text{aq})$  is small relative to the initial concentration of HA likely to be most valid: (a) initial  $[\text{HA}] = 0.100 \text{ M}$  and  $K_a = 1.0 \times 10^{-6}$ , (b) initial  $[\text{HA}] = 0.100 \text{ M}$  and  $K_a = 1.0 \times 10^{-4}$ , (c) initial  $[\text{HA}] = 0.100 \text{ M}$  and  $K_a = 1.0 \times 10^{-3}$ ? [Section 16.6]

- 16.5** (a) Which of these three lines represents the effect of concentration on the percent ionization of a weak acid? (b) Explain in qualitative terms why the curve you choose has the shape it does. [Section 16.6]

**16.6** Refer to the diagrams accompanying Exercise 16.3. (a) Rank the anions,  $X^-$ ,  $Y^-$ , and  $Z^-$ , in order of increasing basicity. (b) Which of the ions would have the largest base-dissociation constant,  $K_b$ ? [Sections 16.2 and 16.8]

**16.7** (a) Draw the Lewis structure for the following molecule and explain why it is able to act as a base. (b) To what class of organic compounds does this substance belong? (See the color key in Exercise 16.1.) [Section 16.7]

**16.8** The following diagram represents an aqueous solution formed by dissolving a sodium salt of a weak acid in water. The diagram shows only the  $\text{Na}^+$  ions, the  $\text{X}^-$  ions, and the  $\text{HX}$  molecules. What ion is missing from the diagram? If the drawing is completed by drawing all the ions, how many of the missing ions should be shown? [Section 16.9]

**16.9** (a) What kinds of acids are represented by the following molecular models? (b) Indicate how the acidity of each molecule is affected by increasing the electronegativity of the atom X, and explain the origin of the effect. [Section 16.10]

**16.10** In this model of acetylsalicylic acid (aspirin), identify the carboxyl group in the molecule. [Section 16.10]

**16.11** Rank the following acids in order of increasing acidity:  $\text{CH}_3\text{COOH}$ ,  $\text{CH}_2\text{ClCOOH}$ ,  $\text{CHCl}_2\text{COOH}$ ,  $\text{CCl}_3\text{COOH}$ ,  $\text{CF}_3\text{COOH}$ . [Section 16.10]

**16.12** (a) The following diagram represents the reaction of  $\text{PCl}_4^+$  with  $\text{Cl}^-$ . Draw the Lewis structures for the reactants and products, and identify the Lewis acid and the Lewis base in the reaction.

(b) The following reaction represents the acidity of a hydrated cation. How does the equilibrium constant for the reaction change as the charge of the cation increases? [Section 16.11]

## EXERCISES

### Arrhenius and Brønsted–Lowry Acids and Bases

**16.13** Although  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$  have very different properties as pure substances, their aqueous solutions possess many common properties. List some general properties of these solutions, and explain their common behavior in terms of the species present.

**16.14** Although pure  $\text{NaOH}$  and  $\text{NH}_3$  have very different properties, their aqueous solutions possess many common properties. List some general properties of these solutions, and explain their common behavior in terms of the species present.

**16.15** (a) What is the difference between the Arrhenius and the Brønsted–Lowry definitions of an acid? (b)  $\text{NH}_3(\text{g})$  and  $\text{HCl}(\text{g})$  react to form the ionic solid  $\text{NH}_4\text{Cl}(\text{s})$  (Figure 16.3). Which substance is the Brønsted–Lowry acid in this reaction? Which is the Brønsted–Lowry base?

**16.16** (a) What is the difference between the Arrhenius and the Brønsted–Lowry definitions of a base? (b) When ammonia is dissolved in water, it behaves both as an Arrhenius base and as a Brønsted–Lowry base. Explain.

**16.17** (a) Give the conjugate base of the following Brønsted–Lowry acids: (i)  $\text{HIO}_3$ , (ii)  $\text{NH}_4^+$ . (b) Give the conjugate acid of the following Brønsted–Lowry bases: (i)  $\text{O}^{2-}$ , (ii)  $\text{H}_2\text{PO}_4^-$ .

**16.18** (a) Give the conjugate base of the following Brønsted–Lowry acids: (i)  $\text{C}_6\text{H}_5\text{COOH}$ , (ii)  $\text{HPO}_4^{2-}$ . (b) Give the conjugate acid of the following Brønsted–Lowry bases: (i)  $\text{CO}_3^{2-}$ , (ii)  $\text{C}_2\text{H}_5\text{NH}_2$ .

**16.19** Designate the Brønsted–Lowry acid and the Brønsted–Lowry base on the left side of each of the following

equations, and also designate the conjugate acid and conjugate base on the right side:

- (a)  $\text{NH}_4^+(aq) + \text{CN}^-(aq) \rightleftharpoons \text{HCN}(aq) + \text{NH}_3(aq)$   
 (b)  $(\text{CH}_3)_3\text{N}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons (\text{CH}_3)_3\text{NH}^+(aq) + \text{OH}^-(aq)$   
 (c)  $\text{HCHO}_2(aq) + \text{PO}_4^{3-}(aq) \rightleftharpoons \text{CHO}_2^-(aq) + \text{HPO}_4^{2-}(aq)$

16.20 Designate the Brønsted–Lowry acid and the Brønsted–Lowry base on the left side of each equation, and also designate the conjugate acid and conjugate base on the right side.

- (a)  $\text{HBrO}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{BrO}^-(aq)$   
 (b)  $\text{HSO}_4^-(aq) + \text{HCO}_3^-(aq) \rightleftharpoons \text{SO}_4^{2-}(aq) + \text{H}_2\text{CO}_3(aq)$   
 (c)  $\text{HSO}_3^-(aq) + \text{H}_3\text{O}^+(aq) \rightleftharpoons \text{H}_2\text{SO}_3(aq) + \text{H}_2\text{O}(l)$

16.21 (a) The hydrogen oxalate ion ( $\text{HC}_2\text{O}_4^-$ ) is amphiprotic. Write a balanced chemical equation showing how it acts as an acid toward water and another equation showing how it acts as a base toward water. (b) What is the conjugate acid of  $\text{HC}_2\text{O}_4^-$ ? What is its conjugate base?

16.22 (a) Write an equation for the reaction in which  $\text{H}_2\text{C}_6\text{H}_7\text{O}_5^-(aq)$  acts as a base in  $\text{H}_2\text{O}(l)$ . (b) Write an equation for the reaction in which  $\text{H}_2\text{C}_6\text{H}_7\text{O}_5^-(aq)$  acts as an acid in  $\text{H}_2\text{O}(l)$ . (c) What is the conjugate acid of  $\text{H}_2\text{C}_6\text{H}_7\text{O}_5^-$ ? What is its conjugate base?

16.23 Label each of the following as being a strong base, a weak base, or a species with negligible basicity. In each case write the formula of its conjugate acid, and indicate whether the conjugate acid is a strong acid, a weak acid,

or a species with negligible acidity: (a)  $\text{CH}_3\text{COO}^-$ , (b)  $\text{HCO}_3^-$ , (c)  $\text{O}^{2-}$ , (d)  $\text{Cl}^-$ , (e)  $\text{NH}_3$ .

16.24 Label each of the following as being a strong acid, a weak acid, or a species with negligible acidity. In each case write the formula of its conjugate base, and indicate whether the conjugate base is a strong base, a weak base, or a species with negligible basicity: (a)  $\text{HNO}_2$ , (b)  $\text{H}_2\text{SO}_4$ , (c)  $\text{HPO}_4^{2-}$ , (d)  $\text{CH}_4$ , (e)  $\text{CH}_3\text{NH}_3^+$  (an ion related to  $\text{NH}_4^+$ ).

16.25 (a) Which of the following is the stronger Brønsted–Lowry acid,  $\text{HBrO}$  or  $\text{HBr}$ ? (b) Which is the stronger Brønsted–Lowry base,  $\text{F}^-$  or  $\text{Cl}^-$ ? Briefly explain your choices.

16.26 (a) Which of the following is the stronger Brønsted–Lowry acid,  $\text{HNO}_3$  or  $\text{HNO}_2$ ? (b) Which is the stronger Brønsted–Lowry base,  $\text{NH}_3$  or  $\text{H}_2\text{O}$ ? Briefly explain your choices.

16.27 Predict the products of the following acid–base reactions, and predict whether the equilibrium lies to the left or to the right of the equation:

- (a)  $\text{O}^{2-}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons$   
 (b)  $\text{CH}_3\text{COOH}(aq) + \text{HS}^-(aq) \rightleftharpoons$   
 (c)  $\text{NO}_2^-(aq) + \text{H}_2\text{O}(l) \rightleftharpoons$

16.28 Predict the products of the following acid–base reactions, and predict whether the equilibrium lies to the left or to the right of the equation:

- (a)  $\text{NH}_4^+(aq) + \text{OH}^-(aq) \rightleftharpoons$   
 (b)  $\text{CH}_3\text{COO}^-(aq) + \text{H}_3\text{O}^+(aq) \rightleftharpoons$   
 (c)  $\text{HCO}_3^-(aq) + \text{F}^-(aq) \rightleftharpoons$

## Autoionization of Water

16.29 (a) What does the term *autoionization* mean? (b) Explain why pure water is a poor conductor of electricity. (c) You are told that an aqueous solution is acidic. What does this statement mean?

16.30 (a) Write a chemical equation that illustrates the autoionization of water. (b) Write the expression for the ion-product constant for water,  $K_w$ . Why is  $[\text{H}_2\text{O}]$  absent from this expression? (c) A solution is described as basic. What does this statement mean?

16.31 Calculate  $[\text{H}^+]$  for each of the following solutions, and indicate whether the solution is acidic, basic, or neutral: (a)  $[\text{OH}^-] = 0.00045 \text{ M}$ ; (b)  $[\text{OH}^-] = 8.8 \times 10^{-9} \text{ M}$ ; (c) a solution in which  $[\text{OH}^-]$  is 100 times greater than  $[\text{H}^+]$ .

16.32 Calculate  $[\text{OH}^-]$  for each of the following solutions, and indicate whether the solution is acidic, basic, or neutral: (a)  $[\text{H}^+] = 0.0045 \text{ M}$ ; (b)  $[\text{H}^+] = 1.5 \times 10^{-9} \text{ M}$ ; (c) a solution in which  $[\text{H}^+]$  is 10 times greater than  $[\text{OH}^-]$ .

16.33 At the freezing point of water ( $0^\circ\text{C}$ ),  $K_w = 1.2 \times 10^{-15}$ . Calculate  $[\text{H}^+]$  and  $[\text{OH}^-]$  for a neutral solution at this temperature.

16.34 Deuterium oxide ( $\text{D}_2\text{O}$ , where D is deuterium, the hydrogen-2 isotope) has an ion-product constant,  $K_w$ , of  $8.9 \times 10^{-16}$  at  $20^\circ\text{C}$ . Calculate  $[\text{D}^+]$  and  $[\text{OD}^-]$  for pure (neutral)  $\text{D}_2\text{O}$  at this temperature.

## The pH Scale

16.35 By what factor does  $[\text{H}^+]$  change for a pH change of (a) 2.00 units, (b) 0.50 units?

16.36 Consider two solutions, solution A and solution B.  $[\text{H}^+]$  in solution A is 500 times greater than that in solution B. What is the difference in the pH values of the two solutions?

16.37 (a) If  $\text{NaOH}$  is added to water, how does  $[\text{H}^+]$  change? How does pH change? (b) Use the pH values in Figure 16.5 to estimate the pH of a solution with  $[\text{H}^+] = 0.0006 \text{ M}$ . Is the solution acidic or basic? (c) If the pH of a solution is 5.2, first estimate and then calculate the molar concentrations of  $\text{H}^+(aq)$  and  $\text{OH}^-(aq)$  in the solution.

**16.38** (a) If  $\text{HNO}_3$  is added to water, how does  $[\text{OH}^-]$  change? How does pH change? (b) Use the pH values in Figure 16.5 to estimate the pH of a solution with  $[\text{OH}^-] = 0.014 \text{ M}$ . Is the solution acidic or basic? (c) If  $\text{pH} = 6.6$ , first estimate and then calculate the molar concentrations of  $\text{H}^+(\text{aq})$  and  $\text{OH}^-(\text{aq})$  in the solution.

**16.39** Complete the following table by calculating the missing entries and indicating whether the solution is acidic or basic.

$[\text{H}^+]$	$\text{OH}^-(\text{aq})$	pH	pOH	Acidic or basic?
$7.5 \times 10^{-3} \text{ M}$	$3.6 \times 10^{-10} \text{ M}$	8.25		
			5.70	

**16.40** Complete the following table by calculating the missing entries. In each case indicate whether the solution is acidic or basic.

pH	pOH	$[\text{H}^+]$	$[\text{OH}^-]$	Acidic or basic?
11.25				
	6.02			
		$4.4 \times 10^{-4} \text{ M}$		
			$8.5 \times 10^{-3} \text{ M}$	

**16.41** The average pH of normal arterial blood is 7.40. At normal body temperature ( $37^\circ\text{C}$ ),  $K_w = 2.4 \times 10^{-14}$ . Calculate  $[\text{H}^+]$ ,  $[\text{OH}^-]$ , and pOH for blood at this temperature.

**16.42** Carbon dioxide in the atmosphere dissolves in raindrops to produce carbonic acid ( $\text{H}_2\text{CO}_3$ ), causing the pH of clean, unpolluted rain to range from about 5.2 to 5.6. What are the ranges of  $[\text{H}^+]$  and  $[\text{OH}^-]$  in the raindrops?

## Strong Acids and Bases

**16.43** (a) What is a strong acid? (b) A solution is labeled  $0.500 \text{ M HCl}$ . What is  $[\text{H}^+]$  for the solution? (c) Which of the following are strong acids: HF, HCl, HBr, HI?

**16.44** (a) What is a strong base? (b) A solution is labeled  $0.035 \text{ M Sr(OH)}_2$ . What is  $[\text{OH}^-]$  for the solution? (c) Is the following statement true or false? Because  $\text{Mg(OH)}_2$  is not very soluble, it cannot be a strong base. Explain.

**16.45** Calculate the pH of each of the following strong acid solutions: (a)  $8.5 \times 10^{-3} \text{ M HBr}$ , (b)  $1.52 \text{ g of HNO}_3$  in  $575 \text{ mL}$  of solution, (c)  $5.00 \text{ mL}$  of  $0.250 \text{ M HClO}_4$  diluted to  $50.0 \text{ mL}$ , (d) a solution formed by mixing  $10.0 \text{ mL}$  of  $0.100 \text{ M HBr}$  with  $20.0 \text{ mL}$  of  $0.200 \text{ M HCl}$ .

**16.46** Calculate the pH of each of the following strong acid solutions: (a)  $0.00135 \text{ M HNO}_3$ , (b)  $0.425 \text{ g of HClO}_4$  in  $2.00 \text{ L}$  of solution, (c)  $5.00 \text{ mL}$  of  $1.00 \text{ M HCl}$  diluted to  $0.500 \text{ L}$ , (d) a mixture formed by adding  $50.0 \text{ mL}$  of  $0.020 \text{ M HCl}$  to  $150 \text{ mL}$  of  $0.010 \text{ M HI}$ .

**16.47** Calculate  $[\text{OH}^-]$  and pH for (a)  $1.5 \times 10^{-3} \text{ M Sr(OH)}_2$ , (b)  $2.250 \text{ g of LiOH}$  in  $250.0 \text{ mL}$  of solution, (c)  $1.00 \text{ mL}$  of  $0.175 \text{ M NaOH}$  diluted to  $2.00 \text{ L}$ , (d) a solution formed by adding  $5.00 \text{ mL}$  of  $0.105 \text{ M KOH}$  to  $15.0 \text{ mL}$  of  $9.5 \times 10^{-2} \text{ M Ca(OH)}_2$ .

**16.48** Calculate  $[\text{OH}^-]$  and pH for each of the following strong base solutions: (a)  $0.082 \text{ M KOH}$ , (b)  $1.065 \text{ g of KOH}$  in  $500.0 \text{ mL}$  of solution, (c)  $10.0 \text{ mL}$  of  $0.0105 \text{ M Ca(OH)}_2$  diluted to  $500.0 \text{ mL}$ , (d) a solution formed by mixing  $10.0 \text{ mL}$  of  $0.015 \text{ M Ba(OH)}_2$  with  $40.0 \text{ mL}$  of  $7.5 \times 10^{-3} \text{ M NaOH}$ .

**16.49** Calculate the concentration of an aqueous solution of  $\text{NaOH}$  that has a pH of 11.50.

**16.50** Calculate the concentration of an aqueous solution of  $\text{Ca(OH)}_2$  that has a pH of 12.05.

## Weak Acids

**16.51** Write the chemical equation and the  $K_a$  expression for the ionization of each of the following acids in aqueous solution. First show the reaction with  $\text{H}^+(\text{aq})$  as a product and then with the hydronium ion: (a)  $\text{HBrO}_2$ , (b)  $\text{C}_2\text{H}_3\text{COOH}$ .

**16.52** Write the chemical equation and the  $K_a$  expression for the acid dissociation of each of the following acids in aqueous solution. First show the reaction with  $\text{H}^+(\text{aq})$  as a product and then with the hydronium ion: (a)  $\text{C}_6\text{H}_5\text{COOH}$ , (b)  $\text{HCO}_3^-$ .

**16.53** Lactic acid ( $\text{CH}_3\text{CH(OH)COOH}$ ) has one acidic hydrogen. A  $0.10 \text{ M}$  solution of lactic acid has a pH of 2.44. Calculate  $K_a$ .

**16.54** Phenylacetic acid ( $\text{C}_6\text{H}_5\text{CH}_2\text{COOH}$ ) is one of the substances that accumulates in the blood of people with phenylketonuria, an inherited disorder that can cause mental retardation or even death. A  $0.085 \text{ M}$  solution of  $\text{C}_6\text{H}_5\text{CH}_2\text{COOH}$  has a pH of 2.68. Calculate the  $K_a$  value for this acid.

- 16.55** A 0.100 M solution of chloroacetic acid ( $\text{ClCH}_2\text{COOH}$ ) is 11.0% ionized. Using this information, calculate  $[\text{ClCH}_2\text{COO}^-]$ ,  $[\text{H}^+]$ ,  $[\text{ClCH}_2\text{COOH}]$ , and  $K_a$  for chloroacetic acid.
- 16.56** A 0.100 M solution of bromoacetic acid ( $\text{BrCH}_2\text{COOH}$ ) is 13.2% ionized. Calculate  $[\text{H}^+]$ ,  $[\text{BrCH}_2\text{COO}^-]$ , and  $[\text{BrCH}_2\text{COOH}]$ .
- 16.57** A particular sample of vinegar has a pH of 2.90. If acetic acid is the only acid that vinegar contains ( $K_a = 1.8 \times 10^{-5}$ ), calculate the concentration of acetic acid in the vinegar.
- 16.58** How many moles of HF ( $K_a = 6.8 \times 10^{-4}$ ) must be present in 0.200 L to form a solution with a pH of 3.25?
- 16.59** The acid-dissociation constant for benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) is  $6.3 \times 10^{-5}$ . Calculate the equilibrium concentrations of  $\text{H}_3\text{O}^+$ ,  $\text{C}_6\text{H}_5\text{COO}^-$ , and  $\text{C}_6\text{H}_5\text{COOH}$  in the solution if the initial concentration of  $\text{C}_6\text{H}_5\text{COOH}$  is 0.050 M.
- 16.60** The acid-dissociation constant for hypochlorous acid ( $\text{HClO}$ ) is  $3.0 \times 10^{-8}$ . Calculate the concentrations of  $\text{H}_3\text{O}^+$ ,  $\text{ClO}^-$ , and  $\text{HClO}$  at equilibrium if the initial concentration of  $\text{HClO}$  is 0.0090 M.
- 16.61** Calculate the pH of each of the following solutions ( $K_a$  and  $K_b$  values are given in Appendix D): (a) 0.095 M propionic acid ( $\text{C}_2\text{H}_5\text{COOH}$ ), (b) 0.100 M hydrogen chromate ion ( $\text{HCrO}_4^-$ ), (c) 0.120 M pyridine ( $\text{C}_5\text{H}_5\text{N}$ ).
- 16.62** Determine the pH of each of the following solutions ( $K_a$  and  $K_b$  values are given in Appendix D): (a) 0.095 M hypochlorous acid, (b) 0.0085 M phenol, (c) 0.095 M hydroxylamine.
- 16.63** Saccharin, a sugar substitute, is a weak acid with  $\text{p}K_a = 2.32$  at 25 °C. It ionizes in aqueous solution as follows:

What is the pH of a 0.10 M solution of this substance?

- 16.64** The active ingredient in aspirin is acetylsalicylic acid ( $\text{HC}_9\text{H}_7\text{O}_4$ ), a monoprotic acid with  $K_a = 3.3 \times 10^{-4}$  at 25 °C. What is the pH of a solution obtained by dissolving two extra-strength aspirin tablets, containing 500 mg of acetylsalicylic acid each, in 250 mL of water?

- 16.65** Calculate the percent ionization of hydrazoic acid ( $\text{HN}_3$ ) in solutions of each of the following concentrations ( $K_a$  is given in Appendix D): (a) 0.400 M, (b) 0.100 M, (c) 0.0400 M.

- 16.66** Calculate the percent ionization of propionic acid ( $\text{C}_2\text{H}_5\text{COOH}$ ) in solutions of each of the following concentrations ( $K_a$  is given in Appendix D): (a) 0.250 M, (b) 0.0800 M, (c) 0.0200 M.

- [16.67]** Show that for a weak acid, the percent ionization should vary as the inverse square root of the acid concentration.

- [16.68]** For solutions of a weak acid, a graph of pH versus the log of the initial acid concentration should be a straight line. What is the magnitude of the slope of that line?

- [16.69]** Citric acid, which is present in citrus fruits, is a triprotic acid (Table 16.3). Calculate the pH and the citrate ion ( $\text{C}_6\text{H}_5\text{O}_7^{3-}$ ) concentration for a 0.050 M solution of citric acid. Explain any approximations or assumptions that you make in your calculations.

- [16.70]** Tartaric acid is found in many fruits, including grapes, and is partially responsible for the dry texture of certain wines. Calculate the pH and the tartarate ion ( $\text{C}_4\text{H}_4\text{O}_6^{2-}$ ) concentration for a 0.250 M solution of tartaric acid, for which the acid-dissociation constants are listed in Table 16.3. Explain any approximations or assumptions that you make in your calculation.

## Weak Bases

- 16.71** What is the essential structural feature of all Brønsted-Lowry bases?
- 16.72** What are two kinds of molecules or ions that commonly function as weak bases?
- 16.73** Write the chemical equation and the  $K_b$  expression for the ionization of each of the following bases in aqueous solution: (a) dimethylamine,  $(\text{CH}_3)_2\text{NH}$ ; (b) carbonate ion,  $\text{CO}_3^{2-}$ ; (c) formate ion,  $\text{CHO}_2^-$ .
- 16.74** Write the chemical equation and the  $K_b$  expression for the reaction of each of the following bases with water: (a) propylamine,  $\text{C}_3\text{H}_7\text{NH}_2$ ; (b) monohydrogen phosphate ion,  $\text{HPO}_4^{2-}$ ; (c) benzoate ion,  $\text{C}_6\text{H}_5\text{CO}_2^-$ .
- 16.75** Calculate the molar concentration of  $\text{OH}^-$  ions in a 0.075 M solution of ethylamine ( $\text{C}_2\text{H}_5\text{NH}_2$ ;  $K_b = 6.4 \times 10^{-4}$ ). Calculate the pH of this solution.
- 16.76** Calculate the molar concentration of  $\text{OH}^-$  ions in a 0.550 M solution of hypobromite ion ( $\text{BrO}^-$ ;  $K_b = 4.0 \times 10^{-6}$ ). What is the pH of this solution?
- 16.77** Ephedrine, a central nervous system stimulant, is used in nasal sprays as a decongestant. This compound is a weak organic base:
- $$\text{C}_{10}\text{H}_{15}\text{ON}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{C}_{10}\text{H}_{15}\text{ONH}^+(\text{aq}) + \text{OH}^-(\text{aq})$$
- A 0.035 M solution of ephedrine has a pH of 11.33. (a) What are the equilibrium concentrations of  $\text{C}_{10}\text{H}_{15}\text{ON}$ ,  $\text{C}_{10}\text{H}_{15}\text{ONH}^+$ , and  $\text{OH}^-$ ? (b) Calculate  $K_b$  for ephedrine.
- 16.78** Codeine ( $\text{C}_{18}\text{H}_{21}\text{NO}_3$ ) is a weak organic base. A  $5.0 \times 10^{-3}$  M solution of codeine has a pH of 9.95. Calculate the value of  $K_b$  for this substance. What is the  $\text{p}K_b$  for this base?

## The $K_a$ – $K_b$ Relationship; Acid–Base Properties of Salts

- 16.79** Although the acid-dissociation constant for phenol ( $C_6H_5OH$ ) is listed in Appendix D, the base-dissociation constant for the phenolate ion ( $C_6H_5O^-$ ) is not. (a) Explain why it is not necessary to list both  $K_a$  for phenol and  $K_b$  for the phenolate ion. (b) Calculate  $K_b$  for the phenolate ion. (c) Is the phenolate ion a weaker or stronger base than ammonia?
- 16.80** We can calculate  $K_b$  for the carbonate ion if we know the  $K_a$  values of carbonic acid ( $H_2CO_3$ ). (a) Is  $K_{a1}$  or  $K_{a2}$  of carbonic acid used to calculate  $K_b$  for the carbonate ion? Explain. (b) Calculate  $K_b$  for the carbonate ion. (c) Is the carbonate ion a weaker or stronger base than ammonia?
- 16.81** (a) Given that  $K_a$  for acetic acid is  $1.8 \times 10^{-5}$  and that for hypochlorous acid is  $3.0 \times 10^{-8}$ , which is the stronger acid? (b) Which is the stronger base, the acetate ion or the hypochlorite ion? (c) Calculate  $K_b$  values for  $CH_3COO^-$  and  $ClO^-$ .
- 16.82** (a) Given that  $K_b$  for ammonia is  $1.8 \times 10^{-5}$  and that for hydroxylamine is  $1.1 \times 10^{-8}$ , which is the stronger base? (b) Which is the stronger acid, the ammonium ion or the hydroxylammonium ion? (c) Calculate  $K_a$  values for  $NH_4^+$  and  $H_3NOH^+$ .
- 16.83** Using data from Appendix D, calculate  $[OH^-]$  and pH for each of the following solutions: (a) 0.10 M NaCN, (b) 0.080 M  $Na_2CO_3$ , (c) a mixture that is 0.10 M in  $NaNO_2$  and 0.20 M in  $Ca(NO_2)_2$ .
- 16.84** Using data from Appendix D, calculate  $[OH^-]$  and pH for each of the following solutions: (a) 0.105 M NaF, (b) 0.035 M  $Na_2S$ , (c) a mixture that is 0.045 M in  $CH_3COONa$  and 0.055 M in  $(CH_3COO)_2Ba$ .
- 16.85** Predict whether aqueous solutions of the following compounds are acidic, basic, or neutral: (a)  $NH_4Br$ , (b)  $FeCl_3$ , (c)  $Na_2CO_3$ , (d)  $KClO_4$ , (e)  $NaHC_2O_4$ .
- 16.86** Predict whether aqueous solutions of the following substances are acidic, basic, or neutral: (a)  $CrBr_3$ , (b)  $LiI$ , (c)  $K_3PO_4$ , (d)  $[CH_3NH_3]Cl$ , (e)  $KHSO_4$ .
- 16.87** An unknown salt is either NaF, NaCl, or NaOCl. When 0.050 mol of the salt is dissolved in water to form 0.500 L of solution, the pH of the solution is 8.08. What is the identity of the salt?
- 16.88** An unknown salt is either KBr,  $NH_4Cl$ , KCN, or  $K_2CO_3$ . If a 0.100 M solution of the salt is neutral, what is the identity of the salt?
- 16.89** Sorbic acid ( $C_5H_7COOH$ ) is a weak monoprotic acid with  $K_a = 1.7 \times 10^{-5}$ . Its salt (potassium sorbate) is added to cheese to inhibit the formation of mold. What is the pH of a solution containing 11.25 g of potassium sorbate in 1.75 L of solution?
- 16.90** Trisodium phosphate ( $Na_3PO_4$ ) is available in hardware stores as TSP and is used as a cleaning agent. The label on a box of TSP warns that the substance is very basic (caustic or alkaline). What is the pH of a solution containing 35.0 g of TSP in a liter of solution?

## Acid–Base Character and Chemical Structure

- 16.91** How does the acid strength of an oxyacid depend on (a) the electronegativity of the central atom; (b) the number of nonprotonated oxygen atoms in the molecule?
- 16.92** (a) How does the strength of an acid vary with the polarity and strength of the H–X bond? (b) How does the acidity of the binary acid of an element vary as a function of the electronegativity of the element? How does this relate to the position of the element in the periodic table?
- 16.93** Explain the following observations: (a)  $HNO_3$  is a stronger acid than  $HNO_2$ ; (b)  $H_2S$  is a stronger acid than  $H_2O$ ; (c)  $H_2SO_4$  is a stronger acid than  $HSO_4^-$ ; (d)  $H_2SO_4$  is a stronger acid than  $H_2SeO_4$ ; (e)  $CCl_3COOH$  is a stronger acid than  $CH_3COOH$ .
- 16.94** Explain the following observations: (a) HCl is a stronger acid than  $H_2S$ ; (b)  $H_3PO_4$  is a stronger acid than  $H_3AsO_4$ ; (c)  $HBrO_3$  is a stronger acid than  $HBrO_2$ ; (d)  $H_2C_2O_4$  is a stronger acid than  $HC_2O_4^-$ ; (e) benzoic acid ( $C_6H_5COOH$ ) is a stronger acid than phenol ( $C_6H_5OH$ ).
- 16.95** Based on their compositions and structures and on conjugate acid–base relationships, select the stronger base in each of the following pairs: (a)  $BrO^-$  or  $ClO^-$ , (b)  $BrO^-$  or  $BrO_2^-$ , (c)  $HPO_4^{2-}$  or  $H_2PO_4^-$ .
- 16.96** Based on their compositions and structures and on conjugate acid–base relationships, select the stronger base in each of the following pairs: (a)  $NO_3^-$  or  $NO_2^-$ , (b)  $PO_4^{3-}$  or  $AsO_4^{3-}$ , (c)  $HCO_3^-$  or  $CO_3^{2-}$ .
- 16.97** Indicate whether each of the following statements is true or false. For each statement that is false, correct the statement to make it true. (a) In general, the acidity of binary acids increases from left to right in a given row of the periodic table. (b) In a series of acids that have the same central atom, acid strength increases with the number of hydrogen atoms bonded to the central atom. (c) Hydrotelluric acid ( $H_2Te$ ) is a stronger acid than  $H_2S$  because Te is more electronegative than S.

- 16.98 Indicate whether each of the following statements is true or false. For each statement that is false, correct the statement to make it true. (a) Acid strength in a series of H—X molecules increases with increasing size of X. (b) For acids of the same general structure

but differing electronegativities of the central atoms, acid strength decreases with increasing electronegativity of the central atom. (c) The strongest acid known is HF because fluorine is the most electronegative element.

## Lewis Acids and Bases

- 16.99 If a substance is an Arrhenius base, is it necessarily a Brønsted–Lowry base? Is it necessarily a Lewis base? Explain.
- 16.100 If a substance is a Lewis acid, is it necessarily a Brønsted–Lowry acid? Is it necessarily an Arrhenius acid? Explain.
- 16.101 Identify the Lewis acid and Lewis base among the reactants in each of the following reactions:
- (a)  $\text{Fe}(\text{ClO}_4)_3(\text{s}) + 6 \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{Fe}(\text{H}_2\text{O})_6^{3+}(\text{aq}) + 3 \text{ClO}_4^-(\text{aq})$
- (b)  $\text{CN}^-(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{HCN}(\text{aq}) + \text{OH}^-(\text{aq})$
- (c)  $(\text{CH}_3)_3\text{N}(\text{g}) + \text{BF}_3(\text{g}) \rightleftharpoons (\text{CH}_3)_3\text{NBF}_3(\text{s})$
- (d)  $\text{HIO}(\text{lq}) + \text{NH}_2^-(\text{lq}) \rightleftharpoons \text{NH}_3(\text{lq}) + \text{IO}^-(\text{lq})$   
(lq denotes liquid ammonia as solvent)
- 16.102 Identify the Lewis acid and Lewis base in each of the following reactions:
- (a)  $\text{HNO}_2(\text{aq}) + \text{OH}^-(\text{aq}) \rightleftharpoons \text{NO}_2^-(\text{aq}) + \text{H}_2\text{O}(\text{l})$
- (b)  $\text{FeBr}_3(\text{s}) + \text{Br}^-(\text{aq}) \rightleftharpoons \text{FeBr}_4^-(\text{aq})$
- (c)  $\text{Zn}^{2+}(\text{aq}) + 4 \text{NH}_3(\text{aq}) \rightleftharpoons \text{Zn}(\text{NH}_3)_4^{2+}(\text{aq})$
- (d)  $\text{SO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}_2\text{SO}_3(\text{aq})$
- 16.103 Predict which member of each pair produces the more acidic aqueous solution: (a)  $\text{K}^+$  or  $\text{Cu}^{2+}$ , (b)  $\text{Fe}^{2+}$  or  $\text{Fe}^{3+}$ , (c)  $\text{Al}^{3+}$  or  $\text{Ga}^{3+}$ . Explain.
- 16.104 Which member of each pair produces the more acidic aqueous solution: (a)  $\text{ZnBr}_2$  or  $\text{CdCl}_2$ , (b)  $\text{CuCl}$  or  $\text{Cu}(\text{NO}_3)_2$ , (c)  $\text{Ca}(\text{NO}_3)_2$  or  $\text{NiBr}_2$ ? Explain.

## ADDITIONAL EXERCISES

- 16.105 In your own words, define or explain (a)  $K_w$ , (b)  $K_a$ , (c) pOH, (d)  $\text{p}K_b$ .
- 16.106 Indicate whether each of the following statements is correct or incorrect. For those that are incorrect, explain why they are wrong.
- (a) Every Brønsted–Lowry acid is also a Lewis acid.  
 (b) Every Lewis acid is also a Brønsted–Lowry acid.  
 (c) Conjugate acids of weak bases produce more acidic solutions than conjugate acids of strong bases.  
 (d)  $\text{K}^+$  ion is acidic in water because it causes hydrating water molecules to become more acidic.  
 (e) The percent ionization of a weak acid in water increases as the concentration of acid decreases.
- 16.107 Predict whether the equilibrium lies to the right or to the left in the following reactions:
- (a)  $\text{NH}_4^+(\text{aq}) + \text{PO}_4^{3-}(\text{aq}) \rightleftharpoons \text{NH}_3(\text{aq}) + \text{HPO}_4^{2-}(\text{aq})$  (The ammonium ion is a stronger acid than the hydrogen phosphate ion.)
- (b)  $\text{CH}_3\text{COOH}(\text{aq}) + \text{CN}^-(\text{aq}) \rightleftharpoons \text{CH}_3\text{COO}^-(\text{aq}) + \text{HCN}(\text{aq})$  (The cyanide ion is a stronger base than the acetate ion.)
- 16.108 The odor of fish is due primarily to amines, especially methylamine ( $\text{CH}_3\text{NH}_2$ ). Fish is often served with a wedge of lemon, which contains citric acid. The amine and the acid react forming a product with no odor, thereby making the less-than-fresh fish more appetizing.
- Using data from Appendix D, calculate the equilibrium constant for the reaction of citric acid with methylamine, if only the first proton of the citric acid ( $K_{a1}$ ) is important in the neutralization reaction.
- 16.109 Hemoglobin plays a part in a series of equilibria involving protonation-deprotonation and oxygenation-deoxygenation. The overall reaction is approximately as follows:
- $$\text{HbH}^+(\text{aq}) + \text{O}_2(\text{aq}) \rightleftharpoons \text{HbO}_2(\text{aq}) + \text{H}^+(\text{aq})$$
- where Hb stands for hemoglobin, and  $\text{HbO}_2$  for oxyhemoglobin. (a) The concentration of  $\text{O}_2$  is higher in the lungs and lower in the tissues. What effect does high  $[\text{O}_2]$  have on the position of this equilibrium? (b) The normal pH of blood is 7.4. Is the blood acidic, basic, or neutral? (c) If the blood pH is lowered by the presence of large amounts of acidic metabolism products, a condition known as acidosis results. What effect does lowering blood pH have on the ability of hemoglobin to transport  $\text{O}_2$ ?
- 16.110 Calculate the pH of a solution made by adding 250 g of lithium oxide ( $\text{Li}_2\text{O}$ ) to enough water to make 1.500 L of solution.
- 16.111 Which of the following solutions has the higher pH? (a) a 0.1 M solution of a strong acid or a 0.1 M solution of a weak acid, (b) a 0.1 M solution of an acid with  $K_a = 2 \times 10^{-3}$  or one with  $K_a = 8 \times 10^{-6}$ , (c) a 0.1 M solution of a base with  $\text{p}K_b = 4.5$  or one with  $\text{p}K_b = 6.5$ .

- [16.112] What is the pH of a solution that is  $2.5 \times 10^{-9} M$  in NaOH? Does your answer make sense?
- 16.113** Caproic acid ( $C_6H_{11}COOH$ ) is found in small amounts in coconut and palm oils and is used in making artificial flavors. A saturated solution of the acid contains 11 g/L and has a pH of 2.94. Calculate  $K_a$  for the acid.
- [16.114] A hypothetical acid  $H_2X$  is both a strong acid and a diprotic acid. (a) Calculate the pH of a 0.050 M solution of  $H_2X$ , assuming that only one proton ionizes per acid molecule. (b) Calculate the pH of the solution from part (a), now assuming that both protons of each acid molecule completely ionize. (c) In an experiment it is observed that the pH of a 0.050 M solution of  $H_2X$  is 1.27. Comment on the relative acid strengths of  $H_2X$  and  $HX^-$ . (d) Would a solution of the salt  $NaHX$  be acidic, basic, or neutral? Explain.
- 16.115** Butyric acid is responsible for the foul smell of rancid butter. The  $pK_a$  of butyric acid is 4.84. (a) Calculate the  $pK_b$  for the butyrate ion. (b) Calculate the pH of a 0.050 M solution of butyric acid. (c) Calculate the pH of a 0.050 M solution of sodium butyrate.
- 16.116** Arrange the following 0.10 M solutions in order of increasing acidity (decreasing pH): (i)  $NH_4NO_3$ , (ii)  $NaNO_3$ , (iii)  $CH_3COONH_4$ , (iv) NaF, (v)  $CH_3COONa$ .
- [16.117] What are the concentrations of  $H^+$ ,  $H_2PO_4^-$ ,  $HPO_4^{2-}$ , and  $PO_4^{3-}$  in a 0.0250 M solution of  $H_3PO_4$ ?
- [16.118] Many moderately large organic molecules containing basic nitrogen atoms are not very soluble in water as neutral molecules, but they are frequently much more soluble as their acid salts. Assuming that pH in the stomach is 2.5, indicate whether each of the following compounds would be present in the stomach as the neutral base or in the protonated form: nicotine,  $K_b = 7 \times 10^{-7}$ ; caffeine,  $K_b = 4 \times 10^{-14}$ ; strychnine,  $K_b = 1 \times 10^{-6}$ ; quinine,  $K_b = 1.1 \times 10^{-6}$ .
- [16.119] The amino acid glycine ( $H_2N-CH_2-COOH$ ) can participate in the following equilibria in water:
- $$H_2N-CH_2-COOH + H_2O \rightleftharpoons H_2N-CH_2-COO^- + H_3O^+ \quad K_a = 4.3 \times 10^{-3}$$
- $$H_2N-CH_2-COOH + H_2O \rightleftharpoons ^+H_3N-CH_2-COOH + OH^- \quad K_b = 6.0 \times 10^{-5}$$
- (a) Use the values of  $K_a$  and  $K_b$  to estimate the equilibrium constant for the intramolecular proton transfer to form a zwitterion:
- $$H_2N-CH_2-COOH \rightleftharpoons ^+H_3N-CH_2-COO^-$$
- What assumptions did you need to make? (b) What is the pH of a 0.050 M aqueous solution of glycine? (c) What would be the predominant form of glycine in a solution with pH 13? With pH 1?
- 16.120** The structural formula for acetic acid is shown in Table 16.2. Replacing hydrogen atoms on the carbon with chlorine atoms causes an increase in acidity, as follows:

Acid	Formula	$K_a$ (25 °C)
Acetic	$CH_3COOH$	$1.8 \times 10^{-5}$
Chloroacetic	$CH_2ClCOOH$	$1.4 \times 10^{-3}$
Dichloroacetic	$CHCl_2COOH$	$3.3 \times 10^{-2}$
Trichloroacetic	$CCl_3COOH$	$2 \times 10^{-1}$

Using Lewis structures as the basis of your discussion, explain the observed trend in acidities in the series. Calculate the pH of a 0.010 M solution of each acid.

## INTEGRATIVE EXERCISES

- 16.121** Calculate the number of  $H^+(aq)$  ions in 1.0 mL of pure water at 25 °C.
- 16.122** How many milliliters of concentrated hydrochloric acid solution (36.0% HCl by mass, density = 1.18 g/mL) are required to produce 10.0 L of a solution that has a pH of 2.05?
- 16.123** The volume of an adult's stomach ranges from about 50 mL when empty to 1 L when full. If the stomach volume is 400 mL and its contents have a pH of 2, how many moles of  $H^+$  does the stomach contain? Assuming that all the  $H^+$  comes from HCl, how many grams of sodium hydrogen carbonate will totally neutralize the stomach acid?
- 16.124** Atmospheric  $CO_2$  levels have risen by nearly 20% over the past 40 years from 315 ppm to 380 ppm. (a) Given that the average pH of clean, unpolluted rain today is 5.4, determine the pH of unpolluted rain 40 years ago. Assume that carbonic acid ( $H_2CO_3$ ) formed by the reaction of  $CO_2$  and water is the only factor influencing pH.
- $$CO_2(g) + H_2O(l) \rightleftharpoons H_2CO_3(aq)$$
- (b) What volume of  $CO_2$  at 25 °C and 1.0 atm is dissolved in a 20.0-L bucket of today's rainwater?
- [16.125] In many reactions the addition of  $AlCl_3$  produces the same effect as the addition of  $H^+$ . (a) Draw a Lewis structure for  $AlCl_3$  in which no atoms carry formal charges, and determine its structure using the VSEPR method. (b) What characteristic is notable about the structure in part (a) that helps us understand the acidic character of  $AlCl_3$ ? (c) Predict the result of the reaction between  $AlCl_3$  and  $NH_3$  in a solvent that does not participate as a reactant. (d) Which acid-base theory is most suitable for discussing the similarities between  $AlCl_3$  and  $H^+$ ?
- [16.126] What is the boiling point of a 0.10 M solution of  $NaHSO_4$  if the solution has a density of 1.002 g/mL?
- [16.127] Cocaine is a weak organic base whose molecular formula is  $C_{17}H_{21}NO_4$ . An aqueous solution of cocaine was found to have a pH of 8.53 and an osmotic pressure of 52.7 torr at 15 °C. Calculate  $K_b$  for cocaine.

[16.128] The iodate ion is reduced by sulfite according to the following reaction:

The rate of this reaction is found to be first order in  $\text{IO}_3^-$ , first order in  $\text{SO}_3^{2-}$ , and first order in  $\text{H}^+$ . (a) Write the rate law for the reaction. (b) By what factor will the rate of the reaction change if the pH is lowered from 5.00 to 3.50? Does the reaction proceed faster or slower at the lower pH? (c) By using the concepts discussed in Section 14.6, explain how the reaction can be pH-dependent even though  $\text{H}^+$  does not appear in the overall reaction.

[16.129] (a) Using dissociation constants from Appendix D, determine the value for the equilibrium constant for each of the following reactions. (Remember that when reactions are added, the corresponding equilibrium constants are multiplied.)

(b) We usually use single arrows for reactions when the forward reaction is appreciable ( $K$  much greater than 1) or when products escape from the system, so that equilibrium is never established. If we follow this convention, which of these equilibria might be written with a single arrow?

[16.130] Lactic acid,  $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$ , received its name because it is present in sour milk as a product of bacterial action. It is also responsible for the soreness in muscles after vigorous exercise. (a) The  $\text{p}K_a$  of lactic acid is 3.85. Compare this with the value for propionic acid ( $\text{CH}_3\text{CH}_2\text{COOH}$ ,  $\text{p}K_a = 4.89$ ), and explain the difference. (b) Calculate the lactate ion concentration in a 0.050  $M$  solution of lactic acid. (c) When a solution of sodium lactate,  $\text{CH}_3\text{CH}(\text{OH})\text{COONa}$ , is mixed with an aqueous copper(II) solution, it is possible to obtain a solid salt of copper(II) lactate as a blue-green hydrate,  $(\text{CH}_3\text{CH}(\text{OH})\text{COO})_2\text{Cu} \cdot x\text{H}_2\text{O}$ . Elemental analysis of the solid tells us that the solid is 22.9% Cu and 26.0% C by mass. What is the value for  $x$  in the formula for the hydrate? (d) The acid-dissociation constant for the  $\text{Cu}^{2+}(aq)$  ion is  $1.0 \times 10^{-8}$ . Based on this value and the acid-dissociation constant of lactic acid, predict whether a solution of copper(II) lactate will be acidic, basic, or neutral. Explain your answer.

CHAPTER  
17

# ADDITIONAL ASPECTS OF AQUEOUS EQUILIBRIA

CANARY SPRING, which is part of Mammoth Hot Springs in Yellowstone National Park.

## WHAT'S AHEAD

---

### 17.1 The Common-Ion Effect

We begin by considering a specific example of Le Châtelier's principle known as the *common-ion effect*.

### 17.2 Buffered Solutions

We then consider the composition of *buffered solutions*, or *buffers*, and learn how they resist pH change upon the addition of small amounts of a strong acid or a strong base.

### 17.3 Acid-Base Titrations

We continue by examining acid-base titration in detail, and we explore how to determine pH at any point in an acid-base titration.

### 17.4 Solubility Equilibria

Next, we learn how to use equilibrium constants known as *solubility-product constants* to determine to what extent a sparingly soluble salt will dissolve in water.

### 17.5 Factors That Affect Solubility

We investigate some of the factors that affect solubility, including the common-ion effect and the effect of acids.

### 17.6 Precipitation and Separation of Ions

Continuing the discussion of solubility equilibria, we learn how to precipitate ions selectively.

### 17.7 Qualitative Analysis for Metallic Elements

We conclude the chapter with an explanation of how the principles of solubility and complexation equilibria can be used to identify ions qualitatively in solution.

**WATER IS THE MOST COMMON AND MOST IMPORTANT SOLVENT ON EARTH.** In a sense, it is the solvent of life. It is difficult to imagine how living matter in all its complexity could exist with any liquid other than water as the solvent. Water occupies its position of importance because of its abundance

and its exceptional ability to dissolve a wide variety of substances. For example, the chapter-opening photograph shows a hot spring; this water contains a high concentration of ions (especially  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Fe}^{2+}$ ,  $\text{CO}_3^{2-}$ , and  $\text{SO}_4^{2-}$ ). The ions are dissolved as the hot water, initially underground, passes through various rocks on its way to the surface and dissolves minerals in the rocks. When the solution reaches the surface and cools, the minerals deposit and make the terracelike formations seen in the photograph.

The various aqueous solutions encountered in nature typically contain many solutes. For example, the aqueous solutions in hot springs and oceans, as well as those in biological fluids, contain a variety of dissolved ions and molecules. Consequently, many equilibria can occur simultaneously in these solutions.

In this chapter we take a step toward understanding such complex solutions by looking first at further applications of acid–base equilibria. The idea is to consider not only solutions in which there is a single solute but also those containing a mixture of solutes. We then broaden our discussion to include two additional types of aqueous equilibria: those involving slightly soluble salts and those involving the formation of metal complexes in solution. For the most part, the discussions and calculations in this chapter are an extension of those in Chapters 15 and 16.

## 17.1 THE COMMON-ION EFFECT

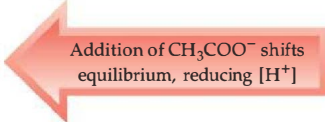

In Chapter 16 we examined the equilibrium concentrations of ions in solutions containing a weak acid or a weak base. We now consider solutions that contain a weak acid, such as acetic acid ( $\text{CH}_3\text{COOH}$ ), and a soluble salt of that acid, such as sodium acetate ( $\text{CH}_3\text{COONa}$ ). Notice that these solutions contain two substances that share a *common ion*  $\text{CH}_3\text{COO}^-$ . It is instructive to view these solutions from the perspective of Le Châtelier's principle.  $\infty$  (Section 15.7) Sodium acetate is a soluble ionic compound and is therefore a strong electrolyte.  $\infty$  (Section 4.1) Consequently, it dissociates completely in aqueous solution to form  $\text{Na}^+$  and  $\text{CH}_3\text{COO}^-$  ions:

In contrast,  $\text{CH}_3\text{COOH}$  is a weak electrolyte that ionizes as follows:

The  $\text{CH}_3\text{COO}^-$  from  $\text{CH}_3\text{COONa}$  causes this equilibrium to shift to the left, thereby decreasing the equilibrium concentration of  $\text{H}^+(aq)$ .

Addition of  $\text{CH}_3\text{COO}^-$  shifts equilibrium, reducing  $[\text{H}^+]$

In other words, the presence of the added acetate ion causes the acetic acid to ionize less than it normally would.

Whenever a weak electrolyte and a strong electrolyte contain a common ion, the weak electrolyte ionizes less than it would if it were alone in solution. We call this observation the **common-ion effect**. Sample Exercises 17.1 and 17.2 illustrate how equilibrium concentrations may be calculated when a solution contains a mixture of a weak electrolyte and a strong electrolyte that have a common ion. The procedures are similar to those encountered for weak acids and weak bases in Chapter 16.

### SAMPLE EXERCISE 17.1 | Calculating the pH When a Common Ion Is Involved

What is the pH of a solution made by adding 0.30 mol of acetic acid and 0.30 mol of sodium acetate to enough water to make 1.0 L of solution?

#### SOLUTION

**Analyze:** We are asked to determine the pH of a solution of a weak electrolyte ( $\text{CH}_3\text{COOH}$ ) and a strong electrolyte ( $\text{CH}_3\text{COONa}$ ) that share a common ion,  $\text{CH}_3\text{COO}^-$ .

**Plan:** In any problem in which we must determine the pH of a solution containing a mixture of solutes, it is helpful to proceed by a series of logical steps:

1. Consider which solutes are strong electrolytes and which are weak electrolytes, and identify the major species in solution.
2. Identify the important equilibrium that is the source of  $\text{H}^+$  and therefore determines pH.
3. Tabulate the concentrations of ions involved in the equilibrium.
4. Use the equilibrium-constant expression to calculate  $[\text{H}^+]$  and then pH.

**Solve:** First, because  $\text{CH}_3\text{COOH}$  is a weak electrolyte and  $\text{CH}_3\text{COONa}$  is a strong electrolyte, the major species in the solution are  $\text{CH}_3\text{COOH}$  (a weak acid),  $\text{Na}^+$  (which is neither acidic nor basic and is therefore a spectator in the acid–base chemistry), and  $\text{CH}_3\text{COO}^-$  (which is the conjugate base of  $\text{CH}_3\text{COOH}$ ).

Second,  $[\text{H}^+]$  and, therefore, the pH are controlled by the dissociation equilibrium of  $\text{CH}_3\text{COOH}$ :

(We have written the equilibrium using  $\text{H}^+(aq)$  rather than  $\text{H}_3\text{O}^+(aq)$  but both representations of the hydrated hydrogen ion are equally valid.)

Third, we tabulate the initial and equilibrium concentrations as we did in solving other equilibrium problems in Chapters 15 and 16:

	$\text{CH}_3\text{COOH}(aq)$	$\rightleftharpoons$	$\text{H}^+(aq)$	+	$\text{CH}_3\text{COO}^-(aq)$
Initial	0.30 M		0		0.30 M
Change	$-x$ M		$+x$ M		$+x$ M
Equilibrium	$(0.30 - x)$ M		$x$ M		$(0.30 + x)$ M

The equilibrium concentration of  $\text{CH}_3\text{COO}^-$  (the common ion) is the initial concentration that is due to  $\text{CH}_3\text{COONa}$  (0.30 M) plus the change in concentration ( $x$ ) that is due to the ionization of  $\text{CH}_3\text{COOH}$ .

Now we can use the equilibrium-constant expression:

$$K_a = 1.8 \times 10^{-5} = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]}$$

(The dissociation constant for  $\text{CH}_3\text{COOH}$  at 25 °C is from Appendix D; addition of  $\text{CH}_3\text{COONa}$  does not change the value of this constant.)

Substituting the equilibrium-constant concentrations from our table into the equilibrium expression gives

$$K_a = 1.8 \times 10^{-5} = \frac{x(0.30 + x)}{0.30 - x}$$

Because  $K_a$  is small, we assume that  $x$  is small compared to the original concentrations of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$  (0.30 M each). Thus, we can ignore the very small  $x$  relative to 0.30 M, giving

$$\begin{aligned} K_a &= 1.8 \times 10^{-5} = \frac{x(0.30)}{0.30} \\ x &= 1.8 \times 10^{-5} \text{ M} = [\text{H}^+] \end{aligned}$$

The resulting value of  $x$  is indeed small relative to 0.30, justifying the approximation made in simplifying the problem.

$$\text{pH} = -\log(1.8 \times 10^{-5}) = 4.74$$

Finally, we calculate the pH from the equilibrium concentration of  $\text{H}^+(aq)$ :

**Comment:** In Section 16.6 we calculated that a 0.30 M solution of  $\text{CH}_3\text{COOH}$  has a pH of 2.64, corresponding to  $[\text{H}^+] = 2.3 \times 10^{-3}$  M. Thus, the addition of  $\text{CH}_3\text{COONa}$  has substantially decreased  $[\text{H}^+]$ , as we would expect from Le Châtelier's principle.

### PRACTICE EXERCISE

Calculate the pH of a solution containing 0.085 M nitrous acid ( $\text{HNO}_2$ ;  $K_a = 4.5 \times 10^{-4}$ ) and 0.10 M potassium nitrite ( $\text{KNO}_2$ ).  
**Answer:** 3.42

**SAMPLE EXERCISE 17.2** | Calculating Ion Concentrations When a Common Ion Is Involved

Calculate the fluoride ion concentration and pH of a solution that is 0.20 M in HF and 0.10 M in HCl.

**SOLUTION**

**Analyze:** We are asked to determine the concentration of  $F^-$  and the pH in a solution containing the weak acid HF and the strong acid HCl. In this case the common ion is  $H^+$ .

**Plan:** We can again use the four steps outlined in Sample Exercise 17.1.

**Solve:** Because HF is a weak acid and HCl is a strong acid, the major species in solution are HF,  $H^+$ , and  $Cl^-$ . The  $Cl^-$ , which is the conjugate base of a strong acid, is merely a spectator ion in any acid–base chemistry. The problem asks for  $[F^-]$ , which is formed by ionization of HF. Thus, the important equilibrium is

The common ion in this problem is the hydrogen (or hydronium) ion. Now we can tabulate the initial and equilibrium concentrations of each species involved in this equilibrium:

	HF(aq)	$H^+(aq)$	+	$F^-(aq)$
Initial	0.20 M	0.10 M		0
Change	$-x$ M	$+x$ M		$+x$ M
Equilibrium	$(0.20 - x)$ M	$(0.10 + x)$ M		$x$ M

The equilibrium constant for the ionization of HF, from Appendix D, is  $6.8 \times 10^{-4}$ . Substituting the equilibrium-constant concentrations into the equilibrium expression gives

$$K_a = 6.8 \times 10^{-4} = \frac{[H^+][F^-]}{[HF]} = \frac{(0.10 + x)(x)}{0.20 - x}$$

If we assume that  $x$  is small relative to 0.10 or 0.20 M, this expression simplifies to

$$\frac{(0.10)(x)}{0.20} = 6.8 \times 10^{-4}$$

$$x = \frac{0.20}{0.10} (6.8 \times 10^{-4}) = 1.4 \times 10^{-3} M = [F^-]$$

This  $F^-$  concentration is substantially smaller than it would be in a 0.20 M solution of HF with no added HCl. The common ion,  $H^+$ , suppresses the ionization of HF. The concentration of  $H^+(aq)$  is

$$[H^+] = (0.10 + x) M \approx 0.10 M$$

Thus,

$$pH = 1.00$$

**Comment:** Notice that for all practical purposes,  $[H^+]$  is due entirely to the HCl; the HF makes a negligible contribution by comparison.

**PRACTICE EXERCISE**

Calculate the formate ion concentration and pH of a solution that is 0.050 M in formic acid ( $HCOOH$ ;  $K_a = 1.8 \times 10^{-4}$ ) and 0.10 M in  $HNO_3$ .

**Answer:**  $[HCOO^-] = 9.0 \times 10^{-5}$ ;  $pH = 1.00$

Sample Exercises 17.1 and 17.2 both involve weak acids. The ionization of a weak base is also decreased by the addition of a common ion. For example, the addition of  $NH_4^+$  (as from the strong electrolyte  $NH_4Cl$ ) causes the base-dissociation equilibrium of  $NH_3$  to shift to the left, decreasing the equilibrium concentration of  $OH^-$  and lowering the pH:

Addition of  $NH_4^+$  shifts equilibrium, reducing  $[OH^-]$

## GIVE IT SOME THOUGHT

A mixture of 0.10 mol of  $\text{NH}_4\text{Cl}$  and 0.12 mol of  $\text{NH}_3$  is added to enough water to make 1.0 L of solution. (a) What are the initial concentrations of the major species in the solution? (b) Which of the ions in this solution is a spectator ion in any acid–base chemistry occurring in the solution? (c) What equilibrium reaction determines  $[\text{OH}^-]$  and therefore the pH of the solution?

## 17.2 BUFFERED SOLUTIONS

Solutions such as those discussed in Section 17.1, which contain a weak conjugate acid–base pair, can resist drastic changes in pH upon the addition of small amounts of strong acid or strong base. These solutions are called **buffered solutions** (or merely **buffers**). Human blood, for example, is a complex aqueous mixture with a pH buffered at about 7.4 (see the “Chemistry and Life” box near the end of this section). Much of the chemical behavior of seawater is determined by its pH, buffered at about 8.1 to 8.3 near the surface. Buffered solutions find many important applications in the laboratory and in medicine (Figure 17.1 ►).

## Composition and Action of Buffered Solutions

A buffer resists changes in pH because it contains both an acid to neutralize  $\text{OH}^-$  ions and a base to neutralize  $\text{H}^+$  ions. The acid and base that make up the buffer, however, must not consume each other through a neutralization reaction. These requirements are fulfilled by a weak acid–base conjugate pair such as  $\text{CH}_3\text{COOH}-\text{CH}_3\text{COO}^-$  or  $\text{NH}_4^+-\text{NH}_3$ . Thus, buffers are often prepared by mixing a weak acid or a weak base with a salt of that acid or base. The  $\text{CH}_3\text{COOH}-\text{CH}_3\text{COO}^-$  buffer can be prepared, for example, by adding  $\text{CH}_3\text{COONa}$  to a solution of  $\text{CH}_3\text{COOH}$ . The  $\text{NH}_4^+-\text{NH}_3$  buffer can be prepared by adding  $\text{NH}_4\text{Cl}$  to a solution of  $\text{NH}_3$ . By choosing appropriate components and adjusting their relative concentrations, we can buffer a solution at virtually any pH.

## GIVE IT SOME THOUGHT

Which of the following conjugate acid–base pairs will *not* function as a buffer:  $\text{C}_2\text{H}_5\text{COOH}$  and  $\text{C}_2\text{H}_5\text{COO}^-$ ;  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$ ;  $\text{HNO}_3$  and  $\text{NO}_3^-$ ? Explain.

To understand better how a buffer works, let’s consider a buffer composed of a weak acid (HX) and one of its salts (MX, where  $\text{M}^+$  could be  $\text{Na}^+$ ,  $\text{K}^+$ , or another cation). The acid-dissociation equilibrium in this buffered solution involves both the acid and its conjugate base:

The corresponding acid-dissociation-constant expression is

$$K_a = \frac{[\text{H}^+][\text{X}^-]}{[\text{HX}]} \quad [17.4]$$

Solving this expression for  $[\text{H}^+]$ , we have

$$[\text{H}^+] = K_a \frac{[\text{HX}]}{[\text{X}^-]} \quad [17.5]$$

We see from this expression that  $[\text{H}^+]$ , and thus the pH, is determined by two factors: the value of  $K_a$  for the weak-acid component of the buffer and the ratio of the concentrations of the conjugate acid–base pair,  $[\text{HX}]/[\text{X}^-]$ .

▲ **Figure 17.1** Buffer solutions. Prepackaged buffer solutions and ingredients for making up buffer solutions of predetermined pH can be purchased.

► **Figure 17.2 Buffer action.** When a small portion of  $\text{OH}^-$  is added to a buffer consisting of a mixture of the weak acid HF and its conjugate base  $\text{F}^-$  (left), the  $\text{OH}^-$  reacts with the HF, decreasing  $[\text{HF}]$  and increasing  $[\text{F}^-]$  in the buffer. Conversely, when a small portion of  $\text{H}^+$  is added to the buffer (right), the  $\text{H}^+$  reacts with the  $\text{F}^-$ , decreasing  $[\text{F}^-]$  and increasing  $[\text{HF}]$  in the buffer. Because pH depends on the ratio of  $\text{F}^-$  to HF, the resulting pH change is small.

If  $\text{OH}^-$  ions are added to the buffered solution, they react with the acid component of the buffer to produce water and  $\text{X}^-$ :

This reaction causes  $[\text{HX}]$  to decrease and  $[\text{X}^-]$  to increase. As long as the amounts of  $\text{HX}$  and  $\text{X}^-$  in the buffer are large compared to the amount of  $\text{OH}^-$  added, however, the ratio  $[\text{HX}]/[\text{X}^-]$  does not change much, and thus the change in pH is small. A specific example of such a buffer, the HF/ $\text{F}^-$  buffer, is shown in Figure 17.2 ▲.

If  $\text{H}^+$  ions are added, they react with the base component of the buffer:

This reaction can also be represented using  $\text{H}_3\text{O}^+$ :

Using either equation, we see that the reaction causes  $[\text{X}^-]$  to decrease and  $[\text{HX}]$  to increase. As long as the change in the ratio  $[\text{HX}]/[\text{X}^-]$  is small, the change in pH will be small.

Figure 17.2 shows a buffer consisting of equal concentrations of hydrofluoric acid and fluoride ion (center). The addition of  $\text{OH}^-$  (left) reduces  $[\text{HF}]$  and increases  $[\text{F}^-]$ . The addition of  $\text{H}^+$  (right) reduces  $[\text{F}^-]$  and increases  $[\text{HF}]$ .

### GIVE IT SOME THOUGHT

- (a) What happens when NaOH is added to a buffer composed of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$ ? (b) What happens when HCl is added to this buffer?

### Calculating the pH of a Buffer

Because conjugate acid–base pairs share a common ion, we can use the same procedures to calculate the pH of a buffer that we used to treat the common-ion effect (see Sample Exercise 17.1). However, we can sometimes take an alternate approach that is based on an equation derived from Equation 17.5.

Taking the negative log of both sides of Equation 17.5, we have

$$-\log[\text{H}^+] = -\log\left(K_a \frac{[\text{HX}]}{[\text{X}^-]}\right) = -\log K_a - \log \frac{[\text{HX}]}{[\text{X}^-]}$$

Because  $-\log[\text{H}^+] = \text{pH}$  and  $-\log K_a = \text{p}K_a$ , we have

$$\text{pH} = \text{p}K_a - \log \frac{[\text{HX}]}{[\text{X}^-]} = \text{p}K_a + \log \frac{[\text{X}^-]}{[\text{HX}]} \quad [17.8]$$

In general,

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \quad [17.9]$$

where [acid] and [base] refer to the equilibrium concentrations of the *conjugate acid–base pair*. Note that when [base] = [acid],  $\text{pH} = \text{p}K_a$ .

Equation 17.9 is known as the **Henderson–Hasselbalch equation**. Biologists, biochemists, and others who work frequently with buffers often use this equation to calculate the pH of buffers. In doing equilibrium calculations, we have seen that we can normally neglect the amounts of the acid and base of the buffer that ionize. Therefore, we can usually use the starting concentrations of the acid and base components of the buffer directly in Equation 17.9.

### SAMPLE EXERCISE 17.3 | Calculating the pH of a Buffer

What is the pH of a buffer that is 0.12 M in lactic acid [ $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$ , or  $\text{HC}_3\text{H}_5\text{O}_3$ ] and 0.10 M in sodium lactate [ $\text{CH}_3\text{CH}(\text{OH})\text{COONa}$  or  $\text{NaC}_3\text{H}_5\text{O}_3$ ]? For lactic acid,  $K_a = 1.4 \times 10^{-4}$ .

#### SOLUTION

**Analyze:** We are asked to calculate the pH of a buffer containing lactic acid  $\text{HC}_3\text{H}_5\text{O}_3$  and its conjugate base, the lactate ion ( $\text{C}_3\text{H}_5\text{O}_3^-$ ).

**Plan:** We will first determine the pH using the method described in Section 17.1. Because  $\text{HC}_3\text{H}_5\text{O}_3$  is a weak electrolyte and  $\text{NaC}_3\text{H}_5\text{O}_3$  is a strong electrolyte, the major species in solution are  $\text{HC}_3\text{H}_5\text{O}_3$ ,  $\text{Na}^+$ , and  $\text{C}_3\text{H}_5\text{O}_3^-$ . The  $\text{Na}^+$  ion is a spectator ion. The  $\text{HC}_3\text{H}_5\text{O}_3$ – $\text{C}_3\text{H}_5\text{O}_3^-$  conjugate acid–base pair determines  $[\text{H}^+]$  and thus pH;  $[\text{H}^+]$  can be determined using the acid–dissociation equilibrium of lactic acid.

**Solve:** The initial and equilibrium concentrations of the species involved in this equilibrium are

Initial	0.12 M	0	0.10 M
Change	$-x$ M	$+x$ M	$+x$ M
Equilibrium	$(0.12 - x)$ M	$x$ M	$(0.10 + x)$ M

The equilibrium concentrations are governed by the equilibrium expression:

$$K_a = 1.4 \times 10^{-4} = \frac{[\text{H}^+][\text{C}_3\text{H}_5\text{O}_3^-]}{[\text{HC}_3\text{H}_5\text{O}_3]} = \frac{x(0.10 + x)}{(0.12 - x)}$$

Because  $K_a$  is small and a common ion is present, we expect  $x$  to be small relative to either 0.12 or 0.10 M. Thus, our equation can be simplified to give

$$K_a = 1.4 \times 10^{-4} = \frac{x(0.10)}{0.12}$$

Solving for  $x$  gives a value that justifies our approximation:

$$[\text{H}^+] = x = \left(\frac{0.12}{0.10}\right)(1.4 \times 10^{-4}) = 1.7 \times 10^{-4} \text{ M}$$

$$\text{pH} = -\log(1.7 \times 10^{-4}) = 3.77$$

Alternatively, we could have used the Henderson–Hasselbalch equation to calculate pH directly:

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log \left( \frac{[\text{base}]}{[\text{acid}]} \right) = 3.85 + \log \left( \frac{0.10}{0.12} \right) \\ &= 3.85 + (-0.08) = 3.77 \end{aligned}$$

### PRACTICE EXERCISE

Calculate the pH of a buffer composed of 0.12 M benzoic acid and 0.20 M sodium benzoate. (Refer to Appendix D.)

**Answer:** 4.42

**SAMPLE EXERCISE 17.4** Preparing a Buffer

How many moles of  $\text{NH}_4\text{Cl}$  must be added to 2.0 L of 0.10 M  $\text{NH}_3$  to form a buffer whose pH is 9.00? (Assume that the addition of  $\text{NH}_4\text{Cl}$  does not change the volume of the solution.)

**SOLUTION**

**Analyze:** Here we are asked to determine the amount of  $\text{NH}_4^+$  ion required to prepare a buffer of a specific pH.

**Plan:** The major species in the solution will be  $\text{NH}_4^+$ ,  $\text{Cl}^-$ , and  $\text{NH}_3$ . Of these, the  $\text{Cl}^-$  ion is a spectator (it is the conjugate base of a strong acid). Thus, the  $\text{NH}_4^+/\text{NH}_3$  conjugate acid–base pair will determine the pH of the buffer solution. The equilibrium relationship between  $\text{NH}_4^+$  and  $\text{NH}_3$  is given by the base-dissociation constant for  $\text{NH}_3$ :

The key to this exercise is to use this  $K_b$  expression to calculate  $[\text{NH}_4^+]$ .

**Solve:** We obtain  $[\text{OH}^-]$  from the given pH:

$$\text{pOH} = 14.00 - \text{pH} = 14.00 - 9.00 = 5.00$$

and so

$$[\text{OH}^-] = 1.0 \times 10^{-5} \text{ M}$$

Because  $K_b$  is small and the common ion  $\text{NH}_4^+$  is present, the equilibrium concentration of  $\text{NH}_3$  will essentially equal its initial concentration:

$$[\text{NH}_3] = 0.10 \text{ M}$$

We now use the expression for  $K_b$  to calculate  $[\text{NH}_4^+]$ :

$$[\text{NH}_4^+] = K_b \frac{[\text{NH}_3]}{[\text{OH}^-]} = (1.8 \times 10^{-5}) \frac{(0.10 \text{ M})}{(1.0 \times 10^{-5} \text{ M})} = 0.18 \text{ M}$$

Thus, for the solution to have  $\text{pH} = 9.00$ ,  $[\text{NH}_4^+]$  must equal 0.18 M. The number of moles of  $\text{NH}_4\text{Cl}$  needed to produce this concentration is given by the product of the volume of the solution and its molarity:

$$(2.0 \text{ L})(0.18 \text{ mol NH}_4\text{Cl/L}) = 0.36 \text{ mol NH}_4\text{Cl}$$

**Comment:** Because  $\text{NH}_4^+$  and  $\text{NH}_3$  are a conjugate acid–base pair, we could use the Henderson–Hasselbalch equation (Equation 17.9) to solve this problem. To do so requires first using Equation 16.41 to calculate  $\text{p}K_a$  for  $\text{NH}_4^+$  from the value of  $\text{p}K_b$  for  $\text{NH}_3$ . We suggest you try this approach to convince yourself that you can use the Henderson–Hasselbalch equation for buffers for which you are given  $K_b$  for the conjugate base rather than  $K_a$  for the conjugate acid.

**PRACTICE EXERCISE**

Calculate the concentration of sodium benzoate that must be present in a 0.20 M solution of benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) to produce a pH of 4.00.

**Answer:** 0.13 M

**Buffer Capacity and pH Range**

Two important characteristics of a buffer are its capacity and its effective pH range. **Buffer capacity** is the amount of acid or base the buffer can neutralize before the pH begins to change to an appreciable degree. The buffer capacity depends on the amount of acid and base from which the buffer is made. The pH of the buffer depends on the  $K_a$  for the acid and on the relative concentrations of the acid and base that comprise the buffer. According to Equation 17.5, for example,  $[\text{H}^+]$  for a 1-L solution that is 1 M in  $\text{CH}_3\text{COOH}$  and 1 M in  $\text{CH}_3\text{COONa}$  will be the same as for a 1-L solution that is 0.1 M in  $\text{CH}_3\text{COOH}$  and 0.1 M in  $\text{CH}_3\text{COONa}$ . The first solution has a greater buffering capacity, however, because it contains more  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$ . The greater the amounts of the conjugate acid–base pair, the more resistant is the ratio of their concentrations, and hence the pH, is to change.

The **pH range** of any buffer is the pH range over which the buffer acts effectively. Buffers most effectively resist a change in pH in *either* direction when the concentrations of weak acid and conjugate base are about the same. From Equation 17.9 we see that when the concentrations of weak acid and conjugate base are equal,  $\text{pH} = \text{p}K_a$ . This relationship gives the optimal pH of any buffer. Thus, we usually try to select a buffer whose acid form has a  $\text{p}K_a$  close to the desired pH. In practice, we find that if the concentration of one component of the buffer is more than 10 times the concentration of the other component, the buffering action is poor. Because  $\log 10 = 1$ , *buffers usually have a usable range within  $\pm 1$  pH unit of  $\text{p}K_a$*  (that is, a range of  $\text{pH} = \text{p}K_a \pm 1$ ).

### GIVE IT SOME THOUGHT

What is the optimal pH buffered by a solution containing  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COONa}$ ? ( $K_a$  for  $\text{CH}_3\text{COOH}$  is  $1.8 \times 10^{-5}$ .)

### Addition of Strong Acids or Bases to Buffers

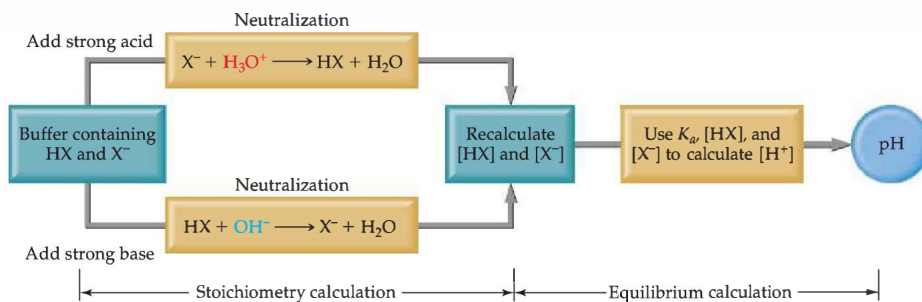

Let's now consider in a more quantitative way the response of a buffered solution to the addition of a strong acid or base. In solving these problems, it is important to understand that reactions between strong acids and weak bases proceed essentially to completion, as do those between strong bases and weak acids. Thus, as long as we do not exceed the buffering capacity of the buffer, we can assume that the strong acid or strong base is completely consumed by reaction with the buffer.

Consider a buffer that contains a weak acid HX and its conjugate base  $\text{X}^-$ . When a strong acid is added to this buffer, the added  $\text{H}^+$  is consumed by  $\text{X}^-$  to produce HX; thus, [HX] increases and  $[\text{X}^-]$  decreases. (See Equation 17.7.) When a strong base is added to the buffer, the added  $\text{OH}^-$  is consumed by HX to produce  $\text{X}^-$ ; in this case [HX] decreases and  $[\text{X}^-]$  increases. (See Equation 17.6.) These two situations are summarized in Figure 17.2.

To calculate how the pH of the buffer responds to the addition of a strong acid or a strong base, we follow the strategy outlined in Figure 17.3 ▼.

1. Consider the acid–base neutralization reaction, and determine its effect on [HX] and  $[\text{X}^-]$ . This step of the procedure is a *stoichiometry calculation*.
2. Use  $K_a$  and the new concentrations of [HX] and  $[\text{X}^-]$  from step 1 to calculate  $[\text{H}^+]$ . This second step of the procedure is a standard *equilibrium calculation* and is most easily done using the Henderson–Hasselbalch equation.

The complete procedure is illustrated in Sample Exercise 17.5.

▲ **Figure 17.3 Calculation of the pH of a buffer after the addition of acid or base.** First consider how the neutralization reaction between the added strong acid or strong base and the buffer affects the composition of the buffer (stoichiometry calculation). Then calculate the pH of the remaining buffer (equilibrium calculation). As long as the amount of added acid or base does not exceed the buffer capacity, the Henderson–Hasselbalch equation, Equation 17.9, can be used for the equilibrium calculation.

**SAMPLE EXERCISE 17.5** Calculating pH Changes in Buffers

A buffer is made by adding 0.300 mol  $\text{CH}_3\text{COOH}$  and 0.300 mol  $\text{CH}_3\text{COONa}$  to enough water to make 1.00 L of solution. The pH of the buffer is 4.74 (Sample Exercise 17.1). (a) Calculate the pH of this solution after 0.020 mol of NaOH is added. (b) For comparison, calculate the pH that would result if 0.020 mol of NaOH were added to 1.00 L of pure water (neglect any volume changes).

**SOLUTION**

**Analyze:** We are asked to determine the pH of a buffer after addition of a small amount of strong base and to compare the pH change to the pH that would result if we were to add the same amount of strong base to pure water.

**Plan:** (a) Solving this problem involves the two steps outlined in Figure 17.3. Thus, we must first do a stoichiometry calculation to determine how the added  $\text{OH}^-$  reacts with the buffer and affects its composition. Then we can use the resultant composition of the buffer and either the Henderson–Hasselbalch equation or the equilibrium-constant expression for the buffer to determine the pH.

**Solve:** *Stoichiometry Calculation:* The  $\text{OH}^-$  provided by NaOH reacts with  $\text{CH}_3\text{COOH}$ , the weak acid component of the buffer. Prior to this neutralization reaction, there are 0.300 mol each of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$ . Neutralizing the 0.020 mol  $\text{OH}^-$  requires 0.020 mol of  $\text{CH}_3\text{COOH}$ . Consequently, the amount of  $\text{CH}_3\text{COOH}$  decreases by 0.020 mol, and the amount of the product of the neutralization,  $\text{CH}_3\text{COO}^-$ , increases by 0.020 mol. We can create a table to see how the composition of the buffer changes as a result of its reaction with  $\text{OH}^-$ :

Buffer before addition	0.300 mol	0	—	0.300 mol
Addition	—	0.020 mol	—	—
Buffer after addition	0.280 mol	0	—	0.320 mol

*Equilibrium Calculation:* We now turn our attention to the equilibrium that will determine the pH of the buffer, namely the ionization of acetic acid.

Using the quantities of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$  remaining in the buffer, we can determine the pH using the Henderson–Hasselbalch equation.

$$\text{pH} = 4.74 + \log \frac{0.320 \text{ mol}/1.00 \text{ L}}{0.280 \text{ mol}/1.00 \text{ L}} = 4.80$$

**Comment** Notice that we could have used mole amounts in place of concentrations in the Henderson–Hasselbalch equation and gotten the same result. The volumes of the acid and base are equal and cancel.

If 0.020 mol of  $\text{H}^+$  was added to the buffer, we would proceed in a similar way to calculate the resulting pH of the buffer. In this case the pH decreases by 0.06 units, giving  $\text{pH} = 4.68$ , as shown in the figure in the margin.

(b) To determine the pH of a solution made by adding 0.020 mol of NaOH to 1.00 L of pure water, we can first determine pOH using Equation 16.18 and subtracting from 14.

$$\text{pH} = 14 - (-\log 0.020) = 12.30$$

Note that although the small amount of NaOH changes the pH of water significantly, the pH of the buffer changes very little.

**PRACTICE EXERCISE**

Determine (a) the pH of the original buffer described in Sample Exercise 17.5 after the addition of 0.020 mol HCl and (b) the pH of the solution that would result from the addition of 0.020 mol HCl to 1.00 L of pure water.

**Answers:** (a) 4.68, (b) 1.70

Many of the chemical reactions that occur in living systems are extremely sensitive to pH. Many of the enzymes that catalyze important biochemical reactions, for example, are effective only within a narrow pH range. For this reason the human body maintains a remarkably intricate system of buffers, both within tissue cells and in the fluids that transport cells. Blood, the fluid that transports oxygen to all parts of the body (Figure 17.4 ▶), is one of the most prominent examples of the importance of buffers in living beings.

Human blood is slightly basic with a normal pH of 7.35 to 7.45. Any deviation from this normal pH range can have extremely disruptive effects on the stability of cell membranes, the structures of proteins, and the activities of enzymes. Death may result if the blood pH falls below 6.8 or rises above 7.8. When the pH falls below 7.35, the condition is called *acidosis*; when it rises above 7.45, the condition is called *alkalosis*. Acidosis is the more common tendency because ordinary metabolism generates several acids within the body.

The major buffer system that is used to control the pH of blood is the *carbonic acid–bicarbonate buffer system*. Carbonic acid ( $\text{H}_2\text{CO}_3$ ) and bicarbonate ion ( $\text{HCO}_3^-$ ) are a conjugate acid–base pair. In addition, carbonic acid can decompose into carbon dioxide gas and water. The important equilibria in this buffer system are

Several aspects of these equilibria are notable. First, although carbonic acid is a diprotic acid, the carbonate ion ( $\text{CO}_3^{2-}$ ) is unimportant in this system. Second, one of the components of this equilibrium,  $\text{CO}_2$ , is a gas, which provides a mechanism for the body to adjust the equilibria. Removal of  $\text{CO}_2$  via exhalation shifts the equilibria to the right, consuming  $\text{H}^+$  ions. Third, the buffer system in blood operates at a pH of 7.4, which is fairly far removed from the  $\text{p}K_{\text{a}1}$  value of  $\text{H}_2\text{CO}_3$  (6.1 at physiological temperatures). For the buffer to have a pH of 7.4, the ratio  $[\text{base}]/[\text{acid}]$  must have a value of about 20. In normal blood plasma the concentrations of  $\text{HCO}_3^-$  and  $\text{H}_2\text{CO}_3$  are about 0.024 M and 0.0012 M, respectively. Consequently, the buffer has a high capacity to neutralize additional acid, but only a low capacity to neutralize additional base.

The principal organs that regulate the pH of the carbonic acid–bicarbonate buffer system are the lungs and kidneys. Some of the receptors in the brain are sensitive to the concentrations of  $\text{H}^+$  and  $\text{CO}_2$  in bodily fluids. When the concentration of  $\text{CO}_2$  rises, the equilibria in Equation 17.10 shift to the left, which leads to the formation of more  $\text{H}^+$ . The receptors trigger a reflex to breathe faster and deeper, increasing the rate of elimination of  $\text{CO}_2$  from the lungs and shifting the equilibria back to the right. The kidneys absorb or release  $\text{H}^+$  and  $\text{HCO}_3^-$ ; much of the excess acid leaves the body in urine, which normally has a pH of 5.0 to 7.0.

▲ **Figure 17.4 Red blood cells.** A scanning electromicrograph of a group of red blood cells traveling through a small branch of an artery. Blood is a buffered solution whose pH is maintained between 7.35 and 7.45.

The regulation of the pH of blood plasma relates directly to the effective transport of  $\text{O}_2$  to bodily tissues. The protein hemoglobin, which is found in red blood cells, carries oxygen. Hemoglobin (Hb) reversibly binds both  $\text{H}^+$  and  $\text{O}_2$ . These two substances compete for the Hb, which can be represented approximately by the following equilibrium:

Oxygen enters the blood through the lungs, where it passes into the red blood cells and binds to Hb. When the blood reaches tissue in which the concentration of  $\text{O}_2$  is low, the equilibrium in Equation 17.11 shifts to the left and  $\text{O}_2$  is released. An increase in  $\text{H}^+$  ion concentration (decrease in blood pH) also shifts this equilibrium to the left, as does increasing temperature.

During periods of strenuous exertion, three factors work together to ensure the delivery of  $\text{O}_2$  to active tissues: (1) As  $\text{O}_2$  is consumed, the equilibrium in Equation 17.11 shifts to the left according to Le Châtelier's principle. (2) Exertion raises the temperature of the body, also shifting the equilibrium to the left. (3) Large amounts of  $\text{CO}_2$  are produced by metabolism, which shifts the equilibrium in Equation 17.10 to the left, thus decreasing the pH. Other acids, such as lactic acid, are also produced during strenuous exertion as tissues become starved for oxygen. The decrease in pH shifts the hemoglobin equilibrium to the left, delivering more  $\text{O}_2$ . In addition, the decrease in pH stimulates an increase in the rate of breathing, which furnishes more  $\text{O}_2$  and eliminates  $\text{CO}_2$ . Without this elaborate arrangement, the  $\text{O}_2$  in tissues would be rapidly depleted, making further activity impossible.

**Related Exercises:** 17.29 and 17.90

**▲ Figure 17.5 Measuring pH during a titration.** A typical setup for using a pH meter to measure data for a titration curve. In this case a standard solution of NaOH (the titrant) is added by buret to a solution of HCl. The HCl solution is stirred during the titration to ensure uniform composition.

## 17.3 ACID–BASE TITRATIONS

In Section 4.6 we briefly described *titrations*. In an acid–base titration, a solution containing a known concentration of base is slowly added to an acid (or the acid is added to the base). Acid–base indicators can be used to signal the *equivalence point* of a titration (the point at which stoichiometrically equivalent quantities of acid and base have been brought together). Alternatively, a pH meter can be used to monitor the progress of the reaction producing a **pH titration curve**, a graph of the pH as a function of the volume of the added titrant. The shape of the titration curve makes it possible to determine the equivalence point in the titration. The titration curve can also be used to select suitable indicators and to determine the  $K_a$  of the weak acid or the  $K_b$  of the weak base being titrated.

A typical apparatus for measuring pH during a titration is illustrated in Figure 17.5 ◀. The titrant is added to the solution from a buret, and the pH is continually monitored using a pH meter. To understand why titration curves have certain characteristic shapes, we will examine the curves for three kinds of titrations: (1) strong acid–strong base, (2) weak acid–strong base, and (3) polyprotic acid–strong base. We will also briefly consider how these curves relate to those involving weak bases.

### GIVE IT SOME THOUGHT

For the setup shown in Figure 17.5, will pH increase or decrease as titrant is added?

### Strong Acid–Strong Base Titrations

The titration curve produced when a strong base is added to a strong acid has the general shape shown in Figure 17.6 ▶. This curve depicts the pH change that occurs as 0.100 M NaOH is added to 50.0 mL of 0.100 M HCl. The pH can be calculated at various stages of the titration. To help understand these calculations, we can divide the curve into four regions:

1. *The initial pH (initial acid):* The pH of the solution before the addition of any base is determined by the initial concentration of the strong acid. For a solution of 0.100 M HCl,  $[\text{H}^+] = 0.100 \text{ M}$ , and hence  $\text{pH} = -\log(0.100) = 1.000$ . Thus, the initial pH is low.
2. *Between the initial pH and the equivalence point (remaining acid):* As NaOH is added, the pH increases slowly at first and then rapidly in the vicinity of the equivalence point. The pH of the solution before the equivalence point is determined by the concentration of acid that has not yet been neutralized. This calculation is illustrated in Sample Exercise 17.6(a).
3. *The equivalence point:* At the equivalence point an equal number of moles of the NaOH and HCl have reacted, leaving only a solution of their salt, NaCl. The pH of the solution is 7.00 because the cation of a strong base (in this case  $\text{Na}^+$ ) and the anion of a strong acid (in this case  $\text{Cl}^-$ ) do not hydrolyze and therefore have no appreciable effect on pH. ⇌ (Section 16.9)
4. *After the equivalence point (excess base):* The pH of the solution after the equivalence point is determined by the concentration of the excess NaOH in the solution. This calculation is illustrated in Sample Exercise 17.6(b).

**▲ Figure 17.6 Adding a strong base to a strong acid.** The pH curve for titration of 50.0 mL of a 0.100 M solution of a strong acid with a 0.100 M solution of a strong base. In this case the acid is HCl and the base is NaOH. The pH starts out at a low value characteristic of the acid and then increases as base is added, rising rapidly at the equivalence point. Both phenolphthalein and methyl red change color at the equivalence point. (For clarity, water molecules have been omitted from the molecular art.)

### ■ SAMPLE EXERCISE 17.6 | Calculating pH for a Strong Acid–Strong Base Titration

Calculate the pH when the following quantities of 0.100 M NaOH solution have been added to 50.0 mL of 0.100 M HCl solution: (a) 49.0 mL, (b) 51.0 mL.

#### SOLUTION

**Analyze:** We are asked to calculate the pH at two points in the titration of a strong acid with a strong base. The first point is just before the equivalence point, so we expect the pH to be determined by the small amount of strong acid that has not yet been neutralized. The second point is just after the equivalence point, so we expect this pH to be determined by the small amount of excess strong base.

**Plan:** (a) As the NaOH solution is added to the HCl solution,  $\text{H}^+(\text{aq})$  reacts with  $\text{OH}^-(\text{aq})$  to form  $\text{H}_2\text{O}$ . Both  $\text{Na}^+$  and  $\text{Cl}^-$  are spectator ions, having negligible effect on the pH. To determine the pH of the solution, we must first determine how many moles of  $\text{H}^+$  were originally present and how many moles of  $\text{OH}^-$  were added. We can then calculate how many moles of each ion remain after the neutralization reaction. To calculate  $[\text{H}^+]$ , and hence pH, we must also remember that the volume of the solution increases as we add titrant, thus diluting the concentration of all solutes present.

**Solve:** The number of moles of  $\text{H}^+$  in the original HCl solution is given by the product of the volume of the solution (50.0 mL = 0.0500 L) and its molarity (0.100 M):

$$(0.0500 \text{ L soln}) \left( \frac{0.100 \text{ mol H}^+}{1 \text{ L soln}} \right) = 5.00 \times 10^{-3} \text{ mol H}^+$$

Likewise, the number of moles of  $\text{OH}^-$  in 49.0 mL of 0.100 M NaOH is

$$(0.0490 \text{ L soln}) \left( \frac{0.100 \text{ mol OH}^-}{1 \text{ L soln}} \right) = 4.90 \times 10^{-3} \text{ mol OH}^-$$

Because we have not yet reached the equivalence point, there are more moles of  $\text{H}^+$  present than  $\text{OH}^-$ . Each mole of  $\text{OH}^-$  will react with one mole of  $\text{H}^+$ . Using the convention introduced in Sample Exercise 17.5,

	$\text{H}^+(aq)$	+	$\text{OH}^-(aq)$	$\longrightarrow$	$\text{H}_2\text{O}(l)$
Before addition	$5.00 \times 10^{-3} \text{ mol}$		0		—
Addition			$4.90 \times 10^{-3} \text{ mol}$		
After addition	$0.10 \times 10^{-3} \text{ mol}$		0		—

During the course of the titration, the volume of the reaction mixture increases as the NaOH solution is added to the HCl solution. Thus, at this point in the titration, the total volume of the solutions is

$$50.0 \text{ mL} + 49.0 \text{ mL} = 99.0 \text{ mL} = 0.0990 \text{ L}$$

(We assume that the total volume is the sum of the volumes of the acid and base solutions.) Thus, the concentration of  $\text{H}^+(aq)$  is

$$[\text{H}^+] = \frac{\text{moles H}^+(aq)}{\text{liters soln}} = \frac{0.10 \times 10^{-3} \text{ mol}}{0.09900 \text{ L}} = 1.0 \times 10^{-3} \text{ M}$$

The corresponding pH equals

$$-\log(1.0 \times 10^{-3}) = 3.00$$

**Plan:** (b) We proceed in the same way as we did in part (a), except we are now past the equivalence point and have more  $\text{OH}^-$  in the solution than  $\text{H}^+$ . As before, the initial number of moles of each reactant is determined from their volumes and concentrations. The reactant present in smaller stoichiometric amount (the limiting reactant) is consumed completely, leaving an excess of hydroxide ion.

**Solve:**

	$\text{H}^+(aq)$	+	$\text{OH}^-(aq)$	$\longrightarrow$	$\text{H}_2\text{O}(l)$
Before addition	$5.00 \times 10^{-3} \text{ mol}$		0		—
Addition			$5.10 \times 10^{-3} \text{ mol}$		
After addition	0		$0.10 \times 10^{-3} \text{ mol}$		—

In this case the total volume of the solution is

$$50.0 \text{ mL} + 51.0 \text{ mL} = 101.0 \text{ mL} = 0.1010 \text{ L}$$

Hence, the concentration of  $\text{OH}^-(aq)$  in the solution is

$$[\text{OH}^-] = \frac{\text{moles OH}^-(aq)}{\text{liters soln}} = \frac{0.10 \times 10^{-3} \text{ mol}}{0.1010 \text{ L}} = 1.0 \times 10^{-3} \text{ M}$$

Thus, the pOH of the solution equals

$$\text{pOH} = -\log(1.0 \times 10^{-3}) = 3.00$$

and the pH equals

$$\text{pH} = 14.00 - \text{pOH} = 14.00 - 3.00 = 11.00$$

### ■ PRACTICE EXERCISE

Calculate the pH when the following quantities of 0.100 M  $\text{HNO}_3$  have been added to 25.0 mL of 0.100 M KOH solution: (a) 24.9 mL, (b) 25.1 mL.

**Answers:** (a) 10.30, (b) 3.70

Optimally, an indicator would change color at the equivalence point in a titration. In practice, however, that is unnecessary. The pH changes very rapidly near the equivalence point, and in this region merely a drop of titrant can change the pH by several units. Thus, an indicator beginning and ending its color change anywhere on this rapid-rise portion of the titration curve will give a sufficiently accurate measure of the volume of titrant needed to reach the equivalence point. The point in a titration where the indicator changes color is called the *end point* to distinguish it from the actual equivalence point that it closely approximates.

◀ **Figure 17.7 Methyl red indicator.** Change in appearance of a solution containing methyl red indicator in the pH range 4.2 to 6.3. The characteristic acidic color is shown in (a), and the characteristic basic color in (b).

In Figure 17.6 we see that the pH changes very rapidly from about 4 to about 10 near the equivalence point. Consequently, an indicator for this strong acid–strong base titration can change color anywhere in this range. Most strong acid–strong base titrations are carried out using phenolphthalein as an indicator (Figure 4.20) because it dramatically changes color in this range. From Figure 16.7, we see that phenolphthalein changes color from pH 8.3 to 10.0. Several other indicators would also be satisfactory, including methyl red, which changes color from pH 4.2 to 6.0 (Figure 17.7 ▲).

Titration of a solution of a strong base with a solution of a strong acid would yield an analogous curve of pH versus added acid. In this case, however, the pH would be high at the outset of the titration and low at its completion, as shown in Figure 17.8 ▶.

### GIVE IT SOME THOUGHT

What is the pH at the equivalence point when 0.10 M  $\text{HNO}_3$  is added to a solution containing 0.30 g of KOH?

### Weak Acid–Strong Base Titrations

The curve for the titration of a weak acid by a strong base is very similar in shape to that for the titration of a strong acid by a strong base. Consider, for example, the titration curve for the titration of 50.0 mL of 0.100 M acetic acid ( $\text{CH}_3\text{COOH}$ ) with 0.100 M NaOH shown in Figure 17.9 ▼. We can calculate the pH at points along this curve, using principles we have discussed earlier. As in the case of the titration of a strong acid by a strong base, we can divide the curve into four regions:

1. *The initial pH (initial acid):* We use  $K_a$  of the acid to calculate this pH, as shown in Section 16.6. The calculated pH of 0.100 M  $\text{CH}_3\text{COOH}$  is 2.89.
2. *Between the initial pH and the equivalence point (buffer mixture):* Prior to reaching the equivalence point, the acid is being neutralized, and its conjugate base is being formed:

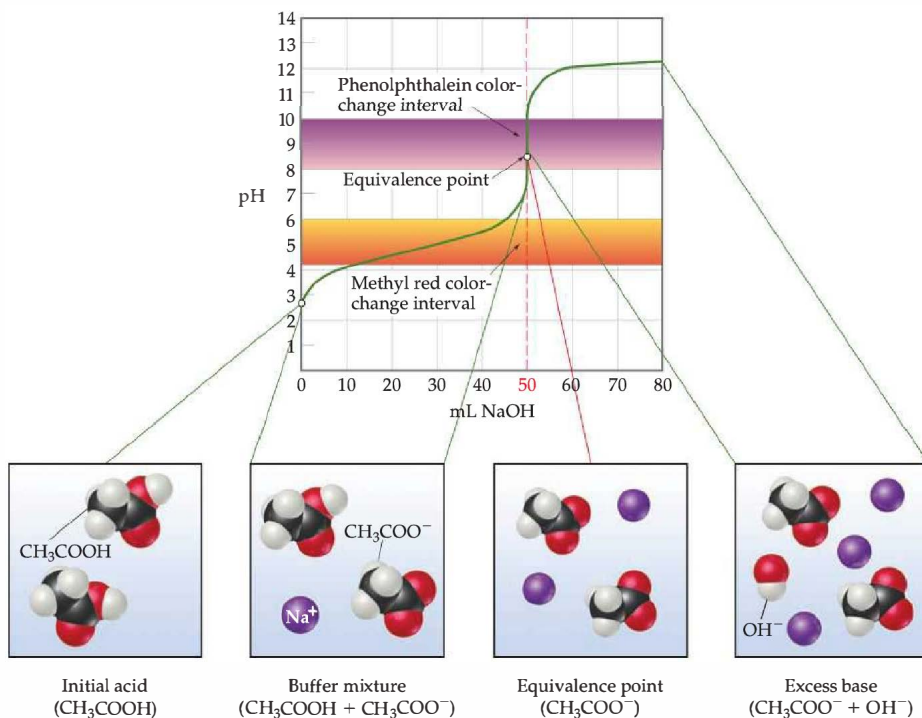

Thus, the solution contains a mixture of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$ .

The approach we take in calculating the pH in this region of the titration curve involves two main steps. First, we consider the neutralization reaction between  $\text{CH}_3\text{COOH}$  and  $\text{OH}^-$  to determine the concentrations of

▲ **Figure 17.8 Adding a strong acid to a strong base.** The shape of a pH curve for titration of a strong base with a strong acid. The pH starts out at a high value characteristic of the base and then decreases as acid is added, dropping rapidly at the equivalence point.

▲ **Figure 17.9 Adding a strong base to a weak acid.** The curve shows the variation in pH as 0.100 M NaOH solution is added to 50.0 mL of 0.100 M acetic acid solution. Phenolphthalein changes color at the equivalence point, but methyl red does not. (For clarity, water molecules have been omitted from the molecular art.)

▼ **Figure 17.10 Procedure for calculating the pH when a weak acid is partially neutralized by a strong base.** First consider the effect of the neutralization reaction (stoichiometry calculation). Then determine the pH of the resultant buffer mixture (equilibrium calculation). An analogous procedure can be used for the addition of strong acid to a weak base.

$\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$  in the solution. Next, we calculate the pH of this buffer pair using procedures developed in Sections 17.1 and 17.2. The general procedure is diagrammed in Figure 17.10 ▼ and illustrated in Sample Exercise 17.7.

- The equivalence point:** The equivalence point is reached after adding 50.0 mL of 0.100 M NaOH to the 50.0 mL of 0.100 M  $\text{CH}_3\text{COOH}$ . At this point the  $5.00 \times 10^{-3}$  mol of NaOH completely reacts with the  $5.00 \times 10^{-3}$  mol of  $\text{CH}_3\text{COOH}$  to form  $5.00 \times 10^{-3}$  mol of their salt,  $\text{CH}_3\text{COONa}$ . The  $\text{Na}^+$  ion of this salt has no significant effect on the pH. The  $\text{CH}_3\text{COO}^-$  ion, however, is a weak base, and the pH at the equivalence point is therefore greater than 7. Indeed, the pH at the equivalence point is always above 7 in a weak acid–strong base titration because the anion of the salt formed is a weak base. The procedure for calculating the pH of the solution of a weak base is described in Section 16.7 and is shown in Sample Exercise 17.8.
- After the equivalence point (excess base):** In this region of the titration curve,  $[\text{OH}^-]$  from the reaction of  $\text{CH}_3\text{COO}^-$  with water is negligible compared to  $[\text{OH}^-]$  from the excess NaOH. Thus, the pH is determined by the concentration of  $\text{OH}^-$  from the excess NaOH. The method for calculating pH

in this region is therefore like that for the strong acid–strong base titration illustrated in Sample Exercise 17.6(b). Thus, the addition of 51.0 mL of 0.100 M NaOH to 50.0 mL of either 0.100 M HCl or 0.100 M CH<sub>3</sub>COOH yields the same pH, 11.00. Notice in Figures 17.6 and 17.9 that the titration curves for the titrations of both the strong acid and the weak acid are the same after the equivalence point.

### ■ SAMPLE EXERCISE 17.7 | Calculating pH for a Weak Acid–Strong Base Titration

Calculate the pH of the solution formed when 45.0 mL of 0.100 M NaOH is added to 50.0 mL of 0.100 M CH<sub>3</sub>COOH ( $K_a = 1.8 \times 10^{-5}$ ).

#### SOLUTION

**Analyze:** We are asked to calculate the pH before the equivalence point of the titration of a weak acid with a strong base.

**Plan:** We first must determine the number of moles of CH<sub>3</sub>COOH and CH<sub>3</sub>COO<sup>−</sup> that are present after the neutralization reaction. We then calculate pH using  $K_a$  together with [CH<sub>3</sub>COOH] and [CH<sub>3</sub>COO<sup>−</sup>].

**Solve:** *Stoichiometry Calculation:* The product of the volume and concentration of each solution gives the number of moles of each reactant present before the neutralization:

$$(0.0500 \text{ L soln}) \left( \frac{0.100 \text{ mol CH}_3\text{COOH}}{1 \text{ L soln}} \right) = 5.00 \times 10^{-3} \text{ mol CH}_3\text{COOH}$$

$$(0.0450 \text{ L soln}) \left( \frac{0.100 \text{ mol NaOH}}{1 \text{ L soln}} \right) = 4.50 \times 10^{-3} \text{ mol NaOH}$$

Before addition	5.00 × 10 <sup>−3</sup> mol	0	0	—
Addition		4.50 × 10 <sup>−3</sup> mol		
After addition	0.50 × 10 <sup>−3</sup> mol	0	4.50 × 10 <sup>−3</sup> mol	—

The total volume of the solution is

$$45.0 \text{ mL} + 50.0 \text{ mL} = 95.0 \text{ mL} = 0.0950 \text{ L}$$

The resulting molarities of CH<sub>3</sub>COOH and CH<sub>3</sub>COO<sup>−</sup> after the reaction are therefore

$$[\text{CH}_3\text{COOH}] = \frac{0.50 \times 10^{-3} \text{ mol}}{0.0950 \text{ L}} = 0.0053 \text{ M}$$

$$[\text{CH}_3\text{COO}^-] = \frac{4.50 \times 10^{-3} \text{ mol}}{0.0950 \text{ L}} = 0.0474 \text{ M}$$

*Equilibrium Calculation:* The equilibrium between CH<sub>3</sub>COOH and CH<sub>3</sub>COO<sup>−</sup> must obey the equilibrium-constant expression for CH<sub>3</sub>COOH

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = 1.8 \times 10^{-5}$$

Solving for [H<sup>+</sup>] gives

$$[\text{H}^+] = K_a \times \frac{[\text{CH}_3\text{COOH}]}{[\text{CH}_3\text{COO}^-]} = (1.8 \times 10^{-5}) \times \left( \frac{0.0053}{0.0474} \right) = 2.0 \times 10^{-6} \text{ M}$$

$$\text{pH} = -\log(2.0 \times 10^{-6}) = 5.70$$

**Comment:** We could have solved for pH equally well using the Henderson–Hasselbalch equation.

### ■ PRACTICE EXERCISE

(a) Calculate the pH in the solution formed by adding 10.0 mL of 0.050 M NaOH to 40.0 mL of 0.0250 M benzoic acid (C<sub>6</sub>H<sub>5</sub>COOH,  $K_a = 6.3 \times 10^{-5}$ ). (b) Calculate the pH in the solution formed by adding 10.0 mL of 0.100 M HCl to 20.0 mL of 0.100 M NH<sub>3</sub>.

**Answers:** (a) 4.20, (b) 9.26

### ■ SAMPLE EXERCISE 17.8 | Calculating the pH at the Equivalence Point

Calculate the pH at the equivalence point in the titration of 50.0 mL of 0.100 M CH<sub>3</sub>COOH with 0.100 M NaOH.

#### SOLUTION

**Analyze:** We are asked to determine the pH at the equivalence point of the titration of a weak acid with a strong base. Because the neutralization of a weak acid produces its anion, which is a weak base, we expect the pH at the equivalence point to be greater than 7.

**Plan:** The initial number of moles of acetic acid will equal the number of moles of acetate ion at the equivalence point. We use the volume of the solution at the equivalence point to calculate the concentration of acetate ion. Because the acetate ion is a weak base, we can calculate the pH using  $K_b$  and  $[\text{CH}_3\text{COO}^-]$ .

**Solve:** The number of moles of acetic acid in the initial solution is obtained from the volume and molarity of the solution:

$$\text{Moles} = M \times L = (0.100 \text{ mol/L})(0.0500 \text{ L}) = 5.00 \times 10^{-3} \text{ mol CH}_3\text{COOH}$$

Hence  $5.00 \times 10^{-3}$  mol of  $\text{CH}_3\text{COO}^-$  is formed. It will take 50.0 mL of NaOH to reach the equivalence point (Figure 17.9). The volume of this salt solution at the equivalence point is the sum of the volumes of the acid and base, 50.0 mL + 50.0 mL = 100.0 mL = 0.1000 L. Thus, the concentration of  $\text{CH}_3\text{COO}^-$  is

$$[\text{CH}_3\text{COO}^-] = \frac{5.00 \times 10^{-3} \text{ mol}}{0.1000 \text{ L}} = 0.0500 \text{ M}$$

The  $\text{CH}_3\text{COO}^-$  ion is a weak base.

The  $K_b$  for  $\text{CH}_3\text{COO}^-$  can be calculated from the  $K_a$  value of its conjugate acid,  $K_b = K_w/K_a = (1.0 \times 10^{-14})/(1.8 \times 10^{-5}) = 5.6 \times 10^{-10}$ . Using the  $K_b$  expression, we have

$$K_b = \frac{[\text{CH}_3\text{COOH}][\text{OH}^-]}{[\text{CH}_3\text{COO}^-]} = \frac{(x)(x)}{0.0500 - x} = 5.6 \times 10^{-10}$$

Making the approximation that  $0.0500 - x \approx 0.0500$ , and then solving for  $x$ , we have  $x = [\text{OH}^-] = 5.3 \times 10^{-6} \text{ M}$ , which gives  $\text{pOH} = 5.28$  and  $\text{pH} = 8.72$ .

**Check:** The pH is above 7, as expected for the salt of a weak acid and strong base.

### PRACTICE EXERCISE

Calculate the pH at the equivalence point when (a) 40.0 mL of 0.025 M benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ,  $K_a = 6.3 \times 10^{-5}$ ) is titrated with 0.050 M NaOH; (b) 40.0 mL of 0.100 M  $\text{NH}_3$  is titrated with 0.100 M HCl.

**Answers:** (a) 8.21, (b) 5.28

**▲ Figure 17.11 Effect of  $K_a$  on titration curves.** This set of curves shows the influence of acid strength ( $K_a$ ) on the shape of the curve for titration with NaOH. Each curve represents titration of 50.0 mL of 0.10 M acid with 0.10 M NaOH. The weaker the acid, the higher the initial pH and the smaller the pH change at the equivalence point.

The pH titration curves for weak acid–strong base titrations differ from those for strong acid–strong base titrations in three noteworthy ways:

1. The solution of the weak acid has a higher initial pH than a solution of a strong acid of the same concentration.
2. The pH change at the rapid-rise portion of the curve near the equivalence point is smaller for the weak acid than it is for the strong acid.
3. The pH at the equivalence point is above 7.00 for the weak acid–strong base titration.

To illustrate these differences further, consider the family of titration curves shown in Figure 17.11. Notice that the initial pH increases as the acid becomes weaker (that is, as  $K_a$  becomes smaller), and that the pH change near the equivalence point becomes less marked. Notice also that the pH at the equivalence point steadily increases as  $K_a$  decreases. It is virtually impossible to determine the equivalence point when  $\text{p}K_a$  is 10 or higher because the pH change is too small and gradual.

Because the pH change near the equivalence point becomes smaller as  $K_a$  decreases, the choice of indicator for a weak acid–strong base titration is more critical than it is for a strong acid–strong base titration. When 0.100 M  $\text{CH}_3\text{COOH}$  ( $K_a = 1.8 \times 10^{-5}$ ) is titrated with 0.100 M NaOH, for example, as shown in Figure 17.9, the pH increases rapidly only over the pH range of about 7 to 10. Phenolphthalein is therefore an ideal indicator because it changes color from pH 8.3 to 10.0, close to the pH at the equivalence point. Methyl red is a poor choice, however, because its color change occurs from 4.2 to 6.0, which begins well before the equivalence point is reached.

Titration of a weak base (such as 0.100 M  $\text{NH}_3$ ) with a strong acid solution (such as 0.100 M  $\text{HCl}$ ) leads to the titration curve shown in Figure 17.12. In this particular example the equivalence point occurs at pH 5.28. Thus, methyl red would be an ideal indicator, but phenolphthalein would be a poor choice.

### GIVE IT SOME THOUGHT

Why is the choice of indicator more crucial for a weak acid–strong base titration than for a strong acid–strong base titration?

## Titration of Polyprotic Acids

When weak acids contain more than one ionizable H atom, as in phosphorous acid ( $\text{H}_3\text{PO}_3$ ), reaction with  $\text{OH}^-$  occurs in a series of steps. Neutralization of  $\text{H}_3\text{PO}_3$  proceeds in two stages. ∞ (Chapter 16 Sample Integrative Exercise)

When the neutralization steps of a polyprotic acid or polybasic base are sufficiently separated, the substance exhibits a titration curve with multiple equivalence points. Figure 17.13 shows the two distinct equivalence points in the titration curve for the  $\text{H}_3\text{PO}_3\text{--H}_2\text{PO}_3^- \text{--HPO}_3^{2-}$  system.

### GIVE IT SOME THOUGHT

Sketch the titration curve for the titration of  $\text{Na}_2\text{CO}_3$  with  $\text{HCl}$ .

## 17.4 SOLUBILITY EQUILIBRIA

The equilibria that we have considered thus far in this chapter have involved acids and bases. Furthermore, they have been homogeneous; that is, all the species have been in the same phase. Through the rest of this chapter we will consider the equilibria involved in the dissolution or precipitation of ionic compounds. These reactions are heterogeneous.

The dissolving and precipitating of compounds are phenomena that occur both within us and around us. Tooth enamel dissolves in acidic solutions, for example, causing tooth decay. The precipitation of certain salts in our kidneys produces kidney stones. The waters of Earth contain salts dissolved as water passes over and through the ground. Precipitation of  $\text{CaCO}_3$  from groundwater is responsible for the formation of stalactites and stalagmites within limestone caves (Figure 4.1).

In our earlier discussion of precipitation reactions, we considered some general rules for predicting the solubility of common salts in water. ∞ (Section 4.2) These rules give us a qualitative sense of whether a compound will have a low or high solubility in water. By considering solubility equilibria, in contrast, we can make quantitative predictions about the amount of a given compound that will dissolve. We can also use these equilibria to analyze the factors that affect solubility.

▲ **Figure 17.12** Adding a strong acid to a base. The blue curve shows pH versus volume of added  $\text{HCl}$  in the titration of 50.0 mL of 0.10 M ammonia (weak base) with 0.10 M  $\text{HCl}$ . The red curve shows pH versus added acid for the titration of 0.10 M  $\text{NaOH}$  (strong base). Both phenolphthalein and methyl red change color at the equivalence point in the titration of the strong base. Phenolphthalein changes color before the equivalence point in the titration of the weak base.

▲ **Figure 17.13** Diprotic acid. Titration curve for the reaction of 50.0 mL of 0.10 M  $\text{H}_3\text{PO}_3$  with 0.10 M  $\text{NaOH}$ .

### The Solubility-Product Constant, $K_{sp}$

Recall that a *saturated solution* is one in which the solution is in contact with undissolved solute.  $\rightleftharpoons$  (Section 13.2) Consider, for example, a saturated aqueous solution of  $\text{BaSO}_4$  that is in contact with solid  $\text{BaSO}_4$ . Because the solid is an ionic compound, it is a strong electrolyte and yields  $\text{Ba}^{2+}(\text{aq})$  and  $\text{SO}_4^{2-}(\text{aq})$  ions upon dissolving. The following equilibrium is readily established between the undissolved solid and hydrated ions in solution:

As with any other equilibrium, the extent to which this dissolution reaction occurs is expressed by the magnitude of its equilibrium constant. Because this equilibrium equation describes the dissolution of a solid, the equilibrium constant indicates how soluble the solid is in water and is referred to as the **solubility-product constant** (or simply the **solubility product**). It is denoted  $K_{sp}$ , where *sp* stands for solubility product.

The equilibrium-constant expression for the equilibrium between a solid and an aqueous solution of its component ions is written according to the rules that apply to any equilibrium-constant expression. Remember, however, that solids do not appear in the equilibrium-constant expressions for heterogeneous equilibria.  $\rightleftharpoons$  (Section 15.4) Thus, the solubility-product expression for  $\text{BaSO}_4$ , which is based on Equation 17.15, is

$$K_{sp} = [\text{Ba}^{2+}][\text{SO}_4^{2-}] \quad [17.16]$$

In general, *the solubility product of a compound equals the product of the concentration of the ions involved in the equilibrium, each raised to the power of its coefficient in the equilibrium equation*. The coefficient for each ion in the equilibrium equation also equals its subscript in the compound's chemical formula.

The values of  $K_{sp}$  at 25 °C for many ionic solids are tabulated in Appendix D. The value of  $K_{sp}$  for  $\text{BaSO}_4$  is  $1.1 \times 10^{-10}$ , a very small number, indicating that only a very small amount of the solid will dissolve in water.

#### **SAMPLE EXERCISE 17.9** | Writing Solubility-Product ( $K_{sp}$ ) Expressions

Write the expression for the solubility-product constant for  $\text{CaF}_2$ , and look up the corresponding  $K_{sp}$  value in Appendix D.

#### **SOLUTION**

**Analyze:** We are asked to write an equilibrium-constant expression for the process by which  $\text{CaF}_2$  dissolves in water.

**Plan:** We apply the same rules for writing any equilibrium-constant expression, excluding the solid reactant from the expression. We assume that the compound dissociates completely into its component ions.

**Solve:** Following the italicized rule stated previously, the expression for  $K_{sp}$  is

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^{-}]^2$$

In Appendix D we see that this  $K_{sp}$  has a value of  $3.9 \times 10^{-11}$ .

#### **PRACTICE EXERCISE**

Give the solubility-product-constant expressions and the values of the solubility-product constants (from Appendix D) for the following compounds: (a) barium carbonate, (b) silver sulfate.

**Answers:** (a)  $K_{sp} = [\text{Ba}^{2+}][\text{CO}_3^{2-}] = 5.0 \times 10^{-9}$ , (b)  $K_{sp} = [\text{Ag}^{+}]^2[\text{SO}_4^{2-}] = 1.5 \times 10^{-5}$

### Solubility and $K_{sp}$

It is important to distinguish carefully between solubility and the solubility-product constant. The solubility of a substance is the quantity that dissolves to form a saturated solution.  $\rightleftharpoons$  (Section 13.2) Solubility is often expressed as grams of solute per liter of solution (g/L). *Molar solubility* is the number of moles of the

solute that dissolve in forming a liter of saturated solution of the solute (mol/L). The solubility-product constant ( $K_{sp}$ ) is the equilibrium constant for the equilibrium between an ionic solid and its saturated solution and is a unitless number. Thus, the magnitude of  $K_{sp}$  is a measure of how much of the solid dissolves to form a saturated solution.

▲ **Figure 17.14 Relationships between solubility and  $K_{sp}$ .** The solubility of any compound in grams per liter can be converted to molar solubility. The molar solubility can be used to determine the concentrations of ions in solution. The concentration of ions can be used to calculate  $K_{sp}$ . The steps can be reversed, and solubility calculated from  $K_{sp}$ .

### GIVE IT SOME THOUGHT

Without doing a calculation, predict which of the following compounds will have the greatest molar solubility in water: AgCl ( $K_{sp} = 1.8 \times 10^{-10}$ ), AgBr ( $K_{sp} = 5.0 \times 10^{-13}$ ), or AgI ( $K_{sp} = 8.3 \times 10^{-17}$ ).

The solubility of a substance can change considerably as the concentrations of other solutes change. The solubility of  $\text{Mg}(\text{OH})_2$ , for example, depends highly on pH. The solubility is also affected by the concentrations of other ions in solution, especially  $\text{Mg}^{2+}$ . In contrast, the solubility-product constant,  $K_{sp}$ , has only one value for a given solute at any specific temperature.\*

In principle, it is possible to use the  $K_{sp}$  value of a salt to calculate solubility under a variety of conditions. In practice, great care must be taken in doing so for the reasons indicated in "A Closer Look: Limitations of Solubility Products" at the end of this section. Agreement between measured solubility and that calculated from  $K_{sp}$  is usually best for salts whose ions have low charges (1+ and 1-) and do not hydrolyze. Figure 17.14▲ summarizes the relationships among various expressions of solubility and  $K_{sp}$ .

### SAMPLE EXERCISE 17.10 | Calculating $K_{sp}$ from Solubility

Solid silver chromate is added to pure water at 25 °C. Some of the solid remains undissolved at the bottom of the flask. The mixture is stirred for several days to ensure that equilibrium is achieved between the undissolved  $\text{Ag}_2\text{CrO}_4(\text{s})$  and the solution. Analysis of the equilibrated solution shows that its silver ion concentration is  $1.3 \times 10^{-4} \text{ M}$ . Assuming that  $\text{Ag}_2\text{CrO}_4$  dissociates completely in water and that there are no other important equilibria involving the  $\text{Ag}^+$  or  $\text{CrO}_4^{2-}$  ions in the solution, calculate  $K_{sp}$  for this compound.

#### SOLUTION

**Analyze:** We are given the equilibrium concentration of  $\text{Ag}^+$  in a saturated solution of  $\text{Ag}_2\text{CrO}_4$ . From this information, we are asked to determine the value of the solubility-product constant,  $K_{sp}$ , for  $\text{Ag}_2\text{CrO}_4$ .

**Plan:** The equilibrium equation and the expression for  $K_{sp}$  are

To calculate  $K_{sp}$ , we need the equilibrium concentrations of  $\text{Ag}^+$  and  $\text{CrO}_4^{2-}$ . We know that at equilibrium  $[\text{Ag}^+] = 1.3 \times 10^{-4} \text{ M}$ . All the  $\text{Ag}^+$  and  $\text{CrO}_4^{2-}$  ions in the solution come from the  $\text{Ag}_2\text{CrO}_4$  that dissolves. Thus, we can use  $[\text{Ag}^+]$  to calculate  $[\text{CrO}_4^{2-}]$ .

**Solve:** From the chemical formula of silver chromate, we know that there must be 2  $\text{Ag}^+$  ions in solution for each  $\text{CrO}_4^{2-}$  ion in solution. Consequently, the concentration of  $\text{CrO}_4^{2-}$  is half the concentration of  $\text{Ag}^+$ :

$$[\text{CrO}_4^{2-}] = \left( \frac{1.3 \times 10^{-4} \text{ mol Ag}^+}{\text{L}} \right) \left( \frac{1 \text{ mol CrO}_4^{2-}}{2 \text{ mol Ag}^+} \right) = 6.5 \times 10^{-5} \text{ M}$$

We can now calculate the value of  $K_{sp}$ .

$$K_{sp} = [\text{Ag}^+]^2[\text{CrO}_4^{2-}] = (1.3 \times 10^{-4})^2(6.5 \times 10^{-5}) = 1.1 \times 10^{-12}$$

**Check:** We obtain a small value, as expected for a slightly soluble salt. Furthermore, the calculated value agrees well with the one given in Appendix D,  $1.2 \times 10^{-12}$ .

\*This is strictly true only for very dilute solutions. The values of equilibrium constants are somewhat altered when the total concentration of ionic substances in water is increased. However, we will ignore these effects, which are taken into consideration only for work that requires exceptional accuracy.

**PRACTICE EXERCISE**

A saturated solution of  $\text{Mg}(\text{OH})_2$  in contact with undissolved solid is prepared at 25 °C. The pH of the solution is found to be 10.17. Assuming that  $\text{Mg}(\text{OH})_2$  dissociates completely in water and that there are no other simultaneous equilibria involving the  $\text{Mg}^{2+}$  or  $\text{OH}^-$  ions in the solution, calculate  $K_{sp}$  for this compound.

**Answer:**  $1.6 \times 10^{-12}$

**SAMPLE EXERCISE 17.11** | Calculating Solubility from  $K_{sp}$ 

The  $K_{sp}$  for  $\text{CaF}_2$  is  $3.9 \times 10^{-11}$  at 25 °C. Assuming that  $\text{CaF}_2$  dissociates completely upon dissolving and that there are no other important equilibria affecting its solubility, calculate the solubility of  $\text{CaF}_2$  in grams per liter.

**SOLUTION**

**Analyze:** We are given  $K_{sp}$  for  $\text{CaF}_2$  and are asked to determine solubility. Recall that the *solubility* of a substance is the quantity that can dissolve in solvent, whereas the *solubility-product constant*,  $K_{sp}$ , is an equilibrium constant.

**Plan:** We can approach this problem by using our standard techniques for solving equilibrium problems. We write the chemical equation for the dissolution process and set up a table of the initial and equilibrium concentrations. We then use the equilibrium-constant expression. In this case we know  $K_{sp}$ , and so we solve for the concentrations of the ions in solution.

**Solve:** Assume initially that none of the salt has dissolved, and then allow  $x$  moles/liter of  $\text{CaF}_2$  to dissociate completely when equilibrium is achieved.

$$\text{CaF}_2(\text{s}) \rightleftharpoons \text{Ca}^{2+} + 2\text{F}^-(\text{aq})$$

Initial	—	0	0
Change	—	+ $x$ M	+ $2x$ M
Equilibrium	—	$x$ M	$2x$ M

The stoichiometry of the equilibrium dictates that  $2x$  moles/liter of  $\text{F}^-$  are produced for each  $x$  moles/liter of  $\text{CaF}_2$  that dissolve. We now use the expression for  $K_{sp}$  and substitute the equilibrium concentrations to solve for the value of  $x$ :

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^-]^2 = (x)(2x)^2 = 4x^3 = 3.9 \times 10^{-11}$$

$$x = \sqrt[3]{\frac{3.9 \times 10^{-11}}{4}} = 2.1 \times 10^{-4} \text{ M}$$

(Remember that  $\sqrt[3]{y} = y^{1/3}$ ; to calculate the cube root of a number, you can use the  $y^x$  function on your calculator, with  $x = \frac{1}{3}$ .) Thus, the molar solubility of  $\text{CaF}_2$  is  $2.1 \times 10^{-4}$  mol/L. The mass of  $\text{CaF}_2$  that dissolves in water to form a liter of solution is

$$\left(\frac{2.1 \times 10^{-4} \text{ mol CaF}_2}{1 \text{ L soln}}\right)\left(\frac{78.1 \text{ g CaF}_2}{1 \text{ mol CaF}_2}\right) = 1.6 \times 10^{-2} \text{ g CaF}_2/\text{L soln}$$

**Check:** We expect a small number for the solubility of a slightly soluble salt. If we reverse the calculation, we should be able to recalculate the solubility product:  $K_{sp} = (2.1 \times 10^{-4})(4.2 \times 10^{-4})^2 = 3.7 \times 10^{-11}$ , close to the starting value for  $K_{sp}$ ,  $3.9 \times 10^{-11}$ .

**Comment:** Because  $\text{F}^-$  is the anion of a weak acid, you might expect that the hydrolysis of the ion would affect the solubility of  $\text{CaF}_2$ . The basicity of  $\text{F}^-$  is so small ( $K_b = 1.5 \times 10^{-11}$ ), however, that the hydrolysis occurs to only a slight extent and does not significantly influence the solubility. The reported solubility is 0.017 g/L at 25 °C, in good agreement with our calculation.

**PRACTICE EXERCISE**

The  $K_{sp}$  for  $\text{LaF}_3$  is  $2 \times 10^{-19}$ . What is the solubility of  $\text{LaF}_3$  in water in moles per liter?

**Answer:**  $9 \times 10^{-6}$  mol/L

## A Closer Look

## LIMITATIONS OF SOLUBILITY PRODUCTS

The concentrations of ions calculated from  $K_{sp}$  sometimes deviate appreciably from those found experimentally. In part, these deviations are due to electrostatic interactions between ions in solution, which can lead to ion pairs. (See Section 13.5, “A Closer Look: Colligative Properties of Electrolyte Solutions.”) These interactions increase in magnitude both as the concentrations of the ions increase and as their charges increase. The solubility calculated from  $K_{sp}$  tends to be low unless it is corrected to account for these interactions between ions. Chemists have developed procedures for correcting for these “ionic-strength” or “ionic-activity” effects, and these procedures are examined in more advanced chemistry courses. As an example of the effect of these interionic interactions, consider  $\text{CaCO}_3$  (calcite), whose solubility product,  $K_{sp} = 4.5 \times 10^{-9}$ , gives a calculated solubility of  $6.7 \times 10^{-5}$  mol/L. Making corrections for the interionic interactions in the solution yields a higher solubility,  $7.3 \times 10^{-5}$  mol/L. The reported solubility, however, is twice as high ( $1.4 \times 10^{-4}$  mol/L), so there must be one or more additional factors involved.

Another common source of error in calculating ion concentrations from  $K_{sp}$  is ignoring other equilibria that occur simultaneously in the solution. It is possible, for example, that acid-base equilibria take place simultaneously with solubility equilibria. In particular, both basic anions and cations with high charge-to-size ratios undergo hydrolysis reactions that can measurably increase the solubilities of their salts. For example,  $\text{CaCO}_3$  contains the basic carbonate ion ( $K_b = 1.8 \times 10^{-4}$ ), which hydrolyzes in water:  $\text{CO}_3^{2-}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HCO}_3^-(aq) + \text{OH}^-(aq)$ . If we consider both the effect of the interionic interactions in the solution and the effect of the simultaneous solubility and hydrolysis equilibria, we calculate a solubility of  $1.4 \times 10^{-4}$  mol/L, in agreement with the measured value.

Finally, we generally assume that ionic compounds dissociate completely into their component ions when they dissolve. This assumption is not always valid. When  $\text{MgF}_2$  dissolves, for example, it yields not only  $\text{Mg}^{2+}$  and  $\text{F}^-$  ions but also  $\text{MgF}^+$  ions in solution. Thus, we see that calculating solubility using  $K_{sp}$  can be more complicated than it first appears and it requires considerable knowledge of the equilibria occurring in solution.

## 17.5 FACTORS THAT AFFECT SOLUBILITY

The solubility of a substance is affected by temperature as well as by the presence of other solutes. The presence of an acid, for example, can have a major influence on the solubility of a substance. In Section 17.4 we considered the dissolving of ionic compounds in pure water. In this section we examine three factors that affect the solubility of ionic compounds: (1) the presence of common ions, (2) the pH of the solution, and (3) the presence of complexing agents. We will also examine the phenomenon of *amphoterism*, which is related to the effects of both pH and complexing agents.

### Common-Ion Effect

The presence of either  $\text{Ca}^{2+}(aq)$  or  $\text{F}^-(aq)$  in a solution reduces the solubility of  $\text{CaF}_2$ , shifting the solubility equilibrium of  $\text{CaF}_2$  to the left.

← Addition of  $\text{Ca}^{2+}$  or  $\text{F}^-$  shifts equilibrium, reducing solubility

This reduction in solubility is another application of the common-ion effect.  $\infty$  (Section 17.1) In general, the solubility of a slightly soluble salt is decreased by the presence of a second solute that furnishes a common ion. Figure 17.15 shows how the solubility of  $\text{CaF}_2$  decreases as  $\text{NaF}$  is added to the solution. Sample Exercise 17.12 shows how the  $K_{sp}$  can be used to calculate the solubility of a slightly soluble salt in the presence of a common ion.

▲ **Figure 17.15 Common-ion effect.** The way in which  $\text{NaF}$  concentration affects the solubility of  $\text{CaF}_2$  demonstrates the common-ion effect. Notice that the  $\text{CaF}_2$  solubility is on a logarithmic scale.

**SAMPLE EXERCISE 17.12** Calculating the Effect of a Common Ion on Solubility

Calculate the molar solubility of  $\text{CaF}_2$  at 25 °C in a solution that is (a) 0.010 M in  $\text{Ca}(\text{NO}_3)_2$ , (b) 0.010 M in NaF.

**SOLUTION**

**Analyze:** We are asked to determine the solubility of  $\text{CaF}_2$  in the presence of two strong electrolytes, each of which contains an ion common to  $\text{CaF}_2$ . In (a) the common ion is  $\text{Ca}^{2+}$ , and  $\text{NO}_3^-$  is a spectator ion. In (b) the common ion is  $\text{F}^-$ , and  $\text{Na}^+$  is a spectator ion.

**Plan:** Because the slightly soluble compound is  $\text{CaF}_2$ , we need to use the  $K_{sp}$  for this compound, which is available in Appendix D:

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^-]^2 = 3.9 \times 10^{-11}$$

The value of  $K_{sp}$  is unchanged by the presence of additional solutes. Because of the common-ion effect, however, the solubility of the salt will decrease in the presence of common ions. We can again use our standard equilibrium techniques of starting with the equation for  $\text{CaF}_2$  dissolution, setting up a table of initial and equilibrium concentrations, and using the  $K_{sp}$  expression to determine the concentration of the ion that comes only from  $\text{CaF}_2$ .

**Solve:** (a) In this instance the initial concentration of  $\text{Ca}^{2+}$  is 0.010 M because of the dissolved  $\text{Ca}(\text{NO}_3)_2$ :

	$\text{CaF}_2(\text{s})$	$\rightleftharpoons$	$\text{Ca}^{2+}(\text{aq})$	+	$2\text{F}^-(\text{aq})$
Initial	—		0.010 M		0
Change	—		+x M		+2x M
Equilibrium	—		(0.010 + x) M		2x M

Substituting into the solubility-product expression gives

$$K_{sp} = 3.9 \times 10^{-11} = [\text{Ca}^{2+}][\text{F}^-]^2 = (0.010 + x)(2x)^2$$

This would be a messy problem to solve exactly, but fortunately it is possible to simplify matters greatly. Even without the common-ion effect, the solubility of  $\text{CaF}_2$  is very small ( $2.1 \times 10^{-4}$  M). Thus, we assume that the 0.010 M concentration of  $\text{Ca}^{2+}$  from  $\text{Ca}(\text{NO}_3)_2$  is very much greater than the small additional concentration resulting from the solubility of  $\text{CaF}_2$ ; that is,  $x$  is small compared to 0.010 M, and  $0.010 + x \approx 0.010$ . We then have

$$\begin{aligned} 3.9 \times 10^{-11} &= (0.010)(2x)^2 \\ x^2 &= \frac{3.9 \times 10^{-11}}{4(0.010)} = 9.8 \times 10^{-10} \\ x &= \sqrt{9.8 \times 10^{-10}} = 3.1 \times 10^{-5} \text{ M} \end{aligned}$$

The very small value for  $x$  validates the simplifying assumption we have made. Our calculation indicates that  $3.1 \times 10^{-5}$  mol of solid  $\text{CaF}_2$  dissolves per liter of the 0.010 M  $\text{Ca}(\text{NO}_3)_2$  solution.

(b) In this case the common ion is  $\text{F}^-$ , and at equilibrium we have

$$[\text{Ca}^{2+}] = x \quad \text{and} \quad [\text{F}^-] = 0.010 + 2x$$

Assuming that  $2x$  is small compared to 0.010 M (that is,  $0.010 + 2x \approx 0.010$ ), we have

$$\begin{aligned} 3.9 \times 10^{-11} &= x(0.010)^2 \\ x &= \frac{3.9 \times 10^{-11}}{(0.010)^2} = 3.9 \times 10^{-7} \text{ M} \end{aligned}$$

Thus,  $3.9 \times 10^{-7}$  mol of solid  $\text{CaF}_2$  should dissolve per liter of 0.010 M NaF solution.

**Comment:** The molar solubility of  $\text{CaF}_2$  in pure water is  $2.1 \times 10^{-4}$  M (Sample Exercise 17.11). By comparison, our calculations above show that the solubility of  $\text{CaF}_2$  in the presence of 0.010 M  $\text{Ca}^{2+}$  is  $3.1 \times 10^{-5}$  M, and in the presence of 0.010 M  $\text{F}^-$  ion it is  $3.9 \times 10^{-7}$  M. Thus, the addition of either  $\text{Ca}^{2+}$  or  $\text{F}^-$  to a solution of  $\text{CaF}_2$  decreases the solubility. However, the effect of  $\text{F}^-$  on the solubility is more pronounced than that of  $\text{Ca}^{2+}$  because  $[\text{F}^-]$  appears to the second power in the  $K_{sp}$  expression for  $\text{CaF}_2$ , whereas  $\text{Ca}^{2+}$  appears to the first power.

**PRACTICE EXERCISE**

The value for  $K_{sp}$  for manganese(II) hydroxide,  $\text{Mn}(\text{OH})_2$ , is  $1.6 \times 10^{-13}$ . Calculate the molar solubility of  $\text{Mn}(\text{OH})_2$  in a solution that contains 0.020 M NaOH.

**Answer:**  $4.0 \times 10^{-10}$  M

**Solubility and pH**

The pH of a solution will affect the solubility of any substance whose anion is basic. Consider  $\text{Mg}(\text{OH})_2$ , for example, for which the solubility equilibrium is

A saturated solution of  $\text{Mg}(\text{OH})_2$  has a calculated pH of 10.52 and contains  $[\text{Mg}^{2+}] = 1.7 \times 10^{-4} \text{ M}$ . Now suppose that solid  $\text{Mg}(\text{OH})_2$  is equilibrated with a solution buffered at a more acidic pH of 9.0. The pOH, therefore, is 5.0, so  $[\text{OH}^-] = 1.0 \times 10^{-5}$ . Inserting this value for  $[\text{OH}^-]$  into the solubility-product expression, we have

$$K_{sp} = [\text{Mg}^{2+}][\text{OH}^-]^2 = 1.8 \times 10^{-11}$$

$$[\text{Mg}^{2+}](1.0 \times 10^{-5})^2 = 1.8 \times 10^{-11}$$

$$[\text{Mg}^{2+}] = \frac{1.8 \times 10^{-11}}{(1.0 \times 10^{-5})^2} = 0.18 \text{ M}$$

Thus,  $\text{Mg}(\text{OH})_2$  dissolves in the solution until  $[\text{Mg}^{2+}] = 0.18 \text{ M}$ . It is apparent that  $\text{Mg}(\text{OH})_2$  is quite soluble in this solution. If the concentration of  $\text{OH}^-$  were reduced even further by making the solution more acidic, the  $\text{Mg}^{2+}$  concentration would have to increase to maintain the equilibrium condition. Thus, a sample of  $\text{Mg}(\text{OH})_2$  will dissolve completely if sufficient acid is added (Figure 17.16 ▼).

▼ **Figure 17.16 Dissolution of a precipitate in acid.** A white precipitate of  $\text{Mg}(\text{OH})_2(\text{s})$  in contact with its saturated solution is in the test tube on the left. The dropper poised above the solution surface contains hydrochloric acid. (The anions accompanying the acid have been omitted to simplify the art.)

## Chemistry and Life

### SINKHOLES

A principal cause of sinkholes is the dissolution of limestone, which is calcium carbonate, by groundwater. Although  $\text{CaCO}_3$  has a relatively small solubility-product constant, it is quite soluble in the presence of acid.

Rainwater is naturally acidic, with a pH range of 5 to 6, and can become more acidic when it comes into contact with decaying plant matter. Because carbonate ion is the conjugate base of the weak acid, hydrogen carbonate ion ( $\text{HCO}_3^-$ ), it readily combines with hydrogen ion.

The consumption of carbonate ion shifts the dissolution equilibrium to the right, thus increasing the solubility of  $\text{CaCO}_3$ . This can have profound consequences in areas where the terrain consists of porous calcium carbonate bedrock covered by a relatively thin layer of clay and/or topsoil. As acidic water percolates through and gradually dissolves the limestone, it creates underground voids. A sinkhole results when the overlying ground can no longer be supported by the remaining bedrock and collapses into the underground cavity [Figure 17.17 ▶].

The sudden formation of large sinkholes can pose a serious threat to life and property. The existence of deep sinkholes also increases the risk of contamination of the aquifer.

▲ **Figure 17.17 Sinkhole formation.** An underground void develops as limestone,  $\text{CaCO}_3(s)$ , dissolves. Collapse of the overlying ground into an underground cavity causes sinkhole formation. The large sinkhole shown here occurred in Orlando, Florida and destroyed several buildings and part of a highway.

▲ **Figure 17.18 The effect of pH on the solubility of  $\text{CaF}_2$ .** The solubility increases as the solution becomes more acidic (lower pH). Notice that the vertical scale has been multiplied by  $10^3$ .

The solubility of almost any ionic compound is affected if the solution is made sufficiently acidic or basic. The effects are very noticeable, however, only when one or both ions involved are at least moderately acidic or basic. The metal hydroxides, such as  $\text{Mg}(\text{OH})_2$ , are examples of compounds containing a strongly basic ion, the hydroxide ion.

In general, if a compound contains a basic anion (that is, the anion of a weak acid), its solubility will increase as the solution becomes more acidic. As we have seen, the solubility of  $\text{Mg}(\text{OH})_2$  greatly increases as the acidity of the solution increases. The solubility of  $\text{CaF}_2$  increases as the solution becomes more acidic, too, because the  $\text{F}^-$  ion is a weak base; it is the conjugate base of the weak acid HF. As a result, the solubility equilibrium of  $\text{CaF}_2$  is shifted to the right as the concentration of  $\text{F}^-$  ions is reduced by protonation to form HF. Thus, the solution process can be understood in terms of two consecutive reactions:

The equation for the overall process is

Figure 17.18 ◀ shows how the solubility of  $\text{CaF}_2$  changes with pH.

Other salts that contain basic anions, such as  $\text{CO}_3^{2-}$ ,  $\text{PO}_4^{3-}$ ,  $\text{CN}^-$ , or  $\text{S}^{2-}$ , behave similarly. These examples illustrate a general rule: *The solubility of slightly soluble salts containing basic anions increases as  $[\text{H}^+]$  increases (as pH is lowered).* The more basic the anion, the more the solubility is influenced by pH. Salts with anions of negligible basicity (the anions of strong acids) are unaffected by pH changes.

**SAMPLE EXERCISE 17.13** | Predicting the Effect of Acid on Solubility

Which of the following substances will be more soluble in acidic solution than in basic solution: (a)  $\text{Ni}(\text{OH})_2(\text{s})$ , (b)  $\text{CaCO}_3(\text{s})$ , (c)  $\text{BaF}_2(\text{s})$ , (d)  $\text{AgCl}(\text{s})$ ?

**SOLUTION**

**Analyze:** The problem lists four sparingly soluble salts, and we are asked to determine which will be more soluble at low pH than at high pH.

**Plan:** Ionic compounds that dissociate to produce a basic anion will be more soluble in acid solution.

**Solve:**

(a)  $\text{Ni}(\text{OH})_2(\text{s})$  will be more soluble in acidic solution because of the basicity of  $\text{OH}^-$ ; the  $\text{H}^+$  ion reacts with the  $\text{OH}^-$  ion, forming water.

(b) Similarly,  $\text{CaCO}_3(\text{s})$  dissolves in acid solutions because  $\text{CO}_3^{2-}$  is a basic anion.

The reaction between  $\text{CO}_3^{2-}$  and  $\text{H}^+$  occurs in a stepwise fashion, first forming  $\text{HCO}_3^-$ .  $\text{H}_2\text{CO}_3$  forms in appreciable amounts only when the concentration of  $\text{H}^+$  is sufficiently high.

(c) The solubility of  $\text{BaF}_2$  is also enhanced by lowering the pH, because  $\text{F}^-$  is a basic anion.

(d) The solubility of  $\text{AgCl}$  is unaffected by changes in pH because  $\text{Cl}^-$  is the anion of a strong acid and therefore has negligible basicity.

**PRACTICE EXERCISE**

Write the net ionic equation for the reaction of the following copper(II) compounds with acid: (a)  $\text{CuS}$ , (b)  $\text{Cu}(\text{N}_3)_2$ .

**Answers:** (a)  $\text{CuS}(\text{s}) + \text{H}^+(\text{aq}) \rightleftharpoons \text{Cu}^{2+}(\text{aq}) + \text{HS}^-(\text{aq})$

(b)  $\text{Cu}(\text{N}_3)_2(\text{s}) + 2 \text{H}^+(\text{aq}) \rightleftharpoons \text{Cu}^{2+}(\text{aq}) + 2 \text{HN}_3(\text{aq})$

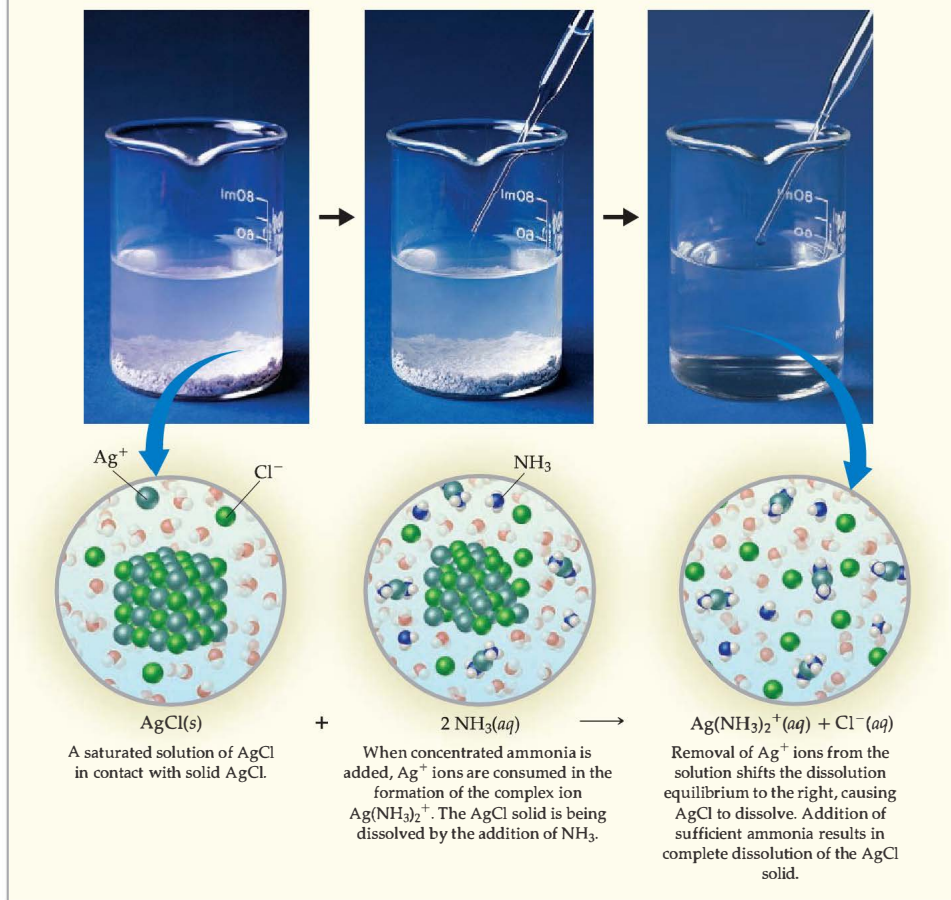

**Formation of Complex Ions**

A characteristic property of metal ions is their ability to act as Lewis acids, or electron-pair acceptors, toward water molecules, which act as Lewis bases, or electron-pair donors.  $\rightleftharpoons$  (Section 16.11) Lewis bases other than water can also interact with metal ions, particularly with transition-metal ions. Such interactions can dramatically affect the solubility of a metal salt.  $\text{AgCl}$ , for example, which has  $K_{\text{sp}} = 1.8 \times 10^{-10}$ , will dissolve in the presence of aqueous ammonia because  $\text{Ag}^+$  interacts with the Lewis base  $\text{NH}_3$ , as shown in Figure 17.19  $\blacktriangledown$ . This process can be viewed as the sum of two reactions, the dissolution of  $\text{AgCl}$  and the Lewis acid–base interaction between  $\text{Ag}^+$  and  $\text{NH}_3$ .

### FORMATION OF COMPLEX IONS

*Lewis bases can interact with metal ions, particularly with transition-metal ions, which can dramatically affect the solubility of a metal salt. AgCl, for example, will dissolve in the presence of aqueous ammonia because  $\text{Ag}^+$  interacts with the Lewis base  $\text{NH}_3$ .*

▲ **Figure 17.19** Using  $\text{NH}_3(aq)$  to dissolve  $\text{AgCl}(s)$ .

The presence of  $\text{NH}_3$  drives the reaction, the dissolution of AgCl, to the right as  $\text{Ag}^+(aq)$  is consumed to form  $\text{Ag}(\text{NH}_3)_2^+$ .

For a Lewis base such as  $\text{NH}_3$  to increase the solubility of a metal salt, it must be able to interact more strongly with the metal ion than water does. The  $\text{NH}_3$  must displace solvating  $\text{H}_2\text{O}$  molecules (Sections 13.1 and 16.11) in order to form  $\text{Ag}(\text{NH}_3)_2^+$ :

**Chemistry and Life** TOOTH DECAY AND FLUORIDATION

Tooth enamel consists mainly of a mineral called hydroxyapatite,  $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ . It is the hardest substance in the body. Tooth cavities are caused when acids dissolve tooth enamel.

The resultant  $\text{Ca}^{2+}$  and  $\text{HPO}_4^{2-}$  ions diffuse out of the tooth enamel and are washed away by saliva. The acids that attack the hydroxyapatite are formed by the action of specific bacteria on sugars and other carbohydrates present in the plaque adhering to the teeth.

Fluoride ion, present in drinking water, toothpaste, and other sources, can react with hydroxyapatite to form fluorapatite,  $\text{Ca}_{10}(\text{PO}_4)_6\text{F}_2$ . This mineral, in which  $\text{F}^-$  has replaced

$\text{OH}^-$ , is much more resistant to attack by acids because the fluoride ion is a much weaker Bronsted-Lowry base than the hydroxide ion.

Because the fluoride ion is so effective in preventing cavities, it is added to the public water supply in many places to give a concentration of 1 mg/L (1 ppm). The compound added may be NaF or  $\text{Na}_2\text{SiF}_6$ .  $\text{Na}_2\text{SiF}_6$  reacts with water to release fluoride ions by the following reaction:

About 80% of all toothpastes now sold in the United States contain fluoride compounds, usually at the level of 0.1% fluoride by mass. The most common compounds in toothpastes are sodium fluoride (NaF), sodium monofluorophosphate ( $\text{Na}_2\text{PO}_3\text{F}$ ), and stannous fluoride ( $\text{SnF}_2$ ).

**Related Exercise:** 17.110

An assembly of a metal ion and the Lewis bases bonded to it, such as  $\text{Ag}(\text{NH}_3)_2^+$ , is called a **complex ion**. The stability of a complex ion in aqueous solution can be judged by the size of the equilibrium constant for its formation from the hydrated metal ion. For example, the equilibrium constant for formation of  $\text{Ag}(\text{NH}_3)_2^+$  (Equation 17.24) is  $1.7 \times 10^7$ :

$$K_f = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2} = 1.7 \times 10^7 \quad [17.25]$$

The equilibrium constant for this kind of reaction is called a **formation constant**,  $K_f$ . The formation constants for several complex ions are listed in Table 17.1  $\blacktriangledown$ .

**TABLE 17.1** ■ Formation Constants for Some Metal Complex Ions in Water at 25 °C

Complex Ion	$K_f$	Equilibrium Equation
$\text{Ag}(\text{NH}_3)_2^+$	$1.7 \times 10^7$	$\text{Ag}^+(aq) + 2 \text{NH}_3(aq) \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+(aq)$
$\text{Ag}(\text{CN})_2^-$	$1 \times 10^{21}$	$\text{Ag}^+(aq) + 2 \text{CN}^-(aq) \rightleftharpoons \text{Ag}(\text{CN})_2^-(aq)$
$\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$	$2.9 \times 10^{13}$	$\text{Ag}^+(aq) + 2 \text{S}_2\text{O}_3^{2-}(aq) \rightleftharpoons \text{Ag}(\text{S}_2\text{O}_3)_2^{3-}(aq)$
$\text{CdBr}_4^{2-}$	$5 \times 10^3$	$\text{Cd}^{2+}(aq) + 4 \text{Br}^-(aq) \rightleftharpoons \text{CdBr}_4^{2-}(aq)$
$\text{Cr}(\text{OH})_4^-$	$8 \times 10^{29}$	$\text{Cr}^{3+}(aq) + 4 \text{OH}^-(aq) \rightleftharpoons \text{Cr}(\text{OH})_4^-(aq)$
$\text{Co}(\text{SCN})_4^{2-}$	$1 \times 10^3$	$\text{Co}^{2+}(aq) + 4 \text{SCN}^-(aq) \rightleftharpoons \text{Co}(\text{SCN})_4^{2-}(aq)$
$\text{Cu}(\text{NH}_3)_4^{2+}$	$5 \times 10^{12}$	$\text{Cu}^{2+}(aq) + 4 \text{NH}_3(aq) \rightleftharpoons \text{Cu}(\text{NH}_3)_4^{2+}(aq)$
$\text{Cu}(\text{CN})_4^{2-}$	$1 \times 10^{25}$	$\text{Cu}^{2+}(aq) + 4 \text{CN}^-(aq) \rightleftharpoons \text{Cu}(\text{CN})_4^{2-}(aq)$
$\text{Ni}(\text{NH}_3)_6^{2+}$	$1.2 \times 10^9$	$\text{Ni}^{2+}(aq) + 6 \text{NH}_3(aq) \rightleftharpoons \text{Ni}(\text{NH}_3)_6^{2+}(aq)$
$\text{Fe}(\text{CN})_6^{4-}$	$1 \times 10^{35}$	$\text{Fe}^{2+}(aq) + 6 \text{CN}^-(aq) \rightleftharpoons \text{Fe}(\text{CN})_6^{4-}(aq)$
$\text{Fe}(\text{CN})_6^{3-}$	$1 \times 10^{42}$	$\text{Fe}^{3+}(aq) + 6 \text{CN}^-(aq) \rightleftharpoons \text{Fe}(\text{CN})_6^{3-}(aq)$

**SAMPLE EXERCISE 17.14** Evaluating an Equilibrium Involving a Complex Ion

Calculate the concentration of  $\text{Ag}^+$  present in solution at equilibrium when concentrated ammonia is added to a 0.010 M solution of  $\text{AgNO}_3$  to give an equilibrium concentration of  $[\text{NH}_3] = 0.20 \text{ M}$ . Neglect the small volume change that occurs when  $\text{NH}_3$  is added.

**SOLUTION**

**Analyze:** When  $\text{NH}_3(\text{aq})$  is added to  $\text{Ag}^+(\text{aq})$ , a reaction occurs forming  $\text{Ag}(\text{NH}_3)_2^+$  as shown in Equation 17.22. We are asked to determine what concentration of  $\text{Ag}^+(\text{aq})$  will remain uncombined when the  $\text{NH}_3$  concentration is brought to 0.20 M in a solution originally 0.010 M in  $\text{AgNO}_3$ .

**Plan:** We first assume that the  $\text{AgNO}_3$  is completely dissociated, giving 0.10 M  $\text{Ag}^+$ . Because  $K_f$  for the formation of  $\text{Ag}(\text{NH}_3)_2^+$  is quite large, we assume that essentially all the  $\text{Ag}^+$  is then converted to  $\text{Ag}(\text{NH}_3)_2^+$  and approach the problem as though we are concerned with the *dissociation* of  $\text{Ag}(\text{NH}_3)_2^+$  rather than its *formation*. To facilitate this approach, we will need to reverse the equation to represent the formation of  $\text{Ag}^+$  and  $\text{NH}_3$  from  $\text{Ag}(\text{NH}_3)_2^+$  and also make the corresponding change to the equilibrium constant.

$$\frac{1}{K_f} = \frac{1}{1.7 \times 10^7} = 5.9 \times 10^{-8}$$

**Solve:** If  $[\text{Ag}^+]$  is 0.010 M initially, then  $[\text{Ag}(\text{NH}_3)_2^+]$  will be 0.010 M following addition of the  $\text{NH}_3$ . We now construct a table to solve this equilibrium problem. Note that the  $\text{NH}_3$  concentration given in the problem is an *equilibrium* concentration rather than an initial concentration.

Initial	0.010 M	0 M	
Change	$-x \text{ M}$	$+x \text{ M}$	
Equilibrium	$0.010 - x \text{ M}$	$x \text{ M}$	0.20 M

Because the concentration of  $\text{Ag}^+$  is very small, we can ignore  $x$  in comparison with 0.010. Thus,  $0.010 - x \approx 0.010 \text{ M}$ . Substituting these values into the equilibrium-constant expression for the dissociation of  $\text{Ag}(\text{NH}_3)_2^+$ , we obtain

$$\frac{[\text{Ag}^+][\text{NH}_3]^2}{[\text{Ag}(\text{NH}_3)_2^+]} = \frac{(x)(0.20)^2}{0.010} = 5.9 \times 10^{-8}$$

Solving for  $x$ , we obtain  $x = 1.5 \times 10^{-8} \text{ M} = [\text{Ag}^+]$ . Thus, formation of the  $\text{Ag}(\text{NH}_3)_2^+$  complex drastically reduces the concentration of free  $\text{Ag}^+$  ion in solution.

**PRACTICE EXERCISE**

Calculate  $[\text{Cr}^{3+}]$  in equilibrium with  $\text{Cr}(\text{OH})_4^-$  when 0.010 mol of  $\text{Cr}(\text{NO}_3)_3$  is dissolved in a liter of solution buffered at pH 10.0.

**Answer:**  $1 \times 10^{-16} \text{ M}$

The general rule is that the solubility of metal salts increases in the presence of suitable Lewis bases, such as  $\text{NH}_3$ ,  $\text{CN}^-$ , or  $\text{OH}^-$ , if the metal forms a complex with the base. The ability of metal ions to form complexes is an extremely important aspect of their chemistry. In Chapter 24 we will take a much closer look at complex ions. In that chapter and others we will see applications of complex ions to areas such as biochemistry, metallurgy, and photography.

**Amphoterism**

Some metal oxides and hydroxides that are relatively insoluble in neutral water dissolve in strongly acidic and strongly basic solutions. These substances are soluble in strong acids and bases because they themselves are capable of behaving as either an acid or base; they are **amphoteric oxides and hydroxides**.

▲ **Figure 17.20 Amphoterism.**

Amphoteric oxides and hydroxides include those of  $\text{Al}^{3+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Zn}^{2+}$ , and  $\text{Sn}^{2+}$ . Notice that the term *amphoteric* is applied to the behavior of insoluble oxides and hydroxides that can be made to dissolve in either acidic or basic solutions. The similar term *amphiprotic*, which we encountered in Section 16.2, relates more generally to any molecule or ion that can either gain or lose a proton.

Amphoteric species dissolve in acidic solutions because they contain basic anions. What makes amphoteric oxides and hydroxides special, though, is that they also dissolve in strongly basic solutions (Figure 17.20 ▲). This behavior results from the formation of complex anions containing several (typically four) hydroxides bound to the metal ion.

Amphoterism is often explained by the behavior of the water molecules that surround the metal ion and that are bonded to it by Lewis acid–base interactions. ∞ (Section 16.11) For example,  $\text{Al}^{3+}(\text{aq})$  is more accurately represented as  $\text{Al}(\text{H}_2\text{O})_6^{3+}(\text{aq})$  because six water molecules are bonded to the  $\text{Al}^{3+}$  in aqueous solution. Recall from Section 16.11 that this hydrated ion is a weak acid.

As a strong base is added,  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  loses protons in a stepwise fashion, eventually forming neutral and water-insoluble  $\text{Al}(\text{H}_2\text{O})_3(\text{OH})_3$ . This substance then dissolves upon removal of an additional proton to form the anion  $\text{Al}(\text{H}_2\text{O})_2(\text{OH})_4^-$ . The reactions that occur are as follows:

Removing additional protons is possible, but each successive reaction occurs less readily than the one before. As the charge on the ion becomes more negative, it becomes increasingly difficult to remove a positively charged proton. Addition of an acid reverses these reactions. The proton adds in a stepwise fashion to convert the  $\text{OH}^-$  groups to  $\text{H}_2\text{O}$ , eventually re-forming  $\text{Al}(\text{H}_2\text{O})_6^{3+}$ . The common practice is to simplify the equations for these reactions by excluding the bound  $\text{H}_2\text{O}$  molecules. Thus, we usually write  $\text{Al}^{3+}$  instead of  $\text{Al}(\text{H}_2\text{O})_6^{3+}$ ,  $\text{Al}(\text{OH})_3$  instead of  $\text{Al}(\text{H}_2\text{O})_3(\text{OH})_3$ ,  $\text{Al}(\text{OH})_4^-$  instead of  $\text{Al}(\text{H}_2\text{O})_2(\text{OH})_4^-$ , and so forth.

The extent to which an insoluble metal hydroxide reacts with either acid or base varies with the particular metal ion involved. Many metal hydroxides—such as  $\text{Ca}(\text{OH})_2$ ,  $\text{Fe}(\text{OH})_2$ , and  $\text{Fe}(\text{OH})_3$ —are capable of dissolving in acidic solution but do not react with excess base. These hydroxides are not amphoteric.

The purification of aluminum ore in the manufacture of aluminum metal provides an interesting application of the property of amphotericism. As we have seen,  $\text{Al}(\text{OH})_3$  is amphoteric, whereas  $\text{Fe}(\text{OH})_3$  is not. Aluminum occurs in large quantities as the ore *bauxite*, which is essentially  $\text{Al}_2\text{O}_3$  with additional water molecules. The ore is contaminated with  $\text{Fe}_2\text{O}_3$  as an impurity. When bauxite is added to a strongly basic solution, the  $\text{Al}_2\text{O}_3$  dissolves because the aluminum forms complex ions, such as  $\text{Al}(\text{OH})_4^-$ . The  $\text{Fe}_2\text{O}_3$  impurity, however, is not amphoteric and remains as a solid. The solution is filtered, getting rid of the iron impurity. Aluminum hydroxide is then precipitated by addition of acid. The purified hydroxide receives further treatment and eventually yields aluminum metal.  $\rightleftharpoons$  (Section 23.3)

### GIVE IT SOME THOUGHT

What kind of behavior characterizes an amphoteric oxide or an amphoteric hydroxide?

## 17.6 PRECIPITATION AND SEPARATION OF IONS

Equilibrium can be achieved starting with the substances on either side of a chemical equation. The equilibrium among  $\text{BaSO}_4(\text{s})$ ,  $\text{Ba}^{2+}(\text{aq})$ , and  $\text{SO}_4^{2-}(\text{aq})$  (Equation 17.15) can be achieved starting with solid  $\text{BaSO}_4$ . It can also be reached starting with solutions of salts containing  $\text{Ba}^{2+}$  and  $\text{SO}_4^{2-}$ , say  $\text{BaCl}_2$  and  $\text{Na}_2\text{SO}_4$ . When these two solutions are mixed,  $\text{BaSO}_4$  will precipitate if the product of the initial ion concentrations,  $Q = [\text{Ba}^{2+}][\text{SO}_4^{2-}]$ , is greater than  $K_{sp}$ .

The use of the reaction quotient,  $Q$ , to determine the direction in which a reaction must proceed to reach equilibrium was discussed earlier.  $\rightleftharpoons$  (Section 15.6) The possible relationships between  $Q$  and  $K_{sp}$  are summarized as follows:

- If  $Q > K_{sp}$ , precipitation occurs until  $Q = K_{sp}$ .
- If  $Q = K_{sp}$ , equilibrium exists (saturated solution).
- If  $Q < K_{sp}$ , solid dissolves until  $Q = K_{sp}$ .

**SAMPLE EXERCISE 17.15** | Predicting Whether a Precipitate Will Form

Will a precipitate form when 0.10 L of  $8.0 \times 10^{-3} M$   $\text{Pb}(\text{NO}_3)_2$  is added to 0.40 L of  $5.0 \times 10^{-3} M$   $\text{Na}_2\text{SO}_4$ ?

**SOLUTION**

**Analyze:** The problem asks us to determine whether a precipitate will form when two salt solutions are combined.

**Plan:** We should determine the concentrations of all ions immediately upon mixing of the solutions and compare the value of the reaction quotient,  $Q$ , to the solubility-product constant,  $K_{sp}$ , for any potentially insoluble product. The possible metathesis products are  $\text{PbSO}_4$  and  $\text{NaNO}_3$ . Sodium salts are quite soluble;  $\text{PbSO}_4$  has a  $K_{sp}$  of  $6.3 \times 10^{-7}$  (Appendix D), however, and will precipitate if the  $\text{Pb}^{2+}$  and  $\text{SO}_4^{2-}$  ion concentrations are high enough for  $Q$  to exceed  $K_{sp}$  for the salt.

**Solve:** When the two solutions are mixed, the total volume becomes 0.10 L + 0.40 L = 0.50 L. The number of moles of  $\text{Pb}^{2+}$  in 0.10 L of  $8.0 \times 10^{-3} M$   $\text{Pb}(\text{NO}_3)_2$  is

$$(0.10 \text{ L}) \left( 8.0 \times 10^{-3} \frac{\text{mol}}{\text{L}} \right) = 8.0 \times 10^{-4} \text{ mol}$$

The concentration of  $\text{Pb}^{2+}$  in the 0.50-L mixture is therefore

$$[\text{Pb}^{2+}] = \frac{8.0 \times 10^{-4} \text{ mol}}{0.50 \text{ L}} = 1.6 \times 10^{-3} M$$

The number of moles of  $\text{SO}_4^{2-}$  in 0.40 L of  $5.0 \times 10^{-3} M$   $\text{Na}_2\text{SO}_4$  is

$$(0.40 \text{ L}) \left( 5.0 \times 10^{-3} \frac{\text{mol}}{\text{L}} \right) = 2.0 \times 10^{-3} \text{ mol}$$

Therefore,  $[\text{SO}_4^{2-}]$  in the 0.50-L mixture is

$$[\text{SO}_4^{2-}] = \frac{2.0 \times 10^{-3} \text{ mol}}{0.50 \text{ L}} = 4.0 \times 10^{-3} M$$

We then have

$$Q = [\text{Pb}^{2+}][\text{SO}_4^{2-}] = (1.6 \times 10^{-3})(4.0 \times 10^{-3}) = 6.4 \times 10^{-6}$$

Because  $Q > K_{sp}$ ,  $\text{PbSO}_4$  will precipitate.

**PRACTICE EXERCISE**

Will a precipitate form when 0.050 L of  $2.0 \times 10^{-2} M$   $\text{NaF}$  is mixed with 0.010 L of  $1.0 \times 10^{-2} M$   $\text{Ca}(\text{NO}_3)_2$ ?

**Answer:** Yes,  $\text{CaF}_2$  precipitates because  $Q = 4.6 \times 10^{-8}$  is larger than  $K_{sp} = 3.9 \times 10^{-11}$

## Selective Precipitation of Ions

Ions can be separated from each other based on the solubilities of their salts.

Consider a solution containing both  $\text{Ag}^+$  and  $\text{Cu}^{2+}$ . If  $\text{HCl}$  is added to the solution,  $\text{AgCl}$  ( $K_{sp} = 1.8 \times 10^{-10}$ ) precipitates, while  $\text{Cu}^{2+}$  remains in solution because  $\text{CuCl}_2$  is soluble. Separation of ions in an aqueous solution by using a reagent that forms a precipitate with one or a few of the ions is called *selective precipitation*.

**SAMPLE EXERCISE 17.16** | Calculating Ion Concentrations for Precipitation

A solution contains  $1.0 \times 10^{-2} M$   $\text{Ag}^+$  and  $2.0 \times 10^{-2} M$   $\text{Pb}^{2+}$ . When  $\text{Cl}^-$  is added to the solution, both  $\text{AgCl}$  ( $K_{sp} = 1.8 \times 10^{-10}$ ) and  $\text{PbCl}_2$  ( $K_{sp} = 1.7 \times 10^{-5}$ ) precipitate from the solution. What concentration of  $\text{Cl}^-$  is necessary to begin the precipitation of each salt? Which salt precipitates first?

**SOLUTION**

**Analyze:** We are asked to determine the concentration of  $\text{Cl}^-$  necessary to begin the precipitation from a solution containing  $\text{Ag}^+$  and  $\text{Pb}^{2+}$  ions, and to predict which metal chloride will begin to precipitate first.

**Plan:** We are given  $K_{sp}$  values for the two possible precipitates. Using these and the metal ion concentrations, we can calculate what concentration of  $\text{Cl}^-$  ion would be necessary to begin precipitation of each. The salt requiring the lower  $\text{Cl}^-$  ion concentration will precipitate first.

**Solve:** For  $\text{AgCl}$  we have

$$K_{sp} = [\text{Ag}^+][\text{Cl}^-] = 1.8 \times 10^{-10}$$

Because  $[\text{Ag}^+] = 1.0 \times 10^{-2} M$ , the greatest concentration of  $\text{Cl}^-$  that can be present without causing precipitation of  $\text{AgCl}$  can be calculated from the  $K_{sp}$  expression:

$$K_{sp} = [1.0 \times 10^{-2}][\text{Cl}^-] = 1.8 \times 10^{-10}$$

$$[\text{Cl}^-] = \frac{1.8 \times 10^{-10}}{1.0 \times 10^{-2}} = 1.8 \times 10^{-8} M$$

Any  $\text{Cl}^-$  in excess of this very small concentration will cause  $\text{AgCl}$  to precipitate from solution. Proceeding similarly for  $\text{PbCl}_2$ , we have

$$\begin{aligned}K_{sp} &= [\text{Pb}^{2+}][\text{Cl}^-]^2 = 1.7 \times 10^{-5} \\[2.0 \times 10^{-2}][\text{Cl}^-]^2 &= 1.7 \times 10^{-5} \\[\text{Cl}^-]^2 &= \frac{1.7 \times 10^{-5}}{2.0 \times 10^{-2}} = 8.5 \times 10^{-4} \\[\text{Cl}^-] &= \sqrt{8.5 \times 10^{-4}} = 2.9 \times 10^{-2} \text{ M}\end{aligned}$$

Thus, a concentration of  $\text{Cl}^-$  in excess of  $2.9 \times 10^{-2} \text{ M}$  will cause  $\text{PbCl}_2$  to precipitate.

Comparing the concentrations of  $\text{Cl}^-$  required to precipitate each salt, we see that as  $\text{Cl}^-$  is added to the solution,  $\text{AgCl}$  will precipitate first because it requires a much smaller concentration of  $\text{Cl}^-$ . Thus,  $\text{Ag}^+$  can be separated from  $\text{Pb}^{2+}$  by slowly adding  $\text{Cl}^-$  so  $[\text{Cl}^-]$  is between  $1.8 \times 10^{-8} \text{ M}$  and  $2.9 \times 10^{-2} \text{ M}$ .

### PRACTICE EXERCISE

A solution consists of  $0.050 \text{ M Mg}^{2+}$  and  $0.020 \text{ M Cu}^{2+}$ . Which ion will precipitate first as  $\text{OH}^-$  is added to the solution? What concentration of  $\text{OH}^-$  is necessary to begin the precipitation of each cation? [ $K_{sp} = 1.8 \times 10^{-11}$  for  $\text{Mg}(\text{OH})_2$ , and  $K_{sp} = 4.8 \times 10^{-20}$  for  $\text{Cu}(\text{OH})_2$ .]

**Answer:**  $\text{Cu}(\text{OH})_2$  precipitates first.  $\text{Cu}(\text{OH})_2$  begins to precipitate when  $[\text{OH}^-]$  exceeds  $1.5 \times 10^{-9} \text{ M}$ ;  $\text{Mg}(\text{OH})_2$  begins to precipitate when  $[\text{OH}^-]$  exceeds  $1.9 \times 10^{-5} \text{ M}$ .

Sulfide ion is often used to separate metal ions because the solubilities of sulfide salts span a wide range and depend greatly on the pH of the solution.  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$ , for example, can be separated by bubbling  $\text{H}_2\text{S}$  gas through an acidified solution. Because  $\text{CuS}$  ( $K_{sp} = 6 \times 10^{-37}$ ) is less soluble than  $\text{ZnS}$  ( $K_{sp} = 2 \times 10^{-25}$ ),  $\text{CuS}$  precipitates from an acidified solution ( $\text{pH} = 1$ ) while  $\text{ZnS}$  does not (Figure 17.21 ▼):

**SELECTIVE PRECIPITATION OF IONS**

*Separation of ions in an aqueous solution by using a reagent that forms a precipitate with one or a few of the ions is called selective precipitation.*

Solution containing  $\text{Zn}^{2+}(\text{aq})$  and  $\text{Cu}^{2+}(\text{aq})$ .     
 When  $\text{H}_2\text{S}$  is added to a solution whose pH exceeds 0.6,  $\text{CuS}$  precipitates.     
 After  $\text{CuS}$  is removed, the pH is increased allowing  $\text{ZnS}$  to precipitate.

▲ **Figure 17.21** Selective precipitation.

The  $\text{CuS}$  can be separated from the  $\text{Zn}^{2+}$  solution by filtration. The  $\text{CuS}$  can then be dissolved by using a high concentration of  $\text{H}^+$ , shifting the equilibrium shown in Equation 17.27 to the left.

### GIVE IT SOME THOUGHT

What experimental conditions will leave the smallest concentration of  $\text{Cu}^{2+}$  ions in solution according to Equation 17.27?

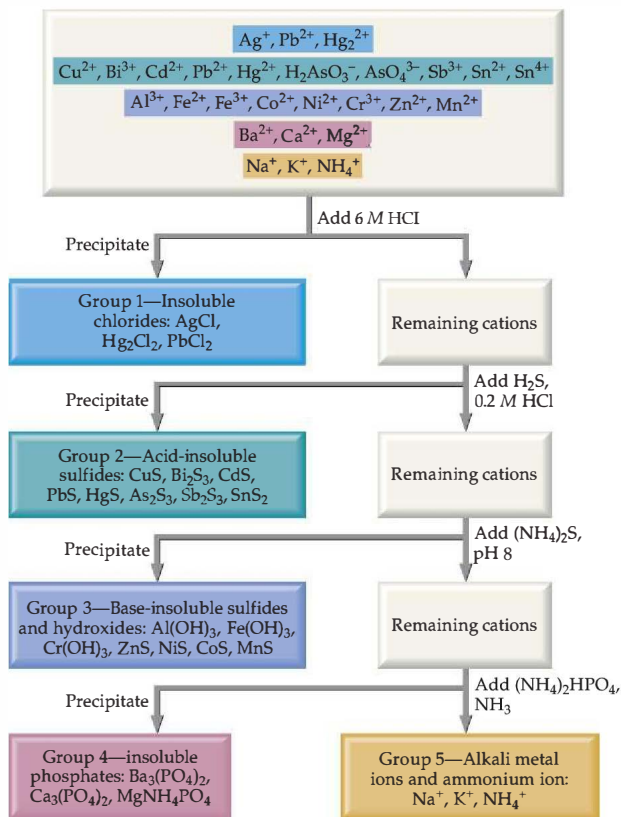

## 17.7 QUALITATIVE ANALYSIS FOR METALLIC ELEMENTS

In this chapter we have seen several examples of equilibria involving metal ions in aqueous solution. In this final section we look briefly at how solubility equilibria and complex-ion formation can be used to detect the presence of particular metal ions in solution. Before the development of modern analytical instrumentation, it was necessary to analyze mixtures of metals in a sample by so-called wet chemical methods. For example, a metallic sample that might contain several metallic elements was dissolved in a concentrated acid solution. This solution was then tested in a systematic way for the presence of various metal ions.

**Qualitative analysis** determines only the presence or absence of a particular metal ion, whereas **quantitative analysis** determines how much of a given substance is present. Wet methods of qualitative analysis have become less important as a means of analysis. They are frequently used in general chemistry laboratory programs, however, to illustrate equilibria, to teach the properties of common metal ions in solution, and to develop laboratory skills. Typically, such analyses proceed in three stages: (1) The ions are separated into broad groups on the basis of solubility properties. (2) The individual ions within each group are then separated by selectively dissolving members in the group. (3) The ions are then identified by means of specific tests.

A scheme in general use divides the common cations into five groups, as shown in Figure 17.22. The order of addition of reagents is important. The most selective separations—those that involve the smallest number of ions—are carried out first. The reactions that are used must proceed so far toward completion that any concentration of cations remaining in the solution is too small to interfere with subsequent tests. Let's take a closer look at each of these five groups of cations, briefly examining the logic used in this qualitative analysis scheme.

- Insoluble chlorides:** Of the common metal ions, only  $\text{Ag}^+$ ,  $\text{Hg}_2^{2+}$ , and  $\text{Pb}^{2+}$  form insoluble chlorides. When dilute  $\text{HCl}$  is added to a mixture of cations, therefore, only  $\text{AgCl}$ ,  $\text{Hg}_2\text{Cl}_2$ , and  $\text{PbCl}_2$  will precipitate, leaving the other cations in solution. The absence of a precipitate indicates that the starting solution contains no  $\text{Ag}^+$ ,  $\text{Hg}_2^{2+}$ , or  $\text{Pb}^{2+}$ .

**Figure 17.22 Qualitative analysis.** A flowchart showing the separation of cations into groups as a part of a common scheme for identifying cations.

2. *Acid-insoluble sulfides:* After any insoluble chlorides have been removed, the remaining solution, now acidic, is treated with  $\text{H}_2\text{S}$ . Only the most insoluble metal sulfides— $\text{CuS}$ ,  $\text{Bi}_2\text{S}_3$ ,  $\text{CdS}$ ,  $\text{PbS}$ ,  $\text{HgS}$ ,  $\text{As}_2\text{S}_3$ ,  $\text{Sb}_2\text{S}_3$ , and  $\text{SnS}_2$ —can precipitate. (Note the very small values of  $K_{sp}$  for some of these sulfides in Appendix D.) Those metal ions whose sulfides are somewhat more soluble—for example,  $\text{ZnS}$  or  $\text{NiS}$ —remain in solution.
3. *Base-insoluble sulfides and hydroxides:* After the solution is filtered to remove any acid-insoluble sulfides, the remaining solution is made slightly basic, and  $(\text{NH}_4)_2\text{S}$  is added. In basic solutions the concentration of  $\text{S}^{2-}$  is higher than in acidic solutions. Thus, the ion products for many of the more soluble sulfides are made to exceed their  $K_{sp}$  values and precipitation occurs. The metal ions precipitated at this stage are  $\text{Al}^{3+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Co}^{2+}$ , and  $\text{Mn}^{2+}$ . (Actually, the  $\text{Al}^{3+}$ ,  $\text{Fe}^{3+}$ , and  $\text{Cr}^{3+}$  ions do not form insoluble sulfides; instead they are precipitated as insoluble hydroxides at the same time.)
4. *Insoluble phosphates:* At this point the solution contains only metal ions from periodic table groups 1A and 2A. Adding  $(\text{NH}_4)_2\text{HPO}_4$  to a basic solution precipitates the group 2A elements  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ , and  $\text{Ba}^{2+}$  because these metals form insoluble phosphates.
5. *The alkali metal ions and  $\text{NH}_4^+$ :* The ions that remain after removing the insoluble phosphates form a small group. We can test the original solution for each ion individually. A flame test can be used to determine the presence of  $\text{K}^+$ , for example, because the flame turns a characteristic violet color if  $\text{K}^+$  is present.

### GIVE IT SOME THOUGHT

If a precipitate forms upon addition of  $\text{HCl}$  to an aqueous solution, what conclusions can you draw about the contents of the solution?

Additional separation and testing is necessary to determine which ions are present within each of the groups. Consider, for example, the ions of the insoluble chloride group. The precipitate containing the metal chlorides is boiled in water. The  $\text{PbCl}_2$  is relatively soluble in hot water, whereas  $\text{AgCl}$  and  $\text{Hg}_2\text{Cl}_2$  are not. The hot solution is filtered, and a solution of  $\text{Na}_2\text{CrO}_4$  is added to the filtrate. If  $\text{Pb}^{2+}$  is present, a yellow precipitate of  $\text{PbCrO}_4$  forms. The test for  $\text{Ag}^+$  consists of treating the metal chloride precipitate with dilute ammonia.

Only  $\text{Ag}^+$  forms an ammonia complex. If  $\text{AgCl}$  is present in the precipitate, it will dissolve in the ammonia solution.

After treatment with ammonia, the solution is filtered and the filtrate made acidic by adding nitric acid. The nitric acid removes ammonia from solution by forming  $\text{NH}_4^+$ , thus releasing  $\text{Ag}^+$ , which re-forms the  $\text{AgCl}$  precipitate.

The analyses for individual ions in the acid-insoluble and base-insoluble sulfides are a bit more complex, but the same general principles are involved. The detailed procedures for carrying out such analyses are given in many laboratory manuals.

**SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

A sample of 1.25 L of HCl gas at 21 °C and 0.950 atm is bubbled through 0.500 L of 0.150 M NH<sub>3</sub> solution. Calculate the pH of the resulting solution assuming that all the HCl dissolves and that the volume of the solution remains 0.500 L.

**SOLUTION**

The number of moles of HCl gas is calculated from the ideal-gas law.

$$n = \frac{PV}{RT} = \frac{(0.950 \text{ atm})(1.25 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(294 \text{ K})} = 0.0492 \text{ mol HCl}$$

The number of moles of NH<sub>3</sub> in the solution is given by the product of the volume of the solution and its concentration.

$$\text{Moles NH}_3 = (0.500 \text{ L})(0.150 \text{ mol NH}_3/\text{L}) = 0.0750 \text{ mol NH}_3$$

The acid HCl and base NH<sub>3</sub> react, transferring a proton from HCl to NH<sub>3</sub>, producing NH<sub>4</sub><sup>+</sup> and Cl<sup>-</sup> ions.

To determine the pH of the solution, we first calculate the amount of each reactant and each product present at the completion of the reaction.

Before addition	0.0492 mol	0 mol	0 mol	0 mol
Addition		0.0750 mol		
After addition	0 mol	0.0258 mol	0.0492 mol	0.0492 mol

Thus, the reaction produces a solution containing a mixture of NH<sub>3</sub>, NH<sub>4</sub><sup>+</sup>, and Cl<sup>-</sup>. The NH<sub>3</sub> is a weak base ( $K_b = 1.8 \times 10^{-5}$ ), NH<sub>4</sub><sup>+</sup> is its conjugate acid, and Cl<sup>-</sup> is neither acidic nor basic. Consequently, the pH depends on [NH<sub>3</sub>] and [NH<sub>4</sub><sup>+</sup>].

$$[\text{NH}_3] = \frac{0.0258 \text{ mol NH}_3}{0.500 \text{ L soln}} = 0.0516 \text{ M}$$

$$[\text{NH}_4^+] = \frac{0.0492 \text{ mol NH}_4^+}{0.500 \text{ L soln}} = 0.0984 \text{ M}$$

We can calculate the pH using either  $K_b$  for NH<sub>3</sub> or  $K_a$  for NH<sub>4</sub><sup>+</sup>. Using the  $K_b$  expression, we have

Initial	0.0516 M	—	0.0984 M	0
Change	-x M	—	+x M	+x M
Equilibrium	(0.0516 - x) M	—	(0.0984 + x) M	x M

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = \frac{(0.0984 + x)(x)}{(0.0516 - x)} \approx \frac{(0.0984)x}{0.0516} = 1.8 \times 10^{-5}$$

$$x = [\text{OH}^-] = \frac{(0.0516)(1.8 \times 10^{-5})}{0.0984} = 9.4 \times 10^{-6} \text{ M}$$

Hence, pOH =  $-\log(9.4 \times 10^{-6}) = 5.03$  and pH = 14.00 - pOH = 14.00 - 5.03 = 8.97.

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Section 17.1** In this chapter we have considered several types of important equilibria that occur in aqueous solution. Our primary emphasis has been on acid–base equilibria in solutions containing two or more solutes and on solubility equilibria. The dissociation of a weak acid or weak base is repressed by the presence of a strong electrolyte that provides an ion common to the equilibrium. This phenomenon is called the **common-ion effect**.

**Section 17.2** A particularly important type of acid–base mixture is that of a weak conjugate acid–base pair. Such mixtures function as **buffered solutions (buffers)**. Addition of small amounts of a strong acid or a strong base to a buffered solution causes only small changes in pH because the buffer reacts with the added acid or base. (Strong acid–strong base, strong acid–weak base, and weak acid–strong base reactions proceed essentially to completion.) Buffered solutions are usually prepared from a weak acid and a salt of that acid or from a weak base and a salt of that base. Two important characteristics of a buffered solution are its **buffer capacity** and its pH. The pH can be calculated using  $K_a$  or  $K_b$ . The relationship between pH,  $pK_a$ , and the concentrations of an acid and its conjugate base can be expressed by the **Henderson–Hasselbalch**

$$\text{equation: } \text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

**Section 17.3** The plot of the pH of an acid (or base) as a function of the volume of added base (or acid) is called a **pH titration curve**. Titration curves aid in selecting a proper pH indicator for an acid–base titration. The titration curve of a strong acid–strong base titration exhibits a large change in pH in the immediate vicinity of the equivalence point; at the equivalence point for this titration,  $\text{pH} = 7$ . For strong acid–weak base or weak acid–strong base titrations, the pH change in the vicinity of the equivalence point is not as large. Furthermore, the pH at the equivalence point is not 7 in either of these cases. Rather, it is the pH of the salt solution that results from the neutralization reaction. It is possible to calculate the pH at any point of the titration curve by first considering the effects of the reaction between the acid and base on solution concentrations and then examining equilibria involving remaining solute species.

**Section 17.4** The equilibrium between a solid compound and its ions in solution provides an example of heterogeneous equilibrium. The **solubility-product**

**constant** (or simply the **solubility product**),  $K_{sp}$ , is an equilibrium constant that expresses quantitatively the extent to which the compound dissolves. The  $K_{sp}$  can be used to calculate the solubility of an ionic compound, and the solubility can be used to calculate  $K_{sp}$ .

**Section 17.5** Several experimental factors, including temperature, affect the solubilities of ionic compounds in water. The solubility of a slightly soluble ionic compound is decreased by the presence of a second solute that furnishes a common ion (the common-ion effect). The solubility of compounds containing basic anions increases as the solution is made more acidic (as pH decreases). Salts with anions of negligible basicity (the anions of strong acids) are unaffected by pH changes.

The solubility of metal salts is also affected by the presence of certain Lewis bases that react with metal ions to form stable **complex ions**. Complex-ion formation in aqueous solution involves the displacement by Lewis bases (such as  $\text{NH}_3$  and  $\text{CN}^-$ ) of water molecules attached to the metal ion. The extent to which such complex formation occurs is expressed quantitatively by the **formation constant** for the complex ion. **Amphoteric oxides and hydroxides** are those that are only slightly soluble in water but dissolve on addition of either acid or base. Acid–base reactions involving the  $\text{OH}^-$  or  $\text{H}_2\text{O}$  groups bound to the metal ions give rise to the amphotericism.

**Section 17.6** Comparison of the ion product,  $Q$ , with the value of  $K_{sp}$  can be used to judge whether a precipitate will form when solutions are mixed or whether a slightly soluble salt will dissolve under various conditions. Precipitates form when  $Q > K_{sp}$ . Ions can be separated from each other based on the solubilities of their salts.

**Section 17.7** Metallic elements vary a great deal in the solubilities of their salts, in their acid–base behavior, and in their tendencies to form complex ions. These differences can be used to separate and detect the presence of metal ions in mixtures. **Qualitative analysis** determines the presence or absence of species in a sample, whereas **quantitative analysis** determines how much of each species is present. The qualitative analysis of metal ions in solution can be carried out by separating the ions into groups on the basis of precipitation reactions and then analyzing each group for individual metal ions.

## KEY SKILLS

- Describe the common-ion effect.
- Explain how a buffer functions.
- Calculate the pH of a buffer solution.
- Calculate the pH of a buffer after the addition of small amounts of a strong acid or a strong base.
- Calculate the pH at any point in an acid–base titration of a strong acid and strong base.
- Calculate the pH at any point in a titration of a weak acid with a strong base or a weak base with a strong acid.
- Understand the differences between the titration curves for a strong acid–strong base titration and those when either the acid or base is weak.
- Calculate  $K_{sp}$  from molar solubility and molar solubility from  $K_{sp}$ .
- Calculate molar solubility in the presence of a common ion.
- Predict the effect of pH on solubility.
- Predict whether a precipitate will form when solutions are mixed by comparing  $Q$  and  $K_{sp}$ .
- Calculate the ion concentrations required to begin precipitation.
- Explain the effect of complex-ion formation on solubility.

## KEY EQUATIONS

- $$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \quad [17.9]$$
 The Henderson–Hasselbalch equation, used to calculate the pH of a buffer from the concentrations of a conjugate acid–base pair

## VISUALIZING CONCEPTS

- 17.1** The following boxes represent aqueous solutions containing a weak acid, HX, and its conjugate base,  $X^-$ . Water molecules and cations are not shown. Which solution has the highest pH? Explain. [Section 17.1]

- 17.2** The beaker on the right contains 0.1 M acetic acid solution with methyl orange as an indicator. The beaker on the left contains a mixture of 0.1 M acetic acid and 0.1 M sodium acetate with methyl orange. (a) Using Figure

- 16.7, estimate the pH of each solution, and explain the difference. (b) Which solution is better able to maintain its pH when small amounts of NaOH are added? Explain. [Sections 17.1 and 17.2]

**17.3** A buffer contains a weak acid, HX, and its conjugate base. The weak acid has a  $pK_a$  of 4.5, and the buffer solution has a pH of 4.3. Without doing a calculation, predict whether  $[HX] = [X^-]$ ,  $[HX] > [X^-]$ , or  $[HX] < [X^-]$ . Explain. [Section 17.2]

**17.4** The drawing on the left represents a buffer composed of equal concentrations of a weak acid, HX, and its conjugate base,  $X^-$ . The heights of the columns are proportional to the concentrations of the components of the buffer. (a) Which of the three drawings, (1), (2), or (3), represents the buffer after the addition of a strong acid? (b) Which of the three represents the buffer after the addition of a strong base? (c) Which of the three represents a situation that cannot arise from the addition of either an acid or a base? [Section 17.2]

**17.5** The following drawings represent solutions at various stages of the titration of a weak acid, HA, with NaOH. (The  $Na^+$  ions and water molecules have been omitted for clarity.) To which of the following regions of the titration curve does each drawing correspond: (a) before addition of NaOH, (b) after addition of NaOH but before equivalence point, (c) at equivalence point, (d) after equivalence point? [Section 17.3]

**17.6** Match the following descriptions of titration curves with the diagrams: (a) strong acid added to strong base, (b) strong base added to weak acid, (c) strong base added to strong acid, (d) strong base added to polyprotic acid. [Section 17.3]

**17.7** Equal volumes of two acids are titrated with 0.10 M NaOH resulting in the two titration curves shown in the following figure. (a) Which curve corresponds to the more concentrated acid solution? (b) Which corresponds to the acid with the largest  $K_a$ ? Explain. [Section 17.3]

**17.8** The following drawings represent saturated solutions of three ionic compounds of silver— $AgX$ ,  $AgY$ , and  $AgZ$ . ( $Na^+$  cations, which might also be present for charge balance, are not shown.) Which compound has the smallest  $K_{sp}$ ? [Section 17.4]

**17.9** The figures below represent the ions in a saturated aqueous solution of the slightly soluble ionic compound MX:  $MX(s) \rightleftharpoons M^{2+}(aq) + X^{2-}(aq)$ . (Only the  $M^{2+}$  and  $X^{2-}$  ions are shown.) (a) Which figure represents a solution prepared by dissolving MX in water? (b) Which figure represents a solution prepared by dissolving MX in a solution containing  $Na_2X$ ? (c) If  $X^{2-}$  is a basic anion, which figure represents a saturated solution with the lowest pH? (d) If you were to calculate the  $K_{sp}$  for MX, would you get the same value in each of the three scenarios? Why or why not? [Sections 17.4 and 17.5]

**17.10** The following graphs represent the behavior of  $BaCO_3$  under different circumstances. In each case the vertical axis indicates the solubility of the  $BaCO_3$  and the

horizontal axis represents the concentration of some other reagent. (a) Which graph represents what happens to the solubility of  $\text{BaCO}_3$  as  $\text{HNO}_3$  is added? (b) Which graph represents what happens to the  $\text{BaCO}_3$  solubility as  $\text{Na}_2\text{CO}_3$  is added? (c) Which represents what happens to the  $\text{BaCO}_3$  solubility as  $\text{NaNO}_3$  is added? [Section 17.5]

- 17.11 What is the name given to the kind of behavior demonstrated by a metal hydroxide in this graph? [Section 17.5]

## EXERCISES

### Common-Ion Effect

- 17.13 (a) What is the common-ion effect? (b) Give an example of a salt that can decrease the ionization of  $\text{HNO}_2$  in solution.
- 17.14 (a) Consider the equilibrium  $\text{B}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HB}^+(aq) + \text{OH}^-(aq)$ . Using Le Châtelier's principle, explain the effect of the presence of a salt of  $\text{HB}^+$  on the ionization of B. (b) Give an example of a salt that can decrease the ionization of  $\text{NH}_3$  in solution.
- 17.15 Use information from Appendix D to calculate the pH of (a) a solution that is 0.060 M in potassium propionate ( $\text{C}_2\text{H}_5\text{COOK}$  or  $\text{KC}_2\text{H}_5\text{O}_2$ ) and 0.085 M in propionic acid ( $\text{C}_2\text{H}_5\text{COOH}$  or  $\text{HC}_2\text{H}_5\text{O}_2$ ); (b) a solution that is 0.075 M in trimethylamine,  $(\text{CH}_3)_3\text{N}$ , and 0.10 M in trimethylammonium chloride,  $(\text{CH}_3)_3\text{NHCl}$ ; (c) a solution that is made by mixing 50.0 mL of 0.15 M acetic acid and 50.0 mL of 0.20 M sodium acetate.
- 17.16 Use information from Appendix D to calculate the pH of (a) a solution that is 0.150 M in sodium formate ( $\text{HCOONa}$ ) and 0.200 M in formic acid ( $\text{HCOOH}$ ); (b) a solution that is 0.210 M in pyridine ( $\text{C}_5\text{H}_5\text{N}$ ) and 0.350 M in pyridinium chloride ( $\text{C}_5\text{H}_5\text{NHCl}$ ); (c) a solution that is made by combining 125 mL of 0.050 M hydrofluoric acid with 50.0 mL of 0.10 M sodium fluoride.
- 17.17 (a) Calculate the percent ionization of 0.0075 M butanoic acid ( $K_a = 1.5 \times 10^{-5}$ ). (b) Calculate the percent ionization of 0.0075 M butanoic acid in a solution containing 0.085 M sodium butanoate.
- 17.18 (a) Calculate the percent ionization of 0.085 M lactic acid ( $K_a = 1.4 \times 10^{-4}$ ). (b) Calculate the percent ionization of 0.095 M lactic acid in a solution containing 0.0075 M sodium lactate.

### Buffers

- 17.19 Explain why a mixture of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COONa}$  can act as a buffer while a mixture of  $\text{HCl}$  and  $\text{NaCl}$  cannot.
- 17.20 Explain why a mixture formed by mixing 100 mL of 0.100 M  $\text{CH}_3\text{COOH}$  and 50 mL of 0.100 M  $\text{NaOH}$  will act as a buffer.
- 17.21 (a) Calculate the pH of a buffer that is 0.12 M in lactic acid and 0.11 M in sodium lactate. (b) Calculate the pH of a buffer formed by mixing 85 mL of 0.13 M lactic acid with 95 mL of 0.15 M sodium lactate.
- 17.22 (a) Calculate the pH of a buffer that is 0.105 M in  $\text{NaHCO}_3$  and 0.125 M in  $\text{Na}_2\text{CO}_3$ . (b) Calculate the pH of a solution formed by mixing 65 mL of 0.20 M  $\text{NaHCO}_3$  with 75 mL of 0.15 M  $\text{Na}_2\text{CO}_3$ .

- 17.12 Three cations,  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$ , and  $\text{Ag}^+$ , are separated using two different precipitating agents. Based on Figure 17.22, what two precipitating agents could be used? Using these agents, indicate which of the cations is A, which is B, and which is C. [Section 17.7]

Cation A ● Cation B ● Cation C ●

- 17.23** A buffer is prepared by adding 20.0 g of acetic acid ( $\text{CH}_3\text{COOH}$ ) and 20.0 g of sodium acetate ( $\text{CH}_3\text{COONa}$ ) to enough water to form 2.00 L of solution. (a) Determine the pH of the buffer. (b) Write the complete ionic equation for the reaction that occurs when a few drops of hydrochloric acid are added to the buffer. (c) Write the complete ionic equation for the reaction that occurs when a few drops of sodium hydroxide solution are added to the buffer.
- 17.24** A buffer is prepared by adding 7.00 g of ammonia ( $\text{NH}_3$ ) and 20.0 g of ammonium chloride ( $\text{NH}_4\text{Cl}$ ) to enough water to form 2.50 L of solution. (a) What is the pH of this buffer? (b) Write the complete ionic equation for the reaction that occurs when a few drops of nitric acid are added to the buffer. (c) Write the complete ionic equation for the reaction that occurs when a few drops of potassium hydroxide solution are added to the buffer.
- 17.25** How many moles of sodium hypobromite ( $\text{NaBrO}$ ) should be added to 1.00 L of 0.050 M hypobromous acid ( $\text{HBrO}$ ) to form a buffer solution of pH 9.15? Assume that no volume change occurs when the  $\text{NaBrO}$  is added.
- 17.26** How many grams of sodium lactate [ $\text{CH}_3\text{CH}(\text{OH})\text{COONa}$  or  $\text{NaC}_3\text{H}_5\text{O}_3$ ] should be added to 1.00 L of 0.150 M lactic acid [ $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$  or  $\text{HC}_3\text{H}_5\text{O}_3$ ] to form a buffer solution with pH 4.00? Assume that no volume change occurs when the sodium lactate is added.
- 17.27** A buffer solution contains 0.10 mol of acetic acid and 0.13 mol of sodium acetate in 1.00 L. (a) What is the pH of this buffer? (b) What is the pH of the buffer after the addition of 0.02 mol of  $\text{KOH}$ ? (c) What is the pH of the buffer after the addition of 0.02 mol of  $\text{HNO}_3$ ?
- 17.28** A buffer solution contains 0.10 mol of propionic acid ( $\text{C}_2\text{H}_5\text{COOH}$ ) and 0.13 mol of sodium propionate ( $\text{C}_2\text{H}_5\text{COONa}$ ) in 1.50 L. (a) What is the pH of this buffer? (b) What is the pH of the buffer after the addition of 0.01 mol of  $\text{NaOH}$ ? (c) What is the pH of the buffer after the addition of 0.01 mol of  $\text{HI}$ ?
- 17.29** (a) What is the ratio of  $\text{HCO}_3^-$  to  $\text{H}_2\text{CO}_3$  in blood of pH 7.4? (b) What is the ratio of  $\text{HCO}_3^-$  to  $\text{H}_2\text{CO}_3$  in an exhausted marathon runner whose blood pH is 7.1?
- 17.30** A buffer, consisting of  $\text{H}_2\text{PO}_4^-$  and  $\text{HPO}_4^{2-}$ , helps control the pH of physiological fluids. Many carbonated soft drinks also use this buffer system. What is the pH of a soft drink in which the major buffer ingredients are 6.5 g of  $\text{NaH}_2\text{PO}_4$  and 8.0 g of  $\text{Na}_2\text{HPO}_4$  per 355 mL of solution?
- 17.31** You have to prepare a pH 3.50 buffer, and you have the following 0.10 M solutions available:  $\text{HCOOH}$ ,  $\text{CH}_3\text{COOH}$ ,  $\text{H}_3\text{PO}_4$ ,  $\text{HCOONa}$ ,  $\text{CH}_3\text{COONa}$ , and  $\text{NaH}_2\text{PO}_4$ . Which solutions would you use? How many milliliters of each solution would you use to make approximately a liter of the buffer?
- 17.32** You have to prepare a pH 4.80 buffer, and you have the following 0.10 M solutions available: formic acid, sodium formate, propionic acid, sodium propionate, phosphoric acid, and sodium dihydrogen phosphate. Which solutions would you use? How many milliliters of each solution would you use to make approximately a liter of the buffer?

## Acid–Base Titrations

- 17.33** The accompanying graph shows the titration curves for two monoprotic acids. (a) Which curve is that of a strong acid? (b) What is the approximate pH at the equivalence point of each titration? (c) How do the original concentrations of the two acids compare if 40.0 mL of each is titrated to the equivalence point with 0.100 M base?
- 
- 17.34** How does titration of a strong, monoprotic acid with a strong base differ from titration of a weak, monoprotic acid with a strong base with respect to the following: (a) quantity of base required to reach the equivalence point, (b) pH at the beginning of the titration, (c) pH at the equivalence point, (d) pH after addition of a slight excess of base, (e) choice of indicator for determining the equivalence point?
- 17.35** Predict whether the equivalence point of each of the following titrations is below, above, or at pH 7: (a)  $\text{NaHCO}_3$  titrated with  $\text{NaOH}$ , (b)  $\text{NH}_3$  titrated with  $\text{HCl}$ , (c)  $\text{KOH}$  titrated with  $\text{HBr}$ .
- 17.36** Predict whether the equivalence point of each of the following titrations is below, above, or at pH 7: (a) formic acid titrated with  $\text{NaOH}$ , (b) calcium hydroxide titrated with perchloric acid, (c) pyridine titrated with nitric acid.
- 17.37** Two monoprotic acids, both 0.100 M in concentration, are titrated with 0.100 M  $\text{NaOH}$ . The pH at the equivalence point for  $\text{HX}$  is 8.8, and that for  $\text{HY}$  is 7.9. (a) Which is the weaker acid? (b) Which indicators in Figure 16.7 could be used to titrate each of these acids?

- 17.38** Assume that 30.0 mL of a 0.10 *M* solution of a weak base B that accepts one proton is titrated with a 0.10 *M* solution of the monoprotic strong acid HX. (a) How many moles of HX have been added at the equivalence point? (b) What is the predominant form of B at the equivalence point? (c) What factor determines the pH at the equivalence point? (d) Which indicator, phenolphthalein or methyl red, is likely to be the better choice for this titration?
- 17.39** How many milliliters of 0.0850 *M* NaOH are required to titrate each of the following solutions to the equivalence point: (a) 40.0 mL of 0.0900 *M* HNO<sub>3</sub>, (b) 35.0 mL of 0.0850 *M* CH<sub>3</sub>COOH, (c) 50.0 mL of a solution that contains 1.85 g of HCl per liter?
- 17.40** How many milliliters of 0.105 *M* HCl are needed to titrate each of the following solutions to the equivalence point: (a) 45.0 mL of 0.0950 *M* NaOH, (b) 225 mL of 0.118 *M* NH<sub>3</sub>, (c) 125.0 mL of a solution that contains 1.35 g of NaOH per liter?
- 17.41** A 20.0-mL sample of 0.200 *M* HBr solution is titrated with 0.200 *M* NaOH solution. Calculate the pH of the solution after the following volumes of base have been added: (a) 15.0 mL, (b) 19.9 mL, (c) 20.0 mL, (d) 20.1 mL, (e) 35.0 mL.
- 17.42** A 30.0-mL sample of 0.150 *M* KOH is titrated with 0.125 *M* HClO<sub>4</sub> solution. Calculate the pH after the following volumes of acid have been added: (a) 30.0 mL, (b) 35.0 mL, (c) 36.0 mL, (d) 37.0 mL, (e) 40.0 mL.
- 17.43** A 35.0-mL sample of 0.150 *M* acetic acid (CH<sub>3</sub>COOH) is titrated with 0.150 *M* NaOH solution. Calculate the pH after the following volumes of base have been added: (a) 0 mL, (b) 17.5 mL, (c) 34.5 mL, (d) 35.0 mL, (e) 35.5 mL, (f) 50.0 mL.
- 17.44** Consider the titration of 30.0 mL of 0.030 *M* NH<sub>3</sub> with 0.025 *M* HCl. Calculate the pH after the following volumes of titrant have been added: (a) 0 mL, (b) 10.0 mL, (c) 20.0 mL, (d) 35.0 mL, (e) 36.0 mL, (f) 37.0 mL.
- 17.45** Calculate the pH at the equivalence point for titrating 0.200 *M* solutions of each of the following bases with 0.200 *M* HBr: (a) sodium hydroxide (NaOH), (b) hydroxylamine (NH<sub>2</sub>OH), (c) aniline (C<sub>6</sub>H<sub>5</sub>NH<sub>2</sub>).
- 17.46** Calculate the pH at the equivalence point in titrating 0.100 *M* solutions of each of the following with 0.080 *M* NaOH: (a) hydrobromic acid (HBr), (b) lactic acid [CH<sub>3</sub>CH(OH)COOH], (c) sodium hydrogen chromate (NaHCrO<sub>4</sub>).

## Solubility Equilibria and Factors Affecting Solubility

- 17.47** (a) Why is the concentration of undissolved solid not explicitly included in the expression for the solubility-product constant? (b) Write the expression for the solubility-product constant for each of the following strong electrolytes: AgI, SrSO<sub>4</sub>, Fe(OH)<sub>2</sub>, and Hg<sub>2</sub>Br<sub>2</sub>.
- 17.48** (a) Explain the difference between solubility and solubility-product constant. (b) Write the expression for the solubility-product constant for each of the following ionic compounds: MnCO<sub>3</sub>, Hg(OH)<sub>2</sub>, and Cu<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>.
- 17.49** (a) If the molar solubility of CaF<sub>2</sub> at 35 °C is 1.24 × 10<sup>-3</sup> mol/L, what is *K*<sub>sp</sub> at this temperature? (b) It is found that 1.1 × 10<sup>-2</sup> g of SrF<sub>2</sub> dissolves per 100 mL of aqueous solution at 25 °C. Calculate the solubility product for SrF<sub>2</sub>. (c) The *K*<sub>sp</sub> of Ba(IO<sub>3</sub>)<sub>2</sub> at 25 °C is 6.0 × 10<sup>-10</sup>. What is the molar solubility of Ba(IO<sub>3</sub>)<sub>2</sub>?
- 17.50** (a) The molar solubility of PbBr<sub>2</sub> at 25 °C is 1.0 × 10<sup>-2</sup> mol/L. Calculate *K*<sub>sp</sub>. (b) If 0.0490 g of AgIO<sub>3</sub> dissolves per liter of solution, calculate the solubility-product constant. (c) Using the appropriate *K*<sub>sp</sub> value from Appendix D, calculate the solubility of Cu(OH)<sub>2</sub> in grams per liter of solution.
- 17.51** A 1.00-L solution saturated at 25 °C with calcium oxalate (CaC<sub>2</sub>O<sub>4</sub>) contains 0.0061 g of CaC<sub>2</sub>O<sub>4</sub>. Calculate the solubility-product constant for this salt at 25 °C.
- 17.52** A 1.00-L solution saturated at 25 °C with lead(II) iodide contains 0.54 g of PbI<sub>2</sub>. Calculate the solubility-product constant for this salt at 25 °C.
- 17.53** Using Appendix D, calculate the molar solubility of AgBr in (a) pure water, (b) 3.0 × 10<sup>-2</sup> *M* AgNO<sub>3</sub> solution, (c) 0.10 *M* NaBr solution.
- 17.54** Calculate the solubility of LaF<sub>3</sub> in grams per liter in (a) pure water, (b) 0.010 *M* KF solution, (c) 0.050 *M* LaCl<sub>3</sub> solution.
- 17.55** Calculate the solubility of Mn(OH)<sub>2</sub> in grams per liter when buffered at pH (a) 7.0, (b) 9.5, (c) 11.8.
- 17.56** Calculate the molar solubility of Fe(OH)<sub>2</sub> when buffered at pH (a) 8.0, (b) 10.0, (c) 12.0.
- 17.57** Which of the following salts will be substantially more soluble in acidic solution than in pure water: (a) ZnCO<sub>3</sub>, (b) ZnS, (c) BiI<sub>3</sub>, (d) AgCN, (e) Ba<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>?
- 17.58** For each of the following slightly soluble salts, write the net ionic equation, if any, for reaction with acid: (a) MnS, (b) PbF<sub>2</sub>, (c) AuCl<sub>3</sub>, (d) Hg<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, (e) CuBr.
- 17.59** From the value of *K*<sub>f</sub> listed in Table 17.1, calculate the concentration of Cu<sup>2+</sup> in 1.0 L of a solution that contains a total of 1 × 10<sup>-3</sup> mol of copper(II) ion and that is 0.10 *M* in NH<sub>3</sub>.

**17.60** To what final concentration of  $\text{NH}_3$  must a solution be adjusted to just dissolve 0.020 mol of  $\text{NiC}_2\text{O}_4$  ( $K_{sp} = 4 \times 10^{-10}$ ) in 1.0 L of solution? (*Hint*: You can neglect the hydrolysis of  $\text{C}_2\text{O}_4^{2-}$  because the solution will be quite basic.)

**17.61** By using the values of  $K_{sp}$  for  $\text{AgI}$  and  $K_f$  for  $\text{Ag}(\text{CN})_2^-$ , calculate the equilibrium constant for the reaction

**17.62** Using the value of  $K_{sp}$  for  $\text{Ag}_2\text{S}$ ,  $K_{a1}$  and  $K_{a2}$  for  $\text{H}_2\text{S}$ , and  $K_f = 1.1 \times 10^5$  for  $\text{AgCl}_2^-$ , calculate the equilibrium constant for the following reaction:

## Precipitation; Qualitative Analysis

**17.63** (a) Will  $\text{Ca}(\text{OH})_2$  precipitate from solution if the pH of a 0.050 M solution of  $\text{CaCl}_2$  is adjusted to 8.0? (b) Will  $\text{Ag}_2\text{SO}_4$  precipitate when 100 mL of 0.050 M  $\text{AgNO}_3$  is mixed with 10 mL of  $5.0 \times 10^{-2}$  M  $\text{Na}_2\text{SO}_4$  solution?

**17.64** (a) Will  $\text{Co}(\text{OH})_2$  precipitate from solution if the pH of a 0.020 M solution of  $\text{Co}(\text{NO}_3)_2$  is adjusted to 8.5? (b) Will  $\text{AgIO}_3$  precipitate when 20 mL of 0.010 M  $\text{AgNO}_3$  is mixed with 10 mL of 0.015 M  $\text{NaIO}_3$ ? ( $K_{sp}$  of  $\text{AgIO}_3$  is  $3.1 \times 10^{-8}$ .)

**17.65** Calculate the minimum pH needed to precipitate  $\text{Mn}(\text{OH})_2$  so completely that the concentration of  $\text{Mn}^{2+}$  is less than 1  $\mu\text{g}$  per liter [1 part per billion (ppb)].

**17.66** Suppose that a 10-mL sample of a solution is to be tested for  $\text{Cl}^-$  ion by addition of 1 drop (0.2 mL) of 0.10 M  $\text{AgNO}_3$ . What is the minimum number of grams of  $\text{Cl}^-$  that must be present for  $\text{AgCl}(s)$  to form?

**17.67** A solution contains  $2.0 \times 10^{-4}$  M  $\text{Ag}^+$  and  $1.5 \times 10^{-3}$  M  $\text{Pb}^{2+}$ . If  $\text{NaI}$  is added, will  $\text{AgI}$  ( $K_{sp} = 8.3 \times 10^{-17}$ ) or  $\text{PbI}_2$  ( $K_{sp} = 7.9 \times 10^{-9}$ ) precipitate first? Specify the concentration of  $\text{I}^-$  needed to begin precipitation.

**17.68** A solution of  $\text{Na}_2\text{SO}_4$  is added dropwise to a solution that is 0.010 M in  $\text{Ba}^{2+}$  and 0.010 M in  $\text{Sr}^{2+}$ . (a) What concentration of  $\text{SO}_4^{2-}$  is necessary to begin precipitation? (Neglect volume changes.  $\text{BaSO}_4$ :  $K_{sp} = 1.1 \times 10^{-10}$ ;  $\text{SrSO}_4$ :  $K_{sp} = 3.2 \times 10^{-7}$ .) (b) Which cation precipitates first? (c) What is the concentration of  $\text{SO}_4^{2-}$  when the second cation begins to precipitate?

**17.69** A solution containing an unknown number of metal ions is treated with dilute  $\text{HCl}$ ; no precipitate forms. The pH is adjusted to about 1, and  $\text{H}_2\text{S}$  is bubbled through. Again, no precipitate forms. The pH of the solution is then adjusted to about 8. Again,  $\text{H}_2\text{S}$  is bubbled through. This time a precipitate forms. The filtrate from this solution is treated with  $(\text{NH}_4)_2\text{HPO}_4$ . No precipitate forms.

Which metal ions discussed in Section 17.7 are possibly present? Which are definitely absent within the limits of these tests?

**17.70** An unknown solid is entirely soluble in water. On addition of dilute  $\text{HCl}$ , a precipitate forms. After the precipitate is filtered off, the pH is adjusted to about 1 and  $\text{H}_2\text{S}$  is bubbled in; a precipitate again forms. After filtering off this precipitate, the pH is adjusted to 8 and  $\text{H}_2\text{S}$  is again added; no precipitate forms. No precipitate forms upon addition of  $(\text{NH}_4)_2\text{HPO}_4$ . The remaining solution shows a yellow color in a flame test. Based on these observations, which of the following compounds might be present, which are definitely present, and which are definitely absent:  $\text{CdS}$ ,  $\text{Pb}(\text{NO}_3)_2$ ,  $\text{HgO}$ ,  $\text{ZnSO}_4$ ,  $\text{Cd}(\text{NO}_3)_2$ , and  $\text{Na}_2\text{SO}_4$ ?

**17.71** In the course of various qualitative analysis procedures, the following mixtures are encountered: (a)  $\text{Zn}^{2+}$  and  $\text{Cd}^{2+}$ , (b)  $\text{Cr}(\text{OH})_3$  and  $\text{Fe}(\text{OH})_3$ , (c)  $\text{Mg}^{2+}$  and  $\text{K}^+$ , (d)  $\text{Ag}^+$  and  $\text{Mn}^{2+}$ . Suggest how each mixture might be separated.

**17.72** Suggest how the cations in each of the following solution mixtures can be separated: (a)  $\text{Na}^+$  and  $\text{Cd}^{2+}$ , (b)  $\text{Cu}^{2+}$  and  $\text{Mg}^{2+}$ , (c)  $\text{Pb}^{2+}$  and  $\text{Al}^{3+}$ , (d)  $\text{Ag}^+$  and  $\text{Hg}^{2+}$ .

**17.73** (a) Precipitation of the group 4 cations (Figure 17.22) requires a basic medium. Why is this so? (b) What is the most significant difference between the sulfides precipitated in group 2 and those precipitated in group 3? (c) Suggest a procedure that would serve to redissolve the group 3 cations following their precipitation.

**17.74** A student who is in a great hurry to finish his laboratory work decides that his qualitative analysis unknown contains a metal ion from the insoluble phosphate group, group 4 (Figure 17.22). He therefore tests his sample directly with  $(\text{NH}_4)_2\text{HPO}_4$ , skipping earlier tests for the metal ions in groups 1, 2, and 3. He observes a precipitate and concludes that a metal ion from group 4 is indeed present. Why is this possibly an erroneous conclusion?

## ADDITIONAL EXERCISES

- 17.75** Derive an equation similar to the Henderson-Hasselbalch equation relating the pOH of a buffer to the  $pK_b$  of its base component.
- 17.76** Benzenesulfonic acid is a monoprotic acid with  $pK_a = 2.25$ . Calculate the pH of a buffer composed of 0.150 M benzenesulfonic acid and 0.125 M sodium benzenesulfonate.
- 17.77** Furoic acid ( $\text{HC}_5\text{H}_3\text{O}_3$ ) has a  $K_a$  value of  $6.76 \times 10^{-4}$  at 25 °C. Calculate the pH at 25 °C of (a) a solution formed by adding 25.0 g of furoic acid and 30.0 g of sodium furoate ( $\text{NaC}_5\text{H}_3\text{O}_3$ ) to enough water to form 0.250 L of solution; (b) a solution formed by mixing 30.0 mL of 0.250 M  $\text{HC}_5\text{H}_3\text{O}_3$  and 20.0 mL of 0.22 M  $\text{NaC}_5\text{H}_3\text{O}_3$  and diluting the total volume to 125 mL; (c) a solution prepared by adding 50.0 mL of 1.65 M NaOH solution to 0.500 L of 0.0850 M  $\text{HC}_5\text{H}_3\text{O}_3$ .
- 17.78** The acid-base indicator bromocresol green is a weak acid. The yellow acid and blue base forms of the indicator are present in equal concentrations in a solution when the pH is 4.68. What is the  $pK_a$  for bromocresol green?
- 17.79** Equal quantities of 0.010 M solutions of an acid HA and a base B are mixed. The pH of the resulting solution is 9.2. (a) Write the equilibrium equation and equilibrium-constant expression for the reaction between HA and B. (b) If  $K_a$  for HA is  $8.0 \times 10^{-5}$ , what is the value of the equilibrium constant for the reaction between HA and B? (c) What is the value of  $K_b$  for B?
- 17.80** Two buffers are prepared by adding an equal number of moles of formic acid ( $\text{HCOOH}$ ) and sodium formate ( $\text{HCOONa}$ ) to enough water to make 1.00 L of solution. Buffer A is prepared using 1.00 mol each of formic acid and sodium formate. Buffer B is prepared by using 0.010 mol of each. (a) Calculate the pH of each buffer, and explain why they are equal. (b) Which buffer will have the greater buffer capacity? Explain. (c) Calculate the change in pH for each buffer upon the addition of 1.0 mL of 1.00 M HCl. (d) Calculate the change in pH for each buffer upon the addition of 10 mL of 1.00 M HCl. (e) Discuss your answers for parts (c) and (d) in light of your response to part (b).
- 17.81** A biochemist needs 750 mL of an acetic acid-sodium acetate buffer with pH 4.50. Solid sodium acetate ( $\text{CH}_3\text{COONa}$ ) and glacial acetic acid ( $\text{CH}_3\text{COOH}$ ) are available. Glacial acetic acid is 99%  $\text{CH}_3\text{COOH}$  by mass and has a density of 1.05 g/mL. If the buffer is to be 0.15 M in  $\text{CH}_3\text{COOH}$ , how many grams of  $\text{CH}_3\text{COONa}$  and how many milliliters of glacial acetic acid must be used?
- 17.82** A sample of 0.2140 g of an unknown monoprotic acid was dissolved in 25.0 mL of water and titrated with 0.0950 M NaOH. The acid required 27.4 mL of base to reach the equivalence point. (a) What is the molar mass of the acid? (b) After 15.0 mL of base had been added in the titration, the pH was found to be 6.50. What is the  $K_a$  for the unknown acid?
- 17.83** Show that the pH at the halfway point of a titration of a weak acid with a strong base (where the volume of added base is half of that needed to reach the equivalence point) is equal to  $pK_a$  for the acid.
- 17.84** Potassium hydrogen phthalate, often abbreviated KHP, can be obtained in high purity and is used to determine the concentrations of solutions of strong bases. Strong bases react with the hydrogen phthalate ion as follows:
- $$\text{HP}^-(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{P}^{2-}(\text{aq})$$
- The molar mass of KHP is 204.2 g/mol and  $K_a$  for the  $\text{HP}^-$  ion is  $3.1 \times 10^{-6}$ . (a) If a titration experiment begins with 0.4885 g of KHP and has a final volume of about 100 mL, which indicator from Figure 16.7 would be most appropriate? (b) If the titration required 38.55 mL of NaOH solution to reach the end point, what is the concentration of the NaOH solution?
- 17.85** If 40.00 mL of 0.100 M  $\text{Na}_2\text{CO}_3$  is titrated with 0.100 M HCl, calculate (a) the pH at the start of the titration; (b) the volume of HCl required to reach the first equivalence point and the predominant species present at this point; (c) the volume of HCl required to reach the second equivalence point and the predominant species present at this point; (d) the pH at the second equivalence point.
- 17.86** A hypothetical weak acid, HA, was combined with NaOH in the following proportions: 0.20 mol of HA, 0.080 mol of NaOH. The mixture was diluted to a total volume of 1.0 L, and the pH measured. (a) If pH = 4.80, what is the  $pK_a$  of the acid? (b) How many additional moles of NaOH should be added to the solution to increase the pH to 5.00?
- [17.87]** What is the pH of a solution made by mixing 0.30 mol NaOH, 0.25 mol  $\text{Na}_2\text{HPO}_4$ , and 0.20 mol  $\text{H}_3\text{PO}_4$  with water and diluting to 1.00 L?
- [17.88]** Suppose you want to do a physiological experiment that calls for a pH 6.5 buffer. You find that the organism with which you are working is not sensitive to the weak acid  $\text{H}_2\text{X}$  ( $K_{a1} = 2 \times 10^{-2}$ ;  $K_{a2} = 5 \times 10^{-7}$ ) or its sodium salts. You have available a 1.0 M solution of this acid and a 1.0 M solution of NaOH. How much of the NaOH solution should be added to 1.0 L of the acid to give a buffer at pH 6.50? (Ignore any volume change.)
- [17.89]** How many microliters of 1.000 M NaOH solution must be added to 25.00 mL of a 0.1000 M solution of lactic acid [ $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$  or  $\text{HC}_3\text{H}_5\text{O}_3$ ] to produce a buffer with pH = 3.75?

- 17.90** A person suffering from anxiety begins breathing rapidly and as a result suffers alkalosis, an increase in blood pH. (a) Using Equation 17.10, explain how rapid breathing can cause the pH of blood to increase. (b) One cure for this problem is breathing in a paper bag. Why does this procedure lower blood pH?
- 17.91** For each pair of compounds, use  $K_{sp}$  values to determine which has the greater molar solubility: (a) CdS or CuS, (b)  $PbCO_3$  or  $BaCrO_4$ , (c)  $Ni(OH)_2$  or  $NiCO_3$ , (d) AgI or  $Ag_2SO_4$ .
- 17.92** Describe the solubility of  $CaCO_3$  in each of the following solutions compared to its solubility in water: (a) in 0.10 M NaCl solution; (b) in 0.10 M  $Ca(NO_3)_2$  solution; (c) 0.10 M  $Na_2CO_3$ ; (d) 0.10 M HCl solution. (Answer same, less soluble, or more soluble.)
- 17.93** Tooth enamel is composed of hydroxyapatite, whose simplest formula is  $Ca_5(PO_4)_3OH$ , and whose corresponding  $K_{sp} = 6.8 \times 10^{-27}$ . As discussed in the "Chemistry and Life" box in Section 17.5, fluoride in fluorinated water or in toothpaste reacts with hydroxyapatite to form fluoroapatite,  $Ca_5(PO_4)_3F$ , whose  $K_{sp} = 1.0 \times 10^{-60}$ . (a) Write the expression for the solubility-constant for hydroxyapatite and for fluoroapatite. (b) Calculate the molar solubility of each of these compounds.
- 17.94** Calculate the solubility of  $Mg(OH)_2$  in 0.50 M  $NH_4Cl$ .
- [17.95]** Seawater contains 0.13% magnesium by mass, and has a density of 1.025 g/mL. What fraction of the magnesium can be removed by adding a stoichiometric quantity of CaO (that is, one mole of CaO for each mole of  $Mg^{2+}$ )?
- 17.96** The solubility-product constant for barium permanganate,  $Ba(MnO_4)_2$ , is  $2.5 \times 10^{-10}$ . Assume that solid  $Ba(MnO_4)_2$  is in equilibrium with a solution of  $KMnO_4$ . What concentration of  $KMnO_4$  is required to establish a concentration of  $2.0 \times 10^{-8}$  M for the  $Ba^{2+}$  ion in solution?
- 17.97** Calculate the ratio of  $[Ca^{2+}]$  to  $[Fe^{2+}]$  in a lake in which the water is in equilibrium with deposits of both  $CaCO_3$  and  $FeCO_3$ . Assume that the water is slightly basic and that the hydrolysis of the carbonate ion can therefore be ignored.
- [17.98]** The solubility products of  $PbSO_4$  and  $SrSO_4$  are  $6.3 \times 10^{-7}$  and  $3.2 \times 10^{-7}$ , respectively. What are the values of  $[SO_4^{2-}]$ ,  $[Pb^{2+}]$ , and  $[Sr^{2+}]$  in a solution at equilibrium with both substances?
- [17.99]** What pH buffer solution is needed to give a  $Mg^{2+}$  concentration of  $3.0 \times 10^{-2}$  M in equilibrium with solid magnesium oxalate?
- [17.100]** The value of  $K_{sp}$  for  $Mg_3(AsO_4)_2$  is  $2.1 \times 10^{-20}$ . The  $AsO_4^{3-}$  ion is derived from the weak acid  $H_3AsO_4$  ( $pK_{a1} = 2.22$ ;  $pK_{a2} = 6.98$ ;  $pK_{a3} = 11.50$ ). When asked to calculate the molar solubility of  $Mg_3(AsO_4)_2$  in water, a student used the  $K_{sp}$  expression and assumed that  $[Mg^{2+}] = 1.5[AsO_4^{3-}]$ . Why was this a mistake?
- [17.101]** The solubility product for  $Zn(OH)_2$  is  $3.0 \times 10^{-16}$ . The formation constant for the hydroxo complex,  $Zn(OH)_4^{2-}$ , is  $4.6 \times 10^{17}$ . What concentration of  $OH^-$  is required to dissolve 0.015 mol of  $Zn(OH)_2$  in a liter of solution?

## INTEGRATIVE EXERCISES

- 17.102** (a) Write the net ionic equation for the reaction that occurs when a solution of hydrochloric acid (HCl) is mixed with a solution of sodium formate ( $NaCHO_2$ ). (b) Calculate the equilibrium constant for this reaction. (c) Calculate the equilibrium concentrations of  $Na^+$ ,  $Cl^-$ ,  $H^+$ ,  $CHO_2^-$ , and  $HCHO_2$  when 50.0 mL of 0.15 M HCl is mixed with 50.0 mL of 0.15 M  $NaCHO_2$ .
- 17.103** (a) A 0.1044-g sample of an unknown monoprotic acid requires 22.10 mL of 0.0500 M NaOH to reach the end point. What is the molecular weight of the unknown? (b) As the acid is titrated, the pH of the solution after the addition of 11.05 mL of the base is 4.89. What is the  $K_a$  for the acid? (c) Using Appendix D, suggest the identity of the acid. Do both the molecular weight and  $K_a$  value agree with your choice?
- 17.104** A sample of 7.5 L of  $NH_3$  gas at 22 °C and 735 torr is bubbled into a 0.50-L solution of 0.40 M HCl. Assuming that all the  $NH_3$  dissolves and that the volume of the solution remains 0.50 L, calculate the pH of the resulting solution.

- 17.105** Aspirin has the structural formula

At body temperature (37 °C),  $K_a$  for aspirin equals  $3 \times 10^{-5}$ . If two aspirin tablets, each having a mass of 325 mg, are dissolved in a full stomach whose volume is 1 L and whose pH is 2, what percent of the aspirin is in the form of neutral molecules?

- 17.106** What is the pH at 25 °C of water saturated with  $CO_2$  at a partial pressure of 1.10 atm? The Henry's law constant for  $CO_2$  at 25 °C is  $3.1 \times 10^{-2}$  mol/L-atm. The  $CO_2$  is an acidic oxide, reacting with  $H_2O$  to form  $H_2CO_3$ .

- 17.107** Excess  $\text{Ca}(\text{OH})_2$  is shaken with water to produce a saturated solution. The solution is filtered, and a 50.00-mL sample titrated with HCl requires 11.23 mL of 0.0983 M HCl to reach the end point. Calculate  $K_{sp}$  for  $\text{Ca}(\text{OH})_2$ . Compare your result with that in Appendix D. Do you think the solution was kept at 25 °C?
- 17.108** The osmotic pressure of a saturated solution of strontium sulfate at 25 °C is 21 torr. What is the solubility product of this salt at 25 °C?
- 17.109** A concentration of 10–100 parts per billion (by mass) of  $\text{Ag}^+$  is an effective disinfectant in swimming pools. However, if the concentration exceeds this range, the  $\text{Ag}^+$  can cause adverse health effects. One way to maintain an appropriate concentration of  $\text{Ag}^+$  is to add a slightly soluble salt to the pool. Using  $K_{sp}$  values from Appendix D, calculate the equilibrium concentration of  $\text{Ag}^+$  in parts per billion that would exist in equilibrium with (a) AgCl, (b) AgBr, (c) AgI.
- [17.110] Fluoridation of drinking water is employed in many places to aid in the prevention of dental caries. Typically the  $\text{F}^-$  ion concentration is adjusted to about 1 ppb. Some water supplies are also “hard”; that is, they contain certain cations such as  $\text{Ca}^{2+}$  that interfere with the action of soap. Consider a case where the concentration of  $\text{Ca}^{2+}$  is 8 ppb. Could a precipitate of  $\text{CaF}_2$  form under these conditions? (Make any necessary approximations.)

CHAPTER  
18

# CHEMISTRY OF THE ENVIRONMENT

PHOTOGRAPH OF EARTH  
taken from Space looking  
south along the Red Sea.

### 18.1 Earth's Atmosphere

We begin this chapter with a general look at Earth's atmosphere. We will consider the temperature profile of the atmosphere, its pressure profile, and its chemical composition.

### 18.2 Outer Regions of the Atmosphere

We next examine the outer (or upper) regions of the atmosphere, where the pressure is very low. These regions absorb a great deal of high-energy radiation from the Sun through *photoionization* and *photodissociation* reactions. By filtering out high-energy radiation, these processes make it possible for life as we know it to exist on Earth.

### 18.3 Ozone in the Upper Atmosphere

We will see that ozone in the *stratosphere* acts as a filter of high-energy ultraviolet light. Human activities have contributed to the depletion of the ozone layer by introducing into the stratosphere chemicals that perturb the natural cycle of ozone formation and decomposition. Notable among these chemicals are *chlorofluorocarbons*.

### 18.4 Chemistry of the Troposphere

We complete our discussion of the atmosphere by examining its innermost region, the *troposphere*, which is the region in which we live. Many minor constituents of the troposphere affect air quality and the acidity of rainwater. The concentrations of

many of these minor constituents, including those that cause *acid rain* and *photochemical smog*, have been increased by human activities. Carbon dioxide is an important minor constituent of the atmosphere because it acts as a "*greenhouse*" gas that warms Earth's atmosphere.

### 18.5 The World Ocean

We next turn our attention to our water environment. Almost all the water on Earth is in the world ocean. Seawater contains many salts that participate in the global cycling of the elements and nutrients.

### 18.6 Freshwater

Our discussion of water concludes with a look at freshwater. Processing seawater to obtain freshwater is energy intensive. We count on freshwater sources to supply most of our needs, but these sources often require treatment to render them usable.

### 18.7 Green Chemistry

We conclude our discussion of the environment by examining *green chemistry*, which seeks to eliminate pollution at its source. Green chemistry is an international initiative to make industrial products, processes, and chemical reactions compatible with a sustainable society and environment.

**IN 1997, REPRESENTATIVES OF 130 NATIONS MET IN KYOTO, JAPAN,**  
to discuss the impact of human activities on global warming.  
Out of that meeting came an initiative to work toward a global  
treaty that would, among other things, spell out actions  
to be taken to reduce emissions of gases that cause

global warming. In 2001 in Bonn, Germany, 178 nations signed a treaty based on the so-called Kyoto Protocols. In 2007, the United Nations Intergovernmental Panel on Climate Change issued a report declaring that human activity has "very likely" been the driving force for the warming trend observed worldwide over the past 50 years. These efforts to address environmental concerns at the international level indicate that many of the most urgent environmental problems are global in nature.

As technology has advanced and the world human population has increased, we have put new and greater stresses on our environment. Paradoxically, the very technology that can cause pollution also provides the tools to help us understand and manage our environment in a beneficial way.

Chemistry is often at the heart of these issues. The economic growth of both developed and developing nations depends critically on chemical processes that range from treatment of water supplies to industrial processes. Some of these processes produce products or by-products that are harmful to the environment.

We are now in a position to apply the principles we have learned in earlier chapters to an understanding of how our environment operates and how human activities affect it. In this chapter we consider some aspects of the chemistry of our environment, focusing on Earth's atmosphere and water. Both the air and water of our planet make life as we know it possible. To understand and maintain the environment in which we live, we must understand how human-made and natural chemical compounds interact on land and in the sea and sky. Our daily decisions as consumers mirror those of the leaders meeting in Bonn and similar international meetings: We must weigh the costs versus the benefits of our actions. Unfortunately, the environmental impacts of our decisions are often very subtle and not immediately evident.

## 18.1 EARTH'S ATMOSPHERE

Because most of us have never been very far from Earth's surface, we often take for granted the many ways in which the atmosphere determines the environment in which we live. In this section we will examine some of the important characteristics of our planet's atmosphere.

The temperature of the atmosphere varies in a complex manner as a function of altitude, as shown in Figure 18.1(a) ◀. The atmosphere is divided into four regions based on this temperature profile. Just above the surface, in the **troposphere**, the temperature normally decreases with increasing altitude, reaching a minimum of about 215 K at about 12 km. Nearly all of us live our entire lives in the troposphere. Howling winds and soft breezes, rain, and sunny skies—all that we normally think of as “weather”—occur in this region. Commercial jet aircraft typically fly about 10 km (33,000 ft) above Earth, an altitude that approaches the upper limit of the troposphere, which we call the **tropopause**.

▼ **Figure 18.1 Temperature and pressure in the atmosphere.**

(a) Temperature variations in the atmosphere at altitudes below 110 km. (b) Variations in atmospheric pressure with altitude. At 80 km the pressure is approximately 0.01 torr.

Above the tropopause the temperature increases with altitude, reaching a maximum of about 275 K at about 50 km. The region from 10 km to 50 km is called the **stratosphere**. Beyond the stratosphere are the *mesosphere* and the *thermosphere*. Notice in Figure 18.1(a) that the temperature extremes that form the boundaries between adjacent regions are denoted by the suffix *-pause*. The boundaries are important because gases mix across them relatively slowly. For example, pollutant gases generated in the troposphere pass through the tropopause and find their way into the stratosphere only very slowly.

Unlike temperature, which varies in a complex way with increased altitude, the pressure of the atmosphere decreases in a regular way with increasing elevation, as shown in Figure 18.1(b). Atmospheric pressure declines much more rapidly at lower elevations than at higher ones because of the atmosphere's compressibility. Thus, the pressure decreases from an average value of 760 torr (101 kPa) at sea level to  $2.3 \times 10^{-3}$  torr ( $3.1 \times 10^{-4}$  kPa) at 100 km, to only  $1.0 \times 10^{-6}$  torr ( $1.3 \times 10^{-7}$  kPa) at 200 km. The troposphere and stratosphere

together account for 99.9% of the mass of the atmosphere, 75% of which is the mass in the troposphere. Consequently, most of the chemistry that follows focuses on the troposphere and stratosphere.

## Composition of the Atmosphere

Earth's atmosphere is an extremely complex system. Its temperature and pressure change over a wide range with altitude, as we have just seen. The atmosphere is constantly bombarded by radiation and energetic particles from the Sun. This barrage of energy has profound chemical effects, especially on the outer reaches of the atmosphere (Figure 18.2 ▶). In addition, because of Earth's gravitational field, lighter atoms and molecules tend to rise to the top of the atmosphere, especially in the stratosphere and upper layers that are not as turbulent as the troposphere. Because of all these factors, the composition of the atmosphere is not uniform.

Table 18.1 ▼ shows the composition by mole fraction of dry air near sea level. Although traces of many substances are present,  $N_2$  and  $O_2$  make up about 99% of the atmosphere. The noble gases and  $CO_2$  make up most of the remainder.

When speaking of trace constituents, we commonly use *parts per million* (ppm) as the unit of concentration. When applied to substances in aqueous solution, parts per million refers to grams of substance per million grams of solution. ∞ (Section 13.4) When dealing with gases, however, one part per million refers to one part by *volume* in 1 million volume units of the whole. Because volume ( $V$ ) is proportional to the number of moles  $n$  of gas via the ideal-gas equation ( $PV = nRT$ ), volume fraction and mole fraction are the same. Thus, 1 ppm of a trace constituent of the atmosphere amounts to one mole of that constituent in 1 million moles of total gas; that is, the concentration in ppm is equal to the mole fraction times  $10^6$ . Table 18.1 lists the mole fraction of  $CO_2$  in the atmosphere as 0.000375. Its concentration in ppm is therefore  $0.000375 \times 10^6 = 375$  ppm.

Before we consider the chemical processes that occur in the atmosphere, let's review some of the important chemical properties of the two major components,  $N_2$  and  $O_2$ . Recall that the  $N_2$  molecule possesses a triple bond between the nitrogen atoms. ∞ (Section 8.3) This very strong bond is largely responsible for the very low reactivity of  $N_2$ , which undergoes reaction only under extreme conditions. The bond energy in  $O_2$ , 495 kJ/mol, is much lower than that in  $N_2$ , which is 941 kJ/mol. ∞ (Table 8.4) Therefore,  $O_2$  is much more reactive than  $N_2$ . For example, oxygen reacts with many substances to form oxides. The oxides of nonmetals, for example  $SO_2$ , usually form acidic solutions when dissolved in water. The oxides of active metals, for example  $CaO$ , form basic solutions when dissolved in water. ∞ (Section 7.7)

▲ **Figure 18.2 The aurora borealis.** This luminous display in the northern sky, also called the northern lights, is produced by collisions of high-speed electrons and protons from the Sun with air molecules. The charged particles are channeled toward the polar regions by Earth's magnetic field.

**TABLE 18.1** ■ Composition of Dry Air Near Sea Level

Component*	Content (mole fraction)	Molar Mass
Nitrogen	0.78084	28.013
Oxygen	0.20948	31.998
Argon	0.00934	39.948
Carbon dioxide	0.000382	44.0099
Neon	0.00001818	20.183
Helium	0.00000524	4.003
Methane	0.000002	16.043
Krypton	0.00000114	83.80
Hydrogen	0.0000005	2.0159
Nitrous oxide	0.0000005	44.0128
Xenon	0.000000087	131.30

\*Ozone, sulfur dioxide, nitrogen dioxide, ammonia, and carbon monoxide are present as trace gases in variable amounts.

**SAMPLE EXERCISE 18.1** Calculating the Concentration of Water in Air

What is the concentration, in parts per million, of water vapor in a sample of air if the partial pressure of the water is 0.80 torr and the total pressure of the air is 735 torr?

**SOLUTION**

**Analyze:** We are given the partial pressure of water vapor and the total pressure of an air sample and asked to determine the water vapor concentration.

**Plan:** Recall that the partial pressure of a component in a mixture of gases is given by the product of its mole fraction and the total pressure of the mixture  $\infty$  (Section 10.6):

$$P_{\text{H}_2\text{O}} = X_{\text{H}_2\text{O}}P_t$$

**Solve:** Solving for the mole fraction of water vapor in the mixture,  $X_{\text{H}_2\text{O}}$ , gives:

$$X_{\text{H}_2\text{O}} = \frac{P_{\text{H}_2\text{O}}}{P_t} = \frac{0.80 \text{ torr}}{735 \text{ torr}} = 0.0011$$

The concentration in ppm is the mole fraction times  $10^6$

$$0.0011 \times 10^6 = 1100 \text{ ppm}$$

**PRACTICE EXERCISE**

The concentration of CO in a sample of air is found to be 4.3 ppm. What is the partial pressure of the CO if the total air pressure is 695 torr?

**Answer:**  $3.0 \times 10^{-3}$  torr

**18.2 OUTER REGIONS OF THE ATMOSPHERE**

Although the outer portion of the atmosphere, beyond the stratosphere, contains only a small fraction of the atmospheric mass, it forms the outer defense against the hail of radiation and high-energy particles that continuously bombard Earth. As the bombarding radiation passes through the upper atmosphere, it causes two basic kinds of chemical changes: photodissociation and photoionization. These processes protect us from high-energy radiation by absorbing most of the radiation before it reaches the troposphere where we live. If it were not for these photochemical processes, plant and animal life as we know it could not exist on Earth.

**Photodissociation**

The Sun emits radiant energy over a wide range of wavelengths (Figure 18.3 ◀). To understand the connection between the wavelength of radiation and its effect on atoms and molecules, recall that electromagnetic radiation can be pictured as a stream of photons.  $\infty$  (Section 6.2) The energy of each photon is given by the relationship  $E = h\nu$ , where  $h$  is Planck's constant and  $\nu$  is the frequency of the radiation. For a chemical change to occur when radiation strikes atoms or molecules, two conditions must be met. First, there must be photons with energy sufficient to accomplish some chemical process such as breaking a chemical bond or removing an electron. Second, molecules must absorb these photons. When these requirements are met, the energy of the photons is used to do the work associated with some chemical change.

The rupture of a chemical bond resulting from absorption of a photon by a molecule is called **photodissociation**.

▼ **Figure 18.3 The solar spectrum.** Shown in this graph is the amount of sunlight (in light energy per area per time, known as flux) at different wavelengths that reaches the top of Earth's atmosphere. For comparison, the corresponding data for the amount of sunlight that reaches sea level is shown. The atmosphere absorbs much of the ultraviolet and visible light emitted by the Sun.

No ions are formed when the bond between two atoms is cleaved by photodissociation. Instead, half the bonding electrons stay with one of the atoms and half stay with the other atom. The result is two neutral particles.

One of the most important processes occurring in the upper atmosphere above about 120-km elevation is the photodissociation of the oxygen molecule:

The minimum energy required to cause this change is determined by the bond energy (or *dissociation energy*) of  $\text{O}_2$ , 495 kJ/mol. In Sample Exercise 18.2 we calculate the longest wavelength photon having sufficient energy to photodissociate the  $\text{O}_2$  molecule.

### SAMPLE EXERCISE 18.2 | Calculating the Wavelength Required to Break a Bond

What is the maximum wavelength of light, in nanometers, that has enough energy per photon to dissociate the  $\text{O}_2$  molecule?

#### SOLUTION

**Analyze:** We are asked to determine the wavelength of a photon that has just enough energy to break the  $\text{O}=\text{O}$  double bond in  $\text{O}_2$ .

**Plan:** We first need to calculate the energy required to break the  $\text{O}=\text{O}$  double bond in one molecule, and then find the wavelength of a photon of this energy.

**Solve:** The dissociation energy of  $\text{O}_2$  is 495 kJ/mol. Using this value and Avogadro's number, we can calculate the amount of energy needed to break the bond in a single  $\text{O}_2$  molecule:

$$\left(495 \times 10^3 \frac{\text{J}}{\text{mol}}\right) \left(\frac{1 \text{ mol}}{6.022 \times 10^{23} \text{ molecules}}\right) = 8.22 \times 10^{-19} \frac{\text{J}}{\text{molecule}}$$

We next use the Planck relationship,  $E = h\nu$ , (Equation 6.2) to calculate the frequency,  $\nu$ , of a photon that has this amount of energy:

$$\nu = \frac{E}{h} = \frac{8.22 \times 10^{-19} \text{ J}}{6.626 \times 10^{-34} \text{ J}\cdot\text{s}} = 1.24 \times 10^{15} \text{ s}^{-1}$$

Finally, we use the relationship between the frequency and wavelength of light (Section 6.1) to calculate the wavelength of the light:

$$= \frac{c}{\nu} = \left(\frac{3.00 \times 10^8 \text{ m/s}}{1.24 \times 10^{15} \text{ /s}}\right) \left(\frac{10^9 \text{ nm}}{1 \text{ m}}\right) = 242 \text{ nm}$$

Thus, light of wavelength 242 nm, which is in the ultraviolet region of the electromagnetic spectrum, has sufficient energy per photon to photodissociate an  $\text{O}_2$  molecule. Because photon energy increases as wavelength *decreases*, any photon of wavelength *shorter* than 242 nm will have sufficient energy to dissociate  $\text{O}_2$ .

#### PRACTICE EXERCISE

The bond energy in  $\text{N}_2$  is 941 kJ/mol (Table 8.4). What is the longest wavelength a photon can have and still have sufficient energy to dissociate  $\text{N}_2$ ?

**Answer:** 127 nm

Fortunately for us,  $\text{O}_2$  absorbs much of the high-energy, short-wavelength radiation from the solar spectrum before that radiation reaches the lower atmosphere. As it does, atomic oxygen,  $:\ddot{\text{O}}:$ , is formed. At higher elevations the dissociation of  $\text{O}_2$  is very extensive. At 400 km, for example, only 1% of the oxygen is in the form of  $\text{O}_2$ ; the other 99% is atomic oxygen. At 130 km,  $\text{O}_2$  and atomic oxygen are just about equally abundant. Below 130 km,  $\text{O}_2$  is more abundant than atomic oxygen because most of the solar energy has been absorbed in the upper atmosphere.

The dissociation energy of  $\text{N}_2$  is very high (Table 8.4). As shown in the Practice Exercise in Sample Exercise 18.2, only photons of very short wavelength possess sufficient energy to dissociate  $\text{N}_2$ . Furthermore,  $\text{N}_2$  does not readily absorb photons, even when they possess sufficient energy. As a result, very little atomic nitrogen is formed in the upper atmosphere by photodissociation of  $\text{N}_2$ .

## Photoionization

In 1901 Guglielmo Marconi received a radio signal in St. John's, Newfoundland, that had been transmitted from Land's End, England, some 2900 km away. Because people at the time thought radio waves traveled in straight lines, they assumed that the curvature of Earth's surface would make radio communication over large distances impossible. Marconi's successful experiment suggested that Earth's atmosphere in some way substantially affects radio-wave propagation. His discovery led to intensive study of the upper atmosphere. In about 1924, the existence of electrons in the upper atmosphere was established by experimental studies.

For each electron present in the upper atmosphere, there must be a corresponding positively charged particle. The electrons in the upper atmosphere result mainly from the **photoionization** of molecules, caused by solar radiation. Photoionization occurs when a molecule absorbs radiation and the absorbed energy causes an electron to be ejected from the molecule. The molecule then becomes a positively charged ion. For photoionization to occur, therefore, a molecule must absorb a photon, and the photon must have enough energy to remove an electron.  $\rightleftharpoons$  (Section 7.4)

**TABLE 18.2** ■ Ionization Processes, Ionization Energies, and Maximum Wavelengths Capable of Causing Ionization

Process	Ionization Energy (kJ/mol)	$\lambda_{\max}$ (nm)
$\text{N}_2 + h\nu \longrightarrow \text{N}_2^+ + \text{e}^-$	1495	80.1
$\text{O}_2 + h\nu \longrightarrow \text{O}_2^+ + \text{e}^-$	1205	99.3
$\text{O} + h\nu \longrightarrow \text{O}^+ + \text{e}^-$	1313	91.2
$\text{NO} + h\nu \longrightarrow \text{NO}^+ + \text{e}^-$	890	134.5

Some of the more important ionization processes occurring in the atmosphere above about 90 km are shown in Table 18.2  $\blacktriangleleft$ , together with the ionization energies and  $\lambda_{\max}$ , the maximum wavelength of a photon capable of causing ionization. Photons with energies sufficient to cause ionization have wavelengths in the high-energy end of the ultraviolet region of the electromagnetic spectrum. These wavelengths are completely filtered out of the radiation reaching Earth, because they are absorbed by the upper atmosphere.

## 18.3 OZONE IN THE UPPER ATMOSPHERE

While  $\text{N}_2$ ,  $\text{O}_2$ , and atomic oxygen absorb photons having wavelengths shorter than 240 nm, ozone,  $\text{O}_3$ , is the key absorber of photons having wavelengths ranging from 240 to 310 nm, in the ultraviolet region of the electromagnetic spectrum. Ozone protects us from these harmful high-energy photons, which would otherwise penetrate to Earth's surface. Let's consider how ozone forms in the upper atmosphere and how it absorbs photons.

Below an altitude of 90 km, most of the short-wavelength radiation capable of photoionization has been absorbed. Radiation capable of dissociating the  $\text{O}_2$  molecule is sufficiently intense, however, for photodissociation of  $\text{O}_2$  (Equation 18.1) to remain important down to an altitude of 30 km. In the region between 30 and 90 km, the concentration of  $\text{O}_2$  is much greater than that of atomic oxygen. Therefore, the oxygen atoms that form in this region undergo frequent collisions with  $\text{O}_2$  molecules, resulting in the formation of ozone,  $\text{O}_3$ :

The asterisk over the  $\text{O}_3$  denotes that the ozone molecule contains an excess of energy. The reaction in Equation 18.2 releases 105 kJ/mol. This energy must be transferred away from the  $\text{O}_3^*$  molecule in a very short time or else the molecule will fly apart again into  $\text{O}_2$  and  $:\ddot{\text{O}}$ —a decomposition that is the reverse of the process by which  $\text{O}_3^*$  is formed.

An energy-rich  $\text{O}_3^*$  molecule can release its excess energy by colliding with another atom or molecule and transferring some of the excess energy to it. Let's represent the atom or molecule with which  $\text{O}_3^*$  collides as M. (Usually M is  $\text{N}_2$  or  $\text{O}_2$  because these are the most abundant molecules in the atmosphere.)

The formation of  $O_3^*$  and the transfer of excess energy to M are summarized by the following equations (where O atoms are shown without valence electrons):

The rate at which  $O_3$  forms according to Equations 18.3 and 18.4 depends on two factors that vary in opposite directions with increasing altitude. First, the formation of  $O_3^*$ , according to Equation 18.3, depends on the presence of O atoms. At low altitudes most of the radiation energetic enough to dissociate  $O_2$  has been absorbed; thus, the formation of O is favored at higher altitudes. Second, both Equations 18.3 and 18.4 depend on molecular collisions.  $\infty$  (Section 14.5) The concentration of molecules is greater at low altitudes, and so the frequency of collisions between O and  $O_2$  (Equation 18.3) and between  $O_3^*$  and M (Equation 18.4) are both greater at lower altitudes. Because these processes vary with altitude in opposite directions, the highest rate of  $O_3$  formation occurs in a band at an altitude of about 50 km, near the stratopause [Figure 18.1(a)]. Overall, roughly 90% of Earth's ozone is found in the stratosphere, between the altitudes of 10 and 50 km.

Once formed, an ozone molecule does not last long. Ozone is capable of absorbing solar radiation, which decomposes the molecule back into  $O_2$  and O. Because only 105 kJ/mol is required for this process, photons of wavelength shorter than 1140 nm are sufficiently energetic to photodissociate  $O_3$ . However, most of the output from the Sun is concentrated in the visible and ultraviolet portions of the electromagnetic spectrum (Figure 18.3). Photons with wavelengths shorter than about 300 nm are energetic enough to break many kinds of single chemical bonds. Thus, the "ozone shield" is essential for our continued well-being. The ozone molecules that form this essential shield against high-energy radiation represent only a tiny fraction of the oxygen atoms present in the stratosphere, however, because they are continually destroyed even as they are formed.

### GIVE IT SOME THOUGHT

Look at Figure 18.3. Based on the relative areas under the curves, what fraction of the radiation with wavelengths in the ultraviolet portion of the spectrum is absorbed by the upper atmosphere?

The photodecomposition of ozone reverses the reaction that forms it. We thus have a cyclic process of ozone formation and decomposition, summarized as follows:

The first and third processes are photochemical; they use a solar photon to initiate a chemical reaction. The second and fourth processes are exothermic chemical reactions. The net result of all four processes is a cycle in which solar radiant energy is converted into thermal energy. The ozone cycle in the stratosphere is responsible for the rise in temperature that reaches its maximum at the stratopause, as illustrated in Figure 18.1(a).

▲ **Figure 18.4 Ozone depletion.** Variation in ozone concentration in the atmosphere, as a function of altitude.

▲ **Figure 18.5 Map of the total ozone present in the Southern Hemisphere, taken on September 24, 2006 from an orbiting satellite.** The different colors represent different ozone concentrations. The center area, which is over Antarctica, is the ozone hole—the area of lowest ozone.

The scheme described for the formation and decomposition of ozone molecules accounts for some, but not all, of the facts about the ozone layer. Many chemical reactions occur that involve substances other than just oxygen. We must also consider the effects of turbulence and winds that mix up the stratosphere. A very complicated picture results. The overall result of ozone formation and removal reactions, coupled with atmospheric turbulence and other factors, is to produce an ozone profile in the upper atmosphere as shown on the left in Figure 18.4, with a maximum ozone concentration occurring at an altitude of about 30 km.

### Depletion of the Ozone Layer

The ozone layer protects Earth's surface from damaging ultraviolet radiation. Satellite monitoring of ozone, which began in 1978, has revealed a depletion of ozone in the stratosphere that is particularly severe over Antarctica, a phenomenon known as the *ozone hole* (Figure 18.5). The first scientific paper on this phenomenon appeared in 1985.

In 1995 the Nobel Prize in Chemistry was awarded to F. Sherwood Rowland, Mario Molina, and Paul Crutzen for their studies of ozone depletion. In 1970 Crutzen showed that naturally occurring nitrogen oxides catalytically destroy ozone. Rowland and Molina recognized in 1974 that chlorine from **chlorofluorocarbons** (CFCs) may deplete the ozone layer. These substances, principally  $\text{CFCl}_3$  and  $\text{CF}_2\text{Cl}_2$ , have been widely used as propellants in spray cans, as refrigerant and air-conditioner gases, and as foaming agents for plastics. They are virtually unreactive in the lower atmosphere. Furthermore, they are relatively insoluble in water and are therefore not removed from the atmosphere by rainfall or by dissolution in the oceans. Unfortunately, the lack of reactivity that makes them commercially useful also allows them to survive in the atmosphere and to diffuse eventually into the stratosphere. It is estimated that several million tons of chlorofluorocarbons are now present in the atmosphere.

As CFCs diffuse into the stratosphere, they are exposed to high-energy radiation, which can cause photodissociation. The C—Cl bonds are considerably weaker than the C—F bonds (Table 8.4). As a result, free chlorine atoms are formed readily in the presence of light with wavelengths in the range of 190 to 225 nm, as shown in this equation for  $\text{CF}_2\text{Cl}_2$ :

Calculations suggest that chlorine atom formation occurs at the greatest rate at an altitude of about 30 km, the altitude at which ozone is at its highest concentration.

Atomic chlorine reacts rapidly with ozone to form chlorine monoxide (ClO) and molecular oxygen ( $\text{O}_2$ ):

Equation 18.7 follows a second-order rate law with a very large rate constant:

$$\text{Rate} = k[\text{Cl}][\text{O}_3] \quad k = 7.2 \times 10^9 \text{ M}^{-1} \text{ s}^{-1} \text{ at } 298 \text{ K} \quad [18.8]$$

Under certain conditions the ClO generated in Equation 18.7 can react to regenerate free Cl atoms. One way that this can happen is by photodissociation of the ClO:

The Cl atoms generated in Equations 18.6 and 18.9 can react with more  $\text{O}_3$ , according to Equation 18.7. The result is a sequence of reactions that accomplishes the Cl atom-catalyzed decomposition of  $\text{O}_3$  to  $\text{O}_2$ , as shown in the following multistep mechanism:

The equation can be simplified by eliminating like species from each side to give

Because the rate of Equation 18.7 increases linearly with [Cl], the rate at which ozone is destroyed increases as the quantity of Cl atoms increases. Thus, the greater the amount of CFCs that diffuse into the stratosphere, the faster the destruction of the ozone layer. Rates of diffusion of molecules from the troposphere into the stratosphere are slow. Nevertheless, a thinning of the ozone layer over the South Pole has been observed, particularly during the months of September and October (Figure 18.5).

Because of the environmental problems associated with CFCs, steps have been taken to limit their manufacture and use. A major step was the signing in 1987 of the Montreal Protocol on Substances That Deplete the Ozone Layer, in which participating nations agreed to reduce CFC production. More stringent limits were set in 1992, when representatives of approximately 100 nations agreed to ban the production and use of CFCs by 1996. Since then, the size of the ozone hole has leveled off. Nevertheless, because CFCs are unreactive and because they diffuse so slowly into the stratosphere, scientists estimate that ozone depletion will continue for many years to come. ∞ (Section 14, "Chemistry Put to Work: The Hole Story")

What substances have replaced CFCs? At this time the main alternatives are hydrofluorocarbons, compounds in which C—H bonds replace the C—Cl bonds of CFCs. One such compound in current use is CH<sub>2</sub>FCF<sub>3</sub>, known as HFC-134a.

There are no naturally occurring CFCs, but some natural sources contribute chlorine and bromine to the atmosphere, and, just like halogens from CFC, these naturally occurring Cl and Br atoms can participate in ozone-depleting reactions. The principal naturally occurring sources are methyl bromide and methyl chloride, CH<sub>3</sub>Br and CH<sub>3</sub>Cl. It is estimated that these molecules contribute less than a third to the total Cl and Br in the atmosphere; the remaining two-thirds is a result of human activities. Volcanoes are a source of HCl, but, generally, the HCl they release reacts with water in the troposphere and does not make it to the upper atmosphere.

### GIVE IT SOME THOUGHT

What process involving CFCs generates a substance that initiates the catalytic decomposition of ozone? Identify the catalyst.

## 18.4 CHEMISTRY OF THE TROPOSPHERE

The troposphere consists primarily of N<sub>2</sub> and O<sub>2</sub>, which together make up 99% of Earth's atmosphere at sea level (Table 18.1). Other gases, although present only at very low concentrations, can have major effects on our environment. Table 18.3 ▼ lists the major sources and typical concentrations of some of the important minor constituents of the troposphere. Many of these substances occur to only a slight extent in the natural environment but exhibit much higher concentrations in certain areas because of human activities. In this section we will discuss the most important characteristics of a few of these substances and their chemical roles as air pollutants. As we will see, most form as either a direct or an indirect result of our widespread use of combustion reactions.

**TABLE 18.3** ■ Sources and Typical Concentrations of Some Minor Atmospheric Constituents

Minor Constituent	Sources	Typical Concentrations
Carbon dioxide, CO <sub>2</sub>	Decomposition of organic matter; release from the oceans; fossil-fuel combustion	375 ppm throughout the troposphere
Carbon monoxide, CO	Decomposition of organic matter; industrial processes; fossil-fuel combustion	0.05 ppm in unpolluted air; 1–50 ppm in urban traffic areas
Methane, CH <sub>4</sub>	Decomposition of organic matter; natural-gas seepage	1.77 ppm throughout the troposphere
Nitric oxide, NO	Electrical discharges; internal combustion engines; combustion of organic matter	0.01 ppm in unpolluted air; 0.2 ppm in smog
Ozone, O <sub>3</sub>	Electrical discharges; diffusion from the stratosphere; photochemical smog	0 to 0.01 ppm in unpolluted air; 0.5 ppm in photochemical smog
Sulfur dioxide, SO <sub>2</sub>	Volcanic gases; forest fires; bacterial action; fossil-fuel combustion; industrial processes	0 to 0.01 ppm in unpolluted air; 0.1–2 ppm in polluted urban environment

**TABLE 18.4** ■ Median Concentrations of Atmospheric Pollutants in a Typical Urban Atmosphere

Pollutant	Concentration (ppm)
Carbon monoxide	10
Hydrocarbons	3
Sulfur dioxide	0.08
Nitrogen oxides	0.05
Total oxidants (ozone and others)	0.02

### Sulfur Compounds and Acid Rain

Sulfur-containing compounds are present to some extent in the natural, unpolluted atmosphere. They originate in the bacterial decay of organic matter, in volcanic gases, and from other sources listed in Table 18.3. The amount of sulfur-containing compounds released into the atmosphere worldwide from natural sources is about  $24 \times 10^{12}$  g per year, which is less than the amount from human activities (about  $79 \times 10^{12}$  g per year). Sulfur compounds, chiefly sulfur dioxide, SO<sub>2</sub>, are among the most unpleasant and harmful of the common pollutant gases. Table 18.4 ◀ shows the concentrations of several pollutant gases in a typical urban environment (not one that is particularly affected by smog). According to these data, the level of sulfur dioxide is 0.08 ppm or higher about half the time. This concentration is considerably lower than that of other pollutants, notably carbon monoxide. Nevertheless, SO<sub>2</sub> is regarded as the most serious health hazard among the pollutants shown, especially for people with respiratory difficulties.

Combustion of coal accounts for about 65% of the SO<sub>2</sub> released annually in the United States. The majority of this amount is from coal-burning electrical power plants, which generate about 50% of our electricity. The extent to which SO<sub>2</sub> emissions are a problem in the burning of coal depends on the level of its sulfur concentration. Because of concern about SO<sub>2</sub> pollution, low-sulfur coal is in greater demand and is thus more expensive. Much of the coal from east of the Mississippi is relatively high in sulfur content, up to 6% by mass. Much of the coal from the western states has a lower sulfur content. This coal, however, also has a lower heat content per unit mass of coal, so the difference in sulfur content per unit of heat produced is not as large as is often assumed.

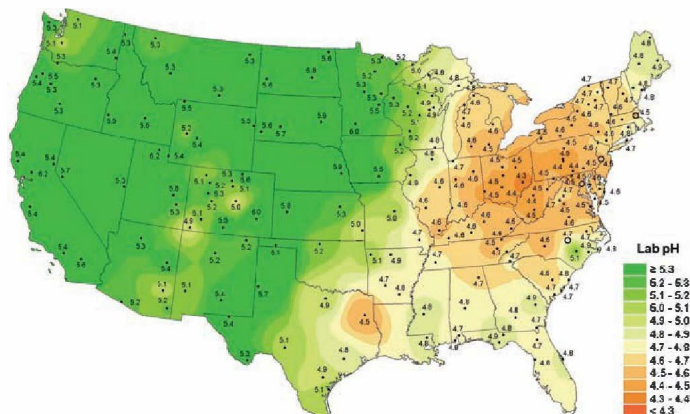

China, which gets 70 percent of its total energy from coal, is the world's largest generator of SO<sub>2</sub>, producing about  $24 \times 10^{12}$  g of SO<sub>2</sub> annually by official Chinese counts and as much as  $34 \times 10^{12}$  g by other counts. As a result, that nation has a major problem with SO<sub>2</sub> pollution.

Sulfur dioxide is harmful to both human health and property; furthermore, atmospheric SO<sub>2</sub> can be oxidized to SO<sub>3</sub> by several pathways (such as reaction with O<sub>2</sub> or O<sub>3</sub>). When SO<sub>3</sub> dissolves in water, it produces sulfuric acid, H<sub>2</sub>SO<sub>4</sub>:

Many of the environmental effects ascribed to SO<sub>2</sub> are actually due to H<sub>2</sub>SO<sub>4</sub>.

The presence of SO<sub>2</sub> in the atmosphere and the sulfuric acid that it produces result in the phenomenon of acid rain. (Nitrogen oxides, which form nitric acid, are also major contributors to acid rain.) Uncontaminated rainwater is

▲ **Figure 18.6** pH values from freshwater sites across the United States, 2005. The numbered dots indicate the locations of monitoring stations.

naturally acidic and generally has a pH value of about 5.6. The primary source of this natural acidity is  $\text{CO}_2$ , which reacts with water to form carbonic acid,  $\text{H}_2\text{CO}_3$ . Acid rain typically has a pH value of about 4. This acidity has affected many lakes in northern Europe, the northern United States, and Canada, reducing fish populations and affecting other parts of the ecological network within the lakes and surrounding forests.

The pH of most natural waters containing living organisms is between 6.5 and 8.5, but as Figure 18.6▲ shows, freshwater pH values are far below 6.5 in many parts of the continental United States. At pH levels below 4.0, all vertebrates, most invertebrates, and many microorganisms are destroyed. The lakes that are most susceptible to damage are those with low concentrations of basic ions, such as  $\text{HCO}_3^-$ , that buffer them against changes in pH. More than 300 lakes in New York State contain no fish, and 140 lakes in Ontario, Canada, are devoid of life. The acid rain that appears to have killed the organisms in these lakes originates hundreds of kilometers upwind in the Ohio Valley and Great Lakes regions. Some of these regions are recovering as sulfur emissions from fossil fuel combustion decrease, in part because of the Clean Air Act, which has resulted in a reduction of more than 40% in  $\text{SO}_2$  emissions from power plants since 1980.

Because acids react with metals and with carbonates, acid rain is corrosive both to metals and to stone building materials. Marble and limestone, for example, whose major constituent is  $\text{CaCO}_3$ , are readily attacked by acid rain (Figure 18.7▶). Billions of dollars each year are lost because of corrosion due to  $\text{SO}_2$  pollution.

One way to reduce the quantity of  $\text{SO}_2$  released into the environment is to remove sulfur from coal and oil before it is burned. Although difficult and expensive, several methods have been developed for removing  $\text{SO}_2$  from the gases formed when coal and oil are combusted. Powdered limestone ( $\text{CaCO}_3$ ), for example, can be injected into the furnace of a power plant, where it decomposes into lime ( $\text{CaO}$ ) and carbon dioxide:

The  $\text{CaO}$  then reacts with  $\text{SO}_2$  to form calcium sulfite:

(a)

(b)

▶ **Figure 18.7** Damage from acid rain. (a) This statue at the Field Museum in Chicago shows the effects of corrosion from acid rain and atmospheric pollutants. (b) The same statue after restoration.

► **Figure 18.8 Common method for removing SO<sub>2</sub> from combusted fuel.**

Powdered limestone decomposes into CaO, which reacts with SO<sub>2</sub> to form CaSO<sub>3</sub>. The CaSO<sub>3</sub> and any unreacted SO<sub>2</sub> enter a purification chamber called a scrubber, where a shower of CaO and water converts the remaining SO<sub>2</sub> into CaSO<sub>3</sub> and precipitates the CaSO<sub>3</sub> into a watery residue called a slurry.

The solid particles of CaSO<sub>3</sub> as well as much of the unreacted SO<sub>2</sub> can be removed from the furnace gas by passing it through an aqueous suspension of lime (Figure 18.8▲). Not all the SO<sub>2</sub> is removed, however, and given the enormous quantities of coal and oil burned worldwide, pollution by SO<sub>2</sub> will probably remain a problem for some time.

### GIVE IT SOME THOUGHT

What chemical behavior associated with sulfur oxides gives rise to acid rain?

## Carbon Monoxide

Carbon monoxide is formed by the incomplete combustion of carbon-containing material, such as fossil fuels. In terms of total mass, CO is the most abundant of all the pollutant gases. The level of CO present in unpolluted air is very low, approximately 0.05 ppm. The estimated total amount of CO in the atmosphere is about  $5.2 \times 10^{14}$  g. In the United States alone, roughly  $1 \times 10^{14}$  g of CO is produced each year, about two-thirds of which comes from automobiles.

Carbon monoxide is a relatively unreactive molecule and consequently poses no direct threat to vegetation or materials. It does affect humans, however. It has the unusual ability to bind very strongly to **hemoglobin**, the iron-containing protein in red blood cells [Figure 18.9(a)◀] that transports oxygen in blood. Hemoglobin consists of four protein chains held together by weak intermolecular forces in a cluster [Figure 18.9(b)]. Each protein chain has a heme molecule within its folds. A schematic structure of heme is shown in Figure 18.9(c). Note that iron is situated in the center of a plane of four nitrogen atoms. A hemoglobin molecule in the lungs picks up an O<sub>2</sub> molecule, which reacts with the iron atom to form a species called *oxyhemoglobin*, abbreviated as HbO<sub>2</sub>.

▲ **Figure 18.9 Hemoglobin binds O<sub>2</sub> and CO.** Red blood cells (a) contain hemoglobin (b). The hemoglobin contains four heme units, each of which can bind an O<sub>2</sub> molecule (c). When exposed to CO, the heme binds CO in preference to O<sub>2</sub>.

As the blood circulates, the oxygen molecule is released in tissues as needed for cell metabolism, that is, for the chemical processes occurring in the cell. [∞ \(Section 17.2, “Chemistry and Life: Blood as a Buffered Solution”\)](#)

Like  $O_2$ , CO also binds very strongly to the iron in hemoglobin. The complex is called *carboxyhemoglobin* and is represented as COHb. The equilibrium binding constant of human hemoglobin for CO is about 210 times greater than that for  $O_2$ . As a result, a relatively small quantity of CO can inactivate a substantial fraction of the hemoglobin in the blood for oxygen transport. For example, a person breathing air that contains only 0.1% of CO takes in enough CO after a few hours of breathing to convert up to 60% of the hemoglobin into COHb, thereby reducing the blood’s normal oxygen-carrying capacity by 60%.

Under normal conditions a nonsmoker breathing unpolluted air has about 0.3 to 0.5% COHb in the bloodstream. This amount arises mainly from the production of small quantities of CO in the course of normal body chemistry and from the small amount of CO present in clean air. Exposure to higher concentrations of CO causes the COHb level to increase, which in turn leaves fewer Hb sites to which  $O_2$  can bind. If the level of COHb becomes too high, oxygen transport is effectively shut down and death occurs. Because CO is colorless and odorless, CO poisoning occurs with very little warning. Improperly ventilated combustion devices, such as kerosene lanterns and stoves, thus pose a potential health hazard (Figure 18.10 ▶).

▲ **Figure 18.10 Carbon monoxide warnings.** Kerosene lamps and stoves have warning labels concerning use in enclosed spaces, such as an indoor room. Incomplete combustion can produce colorless, odorless carbon monoxide, CO, which is toxic.

## Nitrogen Oxides and Photochemical Smog

Nitrogen oxides are primary components of smog, a phenomenon with which city dwellers are all too familiar. The term *smog* refers to a particularly unpleasant condition of pollution in certain urban environments that occurs when weather conditions produce a relatively stagnant air mass. The smog made famous by Los Angeles, but now common in many other urban areas as well, is more accurately described as **photochemical smog** because photochemical processes play a major role in its formation (Figure 18.11 ▶).

The majority of nitrogen oxide emissions (about 50%) comes from cars, buses, and other forms of transportation. Nitric oxide, NO, forms in small quantities in the cylinders of internal combustion engines by the direct combination of nitrogen and oxygen:

As noted in the “Chemistry Put to Work” box in Section 15.7, the equilibrium constant  $K$  for this reaction increases from about  $10^{-15}$  at 300 K (near room temperature) to about 0.05 at 2400 K (approximately the temperature in the cylinder of an engine during combustion). Thus, the reaction is more favorable at higher temperatures. In fact, some NO is formed in any high-temperature combustion. As a result, electrical power plants are also major contributors to nitrogen oxide pollution.

Before the installation of pollution-control devices on automobiles, typical emission levels of  $NO_x$  were 4 grams per mile (g/mi). (The  $x$  is either 1 or 2 because both NO and  $NO_2$  are formed, although NO predominates.) Starting in 2004, the auto emission standards for  $NO_x$  call for a phased-in reduction to 0.07 g/mi by 2009. Table 18.5 ▶ summarizes the federal standards for hydrocarbons and  $NO_x$  emissions since 1975 as well as the more restrictive standards enforced in California.

In air, nitric oxide (NO) is rapidly oxidized to nitrogen dioxide ( $NO_2$ ):

▲ **Figure 18.11 Photochemical smog.** Smog is produced largely by the action of sunlight on automobile exhaust gases.

**TABLE 18.5** ■ National Tailpipe Emission Standards\*

Year	Hydrocarbons (g/mi)	Nitrogen Oxides (g/mi)
1975	1.5 (0.9)	3.1 (2.0)
1980	0.41 (0.41)	2.0 (1.0)
1985	0.41 (0.41)	1.0 (0.4)
1990	0.41 (0.41)	1.0 (0.4)
1995	0.41 (0.25)	0.4 (0.4)
2004	0.075 (0.05)	0.07 (0.05)

\*California standards in parentheses

The equilibrium constant for this reaction decreases from about  $10^{12}$  at 300 K to about  $10^{-5}$  at 2400 K. The photodissociation of  $\text{NO}_2$  initiates the reactions associated with photochemical smog. The dissociation of  $\text{NO}_2$  into NO and O requires 304 kJ/mol, which corresponds to a photon wavelength of 393 nm. In sunlight, therefore,  $\text{NO}_2$  undergoes dissociation to NO and O:

The atomic oxygen formed undergoes several possible reactions, one of which gives ozone, as described earlier:

Ozone is a key component of photochemical smog. Although it is an essential UV screen in the upper atmosphere, ozone is an undesirable pollutant in the troposphere. It is extremely reactive and toxic, and breathing air that contains appreciable amounts of ozone can be especially dangerous for asthma sufferers, exercisers, and the elderly. We therefore have two ozone problems: excessive amounts in many urban environments, where it is harmful, and depletion in the stratosphere, where it is vital.

In addition to nitrogen oxides and carbon monoxide, an automobile engine also emits unburned *hydrocarbons* as pollutants. These organic compounds, which are composed entirely of carbon and hydrogen, are the principal components of gasoline (Section 25.3) and are major ingredients of smog. A typical engine without effective emission controls emits about 10 to 15 grams of these compounds per mile. Current standards require that hydrocarbon emissions be less than 0.075 grams per mile. Hydrocarbons are also emitted naturally from living organisms (see “A Closer Look” box later in this section).

Reduction or elimination of smog requires that the essential ingredients for its formation be removed from automobile exhaust. Catalytic converters are designed to drastically reduce the levels of  $\text{NO}_x$  and hydrocarbons, two of the major ingredients of smog.  (Section 14.7, “Chemistry Put to Work: Catalytic Converters”)

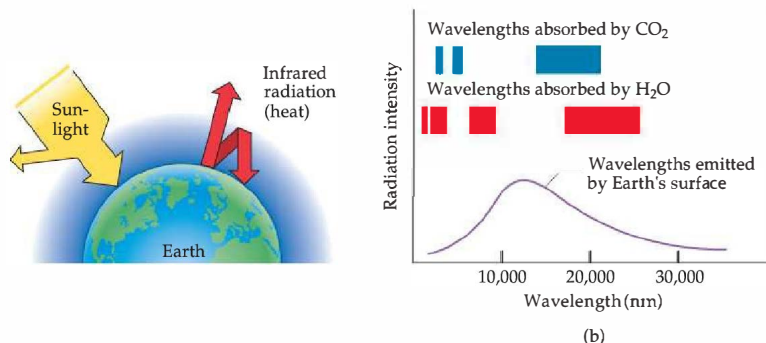

### GIVE IT SOME THOUGHT

What photochemical reaction involving nitrogen oxides initiates the formation of photochemical smog?

## Water Vapor, Carbon Dioxide, and Climate

We have seen how the atmosphere makes life as we know it possible on Earth by screening out harmful short-wavelength radiation. In addition, the atmosphere is essential in maintaining a reasonably uniform and moderate temperature on the surface of the planet. The two atmospheric components of greatest importance in maintaining Earth's surface temperature are carbon dioxide and water. Without them, the average surface temperature of Earth would be 254 K, a temperature too low to sustain life.

Earth is in overall thermal balance with its surroundings. This means that Earth radiates energy into space at a rate equal to the rate at which it absorbs energy from the Sun. The Sun has a surface temperature of about 6000 K. As seen from outer space, Earth is relatively cold (254 K). The temperature of an object determines the distribution of wavelengths in the radiation it emits.  (Section 6.2) Why does Earth, viewed from outside its atmosphere, appear so much colder than the temperature we usually experience at its surface? The troposphere is transparent to visible light but not to infrared radiation. Figure 18.12  shows the distribution of radiation from Earth's surface and the wavelengths absorbed by atmospheric water vapor and carbon dioxide. According to the graph, these atmospheric gases absorb much of the outgoing radiation from Earth's surface. In doing so, they help to maintain a livable uniform temperature at the surface by holding in, as it were, the infrared radiation, that we feel as heat.

◀ **Figure 18.12 Why Earth appears so cold from outer space.** (a) Carbon dioxide and water in the atmosphere absorb certain wavelengths of infrared radiation, which helps keep energy from escaping from Earth's surface. (b) The distribution of the wavelengths absorbed by CO<sub>2</sub> and H<sub>2</sub>O compared to the wavelengths emitted by Earth's surface.

The influence of H<sub>2</sub>O, CO<sub>2</sub>, and certain other atmospheric gases on Earth's temperature is called the *greenhouse effect*, because these heat-trapping gases act much like the glass of a greenhouse. Correspondingly, these gases are called *greenhouse gases*.

Water vapor makes the largest contribution to the greenhouse effect. The partial pressure of water vapor in the atmosphere varies greatly from place to place and time to time, but it is generally highest near Earth's surface and drops off very sharply with increased elevation. Because water vapor absorbs infrared radiation so strongly, it plays the major role in maintaining the atmospheric temperature at night, when the surface is emitting radiation into space and not receiving energy from the Sun. In very dry desert climates, where the water-vapor concentration is unusually low, it may be extremely hot during the day but very cold at night. In the absence of an extensive layer of water vapor to absorb and then radiate part of the infrared radiation back to Earth, the surface loses this radiation into space and cools off very rapidly.

Carbon dioxide plays a secondary, but very important, role in maintaining the surface temperature. The worldwide combustion of fossil fuels, principally coal and oil, on a prodigious scale in the modern era has sharply increased the carbon dioxide level of the atmosphere. To get a sense of the amount of CO<sub>2</sub> produced, for example, by the combustion of hydrocarbons and other carbon-containing substances, which are the components of fossil fuels, consider the combustion of butane, C<sub>4</sub>H<sub>10</sub>. Combustion of 1.00 g of C<sub>4</sub>H<sub>10</sub> produces 3.03 g of CO<sub>2</sub>. ↔ (Section 3.6) Similarly, a gallon (3.78 L) of gasoline (density = 0.70 g/mL and approximate composition C<sub>8</sub>H<sub>18</sub>) produces about 8 kg (18 lb) of CO<sub>2</sub>. Combustion of fossil fuels releases about  $2.2 \times 10^{16}$  g (24 billion tons) of CO<sub>2</sub> into the atmosphere annually with the largest quantity coming from transportation vehicles.

Much CO<sub>2</sub> is absorbed into oceans or used by plants in photosynthesis. Nevertheless, we are now generating CO<sub>2</sub> much faster than it is being absorbed or used. Chemists have monitored atmospheric CO<sub>2</sub> concentrations since 1958. Analysis of air trapped in ice cores taken from Antarctica and Greenland makes it possible to determine the atmospheric levels of CO<sub>2</sub> during the past 160,000 years. These measurements reveal that the level of CO<sub>2</sub> remained fairly constant from the last Ice Age, some 10,000 years ago, until roughly the beginning of the Industrial Revolution, about 300 years ago. Since that time, the concentration of CO<sub>2</sub> has increased by about 30% to a current high of about 386 ppm (Figure 18.13 ▶).

▼ **Figure 18.13 Rising CO<sub>2</sub> levels.** The concentration of atmospheric CO<sub>2</sub> has risen more than 15% since the late 1950s. These data were recorded at the Mauna Loa Observatory in Hawaii by monitoring the absorption of infrared radiation. The sawtooth shape of the graph is due to regular seasonal variations in CO<sub>2</sub> concentration for each year.

A consensus is emerging among scientists that this increase in the concentration of  $\text{CO}_2$  in the atmosphere is already perturbing Earth's climate and that it may be responsible for the observed increase in the average global air temperature of  $0.3\text{ }^\circ\text{C}$  to  $0.6\text{ }^\circ\text{C}$  over the past century. Scientists often use the term climate change instead of global warming to refer to this effect, because as the Earth's temperature increases, it affects winds and ocean currents in ways that can cool some areas and warm others.

On the basis of present and expected future rates of fossil-fuel use, the atmospheric  $\text{CO}_2$  level is expected to double from its present level sometime between 2050 and 2100. Computer models predict that this increase will result in an average global temperature increase of  $1\text{ }^\circ\text{C}$  to  $3\text{ }^\circ\text{C}$ . Major changes in global climate could result from a temperature change of this magnitude. Because so many factors go into determining climate, we cannot predict with certainty what changes will occur. Clearly, however, humanity has acquired the potential, by changing the concentration of  $\text{CO}_2$  and other heat-trapping gases in the atmosphere, to substantially alter the climate of the planet.

The global warming threat posed by atmospheric  $\text{CO}_2$  has sparked considerable research into ways of capturing the gas at its largest combustion sources and storing it deep underground or under the seafloor. There is also much interest in developing new ways to use  $\text{CO}_2$  as a chemical feedstock.

### A Closer Look

#### OTHER GREENHOUSE GASES

Although  $\text{CO}_2$  receives most of the attention, other gases in total make an approximately equal contribution to the greenhouse effect. These gases include methane,  $\text{CH}_4$ , the hydrofluorocarbons (HFCs) such as  $\text{CH}_2\text{FCF}_3$ , and the chlorofluorocarbons (CFCs) such as  $\text{CF}_2\text{Cl}_2$ . The HFCs have replaced CFCs in a host of applications including refrigerants and air-conditioner gases. (Section 18.3) Although they do not contribute to the depletion of the ozone layer, HFCs are nevertheless strong greenhouse gases. Their total concentration in the atmosphere is still small (40 parts per trillion), but this amount is increasing about 10% per year. Thus, these substances are becoming increasingly important contributors to the greenhouse effect.

Methane already makes a significant contribution to the greenhouse effect. Each methane molecule has about 25 times the greenhouse effect of a  $\text{CO}_2$  molecule. Studies of atmospheric gas trapped long ago in the Greenland and Antarctic ice sheets show that the concentration of methane in the atmosphere has increased during the industrial age, from preindustrial values in the range of 0.3 to 0.7 ppm to the present value of about 1.8 ppm. The major sources of methane are associated with agriculture and fossil fuel use.

Methane is formed in biological processes that occur in low-oxygen environments. Anaerobic bacteria, which flourish in swamps and landfills, near the roots of rice plants, and in the digestive systems of cows and other ruminant animals, produce methane (Figure 18.14). It also leaks into the atmosphere during natural-gas extraction and transport (see "Chemistry Put to Work" box, Section 10.5). It is estimated that about two-thirds of present-day methane emissions, which are increasing by about 1% per year, are related to human activities.

Methane has a half-life in the atmosphere of about 10 years, whereas  $\text{CO}_2$  is much longer-lived. This might at

first seem a good thing, but there are indirect effects to consider. Some methane is oxidized in the stratosphere, producing water vapor, a powerful greenhouse gas that is otherwise virtually absent from the stratosphere. In the troposphere methane is attacked by reactive species such as OH radicals or nitrogen oxides, eventually producing other greenhouse gases such as  $\text{O}_3$ . It has been estimated that the climate-changing effects of  $\text{CH}_4$  are more than half those of  $\text{CO}_2$ . Given this large contribution, important reductions of the greenhouse effect could be achieved by reducing methane emissions or capturing the emissions for use as a fuel.

▲ **Figure 18.14 Methane production.** Ruminant animals, such as cows and sheep, produce methane in their digestive systems. In Australia sheep and cattle produce about 14% of the country's total greenhouse emissions.

The approximately 115 million tons of CO<sub>2</sub> used annually by the global chemical industry is but a small fraction of the approximately 24 billion tons of annual CO<sub>2</sub> emissions. However, the use of CO<sub>2</sub> as a raw material will probably never be great enough to reduce its atmospheric concentration.

### GIVE IT SOME THOUGHT

Explain why nighttime temperatures remain higher in locations where there is higher humidity.

## 18.5 THE WORLD OCEAN

Water is the most common liquid on Earth. It covers 72% of Earth's surface and is essential to life. Our bodies are about 65% water by mass. Because of extensive hydrogen bonding, water has unusually high melting and boiling points and a high heat capacity. [↔ \(Section 11.2\)](#) Water's highly polar character is responsible for its exceptional ability to dissolve a wide range of ionic and polar-covalent substances. Many reactions occur in water, including reactions in which H<sub>2</sub>O itself is a reactant. Recall, for example, that H<sub>2</sub>O can participate in acid–base reactions as either a proton donor or a proton acceptor. [↔ \(Section 16.3\)](#) In Chapter 20 we will see that H<sub>2</sub>O can also participate in oxidation–reduction reactions as either a donor or an acceptor of electrons. All these properties play a role in our environment.

### Seawater

The vast layer of salty water that covers so much of the planet is connected and is generally constant in composition. For this reason, oceanographers speak of a world ocean rather than of the separate oceans we learn about in geography books. The world ocean is huge. Its volume is  $1.35 \times 10^9 \text{ km}^3$ . Almost all the water on Earth, 97.2%, is in the world ocean. Of the remaining 2.8%, 2.1% is in the form of ice caps and glaciers. All the freshwater—in lakes, rivers, and groundwater—amounts to only 0.6%. Most of the remaining 0.1% is in brackish (salty) water, such as that in the Great Salt Lake in Utah.

Seawater is often referred to as saline water. The **salinity** of seawater is the mass in grams of dry salts present in 1 kg of seawater. In the world ocean the salinity averages about 35. To put it another way, seawater contains about 3.5% dissolved salts by mass. The list of elements present in seawater is very long. Most, however, are present only in very low concentrations. Table 18.6 [▼](#) lists the 11 ionic species that are most abundant in seawater.

The properties of seawater—its salinity, density, and temperature—vary as a function of depth (Figure 18.15 [▼](#)). Sunlight penetrates well only 200 m into the sea; the region between 200 m and 1000 m deep is the “twilight zone,” where visible light is faint. Below 1000 m in depth, the ocean is pitch-black and cold, about 4 °C. The transport of heat, salt, and other chemicals throughout the ocean is influenced by these changes in the physical properties of seawater, and in turn the changes in the way heat and substances are transported affects ocean currents and the global climate.

The sea is so vast that if a substance is present in seawater to the extent of only 1 part per billion (ppb, that is,  $1 \times 10^{-6}$  g per kilogram of water), there is still  $1 \times 10^{12}$  kg of it in the world ocean. Nevertheless, the ocean is rarely used as a source of raw

**TABLE 18.6** ■ Ionic Constituents of Seawater Present in Concentrations Greater than 0.001 g/kg (1 ppm)

Ionic Constituent	g/kg Seawater	Concentration (M)
Chloride, Cl <sup>−</sup>	19.35	0.55
Sodium, Na <sup>+</sup>	10.76	0.47

materials because the cost of extracting the desired substances is too high. Only three substances are obtained from seawater in commercially important amounts: sodium chloride, bromine (from bromide salts), and magnesium (from its salts).

Absorption of  $\text{CO}_2$  by the ocean plays a large role in global climate. Carbon dioxide reacts with water to form carbonic acid,  $\text{H}_2\text{CO}_3 \rightleftharpoons$  (Section 16.6), and so as  $\text{CO}_2$  from the atmosphere is absorbed by the world ocean, the concentration of  $\text{H}_2\text{CO}_3$  in the ocean increases. Most of the carbon in the ocean, however, is in the form of  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$  ions. These ions form a buffer system that maintains the ocean's average pH between 8.0 and 8.3. The buffering capacity of the world ocean is predicted to decrease as the concentration of  $\text{CO}_2$  in the atmosphere increases, because of the increase in  $\text{H}_2\text{CO}_3$  concentration. With less buffering capacity, the carbonate ion can precipitate out as  $\text{CaCO}_3$ , one of the main ingredients in seashells. Thus, both acid–base equilibrium reactions and solubility equilibrium reactions  $\rightleftharpoons$  (Section 17.4) form a complicated web of interactions that tie the ocean to the atmosphere and to the global climate.

## Desalination

Because of its high salt content, seawater is unfit for human consumption and for most of the uses to which we put water. In the United States the salt content of municipal water supplies is restricted by health codes to no more than about 500 ppm (0.05% by mass). This amount is much lower than the 3.5% dissolved salts present in seawater and the 0.5% or so present in brackish water found underground in some regions. The removal of salts from seawater or brackish water to make the water usable is called **desalination**.

Water can be separated from dissolved salts by *distillation* because water is a volatile substance and the salts are nonvolatile.  $\rightleftharpoons$  (Section 13.5: “A Closer Look: Ideal Solutions with Two or More Volatile Components”) The principle of distillation is simple enough, but carrying out the process on a large scale presents many problems. As water is distilled from seawater, for example, the salts become more and more concentrated and eventually precipitate out.

Seawater can also be desalinated using **reverse osmosis**. Recall that osmosis is the net movement of solvent molecules, but not solute molecules, through a semipermeable membrane.  $\rightleftharpoons$  (Section 13.5) In osmosis the solvent passes from the more dilute solution into the more concentrated one. However, if sufficient external pressure is applied, osmosis can be stopped and, at still higher pressures, reversed. When this occurs, solvent passes from the more concentrated into the more dilute solution. In a modern reverse-osmosis facility tiny

◀ **Figure 18.16 Reverse osmosis.**

(a) A room inside a reverse-osmosis desalination plant. (b) Each cylinder shown in (a) is called a permeator and contains several million tiny hollow fibers. (c) When seawater is introduced under pressure into a permeator, water passes through the fiber wall into the fibers and is thereby separated from all the ions initially present in the seawater.

hollow fibers are used as the semipermeable membrane. Water is introduced under pressure into the fibers, and desalinated water is recovered, as illustrated in Figure 18.16 ▲.

Research and development into improving desalination technologies is ongoing, and already an estimated 11,000 desalination plants exist in some 120 countries around the world. The world's largest desalination plant is located in Jubail, Saudi Arabia. This plant provides 50% of that country's drinking water by using reverse osmosis to desalinate seawater from the Persian Gulf. Such plants are becoming increasingly common in the United States. The largest, near Tampa Bay, Florida, is scheduled to be functional in 2008 and will produce 35 million gallons of drinking water a day by reverse osmosis when fully constructed. Small-scale, manually operated reverse-osmosis desalinators are now also available for use in camping and traveling, and at sea (Figure 18.17 ▶).

## 18.6 FRESHWATER

The United States is fortunate in its abundance of freshwater— $1.7 \times 10^{15}$  liters (660 trillion gallons) is the estimated reserve, which is renewed by rainfall. An estimated  $9 \times 10^{11}$  liters of freshwater is used every day in the United States. Most of this is used for agriculture (41%) and hydroelectric power (39%), with small amounts for industry (6%), household needs (6%), and drinking water (1%). An adult needs about 2 liters of water per day for drinking. In the United States our daily use of water per person far exceeds this subsistence level, amounting to an average of about 300 L/day for personal consumption and hygiene. We use about 8 L/person for cooking and drinking, about 120 L/person for cleaning (bathing, laundering, and housecleaning), 80 L/person for flushing toilets, and 80 L/person for watering lawns.

The total amount of freshwater on Earth is not a very large fraction of the total water present. Indeed, freshwater is one of our most precious resources. It forms by evaporation from the oceans and the land. The water vapor that accumulates in the atmosphere is transported by global atmospheric circulation, eventually returning to Earth as rain, snow, and other forms of precipitation.

▶ **Figure 18.17 A portable desalination device.** This hand-operated water desalinator works by reverse osmosis. It can produce 4.5 L (1.2 gal) of pure water from seawater in an hour.

As rain falls and as water runs off the land on its way to the oceans, it dissolves a variety of cations (mainly  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{Fe}^{2+}$ ), anions (mainly  $\text{Cl}^-$ ,  $\text{SO}_4^{2-}$ , and  $\text{HCO}_3^-$ ), and gases (principally  $\text{O}_2$ ,  $\text{N}_2$ , and  $\text{CO}_2$ ). As we use water, it becomes laden with additional dissolved material, including the wastes of human society. As our population and output of environmental pollutants increase, we find that we must spend ever-increasing amounts of money and resources to guarantee a supply of freshwater.

### Dissolved Oxygen and Water Quality

The amount of dissolved  $\text{O}_2$  in water is an important indicator of water quality. Water fully saturated with air at 1 atm and  $20^\circ\text{C}$  contains about 9 ppm of  $\text{O}_2$ . Oxygen is necessary for fish and most other aquatic life. Cold-water fish require that the water contain at least 5 ppm of dissolved oxygen for survival. Aerobic bacteria consume dissolved oxygen to oxidize organic materials and so meet their energy requirements. The organic material that the bacteria are able to oxidize is said to be **biodegradable**. This oxidation occurs by a complex set of chemical reactions, and the organic material disappears gradually.

Excessive quantities of biodegradable organic materials in water are detrimental because they deplete the water of the oxygen necessary to sustain normal animal life. Typical sources of these biodegradable materials, which are called *oxygen-demanding wastes*, include sewage, industrial wastes from food-processing plants and paper mills, and effluent (liquid waste) from meatpacking plants.

In the presence of oxygen, the carbon, hydrogen, nitrogen, sulfur, and phosphorus in biodegradable material end up mainly as  $\text{CO}_2$ ,  $\text{HCO}_3^-$ ,  $\text{H}_2\text{O}$ ,  $\text{NO}_3^-$ ,  $\text{SO}_4^{2-}$ , and phosphates. The formation of these oxidation products sometimes reduces the amount of dissolved oxygen to the point where aerobic bacteria can no longer survive. Anaerobic bacteria then take over the decomposition process, forming  $\text{CH}_4$ ,  $\text{NH}_3$ ,  $\text{H}_2\text{S}$ ,  $\text{PH}_3$ , and other products, several of which contribute to the offensive odors of some polluted waters.

Plant nutrients, particularly nitrogen and phosphorus, contribute to water pollution by stimulating excessive growth of aquatic plants. The most visible results of excessive plant growth are floating algae and murky water. More significantly, however, as plant growth becomes excessive, the amount of dead and decaying plant matter increases rapidly, a process called *eutrophication* (Figure 18.18 ◀). The decay of plants consumes  $\text{O}_2$  as the plants are biodegraded, leading to the depletion of oxygen in the water. Without sufficient supplies of oxygen, the water, in turn, cannot sustain any form of animal life. The most significant sources of nitrogen and phosphorus compounds in water are domestic sewage (phosphate-containing detergents and nitrogen-containing body wastes), runoff from agricultural land (fertilizers containing both nitrogen and phosphorus), and runoff from livestock areas (animal wastes containing nitrogen).

▲ **Figure 18.18 Eutrophication.**

The growth of algae and duckweed in this pond is due to agricultural wastes. The wastes feed the growth of the algae and weeds, which deplete the oxygen in the water, a process called eutrophication. A eutrophic lake cannot support fish.

### GIVE IT SOME THOUGHT

One common test for water quality involves measuring dissolved oxygen, storing the water in a closed container at a constant temperature for five days, and then remeasuring the dissolved oxygen. If such a test shows a considerable decrease in dissolved oxygen over the five-day period, what can we conclude about the nature of the pollutants present?

### Treatment of Municipal Water Supplies

The water needed for domestic uses, agriculture, and industrial processes is taken either from naturally occurring lakes, rivers, and underground sources or from reservoirs. Much of the water that finds its way into municipal water

▲ Figure 18.19 Common steps in treating water for a public water system.

systems is “used” water: It has already passed through one or more sewage systems or industrial plants. Consequently, this water must be treated before it is distributed to our faucets. Municipal water treatment usually involves five steps: coarse filtration, sedimentation, sand filtration, aeration, and sterilization. Figure 18.19 ▲ shows a typical treatment process.

After coarse filtration through a screen, the water is allowed to stand in large settling tanks in which finely divided sand and other minute particles can settle out. To aid in removing very small particles, the water may first be made slightly basic by adding  $\text{CaO}$ . Then  $\text{Al}_2(\text{SO}_4)_3$  is added. The aluminum sulfate reacts with  $\text{OH}^-$  ions to form a spongy, gelatinous precipitate of  $\text{Al}(\text{OH})_3$  ( $K_{sp} = 1.3 \times 10^{-33}$ ). This precipitate settles slowly, carrying suspended particles down with it, thereby removing nearly all finely divided matter and most bacteria. The water is then filtered through a sand bed. Following filtration, the water may be sprayed into the air to hasten the oxidation of dissolved organic substances.

The final stage of the operation normally involves treating the water with a chemical agent to ensure the destruction of bacteria. Ozone is most effective, but it must be generated at the place where it is used. Chlorine,  $\text{Cl}_2$ , is therefore more convenient. Chlorine can be shipped in tanks as a liquefied gas and dispensed from the tanks through a metering device directly into the water supply. The amount used depends on the presence of other substances with which the chlorine might react and on the concentrations of bacteria and viruses to be removed. The sterilizing action of chlorine is probably due not to  $\text{Cl}_2$  itself, but to hypochlorous acid, which forms when chlorine reacts with water:

As many as a billion people worldwide lack access to clean water. According to the United Nations, 95% of the world’s cities still dump raw sewage into their water supplies. Thus, it should come as no surprise to know that 80% of all the health maladies in developing countries can be traced back to waterborne diseases associated with unsanitary water.

One promising development is a device called the LifeStraw (Figure 18.20 ►). When a person sucks water through the straw, the water first encounters a textile prefilter with a mesh opening of  $100 \mu\text{m}$  followed by a second textile filter with a mesh opening of  $15 \mu\text{m}$ . These filters remove debris and even clusters of bacteria. The water next encounters a chamber of iodine-impregnated beads, where bacteria, viruses, and parasites are killed. Finally, the water passes through granulated active carbon, which removes the smell of iodine as well as the parasites that have not been taken by the prefilter or killed by the iodine.

▲ Figure 18.20 LifeStraw. A LifeStraw is a drinking straw that purifies water as it is drunk.

## A Closer Look WATER SOFTENING

Water containing a relatively high concentration of  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ , and other divalent cations is called **hard water**. Although the presence of these ions is generally not a health threat, they can make water unsuitable for some household and industrial uses. For example, these ions react with soaps to form an insoluble soap scum, the stuff of bathtub rings. In addition, mineral deposits may form when water containing these ions is heated. When water containing calcium ions and bicarbonate ions is heated, some carbon dioxide is driven off. As a result, the solution becomes less acidic and insoluble calcium carbonate forms:

The solid  $\text{CaCO}_3$  coats the surface of hot-water systems and teakettles, thereby reducing heating efficiency. These deposits, called *scale*, can be especially serious in boilers where water is heated under pressure in pipes running through a furnace. Formation of scale reduces the efficiency of heat transfer and reduces the flow of water through pipes (Figure 18.21 ▼).

The removal of the ions that cause hard water is called *water softening*. Not all municipal water supplies require water softening. In those that do, the water is generally taken from underground sources in which it has had considerable contact with limestone,  $\text{CaCO}_3$ , and other minerals containing  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ , and  $\text{Fe}^{2+}$ . The **lime-soda process** is used for

◀ **Figure 18.21 Scale formation.** A section of water pipe that has been coated on the inside with  $\text{CaCO}_3$  and other insoluble salts deposited from hard water.

large-scale municipal water-softening operations. The water is treated with lime,  $\text{CaO}$  [or slaked lime,  $\text{Ca}(\text{OH})_2$ ], and soda ash,  $\text{Na}_2\text{CO}_3$ . These chemicals precipitate  $\text{Ca}^{2+}$  as  $\text{CaCO}_3$  ( $K_{sp} = 4.5 \times 10^{-9}$ ) and  $\text{Mg}^{2+}$  as  $\text{Mg}(\text{OH})_2$  ( $K_{sp} = 1.6 \times 10^{-12}$ ):

**Ion exchange** is a typical household method for water softening. In this procedure the hard water is passed through a bed of an ion-exchange resin: plastic beads with covalently bound anion groups such as  $-\text{COO}^{-}$  or  $-\text{SO}_3^{-}$ . These negatively charged groups have  $\text{Na}^{+}$  ions attached to balance their charges. The  $\text{Ca}^{2+}$  and other cations in the hard water are attracted to the anionic groups and displace the lower-charged  $\text{Na}^{+}$  into the water. Thus, one type of ion is exchanged for another. To maintain charge balance, 2  $\text{Na}^{+}$  enter the water for each  $\text{Ca}^{2+}$  removed. If we represent the resin with its anionic site as  $\text{R}-\text{COO}^{-}$ , we can write the equation for the process as follows:

Water softened in this way contains an increased concentration of  $\text{Na}^{+}$ . Although  $\text{Na}^{+}$  does not form precipitates or cause other problems associated with hard-water cations, individuals concerned about their sodium intake, such as those who have high blood pressure (hypertension), should avoid drinking water softened in this way.

When all the available  $\text{Na}^{+}$  have been displaced from the ion-exchange resin, the resin is regenerated by flushing it with a concentrated solution of  $\text{NaCl}$ . Homeowners can do this by charging their units with large amounts of  $\text{NaCl}(\text{s})$ , which can be purchased at most grocery stores. The high concentration of  $\text{Na}^{+}$  forces the equilibrium shown in the earlier equation to shift to the left, causing the  $\text{Na}^{+}$  to displace the hard-water cations, which are flushed down the drain.

## 18.7 GREEN CHEMISTRY

The planet on which we live is, to a large extent, a closed system, one that exchanges energy but not matter with its environment. If humankind is to thrive in the future, all the processes we carry out should be in balance with Earth's natural processes and physical resources. This goal requires that no toxic materials are released to the environment, that our needs are met with renewable resources, and that we consume the least possible amount of energy. Although the chemical industry is but a small part of human activity, chemical processes are involved in nearly all aspects of modern life. Chemistry is therefore at the heart of efforts to accomplish these goals.

**Green chemistry** is an initiative that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. Some of the major principles that govern green chemistry are the following:

- The potential hazards of substances should be a major consideration in the design of chemical processes. It is better to prevent waste than to treat or clean it up after it has been created.

- The methods employed in synthesizing substances should generate as little waste product as possible.
- Chemical processes should be designed to be as energy efficient as possible, avoiding high temperatures and pressures. Thus, catalysts should be sought that facilitate reactions under mild reaction conditions.
- The raw materials for chemical processes should be renewable whenever technically and economically feasible.

To illustrate how green chemistry works in practice, consider the manufacture of styrene, a very important building block in the formation of many polymers, including the expanded polystyrene packages used to pack eggs and restaurant takeout food. The global demand for styrene is more than 25 million metric tons per year. For many years styrene has been produced in a two-step process. In the first step, benzene and ethylene react in the presence of a solid catalyst, forming ethyl benzene. In the second step, the ethyl benzene is mixed with high temperature steam and passed over an iron oxide catalyst at 625 °C yielding styrene:

This process has several shortcomings. One is that both benzene, which is formed from crude oil, and ethylene, which is formed from natural gas, are high-priced starting materials for a product that should be a low-priced commodity. From an environmental point of view, the high toxicity of benzene and the high energy cost overall for the process are both undesirable.

Researchers at Exelus Inc. have demonstrated a process that bypasses some of these shortcomings. The two-step process is replaced by a one-step process in which toluene is reacted with methanol at 425 °C over a special catalyst:

The new process saves money because toluene and methanol are less expensive than benzene and ethylene, and the reaction conditions require much lower energy input. Additional benefits are that the methanol could be produced from biomass, and that benzene is replaced by less toxic toluene. The hydrogen formed in the reaction can be recycled as a source of energy. This example demonstrates how finding the right catalyst was key in discovering the new process.

Let's consider some other examples in which green chemistry can operate to improve environmental quality.

## Solvents and Reagents

A major area of concern in chemical processes is the use of volatile organic compounds as solvents for reactions. Generally, the solvent in which a reaction is run is not consumed in the reaction, and there are unavoidable releases of solvent into the atmosphere even in the most carefully controlled processes. Further, the solvent may be toxic or may decompose to some extent during the reaction, thus creating waste products. The use of supercritical fluids (Section 11.4: "Chemistry Put to Work: Supercritical Fluid Extraction") represents a way to replace conventional solvents with other reagents. Recall that a supercritical fluid is an unusual state of matter that has properties of both a gas and a liquid. ∞ (Section 11.4) Water and carbon dioxide are the two most popular choices as supercritical fluid solvents. One recently developed industrial process,

for example, replaces chlorofluorocarbon solvents with liquid or supercritical CO<sub>2</sub> in the production of polytetrafluoroethylene ((CF<sub>2</sub>CF<sub>2</sub>)<sub>n</sub>, sold as Teflon®). The chlorofluorocarbon solvents have harmful effects on Earth's ozone layer (Section 18.3). Though CO<sub>2</sub> is a greenhouse gas, no new CO<sub>2</sub> need be manufactured for use as a supercritical fluid solvent.

As a further example, *para*-xylene is oxidized to form terephthalic acid, which in turn is used to make polyethylene terephthalate (PET) plastic and polyester fiber (Section 12.6, Table 12.5):

This commercial process requires pressurization and a relatively high temperature. Oxygen is the oxidizing agent, and acetic acid (CH<sub>3</sub>COOH) is the solvent. An alternative route employs supercritical water as the solvent (Table 11.5) and hydrogen peroxide as the oxidant. This alternative process has several potential advantages, most particularly the elimination of acetic acid as solvent and the use of a different oxidizing agent. Whether it can successfully replace the existing commercial process, however, depends on many factors, which will require further study.

### GIVE IT SOME THOUGHT

We noted earlier that increasing carbon dioxide levels contribute to global warming, which seems like a bad thing, but now we are saying that using carbon dioxide in industrial processes is a good thing for the environment. Explain this seeming contradiction.

### Other Processes

Many processes that are important in modern society use chemicals not found in nature. Let's briefly examine two of these processes, dry cleaning and the coating of automotive bodies to prevent corrosion, and consider alternatives being developed to reduce harmful environmental impacts.

Dry cleaning of clothing typically uses a chlorinated organic solvent such as tetrachloroethylene (Cl<sub>2</sub>C=CCl<sub>2</sub>), which may cause cancer in humans. The widespread use of this and related solvents in dry cleaning, metal cleaning, and other industrial processes has contaminated groundwater in some areas. Alternative dry-cleaning methods that employ liquid CO<sub>2</sub>, along with special cleaning agents, are being successfully commercialized (Figure 18.22 ◀).

The metal bodies of cars are coated extensively during manufacture to prevent corrosion. One of the key steps is the electrodeposition of a layer of metal ions that creates an interface between the vehicle body and the polymeric coatings that serve as the undercoat for painting. In the past, lead was the metal of choice for inclusion in the electrodeposition mixture. Because lead is highly toxic, however, its use in other paints and coatings has been virtually eliminated, and a relatively nontoxic yttrium hydroxide alternative to lead has been developed as an automotive coating (Figure 18.23 ▶). When this coating is subsequently heated, the hydroxide is converted to the oxide, producing an insoluble ceramiclike coating. ⇌ (Section 12.4)

▲ **Figure 18.22 Green chemistry for your clothes.** This dry-cleaning apparatus employs liquid CO<sub>2</sub> as the solvent.

### The Challenges of Water Purification

Access to clean water is essential to the workings of a stable, thriving society. We have seen in the previous section that disinfection of water is an important step in water treatment for human consumption. Water disinfection is one of the greatest

public health innovations in human history. It has dramatically decreased the incidences of waterborne bacterial diseases such as cholera and typhus. But this great benefit comes at a price.

In 1974 scientists in both Europe and the United States discovered that chlorination of water produces a group of by-products that had previously gone undetected. These by-products are called *trihalomethanes* (THMs) because all have a single carbon atom and three halogen atoms:  $\text{CHCl}_3$ ,  $\text{CHCl}_2\text{Br}$ ,  $\text{CHClBr}_2$ , and  $\text{CHBr}_3$ . These and many other chlorine- and bromine-containing organic substances are produced by the reaction of aqueous chlorine with organic materials present in nearly all natural waters, as well as with substances that are by-products of human activity. Recall that chlorine dissolves in water to form  $\text{HClO}$ , which is the active oxidizing agent  $\rightleftharpoons$  (Section 7.8):

$\text{HClO}$  in turn reacts with organic substances to form the THMs. Bromine enters through the reaction of  $\text{HClO}$  with dissolved bromide ion:

$\text{HBrO}(aq)$  halogenates organic substances analogously to  $\text{HClO}(aq)$ .

Some THMs and other halogenated organic substances are suspected carcinogens; others interfere with the body's endocrine system. As a result, the World Health Organization and the Environmental Protection Agency (EPA) have placed concentration limits of  $80 \mu\text{g}/\text{L}$  (80 ppb) on the total quantity of such substances in drinking water. The goal is to reduce the levels of THMs and related substances in the drinking water supply while preserving the antibacterial effectiveness of the water treatment. In some cases simply lowering the concentration of chlorine may provide adequate disinfection while reducing the concentrations of THMs formed. Alternative oxidizing agents, such as ozone ( $\text{O}_3$ ) or chlorine dioxide ( $\text{ClO}_2$ ), produce less of the halogenated substances, but they have their own disadvantages. For example, each is capable of oxidizing aqueous bromide, as shown here for ozone:

As we have seen,  $\text{HBrO}(aq)$  is capable of reacting with dissolved organic substances to form halogenated organic compounds. Furthermore, bromate ion has been shown to cause cancer in animal tests.

There seem to be no completely satisfactory alternatives to chlorination or ozonation at present. The risks of cancer from THMs and related substances in municipal water are very low, however, compared to the risks of cholera, typhus, and gastrointestinal disorders from untreated water. When the water supply is cleaner to begin with, less disinfectant is needed; thus, the danger of contamination through disinfection is reduced. Once the THMs are formed, their concentrations in the water supply can be reduced by aeration because the THMs are more volatile than water. Alternatively, they can be removed by adsorption onto activated charcoal or other adsorbents.

▲ **Figure 18.23 Green chemistry for your car.** An automobile body receives a corrosion-protection coating containing yttrium in place of lead.

**SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

(a) Acids from acid rain or other sources are no threat to lakes in areas where the rock is limestone (calcium carbonate), which can neutralize the excess acid. Where the rock is granite, however, no such neutralization occurs. How does the limestone neutralize the acid? (b) Acidic water can be treated with basic substances to increase the pH, although such a procedure is usually only a temporary cure. Calculate the minimum mass of lime, CaO, needed to adjust the pH of a small lake ( $V = 4 \times 10^9$  L) from 5.0 to 6.5. Why might more lime be needed?

**SOLUTION**

**Analyze:** We need to remember what a neutralization reaction is, and calculate the amount of a substance needed to effect a certain change in pH.

**Plan:** For (a), we need to think about how acid can react with calcium carbonate, which evidently does not happen with acid and granite. For (b), we need to think about what reaction would happen with acid and CaO and do stoichiometric calculations. From the proposed change in pH, we can calculate the change in proton concentration needed and then figure out how much CaO it would take to do the reaction.

**Solve:**

(a) The carbonate ion, which is the anion of a weak acid, is basic.  $\infty$  (Sections 16.2 and 16.7) Thus, the carbonate ion,  $\text{CO}_3^{2-}$ , reacts with  $\text{H}^+(\text{aq})$ . If the concentration of  $\text{H}^+(\text{aq})$  is small, the major product is the bicarbonate ion,  $\text{HCO}_3^-$ . If the concentration of  $\text{H}^+(\text{aq})$  is higher, however,  $\text{H}_2\text{CO}_3$  forms and decomposes to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .  $\infty$  (Section 4.3)

(b) The initial and final concentrations of  $\text{H}^+(\text{aq})$  in the lake are obtained from their pH values:

$$[\text{H}^+]_{\text{initial}} = 10^{-5.0} = 1 \times 10^{-5} \text{ M} \quad \text{and} \quad [\text{H}^+]_{\text{final}} = 10^{-6.5} = 3 \times 10^{-7} \text{ M}$$

Using the volume of the lake, we can calculate the number of moles of  $\text{H}^+(\text{aq})$  at both pH values:

$$(1 \times 10^{-5} \text{ mol/L})(4.0 \times 10^9 \text{ L}) = 4 \times 10^4 \text{ mol}$$

$$(3 \times 10^{-7} \text{ mol/L})(4.0 \times 10^9 \text{ L}) = 1 \times 10^3 \text{ mol}$$

Hence, the change in the amount of  $\text{H}^+(\text{aq})$  is  $4 \times 10^4 \text{ mol} - 1 \times 10^3 \text{ mol} \approx 4 \times 10^4 \text{ mol}$ .

Let's assume that all the acid in the lake is completely ionized, so that only the free  $\text{H}^+(\text{aq})$  measured by the pH needs to be neutralized. We will need to neutralize at least that much acid, although there may be a great deal more acid in the lake than that.

The oxide ion of CaO is very basic.  $\infty$  (Section 16.5) In the neutralization reaction 1 mol of  $\text{O}^{2-}$  reacts with 2 mol of  $\text{H}^+$  to form  $\text{H}_2\text{O}$ . Thus,  $4 \times 10^4 \text{ mol}$  of  $\text{H}^+$  requires the following number of grams of CaO:

$$(4 \times 10^4 \text{ mol H}^+) \left( \frac{1 \text{ mol CaO}}{2 \text{ mol H}^+} \right) \left( \frac{56.1 \text{ g CaO}}{1 \text{ mol CaO}} \right) = 1 \times 10^6 \text{ g CaO}$$

This amounts to slightly more than a ton of CaO. That would not be very costly because CaO is an inexpensive base, selling for less than \$100 per ton when purchased in large quantities. The amount of CaO calculated above, however, is the very minimum amount needed because there are likely to be weak acids in the water that must also be neutralized. This liming procedure has been used to adjust the pH of some small lakes to bring their pH into the range necessary for fish to live. The lake in our example would be about a half mile long, a half mile wide, and have an average depth of 20 ft.

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Sections 18.1 and 18.2** In these sections we examined the physical and chemical properties of Earth's atmosphere. The complex temperature variations in the atmosphere give rise to four regions, each with characteristic properties. The lowest of these regions, the **troposphere**, extends

from Earth's surface up to an altitude of about 12 km. Above the troposphere, in order of increasing altitude, are the **stratosphere**, mesosphere, and thermosphere. In the upper reaches of the atmosphere, only the simplest chemical species can survive the bombardment of highly

energetic particles and radiation from the Sun. The average molecular weight of the atmosphere at high elevations is lower than that at Earth's surface because the lightest atoms and molecules diffuse upward and also because of **photodissociation**, which is the breaking of bonds in molecules because of the absorption of light. Absorption of radiation may also lead to the formation of ions via **photoionization**.

**Section 18.3** Ozone is produced in the upper atmosphere from the reaction of atomic oxygen with  $O_2$ . Ozone is itself decomposed by absorption of a photon or by reaction with an active species such as Cl. **Chlorofluorocarbons** can undergo photodissociation in the stratosphere, introducing atomic chlorine, which is capable of catalytically destroying ozone. A marked reduction in the ozone level in the upper atmosphere would have serious adverse consequences because the ozone layer filters out certain wavelengths of ultraviolet light that are not removed by any other atmospheric component.

**Section 18.4** In the troposphere the chemistry of trace atmospheric components is of major importance. Many of these minor components are pollutants. Sulfur dioxide is one of the more noxious and prevalent examples. It is oxidized in air to form sulfur trioxide, which, upon dissolving in water, forms sulfuric acid. The oxides of sulfur are major contributors to **acid rain**. One method of preventing the escape of  $SO_2$  from industrial operations is to react the  $SO_2$  with CaO to form calcium sulfite ( $CaSO_3$ ).

Carbon monoxide (CO) is found in high concentrations in automobile engine exhaust and in cigarette smoke. CO is a health hazard because it can form a strong bond with **hemoglobin** and thus reduce the capacity for blood to transfer oxygen from the lungs.

**Photochemical smog** is a complex mixture of components in which both nitrogen oxides and ozone play important roles. Smog components are generated mainly in automobile engines, and smog control consists largely of controlling auto emissions.

Carbon dioxide and water vapor are the major components of the atmosphere that strongly absorb infrared radiation.  $CO_2$  and  $H_2O$  are therefore critical in maintaining Earth's temperature. The concentrations of  $CO_2$  and other so-called greenhouse gases in the atmosphere are thus important in determining worldwide climate. Because of the

extensive combustion of fossil fuels (coal, oil, and natural gas), the concentration of carbon dioxide in the atmosphere is steadily increasing.

**Section 18.5** Seawater contains about 3.5% by mass of dissolved salts and is described as having a **salinity** of 35. Seawater's density and salinity vary with depth. Because most of the world's water is in the oceans, humans may eventually look to the seas for freshwater. **Desalination** is the removal of dissolved salts from seawater or brackish water to make it fit for human consumption. Desalination may be accomplished by distillation or by **reverse osmosis**.

**Section 18.6** Freshwater contains many dissolved substances, including dissolved oxygen, which is necessary for fish and other aquatic life. Substances that are decomposed by bacteria are said to be **biodegradable**. Because the oxidation of biodegradable substances by aerobic bacteria consumes dissolved oxygen, these substances are called oxygen-demanding wastes. The presence of an excess amount of oxygen-demanding wastes in water can sufficiently deplete the dissolved oxygen to kill fish and produce offensive odors. Plant nutrients can contribute to the problem by stimulating the growth of plants that become oxygen-demanding wastes when they die.

The water available from freshwater sources may require treatment before it can be used domestically. The several steps generally used in municipal water treatment include coarse filtration, sedimentation, sand filtration, aeration, sterilization, and sometimes water softening. Water softening is required when the water contains ions such as  $Mg^{2+}$  and  $Ca^{2+}$ , which react with soap to form soap scum. Water containing such ions is called **hard water**. The **lime-soda process**, which involves adding CaO and  $Na_2CO_3$  to hard water, is sometimes used for large-scale municipal water softening. Individual homes usually rely on **ion exchange**, a process by which hard-water ions are exchanged for  $Na^+$  ions.

**Section 18.7** The **green chemistry** initiative promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. The areas in which the principles of green chemistry can operate to improve environmental quality include choices of solvents and reagents for chemical reactions, development of alternative processes, and improvements in existing systems and practices.

## KEY SKILLS

- Describe the regions of Earth's atmosphere in terms of how temperature varies with altitude.
- Describe the composition of the atmosphere in terms of the major components in dry air at sea level.
- Calculate concentrations of gases in parts per million (ppm).
- Describe the processes of photodissociation and photoionization and their role in the upper atmosphere.
- Use bond energies and ionization energies to calculate the minimum frequency or maximum wavelength needed to cause photodissociation or photoionization.
- Explain the role of ozone in the upper atmosphere.
- Explain how chlorofluorocarbons (CFCs) are involved in depleting the ozone layer.

- Describe the origins and behavior of sulfur oxides, carbon monoxide, and nitrogen oxides as air pollutants, including the generation of acid rain and photochemical smog.
- Describe how water and carbon dioxide in the atmosphere affect atmospheric temperature via the greenhouse effect.
- Explain what is meant by the salinity of water and describe the process of reverse osmosis as a means of desalination.
- List the major cations, anions, and gases present in natural waters and describe the relationship between dissolved oxygen and water quality.
- List the main steps involved in treating water for domestic uses.
- Describe the main goals of green chemistry.

## VISUALIZING CONCEPTS

- 18.1** At room temperature (298 K) and 1 atm pressure, one mole of an ideal gas occupies 22.4 L. (Section 10.4)
- (a) Looking back at Figure 18.1, do you predict that 1 mole of an ideal gas in the middle of the stratosphere would occupy a greater or smaller volume than 22.4 L?
- (b) Looking at Figure 18.1(a), we see that the temperature is lower at 85 km altitude than at 50 km. Does this mean that one mole of an ideal gas would occupy less volume at 85 km than at 50 km? Explain. [Section 18.1]
- 18.2** Molecules in the upper atmosphere tend to contain double and triple bonds rather than single bonds. Suggest an explanation. [Section 18.2]
- 18.3** Why does ozone concentration in the atmosphere vary as a function of altitude (see Figure 18.4)? [Section 18.3]
- 18.4** You are working with an artist who has been commissioned to make a sculpture for a big city in the eastern United States. The artist is wondering what material to use to make her sculpture, because she has heard that acid rain in the eastern U.S. might destroy it over time. You take samples of granite, marble, bronze, and other materials, and place them outdoors for a long time in the big city. You periodically examine the appearance and measure the mass of the samples. (a) What observations would lead you to conclude that one, or more, of the materials were well-suited for the sculpture? (b) What chemical process (or processes) is (are) the most likely responsible for any observed changes in the materials? [Section 18.4]
- 18.5** How does carbon dioxide interact with the world ocean? [Section 18.5]
- 18.6** The following picture represents an ion-exchange column, in which water containing “hard” ions, such as  $\text{Ca}^{2+}$ , is added to the top of the column, and water containing “soft” ions such as  $\text{Na}^+$  come out the bottom. Explain what is happening in the column. [Section 18.6]

- 18.7** Describe the basic goals of green chemistry. [Section 18.7]
- 18.8** One mystery in environmental science is the imbalance in the “carbon dioxide budget.” Considering only human activities, scientists have estimated that 1.6 billion metric tons of  $\text{CO}_2$  is added to the atmosphere every year because of deforestation (plants use  $\text{CO}_2$ , and fewer plants will leave more  $\text{CO}_2$  in the atmosphere). Another 5.5 billion tons per year is put into the atmosphere because of burning fossil fuels. It is further estimated (again, considering only human activities) that the atmosphere actually takes up about 3.3 billion tons of  $\text{CO}_2$  per year, while the oceans take up 2 billion tons per year, leaving about 1.8 billion tons of  $\text{CO}_2$  per year unaccounted for. This “missing”  $\text{CO}_2$  is assumed to be taken up by the “land.” What do you think might be happening?

## EXERCISES

### Earth's Atmosphere

- 18.9** (a) What is the primary basis for the division of the atmosphere into different regions? (b) Name the regions of the atmosphere, indicating the altitude interval for each one.
- 18.10** (a) How are the boundaries between the regions of the atmosphere determined? (b) Explain why the stratosphere, which is more than 20 miles thick, has a smaller total mass than the troposphere, which is less than 10 miles thick.

- 18.11** Air pollution in the Mexico City metropolitan area is among the worst in the world. The concentration of ozone in Mexico City has been measured at 441 ppb (0.441 ppm). Mexico City sits at an altitude of 7400 feet, which means its atmospheric pressure is only 0.67 atm. Calculate the partial pressure of ozone at 441 ppb if the atmospheric pressure is 0.67 atm.
- 18.12** From the data in Table 18.1, calculate the partial pressures of carbon dioxide and argon when the total atmospheric pressure is 96.5 kPa.
- 18.13** The average concentration of carbon monoxide in air in an Ohio city in 2006 was 3.5 ppm. Calculate the number of CO molecules in 1.0 L of this air at a pressure of 755 torr and a temperature of 18 °C.
- 18.14** (a) From the data in Table 18.1, what is the concentration of neon in the atmosphere in ppm? (b) What is the concentration of neon in the atmosphere in molecules per L, assuming an atmospheric pressure of 733 torr and a temperature of 292 K?

## The Upper Atmosphere; Ozone

- 18.15** The dissociation energy of a carbon–bromine bond is typically about 210 kJ/mol. What is the maximum wavelength of photons that can cause C—Br bond dissociation?
- 18.16** In CF<sub>3</sub>Cl the C—Cl bond-dissociation energy is 339 kJ/mol. In CCl<sub>4</sub> the C—Cl bond-dissociation energy is 293 kJ/mol. What is the range of wavelengths of photons that can cause C—Cl bond rupture in one molecule but not in the other?
- 18.17** (a) Distinguish between *photodissociation* and *photoionization*. (b) Use the energy requirements of these two processes to explain why photodissociation of oxygen is more important than photoionization of oxygen at altitudes below about 90 km.
- 18.18** Why is the photodissociation of N<sub>2</sub> in the atmosphere relatively unimportant compared with the photodissociation of O<sub>2</sub>?
- 18.19** What is a hydrofluorocarbon? Why are these compounds potentially less harmful to the ozone layer than CFCs?
- 18.20** Draw the Lewis structure for the chlorofluorocarbon CFC-11, CFCl<sub>3</sub>. What chemical characteristics of this substance allow it to effectively deplete stratospheric ozone?
- 18.21** (a) Why is the fluorine present in chlorofluorocarbons not a major contributor to depletion of the ozone layer? (b) What are the chemical forms in which chlorine exists in the stratosphere following cleavage of the carbon–chlorine bond?
- 18.22** Would you expect the substance CBrF<sub>3</sub> to be effective in depleting the ozone layer, assuming that it is present in the stratosphere? Explain.

## Chemistry of the Troposphere

- 18.23** For each of the following gases, make a list of known or possible naturally occurring sources: (a) CH<sub>4</sub>, (b) SO<sub>2</sub>, (c) NO, (d) CO.
- 18.24** Why is rainwater naturally acidic, even in the absence of polluting gases such as SO<sub>2</sub>?
- 18.25** (a) Write a chemical equation that describes the attack of acid rain on limestone, CaCO<sub>3</sub>. (b) If a limestone sculpture were treated to form a surface layer of calcium sulfate, would this help to slow down the effects of acid rain? Explain.
- 18.26** The first stage in corrosion of iron upon exposure to air is oxidation to Fe<sup>2+</sup>. (a) Write a balanced chemical equation to show the reaction of iron with oxygen and protons from acid rain. (b) Would you expect the same sort of reaction to occur with a silver surface? Explain.
- 18.27** Alcohol-based fuels for automobiles lead to the production of formaldehyde (CH<sub>2</sub>O) in exhaust gases. Formaldehyde undergoes photodissociation, which contributes to photochemical smog:
- $$\text{CH}_2\text{O} + h\nu \longrightarrow \text{CHO} + \text{H}$$
- The maximum wavelength of light that can cause this reaction is 335 nm. (a) In what part of the electromagnetic spectrum is light with this wavelength found? (b) What is the maximum strength of a bond, in kJ/mol, that can be broken by absorption of a photon of 335-nm light? (c) Compare your answer from part (b) to the appropriate value from Table 8.4. What do you conclude about the C—H bond energy in formaldehyde? (d) Write out the formaldehyde photodissociation reaction, showing Lewis-dot structures.
- 18.28** An important reaction in the formation of photochemical smog is the photodissociation of NO<sub>2</sub>:
- $$\text{NO}_2 + h\nu \longrightarrow \text{NO(g)} + \text{O(g)}$$
- The maximum wavelength of light that can cause this reaction is 420 nm. (a) In what part of the electromagnetic spectrum is light with this wavelength found? (b) What is the maximum strength of a bond, in kJ/mol, that can be broken by absorption of a photon of 420-nm light? (c) Write out the photodissociation reaction showing Lewis-dot structures.
- 18.29** Explain why increasing concentrations of CO<sub>2</sub> in the atmosphere affect the quantity of energy leaving Earth but do not affect the quantity entering from the Sun.
- 18.30** (a) With respect to absorption of radiant energy, what distinguishes a greenhouse gas from a nongreenhouse gas? (b) CH<sub>4</sub> is a greenhouse gas, but Ar is not. How might the molecular structure of CH<sub>4</sub> explain why it is a greenhouse gas?

## The World Ocean

- 18.31** What is the molarity of  $\text{Na}^+$  in a solution of  $\text{NaCl}$  whose salinity is 5.6 if the solution has a density of 1.03 g/mL?
- 18.32** Phosphorus is present in seawater to the extent of 0.07 ppm by mass. If the phosphorus is present as phosphate,  $\text{PO}_4^{3-}$ , calculate the corresponding molar concentration of phosphate in seawater.
- 18.33** A first-stage recovery of magnesium from seawater is precipitation of  $\text{Mg}(\text{OH})_2$  with  $\text{CaO}$ :
- $$\text{Mg}^{2+}(\text{aq}) + \text{CaO}(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{Mg}(\text{OH})_2(\text{s}) + \text{Ca}^{2+}(\text{aq})$$
- What mass of  $\text{CaO}$ , in grams, is needed to precipitate 1000 lb of  $\text{Mg}(\text{OH})_2$ ?
- 18.34** Gold is found in seawater at very low levels, about 0.05 ppb by mass. Assuming that gold is worth about \$800 per troy ounce, how many liters of seawater would you have to process to obtain \$1,000,000 worth of gold?

Assume the density of seawater is 1.03 g/mL and that your gold recovery process is 50% efficient.

- 18.35** Suppose that one wishes to use reverse osmosis to reduce the salt content of brackish water containing 0.22 M total salt concentration to a value of 0.01 M, thus rendering it usable for human consumption. What is the minimum pressure that needs to be applied in the permeators (Figure 18.16) to achieve this goal, assuming that the operation occurs at 298 K? (*Hint:* Refer to Section 13.5.)
- 18.36** Assume that a portable reverse-osmosis apparatus such as that shown in Figure 18.17 operates on seawater, whose concentrations of constituent ions are listed in Table 18.6, and that the desalinated water output has an effective molarity of about 0.02 M. What minimum pressure must be applied by hand pumping at 297 K to cause reverse osmosis to occur? (*Hint:* Refer to Section 13.5.)

## Freshwater

- 18.37** List the common products formed when an organic material containing the elements carbon, hydrogen, oxygen, sulfur, and nitrogen decomposes (a) under aerobic conditions, (b) under anaerobic conditions.
- 18.38** (a) Explain why the concentration of dissolved oxygen in freshwater is an important indicator of the quality of the water. (b) How is the solubility of oxygen in water affected by increasing temperature?
- 18.39** The organic anion

is found in most detergents. Assume that the anion undergoes aerobic decomposition in the following manner:

What is the total mass of  $\text{O}_2$  required to biodegrade 1.0 g of this substance?

- 18.40** The average daily mass of  $\text{O}_2$  taken up by sewage discharged in the United States is 59 g per person. How many liters of water at 9 ppm  $\text{O}_2$  are totally depleted of oxygen in 1 day by a population of 120,000 people?

- 18.41** Write a balanced chemical equation to describe how magnesium ions are removed in water treatment by the addition of slaked lime,  $\text{Ca}(\text{OH})_2$ .
- 18.42** (a) Which of the following ionic species could be, responsible for hardness in a water supply:  $\text{Ca}^{2+}$ ,  $\text{K}^+$ ,  $\text{Mg}^{2+}$ ,  $\text{Fe}^{2+}$ ,  $\text{Na}^+$ ? (b) What properties of an ion determine whether it will contribute to water hardness?

- 18.43** How many moles of  $\text{Ca}(\text{OH})_2$  and  $\text{Na}_2\text{CO}_3$  should be added to soften 1200 L of water in which  $[\text{Ca}^{2+}] = 5.0 \times 10^{-4} \text{ M}$  and  $[\text{HCO}_3^-] = 7.0 \times 10^{-4} \text{ M}$ ?
- 18.44** The concentration of  $\text{Ca}^{2+}$  in a particular water supply is  $5.7 \times 10^{-3} \text{ M}$ . The concentration of bicarbonate ion,  $\text{HCO}_3^-$ , in the same water is  $1.7 \times 10^{-3} \text{ M}$ . What masses of  $\text{Ca}(\text{OH})_2$  and  $\text{Na}_2\text{CO}_3$  must be added to  $5.0 \times 10^7 \text{ L}$  of this water to reduce the level of  $\text{Ca}^{2+}$  to 20% of its original level?

- 18.45** Ferrous sulfate ( $\text{FeSO}_4$ ) is often used as a coagulant in water purification. The iron(II) salt is dissolved in the water to be purified, then oxidized to the iron(III) state by dissolved oxygen, at which time gelatinous  $\text{Fe}(\text{OH})_3$  forms, assuming the pH is above approximately 6. Write balanced chemical equations for the oxidation of  $\text{Fe}^{2+}$  to  $\text{Fe}^{3+}$  by dissolved oxygen, and for the formation of  $\text{Fe}(\text{OH})_3(\text{s})$  by reaction of  $\text{Fe}^{3+}(\text{aq})$  with  $\text{HCO}_3^-(\text{aq})$ .
- 18.46** What properties make a substance a good coagulant for water purification?

## Green Chemistry

- 18.47** One of the principles of green chemistry is that it is better to use as few steps as possible in making new chemicals. How does this principle relate to energy efficiency?

- 18.48** Discuss how catalysts can make processes more energy efficient.

- 18.49 The Baeyer–Villiger reaction is a classic organic oxidation reaction for converting ketones to lactones, as in this reaction:

The reaction is used in the manufacture of plastics and pharmaceuticals. The reactant 3-chloroperbenzoic acid is somewhat shock sensitive, however, and prone to explode. Also, 3-chlorobenzoic acid is a waste product. An alternative process being developed uses hydrogen peroxide and a catalyst consisting of tin deposited within a solid support. The catalyst is readily recovered from the reaction mixture. (a) What would you expect to be the other product of oxidation of the ketone to lactone by hydrogen peroxide? (b) What principles of green chemistry are addressed by use of the proposed process?

## ADDITIONAL EXERCISES

- 18.51 A friend of yours has seen each of the following items in newspaper articles and would like an explanation: (a) acid rain, (b) greenhouse gas, (c) photochemical smog, (d) ozone depletion. Give a brief explanation of each term, and identify one or two of the chemicals associated with each.
- 18.52 Suppose that on another planet the atmosphere consists of 17% Kr, 38% CH<sub>4</sub>, and 45% O<sub>2</sub>. What is the average molar mass at the surface? What is the average molar mass at an altitude at which all the O<sub>2</sub> is photodissociated?
- 18.53 If an average O<sub>3</sub> molecule “lives” only 100–200 seconds in the stratosphere before undergoing dissociation, how can O<sub>3</sub> offer any protection from ultraviolet radiation?
- 18.54 Show how Equations 18.7 and 18.9 can be added to give Equation 18.10. (You may need to multiply one of the reactions by a factor to have them add properly.)
- 18.55 What properties of CFCs make them ideal for various commercial applications but also make them a long-term problem in the stratosphere?
- 18.56 Halons are fluorocarbons that contain bromine, such as CBrF<sub>3</sub>. They are used extensively as foaming agents for fighting fires. Like CFCs, halons are very unreactive and ultimately can diffuse into the stratosphere. (a) Based on the data in Table 8.4, would you expect photodissociation of Br atoms to occur in the stratosphere?

- 18.50 The reaction shown here was performed with an iridium catalyst, both in supercritical CO<sub>2</sub> (scCO<sub>2</sub>) and in the chlorinated solvent CH<sub>2</sub>Cl<sub>2</sub>. The kinetic data for the reaction in both solvents are plotted in the graph. Why is this a good example of a green chemical reaction?

- (b) Propose a mechanism by which the presence of halons in the stratosphere could lead to the depletion of stratospheric ozone.
- 18.57 It is estimated that the lifetime for HFCs in the stratosphere is 2–7 years. If HFCs have such long lifetimes, why are they being used to replace CFCs?
- [18.58] The hydroxyl radical, OH, is formed at low altitudes via the reaction of excited oxygen atoms with water:
- $$\text{O}^*(\text{g}) + \text{H}_2\text{O}(\text{g}) \longrightarrow 2 \text{OH}(\text{g})$$
- (a) Write the Lewis structure for the hydroxyl radical. (Hint: It has one unpaired electron.) Once produced, the hydroxyl radical is very reactive. Explain why each of the following series of reactions affects the pollution in the troposphere:
- (b)  $\text{OH} + \text{NO}_2 \longrightarrow \text{HNO}_3$
- (c)  $\text{OH} + \text{CO} + \text{O}_2 \longrightarrow \text{CO}_2 + \text{OOH}$   
 $\text{OOH} + \text{NO} \longrightarrow \text{OH} + \text{NO}_2$
- (d)  $\text{OH} + \text{CH}_4 \longrightarrow \text{H}_2\text{O} + \text{CH}_3$   
 $\text{CH}_3 + \text{O}_2 \longrightarrow \text{OOCH}_3$   
 $\text{OOCH}_3 + \text{NO} \longrightarrow \text{OCH}_3 + \text{NO}_2$
- 18.59 Explain, using Le Châtelier’s principle, why the equilibrium constant for the formation of NO from N<sub>2</sub> and O<sub>2</sub> increases with increasing temperature, whereas the equilibrium constant for the formation of NO<sub>2</sub> from NO and O<sub>2</sub> decreases with increasing temperature.

- 18.60** The affinity of carbon monoxide for hemoglobin is about 210 times that of  $O_2$ . Assume a person is inhaling air that contains 125 ppm of CO. If all the hemoglobin leaving the lungs carries either oxygen or CO, calculate the fraction in the form of carboxyhemoglobin.
- 18.61** Natural gas consists primarily of methane,  $CH_4(g)$ . (a) Write a balanced chemical equation for the complete combustion of methane to produce  $CO_2(g)$  as the only carbon-containing product. (b) Write a balanced chemical equation for the incomplete combustion of methane to produce CO(g) as the only carbon-containing product. (c) At 25 °C and 1.0 atm pressure, what is the minimum quantity of dry air needed to combust 1.0 L of  $CH_4(g)$  completely to  $CO_2(g)$ ?
- 18.62** One of the possible consequences of global warming is an increase in the temperature of ocean water. The oceans serve as a "sink" for  $CO_2$  by dissolving large amounts of it. (a) How would the solubility of  $CO_2$  in the oceans be affected by an increase in the temperature of the water? (b) Discuss the implications of your answer to part (a) for the problem of global warming.
- 18.63** The rate of solar energy striking Earth averages 169 watts per square meter. The rate of energy radiated from Earth's surface averages 390 watts per square meter. Comparing these numbers, one might expect that the planet would cool quickly, yet it does not. Why not?
- 18.64** The solar power striking Earth every day averages 169 watts per square meter. The peak electrical power usage in New York City is 12,000 megawatts. Considering
- that present technology for solar energy conversion is only about 10% efficient, from how many square meters of land must sunlight be collected in order to provide this peak power? (For comparison, the total area of the city is  $830 \text{ km}^2$ .)
- 18.65** Write balanced chemical equations for each of the following reactions: (a) The nitric oxide molecule undergoes photodissociation in the upper atmosphere. (b) The nitric oxide molecule undergoes photoionization in the upper atmosphere. (c) Nitric oxide undergoes oxidation by ozone in the stratosphere. (d) Nitrogen dioxide dissolves in water to form nitric acid and nitric oxide.
- 18.66** (a) Explain why  $Mg(OH)_2$  precipitates when  $CO_3^{2-}$  ion is added to a solution containing  $Mg^{2+}$ . (b) Will  $Mg(OH)_2$  precipitate when 4.0 g of  $Na_2CO_3$  is added to 1.00 L of a solution containing 125 ppm of  $Mg^{2+}$ ?
- [18.67]** It has been pointed out that there may be increased amounts of NO in the troposphere as compared with the past because of massive use of nitrogen-containing compounds in fertilizers. Assuming that NO can eventually diffuse into the stratosphere, how might it affect the conditions of life on Earth? Using the index to this text, look up the chemistry of nitrogen oxides. What chemical pathways might NO in the troposphere follow?
- [18.68]** As of the writing of this text, EPA standards limit atmospheric ozone levels in urban environments to 84 ppb. How many moles of ozone would there be in the air above Los Angeles County (area about 4000 square miles; consider a height of 10 m above the ground) if ozone was at this concentration?

## INTEGRATIVE EXERCISES

- 18.69** The estimated average concentration of  $NO_2$  in air in the United States in 2006 was 0.016 ppm. (a) Calculate the partial pressure of the  $NO_2$  in a sample of this air when the atmospheric pressure is 755 torr (99.1 kPa). (b) How many molecules of  $NO_2$  are present under these conditions at 20 °C in a room that measures  $15 \times 14 \times 8 \text{ ft}$ ?
- [18.70]** In 1986 an electrical power plant in Taylorsville, Georgia, burned 8,376,726 tons of coal, a national record at that time. (a) Assuming that the coal was 83% carbon and 2.5% sulfur and that combustion was complete, calculate the number of tons of carbon dioxide and sulfur dioxide produced by the plant during the year. (b) If 55% of the  $SO_2$  could be removed by reaction with powdered CaO to form  $CaSO_3$ , how many tons of  $CaSO_3$  would be produced?
- 18.71** The water supply for a midwestern city contains the following impurities: coarse sand, finely divided particulates, nitrate ion, trihalomethanes, dissolved phosphorus in the form of phosphates, potentially harmful bacterial strains, dissolved organic substances. Which of the following processes or agents, if any, is effective in removing each of these impurities: coarse sand filtration, activated carbon filtration, aeration, ozonation, precipitation with aluminum hydroxide?
- 18.72** The concentration of  $H_2O$  in the stratosphere is about 5 ppm. It undergoes photodissociation as follows:
- $$H_2O(g) \longrightarrow H(g) + OH(g)$$
- (a) Write out the Lewis-dot structures for both products and reactant.
- (b) Using Table 8.4, calculate the wavelength required to cause this dissociation.
- (c) The hydroxyl radicals, OH, can react with ozone, giving the following reactions:
- $$OH(g) + O_3(g) \longrightarrow HO_2(g) + O_2(g)$$
- $$HO_2(g) + O(g) \longrightarrow OH(g) + O_2(g)$$
- What overall reaction results from these two elementary reactions? What is the catalyst in the overall reaction? Explain.
- 18.73** Bioremediation is the process by which bacteria repair their environment in response, for example, to an oil spill. The efficiency of bacteria for "eating" hydrocarbons depends on the amount of oxygen in the system, pH, temperature, and many other factors. In a certain oil spill, hydrocarbons from the oil disappeared with a first-order rate constant of  $2 \times 10^{-6} \text{ s}^{-1}$ . How many days did it take for the hydrocarbons to decrease to 10% of their initial value?
- 18.74** The standard enthalpies of formation of ClO and  $ClO_2$  are 101 and 102 kJ/mol, respectively. Using these data and the thermodynamic data in Appendix C, calculate the overall enthalpy change for each step in the following catalytic cycle:
- $$ClO(g) + O_3(g) \longrightarrow ClO_2(g) + O_2(g)$$
- $$ClO_2(g) + O(g) \longrightarrow ClO(g) + O_2(g)$$

What is the enthalpy change for the overall reaction that results from these two steps?

- 18.75** The main reason that distillation is a costly method for purifying water is the high energy required to heat and vaporize water. (a) Using the density, specific heat, and heat of vaporization of water from Appendix B, calculate the amount of energy required to vaporize 1.00 gal of water beginning with water at 20 °C. (b) If the energy is provided by electricity costing \$0.085/kWh, calculate its cost. (c) If distilled water sells in a grocery store for \$1.26 per gal, what percentage of the sales price is represented by the cost of the energy?

- [18.76] A reaction that contributes to the depletion of ozone in the stratosphere is the direct reaction of oxygen atoms with ozone:

At 298 K the rate constant for this reaction is  $4.8 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ . (a) Based on the units of the rate constant, write the likely rate law for this reaction. (b) Would you expect this reaction to occur via a single elementary process? Explain why or why not. (c) From the magnitude of the rate constant, would you expect the activation energy of this reaction to be large or small? Explain. (d) Use  $\Delta H_f^\circ$  values from Appendix C to estimate the enthalpy change for this reaction. Would this reaction raise or lower the temperature of the stratosphere?

- 18.77** Nitrogen dioxide ( $\text{NO}_2$ ) is the only important gaseous species in the lower atmosphere that absorbs visible light. (a) Write the Lewis structure(s) for  $\text{NO}_2$ . (b) How does this structure account for the fact that  $\text{NO}_2$  dimerizes to form  $\text{N}_2\text{O}_4$ ? Based on what you can find about this dimerization reaction in the text, would you expect to find the  $\text{NO}_2$  that forms in an urban environment to be in the form of dimer? Explain. (c) What would you expect as products, if any, for the reaction of  $\text{NO}_2$  with  $\text{CO}$ ? (d) Would you expect  $\text{NO}_2$  generated in an urban environment to migrate to the stratosphere? Explain.

- 18.78** The following data was collected for the destruction of  $\text{O}_3$  by  $\text{H}$  ( $\text{O}_3 + \text{H} \rightarrow \text{O}_2 + \text{OH}$ ) at very low concentrations:

Experiment	$[\text{O}_3], M$	$[\text{H}], M$	Initial Rate, $M/s$
1	$5.17 \times 10^{-33}$	$3.22 \times 10^{-26}$	$1.88 \times 10^{-14}$
2	$2.59 \times 10^{-33}$	$3.25 \times 10^{-26}$	$9.44 \times 10^{-15}$
3	$5.19 \times 10^{-33}$	$6.46 \times 10^{-26}$	$3.77 \times 10^{-14}$

- (a) Write the rate law for the reaction.  
 (b) Calculate the rate constant.

- 18.79** The degradation of  $\text{CF}_3\text{CH}_2\text{F}$  (an HFC) by OH radicals in the troposphere is first order in each reactant and has a rate constant of  $k = 1.6 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$  at 4 °C. If the tropospheric concentrations of OH and  $\text{CF}_3\text{CH}_2\text{F}$  are  $8.1 \times 10^5$  and  $6.3 \times 10^8$  molecules  $\text{cm}^{-3}$ , respectively, what is the rate of reaction at this temperature in  $M/s$ ?

- [18.80] The Henry's law constant for  $\text{CO}_2$  in water at 25 °C is  $3.1 \times 10^{-2} \text{ M atm}^{-1}$ . (a) What is the solubility of  $\text{CO}_2$  in water at this temperature if the solution is in contact with air at normal atmospheric pressure? (b) Assume that all of this  $\text{CO}_2$  is in the form of  $\text{H}_2\text{CO}_3$  produced by the reaction between  $\text{CO}_2$  and  $\text{H}_2\text{O}$ :

What is the pH of this solution?

- [18.81] If the pH of a 1.0-in. rainfall over 1500  $\text{mi}^2$  is 3.5, how many kilograms of  $\text{H}_2\text{SO}_4$  are present, assuming that it is the only acid contributing to the pH?
- [18.82] The precipitation of  $\text{Al}(\text{OH})_3$  ( $K_{sp} = 1.3 \times 10^{-33}$ ) is sometimes used to purify water. (a) Estimate the pH at which precipitation of  $\text{Al}(\text{OH})_3$  will begin if 5.0 lb of  $\text{Al}_2(\text{SO}_4)_3$  is added to 2000 gal of water. (b) Approximately how many pounds of  $\text{CaO}$  must be added to the water to achieve this pH?

# CHAPTER 19

## CHEMICAL THERMODYNAMICS

**THE ORANGE EXTERNAL TANK** under the Space Shuttle holds tanks of hydrogen and oxygen. The reaction of hydrogen and oxygen producing water propels the Space Shuttle into orbit. Once the mixture is ignited, the reaction proceeds spontaneously to completion, generating heat and light. The reverse process, formation of hydrogen and oxygen from water, does not occur of its own accord.

## WHAT'S AHEAD

---

### 19.1 Spontaneous Processes

In this chapter we will see why changes that occur in nature have a directional character. They move *spontaneously* in one direction but not in the reverse direction.

### 19.2 Entropy and the Second Law of Thermodynamics

We will discuss *entropy*, which is a thermodynamic state function that is important in determining whether a process is spontaneous. The *second law of thermodynamics* tells us that in any spontaneous process the entropy of the universe (system plus surroundings) increases.

### 19.3 The Molecular Interpretation of Entropy

On a molecular level, we will see that an entropy increase is associated with an increase in the number of accessible *microstates*. Entropy change can also be thought of as a measure of a system's randomness at a stated temperature. The *third law of thermodynamics* states that the entropy of a perfect crystalline solid at 0 K is zero.

### 19.4 Entropy Changes in Chemical Reactions

Using tabulated *standard molar entropies*, we can calculate the standard entropy changes for systems undergoing reaction.

### 19.5 Gibbs Free Energy

We next encounter another thermodynamic state function, *free energy* (or *Gibbs free energy*), which is a measure of how far removed the system is from equilibrium. Free energy change measures the maximum amount of useful work obtainable from a process and yields information on the direction in which a chemical reaction will proceed spontaneously.

### 19.6 Free Energy and Temperature

We will consider how the relationship among free-energy change, enthalpy change, and entropy change provides insight into how temperature affects the spontaneity of a process.

### 19.7 Free Energy and the Equilibrium Constant

Finally, we will consider how the standard free-energy change for a chemical reaction can be used to calculate the equilibrium constant for the process.

## THE ENERGY REQUIRED TO PROPEL THE SPACE SHUTTLE INTO SPACE

is obtained from two solid-fuel booster rockets and a rocket engine that relies on the combustion of hydrogen and oxygen to form water. The hydrogen and oxygen are stored as liquids at very low temperatures in tanks mounted below the

Space Shuttle. As the hydrogen and oxygen vapors are ignited, they react very rapidly and virtually completely, producing enormous quantities of water vapor and heat. Two of the most important questions chemists ask when designing and using chemical reactions are "How fast is the reaction?" and "How far does it proceed?" The first question is addressed by the study of chemical kinetics, which we discussed in Chapter 14. The second question involves the equilibrium constant, which was the focus of Chapter 15.

In Chapter 14 we learned that the rates of chemical reactions are controlled largely by a factor related to energy, namely the activation energy of the reaction.  $\infty$  (Section 14.5) In general, the lower the activation energy, the faster a reaction proceeds. In Chapter 15 we saw that equilibrium depends on

the rates of the forward and reverse reactions: Equilibrium is reached when the opposing reactions occur at equal rates.  $\infty$  (Section 15.1) Because reaction rates are closely tied to energy, it is logical that equilibrium also depends in some way on energy.

In this chapter we will explore the connection between energy and the extent of a reaction. Doing so requires us to take a deeper look at *chemical thermodynamics*, the area of chemistry that deals with energy relationships. We first encountered thermodynamics in Chapter 5, where we discussed the nature of energy, the first law of thermodynamics, and the concept of enthalpy. Recall that the enthalpy change is the heat transferred between the system and its surroundings during a constant-pressure process.  $\infty$  (Section 5.3)

Now we will see that reactions involve not only changes in enthalpy but also changes in *entropy*—another important thermodynamic quantity. Our discussion of entropy will lead us to the second law of thermodynamics, which provides insight into why physical and chemical changes tend to favor one direction over another. We drop a brick, for example, and it falls to the ground. We do not expect bricks to spontaneously rise from the ground to our outstretched hand. We light a candle, and it burns down. We do not expect a half-consumed candle to regenerate itself spontaneously, even if we have kept all the gases produced when the candle burned. Thermodynamics helps us understand the significance of this directional character of processes, whether they are exothermic or endothermic.

## 19.1 SPONTANEOUS PROCESSES

The first law of thermodynamics states that *energy is conserved*.  $\infty$  (Section 5.2) In other words, energy is neither created nor destroyed in any process, whether it is the falling of a brick, the burning of a candle, or the melting of an ice cube. Energy can be transferred between a system and the surroundings or can be converted from one form to another, but the total energy remains constant. We expressed the first law of thermodynamics mathematically as  $\Delta E = q + w$ , where  $\Delta E$  is the change in the internal energy of a system,  $q$  is the heat absorbed by the system from the surroundings, and  $w$  is the work done on the system by the surroundings.

The first law helps us balance the books, so to speak, on the heat transferred between a system and its surroundings and the work done by a particular process or reaction. But the first law does not address another important feature of reactions—the extent to which they occur. As we noted in the introduction, our experience tells us that physical and chemical processes have a directional character. For instance, sodium metal and chlorine gas combine readily to form sodium chloride, which we also know as table salt. We never find table salt decomposing of its own accord to form sodium and chlorine. (Have you ever smelled chlorine gas in the kitchen or seen sodium metal on your table salt?) In both processes—the formation of sodium chloride from sodium and chlorine and the decomposition of sodium chloride into sodium and chlorine—energy is conserved, as it must be according to the first law of thermodynamics. Yet one process occurs, and the other does not. A process that occurs of its own accord without any ongoing outside intervention is said to be spontaneous. A **spontaneous process** is one that proceeds on its own without any outside assistance.

A spontaneous process occurs in a definite direction. Imagine you were to see a video clip in which a brick rises from the ground. You would conclude that the video is running in reverse—bricks do not magically rise from the ground! A brick falling is a spontaneous process, whereas the reverse process is *nonspontaneous*.

A gas will expand into a vacuum as shown in Figure 19.1  $\blacktriangleleft$ , but the process will never reverse itself. The expansion of the gas is spontaneous. Likewise, a nail left out in the weather will rust (Figure 19.2  $\blacktriangleright$ ). In this process the iron in the nail reacts with oxygen from the air to form an iron oxide. We would never expect the rusty nail to reverse this process and become shiny. The rusting process

**▲ Figure 19.1 Spontaneous expansion of an ideal gas into an evacuated space.** In (a) flask B holds an ideal gas at 1 atm pressure and flask A is evacuated. In (b) the stopcock connecting the flasks has been opened. The ideal gas expands to occupy both flasks A and B at a pressure of 0.5 atm. The reverse process—all the gas molecules moving back into flask B—is not spontaneous.

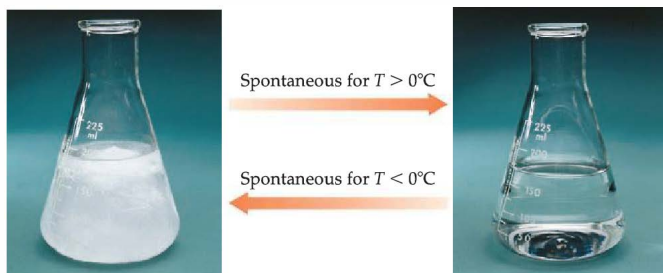

is spontaneous, whereas the reverse process is nonspontaneous. There are countless other examples we could cite that illustrate the same idea: *Processes that are spontaneous in one direction are nonspontaneous in the opposite direction.*

Experimental conditions, such as temperature and pressure, are often important in determining whether a process is spontaneous. Consider, for example, the melting of ice. When the temperature of the surroundings is above  $0\text{ }^{\circ}\text{C}$  at ordinary atmospheric pressures, ice melts spontaneously and the reverse process—liquid water turning into ice—is not spontaneous. However, when the surroundings are below  $0\text{ }^{\circ}\text{C}$ , the opposite is true. Liquid water converts into ice spontaneously, and the conversion of ice into water is *not* spontaneous (Figure 19.3  $\blacktriangledown$ ).

What happens at  $T = 0\text{ }^{\circ}\text{C}$ , the normal melting point of water, when the flask of Figure 19.3 contains both water and ice? At the normal melting point of a substance, the solid and liquid phases are in equilibrium.  $\infty$  (Section 11.5) At this temperature the two phases are interconverting at the same rate and there is no preferred direction for the process.

It is important to realize that the fact that a process is spontaneous does not necessarily mean that it will occur at an observable rate. A chemical reaction is spontaneous if it occurs on its own accord, regardless of its speed. A spontaneous reaction can be very fast, as in the case of acid–base neutralization, or very slow, as in the rusting of iron. Thermodynamics can tell us the *direction* and *extent* of a reaction but tells us nothing about the *speed* of the reaction.

$\blacktriangle$  **Figure 19.3 Spontaneity can depend on the temperature.** At  $T > 0\text{ }^{\circ}\text{C}$  ice melts spontaneously to liquid water. At  $T < 0\text{ }^{\circ}\text{C}$  the reverse process, water freezing to ice, is spontaneous. At  $T = 0\text{ }^{\circ}\text{C}$  the two states are in equilibrium.

Spontaneous  $\rightleftharpoons$  Non-spontaneous

$\blacktriangle$  **Figure 19.2 A spontaneous process.** Elemental iron in the shiny nail in the top photograph spontaneously combines with  $\text{H}_2\text{O}$  and  $\text{O}_2$  in the surrounding air to form a layer of rust— $\text{Fe}_2\text{O}_3$ —on the nail surface.

### SAMPLE EXERCISE 19.1 | Identifying Spontaneous Processes

Predict whether the following processes are spontaneous as described, spontaneous in the reverse direction, or in equilibrium: (a) When a piece of metal heated to  $150\text{ }^{\circ}\text{C}$  is added to water at  $40\text{ }^{\circ}\text{C}$ , the water gets hotter. (b) Water at room temperature decomposes into  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$ , (c) Benzene vapor,  $\text{C}_6\text{H}_6(\text{g})$ , at a pressure of 1 atm condenses to liquid benzene at the normal boiling point of benzene,  $80.1\text{ }^{\circ}\text{C}$ .

#### SOLUTION

**Analyze:** We are asked to judge whether each process will proceed spontaneously in the direction indicated, in the reverse direction, or in neither direction.

**Plan:** We need to think about whether each process is consistent with our experience about the natural direction of events or whether we expect the reverse process to occur.

**Solve:** (a) This process is spontaneous. Whenever two objects at different temperatures are brought into contact, heat is transferred from the hotter object to the colder one. Thus, heat is transferred from the hot metal to the cooler water. The final temperature, after the metal and water achieve the same temperature (thermal equilibrium), will be somewhere between the initial temperatures of the metal and the water. (b) Experience tells us that this process is not spontaneous—we certainly have never seen hydrogen and oxygen gases spontaneously bubbling up out of water! Rather, the

*reverse* process—the reaction of  $\text{H}_2$  and  $\text{O}_2$  to form  $\text{H}_2\text{O}$ —is spontaneous. (c) By definition, the normal boiling point is the temperature at which a vapor at 1 atm is in equilibrium with its liquid. Thus, this is an equilibrium situation. If the temperature were below  $80.1\text{ }^\circ\text{C}$ , condensation would be spontaneous.

#### **PRACTICE EXERCISE**

Under 1 atm pressure  $\text{CO}_2(\text{s})$  sublimates at  $-78\text{ }^\circ\text{C}$ . Is the transformation of  $\text{CO}_2(\text{s})$  to  $\text{CO}_2(\text{g})$  a spontaneous process at  $-100\text{ }^\circ\text{C}$  and 1 atm pressure?

*Answer:* No, the reverse process is spontaneous at this temperature.

## Seeking a Criterion for Spontaneity

A marble rolling down an incline or a brick falling from your hand loses energy. The loss of energy is a common feature of spontaneous change in mechanical systems. During the 1870s Marcellin Bertholet (1827–1907), a famous chemist of that era, suggested that the direction of spontaneous changes in chemical systems was also determined by the loss of energy. He proposed that all spontaneous chemical and physical changes were exothermic. It takes only a few moments, however, to find exceptions to this generalization. For example, the melting of ice at room temperature is spontaneous even though melting is an endothermic process. Similarly, many spontaneous solution processes, such as the dissolving of  $\text{NH}_4\text{NO}_3$ , are endothermic, as we discovered in Section 13.1. We conclude therefore that, although the majority of spontaneous reactions are exothermic, there are spontaneous endothermic ones as well. Clearly, some other factor must be at work in determining the natural direction of processes. What is this factor?

To understand why certain processes are spontaneous, we need to consider more closely the ways in which the state of a system can change. Recall that quantities such as temperature, internal energy, and enthalpy are *state functions*, properties that define a state and do not depend on how we reach that state.  (Section 5.2) The heat transferred between a system and its surroundings,  $q$ , and the work done by or on the system,  $w$ , are *not* state functions. The values of  $q$  and  $w$  depend on the specific path taken from one state to another. One of the keys to understanding spontaneity is distinguishing between reversible and irreversible paths between states.

### **GIVE IT SOME THOUGHT**

If a process is nonspontaneous, does that mean the process cannot occur under any circumstances?

## Reversible and Irreversible Processes

In 1824 a 28-year-old French engineer named Sadi Carnot (1796–1832) published an analysis of the factors that determine how efficiently a steam engine can convert heat to work. Carnot considered what an ideal engine, one with the highest possible efficiency, would be like. He observed that it is impossible to convert the energy content of a fuel completely to work because a significant amount of heat is always lost to the surroundings. Carnot's analysis gave insight into how to build better, more efficient engines, and it was one of the earliest studies in what has developed into the discipline of thermodynamics.

About 40 years later, Rudolph Clausius (1822–1888), a German physicist, extended Carnot's work in an important way. Clausius concluded that a special significance could be ascribed to the ratio of the heat delivered to an ideal engine and the temperature at which it is delivered,  $q/T$ . He was so convinced of the importance of this ratio that he gave it a special name, *entropy*. He deliberately selected the name to sound like energy to emphasize his belief that the importance of entropy was comparable to that of energy.

An ideal engine, one with the maximum efficiency, operates under an ideal set of conditions in which all the processes are reversible. In a **reversible process**, a system is changed in such a way that the system and surroundings can be restored to their original state by *exactly* reversing the change. In other words, we can completely restore the system to its original condition with no net change to either the system or its surroundings. An **irreversible process** is one that cannot simply be reversed to restore the system and its surroundings to their original states. What Carnot discovered is that the amount of work we can extract from any spontaneous process depends on the manner in which the process is carried out. *A reversible change produces the maximum amount of work that can be achieved by the system on the surroundings* ( $w_{rev} = w_{max}$ ).

### GIVE IT SOME THOUGHT

If you evaporate water and then condense it, have you necessarily performed a reversible process?

Let's examine some examples of reversible and irreversible processes. When two objects at different temperatures are in contact, heat will flow spontaneously from the hotter object to the colder one. Because it is impossible to make heat flow in the opposite direction, the flow of heat is irreversible. Given these facts, can we imagine any conditions under which heat transfer can be made reversible? Consider two objects or a system and its surroundings that are at essentially the same temperature, with just an infinitesimal difference (an extremely small temperature difference,  $\Delta T$ ) to make heat flow in the desired direction (Figure 19.4 ▶). We can then reverse the direction of heat flow by making an infinitesimal change of temperature in the opposite direction. *Reversible processes are those that reverse direction whenever an infinitesimal change is made in some property of the system.*

Now consider another example, the expansion of an ideal gas at constant temperature. A constant-temperature process such as this is said to be **isothermal**. To keep the example simple, consider the gas in the cylinder-and-piston arrangement shown in Figure 19.5 ▼. When the partition is removed, the gas expands spontaneously to fill the evacuated space. Because the gas is expanding into a vacuum with no external pressure, it does no  $P$ - $V$  work on the surroundings ( $w = 0$ ). ∞ (Section 5.3) We can use the piston to compress the gas back to its original state, but doing so requires that the surroundings do work on the system ( $w > 0$ ). That is, reversing the process has produced a change in the surroundings as energy is used to do work on the system. The fact that the system and the surroundings are not both returned to their original conditions indicates that the process is irreversible.

▲ **Figure 19.5 An irreversible process.** Restoring the system to its original state after an irreversible process changes the surroundings. In (a) the gas is confined to the right half of the cylinder by a partition. When the partition is removed (b), the gas spontaneously (irreversibly) expands to fill the whole cylinder. No work is done by the system during this expansion. In (c) we can use the piston to compress the gas back to its original state. Doing so requires that the surroundings do work on the system, which changes the surroundings forever.

(a)

(b)

▲ **Figure 19.4 Reversible flow of heat.** Heat can flow reversibly between a system and its surroundings if the two have only an infinitesimally small difference in temperature,  $\Delta T$ . The direction of heat flow can be changed by increasing or decreasing the temperature of the system by  $\Delta T$ . (a) Increasing the temperature of the system by  $\Delta T$  causes heat to flow from the system to the surroundings. (b) Decreasing the temperature of the system by  $\Delta T$  causes heat to flow from the surroundings into the system.

What might a reversible, isothermal expansion of an ideal gas be like? It will occur only if the external pressure acting on the piston exactly balances the pressure exerted by the gas. Under these conditions, the piston will not move unless the external pressure is reduced infinitely slowly, allowing the pressure of the confined gas to readjust to maintain a balance in the two pressures. This gradual, infinitely slow process in which the external pressure and internal pressure are always in equilibrium is reversible. If we reverse the process and compress the gas in the same infinitely slow manner, we can return the gas to its original volume. The complete cycle of expansion and compression in this hypothetical process, moreover, is accomplished without any net change to the surroundings.

Because real processes can at best only approximate the slow, ever-in-equilibrium change associated with reversible processes, all real processes are irreversible. Further, the reverse of any spontaneous process is a nonspontaneous process. A nonspontaneous process can occur only if the surroundings do work on the system. Thus, *any spontaneous process is irreversible*. Even if we return the system to the original condition, the surroundings will have changed.

## 19.2 ENTROPY AND THE SECOND LAW OF THERMODYNAMICS

We are now closer to understanding spontaneity because we know that any spontaneous process is irreversible. But how can we use this idea to make predictions about the spontaneity of an unfamiliar process? Understanding spontaneity requires us to examine the thermodynamic quantity called **entropy**. Entropy has been variously associated with the extent of *randomness* in a system or with the extent to which energy is distributed or dispersed among the various motions of the molecules of the system. In fact, entropy is a multifaceted concept whose interpretations are not so quickly summarized by a simple definition. In this section we consider how we can relate entropy changes to heat transfer and temperature. Our analysis will bring us to a profound statement about spontaneity that we call the second law of thermodynamics. In Section 19.3 we examine the molecular significance of entropy.

### Entropy Change

The entropy,  $S$ , of a system is a state function just like the internal energy,  $E$ , and enthalpy,  $H$ . As with these other quantities, the value of  $S$  is a characteristic of the state of a system. [∞ \(Section 5.2\)](#) Thus, the change in entropy,  $\Delta S$ , in a system depends only on the initial and final states of the system and not on the path taken from one state to the other:

$$\Delta S = S_{\text{final}} - S_{\text{initial}} \quad [19.1]$$

For the special case of an isothermal process,  $\Delta S$  is equal to the heat that would be transferred if the process were reversible,  $q_{\text{rev}}$ , divided by the temperature at which the process occurs:

$$\Delta S = \frac{q_{\text{rev}}}{T} \quad (\text{constant } T) \quad [19.2]$$

Because  $S$  is a state function, we can use Equation 19.2 to calculate  $\Delta S$  for *any* isothermal process, not just those that are reversible. If a change between two states is irreversible, we calculate  $\Delta S$  by using a reversible path between the states.

## GIVE IT SOME THOUGHT

How do we reconcile the fact that  $S$  is a state function but that  $\Delta S$  depends on  $q$ , which is not a state function?

 $\Delta S$  for Phase Changes

The melting of a substance at its melting point and the vaporization of a substance at its boiling point are isothermal processes. Consider the melting of ice. At 1 atm pressure, ice and liquid water are in equilibrium with each other at 0 °C. Imagine that we melt one mole of ice at 0 °C, 1 atm to form one mole of liquid water at 0 °C, 1 atm. We can achieve this change by adding a certain amount of heat to the system from the surroundings:  $q = \Delta H_{\text{fusion}}$ . Now imagine that we carry out the change by adding the heat infinitely slowly, raising the temperature of the surroundings only infinitesimally above 0 °C. When we make the change in this fashion, the process is reversible. We can reverse the process simply by infinitely slowly removing the same amount of heat,  $\Delta H_{\text{fusion}}$ , from the system, using immediate surroundings that are infinitesimally below 0 °C. Thus,  $q_{\text{rev}} = \Delta H_{\text{fusion}}$  and  $T = 0 \text{ °C} = 273 \text{ K}$ .

The enthalpy of fusion for  $\text{H}_2\text{O}$  is  $\Delta H_{\text{fusion}} = 6.01 \text{ kJ/mol}$ . (The melting is an endothermic process, and so the sign of  $\Delta H$  is positive.) Thus, we can use Equation 19.2 to calculate  $\Delta S_{\text{fusion}}$  for melting one mole of ice at 273 K:

$$\Delta S_{\text{fusion}} = \frac{q_{\text{rev}}}{T} = \frac{\Delta H_{\text{fusion}}}{T} = \frac{(1 \text{ mol})(6.01 \times 10^3 \text{ J/mol})}{273 \text{ K}} = 22.0 \frac{\text{J}}{\text{K}}$$

Notice that the units for  $\Delta S$ ,  $\text{J/K}$ , are energy divided by absolute temperature, as we expect from Equation 19.2.

SAMPLE EXERCISE 19.2 | Calculating  $\Delta S$  for a Phase Change

The element mercury, Hg, is a silvery liquid at room temperature. The normal freezing point of mercury is  $-38.9 \text{ °C}$ , and its molar enthalpy of fusion is  $\Delta H_{\text{fusion}} = 2.29 \text{ kJ/mol}$ . What is the entropy change of the system when 50.0 g of  $\text{Hg}(l)$  freezes at the normal freezing point?

## SOLUTION

**Analyze:** We first recognize that freezing is an *exothermic* process; heat is transferred from the system to the surroundings when a liquid freezes ( $q < 0$ ). The enthalpy of fusion is  $\Delta H$  for the melting process. Because freezing is the reverse of melting, the enthalpy change that accompanies the freezing of 1 mol of Hg is  $-\Delta H_{\text{fusion}} = -2.29 \text{ kJ/mol}$ .

**Plan:** We can use  $-\Delta H_{\text{fusion}}$  and the atomic weight of Hg to calculate  $q$  for freezing 50.0 g of Hg:

$$q = (50.0 \text{ g Hg}) \left( \frac{1 \text{ mol Hg}}{200.59 \text{ g Hg}} \right) \left( \frac{-2.29 \text{ kJ}}{1 \text{ mol Hg}} \right) \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) = -571 \text{ J}$$

We can use this value of  $q$  as  $q_{\text{rev}}$  in Equation 19.2. We must first, however, convert the temperature to K:

$$-38.9 \text{ °C} = (-38.9 + 273.15) \text{ K} = 234.3 \text{ K}$$

**Solve:** We can now calculate the value of  $\Delta S_{\text{sys}}$

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{-571 \text{ J}}{234.3 \text{ K}} = -2.44 \text{ J/K}$$

**Check:** The entropy change is negative because heat flows from the system, making  $q_{\text{rev}}$  negative.

**Comment:** The procedure we have used here can be used to calculate  $\Delta S$  for other isothermal phase changes, such as the vaporization of a liquid at its boiling point.

## PRACTICE EXERCISE

The normal boiling point of ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , is  $78.3 \text{ °C}$ , and its molar enthalpy of vaporization is  $38.56 \text{ kJ/mol}$ . What is the change in entropy in the system when 68.3 g of  $\text{C}_2\text{H}_5\text{OH}(g)$  at 1 atm condenses to liquid at the normal boiling point?

**Answer:**  $-163 \text{ J/K}$

## A Closer Look THE ENTROPY CHANGE WHEN A GAS EXPANDS ISOTHERMALLY

In general, we will see that if a system becomes more spread out, or more random, the system's entropy increases. Thus, we expect the spontaneous expansion of a gas to result in an increase in entropy. To illustrate how the entropy change associated with an expanding gas can be calculated, consider the expansion of an ideal gas that is initially constrained by a piston, as in Figure 19.5(c). If the gas undergoes a reversible isothermal expansion, the work done on the surroundings by the moving piston can be calculated with the aid of calculus:

$$w_{\text{rev}} = -nRT \ln \frac{V_2}{V_1}$$

In this equation,  $n$  is the number of moles of gas,  $R$  is the gas constant,  $T$  is the absolute temperature,  $V_1$  is the initial volume, and  $V_2$  is the final volume. Notice that if  $V_2 > V_1$ , as it must be in our expansion, then  $w_{\text{rev}} < 0$ , meaning that the expanding gas does work on the surroundings.

One of the characteristics of an ideal gas is that its internal energy depends only on temperature, not on pressure. Thus, when an ideal gas expands at a constant temperature,  $\Delta E = 0$ . Because  $\Delta E = q_{\text{rev}} + w_{\text{rev}} = 0$ , we see that

$q_{\text{rev}} = -w_{\text{rev}} = nRT \ln(V_2/V_1)$ . Then, using Equation 19.2, we can calculate the entropy change in the system:

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{nRT \ln \frac{V_2}{V_1}}{T} = nR \ln \frac{V_2}{V_1} \quad [19.3]$$

For 1.00 L of an ideal gas at 1.00 atm and 0 °C, we can calculate the number of moles,  $n = 4.46 \times 10^{-2}$  mol. The gas constant,  $R$ , can be expressed in units of J/mol·K, 8.314 J/mol·K (Table 10.2). Thus, for the expansion of the gas from 1.00 L to 2.00 L, we have

$$\begin{aligned} \Delta S_{\text{sys}} &= (4.46 \times 10^{-2} \text{ mol}) \left( 8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) \left( \ln \frac{2.00 \text{ L}}{1.00 \text{ L}} \right) \\ &= 0.26 \text{ J/K} \end{aligned}$$

In Section 19.3 we will see that this increase in entropy is a measure of the increased randomness of the molecules because of the expansion.

**Related Exercises:** 19.27 and 19.28

## The Second Law of Thermodynamics

The key idea of the first law of thermodynamics is that energy is conserved in any process. Thus, the quantity of energy lost by a system equals the quantity gained by its surroundings.  $\infty$  (Section 5.1) We will see, however, that entropy is different because it actually increases in any spontaneous process. Thus, the sum of the entropy change of the system and surroundings for any spontaneous process is always greater than zero. Entropy change is like a signpost indicating whether a process is spontaneous. Let's illustrate this generalization by again considering the melting of ice, designating the ice and water as our system.

Let's calculate the entropy change of the system and the entropy change of the surroundings when a mole of ice (a piece roughly the size of an ordinary ice cube) melts in the palm of your hand. The process is not reversible because the system and surroundings are at different temperatures. Nevertheless, because  $\Delta S$  is a state function, the entropy change of the system is the same regardless of whether the process is reversible or irreversible. We calculated the entropy change of the system just before Sample Exercise 19.2:

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{(1 \text{ mol})(6.01 \times 10^3 \text{ J/mol})}{273 \text{ K}} = 22.0 \frac{\text{J}}{\text{K}}$$

The surroundings immediately in contact with the ice are your hand, which we will assume is at body temperature, 37 °C = 310 K. The heat lost by your hand is equal in magnitude to the heat gained by the ice but has the opposite sign,  $-6.01 \times 10^3$  J/mol. Hence the entropy change of the surroundings is

$$\Delta S_{\text{surr}} = \frac{q_{\text{rev}}}{T} = \frac{(1 \text{ mol})(-6.01 \times 10^3 \text{ J/mol})}{310 \text{ K}} = -19.4 \frac{\text{J}}{\text{K}}$$

Thus, the total entropy change is positive:

$$\Delta S_{\text{total}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = \left( 22.0 \frac{\text{J}}{\text{K}} \right) + \left( -19.4 \frac{\text{J}}{\text{K}} \right) = 2.6 \frac{\text{J}}{\text{K}}$$

If the temperature of the surroundings were not 310 K but rather some temperature infinitesimally above 273 K, the melting would be reversible instead of irreversible. In that case the entropy change of the surroundings would equal  $-22.0 \text{ J/K}$  and  $\Delta S_{\text{total}}$  would be zero.

In general, any irreversible process results in an overall increase in entropy, whereas a reversible process results in no overall change in entropy. This general statement is known as the **second law of thermodynamics**. The sum of the entropy of a system plus the entropy of the surroundings is everything there is, and so we refer to the total entropy change as the entropy change of the universe,  $\Delta S_{\text{univ}}$ . We can therefore state the second law of thermodynamics in terms of the following equations:

$$\begin{aligned} \text{Reversible process: } \quad \Delta S_{\text{univ}} &= \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0 \\ \text{Irreversible process: } \quad \Delta S_{\text{univ}} &= \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0 \end{aligned} \quad [19.4]$$

All real processes that occur of their own accord are irreversible (with reversible processes being a useful idealization). These processes are also spontaneous. Thus, *the total entropy of the universe increases in any spontaneous process*. This profound generalization is yet another way of expressing the second law of thermodynamics.

### GIVE IT SOME THOUGHT

The rusting of iron is accompanied by a decrease in the entropy of the system (the iron and oxygen). What can we conclude about the entropy change of the surroundings?

The second law of thermodynamics tells us the essential character of any spontaneous change—it is always accompanied by an overall increase in entropy. We can, in fact, use this criterion to predict whether processes will be spontaneous. Before beginning to use the second law to predict spontaneity, however, we will find it useful to explore further the meaning of entropy from a molecular perspective.

Throughout most of the remainder of this chapter, we will focus mainly on the systems we encounter rather than on their surroundings. To simplify the notation, we will usually refer to the entropy change of the system merely as  $\Delta S$  rather than explicitly indicating  $\Delta S_{\text{sys}}$ .

## 19.3 THE MOLECULAR INTERPRETATION OF ENTROPY

As chemists, we are interested in molecules. What does entropy have to do with them and their transformations? What molecular property does entropy reflect? Ludwig Boltzmann (1844–1906) gave conceptual meaning to entropy. To understand Boltzmann's contribution, we need to examine the ways in which molecules can store energy.

### Molecular Motions and Energy

When a substance is heated, the motion of its molecules increases. When we studied the kinetic-molecular theory of gases, we found that the average kinetic energy of the molecules of an ideal gas is directly proportional to the absolute temperature of the gas.  $\infty$  (Section 10.7) That means the higher the temperature, the faster the molecules are moving and the more kinetic energy they possess. Moreover, hotter systems have a *broader distribution* of molecular speeds, as you can see by referring back to Figure 10.18. The particles of an ideal gas, however, are merely idealized points with no volume and no bonds, points that we visualize as flitting around through space. Real molecules can undergo more complex kinds of motions.

▲ **Figure 19.6 Vibrational and rotational motions in a water molecule.** Vibrational motions in the molecule involve periodic displacements of the atoms with respect to one another. Rotational motions involve the spinning of a molecule about an axis.

Molecules can undergo three kinds of motion. The entire molecule can move in one direction, as in the motions of the particles of an ideal gas or the motions of larger objects, such as a baseball being thrown around a baseball field. We call such movement **translational motion**. The molecules in a gas have more freedom of translational motion than those in a liquid, which in turn have more translational freedom than the molecules of a solid.

A molecule may also undergo **vibrational motion**, in which the atoms in the molecule move periodically toward and away from one another, much as a tuning fork vibrates about its equilibrium shape. In addition, molecules may possess **rotational motion**, as though they were spinning like tops. Figure 19.6▲ shows the vibrational motions and one of the rotational motions possible for the water molecule. These different forms of motion are ways in which a molecule can store energy, and we refer to the various forms collectively as the “motional energy” of the molecule.

### GIVE IT SOME THOUGHT

What kinds of motion can a molecule undergo that a single atom cannot?

## Boltzmann’s Equation and Microstates

The science of thermodynamics developed as a means of describing the properties of matter in our macroscopic world without regard to the microscopic structure of the matter. In fact, thermodynamics was a well-developed field before the modern views of atomic and molecular structure were even known. The thermodynamic properties of water, for example, addressed the behavior of bulk water (or ice or water vapor) as a substance, without considering any specific properties of individual  $\text{H}_2\text{O}$  molecules.

To connect the microscopic and macroscopic descriptions of matter, scientists have developed the field of *statistical thermodynamics*, which uses the tools of statistics and probability to provide the link between the microscopic and macroscopic worlds. Here we will show how entropy, which is a property of bulk matter, can be connected to the behavior of atoms and molecules. Because the mathematics of statistical thermodynamics is quite complex, our discussion will be largely conceptual.

Let’s begin by considering one mole of an ideal gas in a particular thermodynamic state, which we can define by specifying the temperature,  $T$ , and volume,  $V$ , of the gas. (Remember that the energy,  $E$ , of an ideal gas depends only on its temperature and that by fixing the values of  $n$ ,  $T$ , and  $V$ , we also fix the value of the pressure,  $P$ .) What is happening to our ideal gas sample at the microscopic level, and how does what is going on at the microscopic level relate to the entropy of the sample? To address these questions, we need to consider both the positions of the gas molecules and their individual kinetic energies, which depend on the speeds of the molecules. In our discussion of the kinetic-molecular theory, we considered the gas molecules to be in constant motion within the entire volume of the container. We also saw that the speeds of the gas molecules follow a well-defined distribution at a given temperature, such as that shown in Figure 10.18. ⇐ (Section 10.7)

Now imagine that we could take a “snapshot” of the positions and speeds of all of the molecules at a given instant. That particular set of  $6 \times 10^{23}$  positions and energies of the individual gas molecules is what we call a **microstate** of the thermodynamic system. A microstate is a single possible arrangement of the positions and kinetic energies of the gas molecules when the gas is in a specific thermodynamic state. We could envision continuing to take snapshots of our system to see other possible microstates. In fact, as you no doubt see, there would be such a staggeringly large number of microstates that taking individual snapshots of all of them is not feasible. Because we are examining such a large number of particles, however, we can use the tools of statistics and probability to determine the total number of microstates for the thermodynamic state. (That is where the *statistical* part of statistical thermodynamics comes in.) Each thermodynamic state has a characteristic number of microstates associated with it, and we will use the symbol  $W$  for that number.

The connection between the number of microstates of a system,  $W$ , and its entropy,  $S$ , is expressed in a beautifully simple equation developed by Boltzmann:

$$S = k \ln W \quad [19.5]$$

In this equation,  $k$  is Boltzmann’s constant,  $1.38 \times 10^{-23}$  J/K. Thus, *entropy is a measure of how many microstates are associated with a particular macroscopic state.* Equation 19.5 appears on Boltzmann’s gravestone (Figure 19.7 ▶).

▲ **Figure 19.7 Ludwig Boltzmann’s gravestone.** Boltzmann’s gravestone in Vienna is inscribed with his famous relationship between the entropy of a state and the number of available microstates. (In Boltzmann’s time, “log” was used to represent the natural logarithm.)

### GIVE IT SOME THOUGHT

What is the entropy of a system that has only a single microstate?

The entropy change accompanying any process is

$$\Delta S = k \ln W_{\text{final}} - k \ln W_{\text{initial}} = k \ln \frac{W_{\text{final}}}{W_{\text{initial}}} \quad [19.6]$$

Thus, any change in the system that leads to an increase in the number of microstates leads to a positive value of  $\Delta S$ : *Entropy increases with the number of microstates of the system.*

Let’s briefly consider two simple changes to our ideal-gas sample and see how the entropy changes in each case. First, suppose we increase the volume of the system, which is analogous to allowing the gas to expand isothermally. A greater volume means that there are a greater number of positions available to the gas atoms. Thus, there will be a greater number of microstates for the system after the increase in volume. The entropy therefore increases as the volume increases, as we saw in the “A Closer Look” box in Section 19.2. Second, suppose we keep the volume fixed but increase the temperature. How will this change affect the entropy of the system? Recall the distribution of molecular speeds presented in Figure 10.18. An increase in temperature increases the average (rms) speed of the molecules and broadens the distribution of speeds. Hence, the molecules have a greater number of possible kinetic energies, and the number of microstates will once again increase. The entropy of the system will therefore increase with increasing temperature.

If we consider real molecules instead of ideal-gas particles, we must also consider the different amounts of vibrational and rotational energies the molecules have in addition to their kinetic energies. A collection of real molecules therefore has a greater number of microstates available than does the same number of ideal-gas particles. In general, *the number of microstates available to a system increases with an increase in volume, an increase in temperature, or an increase in the number of molecules because any of these changes increases the possible positions and energies of the molecules of the system.*

## A Closer Look

### ENTROPY AND PROBABILITY

The game of poker is sometimes used as an analogy to explore the idea of the microstates associated with a particular state. There are about 2.6 million different five-card poker hands that can be dealt, and each of these hands can be viewed as a possible “microstate” for the hand dealt to any one player in a game. Table 19.1 ▼ shows two poker hands. The probability that a particular hand will contain five *specific* cards is the same regardless of which five cards are specified. Thus, there is an equal probability of dealing either of the hands shown in Table 19.1. However, the first hand, a royal flush (the ten through ace of a single suit), strikes us as much more highly ordered than the second hand, a “nothing.” The reason for this is clear if we compare the number of five-card arrangements that correspond to a royal flush to the number corresponding to a nothing: only four hands (microstates) for a royal flush but more than 1.3 million for a nothing hand. The nothing state has a higher probability of being dealt from a shuffled deck than the royal-flush state because there are so many more arrangements of cards that correspond to the nothing state. In other words, the value of  $W$  in Boltzmann’s equation (Equation 19.5) is much greater for a nothing than for a royal flush. This example teaches us that there is a connection between probability and entropy.

The entropy of any system has a natural tendency to increase, because increased entropy represents a movement toward a state of higher probability. Let’s use this reasoning to explain the isothermal expansion of a gas,

such as that depicted in Figure 19.1. When the stopcock is opened, the gas molecules are less constrained, and there are more possible arrangements for them (more microstates) in the larger volume. The various microstates are depicted in a schematic way in Figure 19.8 ▼. In this figure, we make no attempt to describe the motion of the particles, focusing instead only on their locations. The spreading of the molecules over the larger volume represents movement to the more probable state.

When we use the terms randomness and disorder to describe entropy, we have to be careful not to carry an aesthetic sense of what we mean. What we must remember is that the fundamental connection to entropy is not tied directly with randomness, disorder, or energy dispersal, but with the number of available microstates.

▲ **Figure 19.8** Probability and the locations of gas molecules. The two molecules are colored red and blue to keep track of them. (a) Before the stopcock is opened, both molecules are in the right-hand flask. (b) After the stopcock is opened, there are four possible arrangements of the two molecules. Only one of the four arrangements corresponds to both molecules being in the right-hand flask. The greater number of possible arrangements corresponds to greater disorder in the system. In general, the probability that the molecules will stay in the original flask is  $(\frac{1}{2})^n$ , where  $n$  is the number of molecules.

**TABLE 19.1** ■ A Comparison of the Number of Combinations that Can Lead to a Royal Flush and to a “Nothing” Hand in Poker

Hand	State	Number of Hands that Lead to This State
	Royal flush	4
	“Nothing”	1,302,540

Chemists use several different ways to describe an increase in the number of microstates and therefore an increase in the entropy for a system. Each of these ways seeks to capture a sense of the increased freedom of motion that causes molecules to spread out if not restrained by physical barriers or chemical bonds.

Some say the increase in entropy represents an increase in the *randomness* or *disorder* of the system. Others liken an increase in entropy to an increased *dispersion* (*spreading out*) of energy because there is an increase in the number of ways the positions and energies of the molecules can be distributed throughout the system. Each of these descriptions (randomness, disorder, and energy dispersal) is conceptually helpful if applied correctly. Indeed, you will find it useful to keep these descriptions in mind as you evaluate entropy changes.

### Making Qualitative Predictions About $\Delta S$

It is usually not difficult to construct a mental picture to estimate qualitatively how the entropy of a system changes during a simple process. In most instances, an increase in the number of microstates, and hence an increase in entropy, parallels an increase in

1. temperature
2. volume
3. number of independently moving particles

Thus, we can usually make qualitative predictions about entropy changes by focusing on these factors. For example, when water vaporizes, the molecules spread out into a larger volume. Because they occupy a larger space, there is an increase in their freedom of motion, giving rise to more accessible microstates and hence to an increase in entropy.

Consider the melting of ice. The rigid structure of the water molecules, shown in Figure 19.9 ▲, restricts motion to only tiny vibrations throughout the crystal. In contrast, the molecules in liquid water are free to move about with respect to one another (translation) and to tumble around (rotation) as well as vibrate. During melting, therefore, the number of accessible microstates increases and so does the entropy.

When an ionic solid, such as KCl, dissolves in water, a mixture of water and ions replaces the pure solid and pure water (Figure 19.10 ▼). The ions now move in a larger volume and possess more motional energy than in the rigid solid. We have to be careful, however, because water molecules are held around the ions as water of hydration. ∞(Section 13.1) These water molecules have less motional energy than before because they are now confined to the immediate environment of the ions. The greater the charge of an ion, the greater are the ion–dipole attractions that hold the ion and the water together, thereby restricting motions. Thus, even though the solution process is normally accompanied by a net increase in entropy, the dissolving of salts with highly charged ions can result in a net *decrease* in entropy.

▲ **Figure 19.9 Structure of ice.** The intermolecular attractions in the three-dimensional lattice restrict the molecules to vibrational motion only.

▶ **Figure 19.10 Dissolving an ionic solid in water.** The ions become more spread out and random in their motions, but the water molecules that hydrate the ions become less random.

**▲ Figure 19.11 Entropy change for a reaction.** A decrease in the number of gaseous molecules leads to a decrease in the entropy of the system. When the  $\text{NO}(g)$  and  $\text{O}_2(g)$  (left) react to form the  $\text{NO}_2(g)$  (right), the number of gaseous molecules decreases. The atoms have fewer degrees of freedom because new N—O bonds form and the entropy decreases.

The same ideas apply to systems involving chemical reactions. Consider the reaction between nitric oxide gas and oxygen gas to form nitrogen dioxide gas:

In this case the reaction results in a decrease in the number of molecules—three molecules of gaseous reactants form two molecules of gaseous products (Figure 19.11 ◀). The formation of new N—O bonds reduces the motions of the atoms in the system. The formation of new bonds decreases the *number of degrees of freedom*, or forms of motion, available to the atoms. That is, the atoms are less free to move in random fashion because of the formation of new bonds. The decrease in the number of molecules and the resultant decrease in motion result in fewer accessible microstates and therefore a decrease in the entropy of the system.

In summary, we generally expect the entropy of the system to increase for processes in which

1. Gases are formed from either solids or liquids.
2. Liquids or solutions are formed from solids.
3. The number of gas molecules increases during a chemical reaction.

### ■ SAMPLE EXERCISE 19.3 Predicting the Sign of $\Delta S$

Predict whether  $\Delta S$  is positive or negative for each of the following processes, assuming each occurs at constant temperature:

- (a)  $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g)$
- (b)  $\text{Ag}^+(aq) + \text{Cl}^-(aq) \longrightarrow \text{AgCl}(s)$
- (c)  $4 \text{Fe}(s) + 3 \text{O}_2(g) \longrightarrow 2 \text{Fe}_2\text{O}_3(s)$
- (d)  $\text{N}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{NO}(g)$

#### SOLUTION

**Analyze:** We are given four equations and asked to predict the sign of  $\Delta S$  for each chemical reaction.

**Plan:** The sign of  $\Delta S$  will be positive if there is an increase in temperature, an increase in the volume in which the molecules move, or an increase in the number of gas particles in the reaction. The question states that the temperature is constant. Thus, we need to evaluate each equation with the other two factors in mind.

**Solve:**

- (a) The evaporation of a liquid is accompanied by a large increase in volume. One mole of water (18 g) occupies about 18 mL as a liquid and if it could exist as a gas at STP it would occupy 22.4 L. Because the molecules are distributed throughout a much larger volume in the gaseous state than in the liquid state, an increase in motional freedom accompanies vaporization. Therefore,  $\Delta S$  is positive.
- (b) In this process the ions, which are free to move throughout the volume of the solution, form a solid in which they are confined to a smaller volume and restricted to more highly constrained positions. Thus,  $\Delta S$  is negative.
- (c) The particles of a solid are confined to specific locations and have fewer ways to move (fewer microstates) than do the molecules of a gas. Because  $\text{O}_2$  gas is converted into part of the solid product  $\text{Fe}_2\text{O}_3$ ,  $\Delta S$  is negative.
- (d) The number of moles of gases is the same on both sides of the equation, and so the entropy change will be small. The sign of  $\Delta S$  is impossible to predict based on our discussions thus far, but we can predict that  $\Delta S$  will be close to zero.

#### ■ PRACTICE EXERCISE

Indicate whether each of the following processes produces an increase or decrease in the entropy of the system:

- (a)  $\text{CO}_2(s) \longrightarrow \text{CO}_2(g)$
- (b)  $\text{CaO}(s) + \text{CO}_2(g) \longrightarrow \text{CaCO}_3(s)$
- (c)  $\text{HCl}(g) + \text{NH}_3(g) \longrightarrow \text{NH}_4\text{Cl}(s)$
- (d)  $2 \text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{SO}_3(g)$

**Answers:** (a) increase, (b) decrease, (c) decrease, (d) decrease

### SAMPLE EXERCISE 19.4 Predicting Which Sample of Matter Has the Higher Entropy

Choose the sample of matter that has greater entropy in each pair, and explain your choice: (a) 1 mol of NaCl(s) or 1 mol of HCl(g) at 25 °C, (b) 2 mol of HCl(g) or 1 mol of HCl(g) at 25 °C, (c) 1 mol of HCl(g) or 1 mol of Ar(g) at 298 K.

#### SOLUTION

**Analyze:** We need to select the system in each pair that has the greater entropy.

**Plan:** To do this, we examine the state of the system and the complexity of the molecules it contains.

**Solve:** (a) Gaseous HCl has the higher entropy because gases have more available motions than solids. (b) The sample containing 2 mol of HCl has twice the number of molecules as the sample containing 1 mol. Thus, the 2-mol sample has twice the number of microstates and twice the entropy when they are at the same pressure. (c) The HCl sample has the higher entropy because the HCl molecule is capable of storing energy in more ways than is Ar. HCl molecules can rotate and vibrate; Ar atoms cannot.

#### PRACTICE EXERCISE

Choose the substance with the greater entropy in each case: (a) 1 mol of H<sub>2</sub>(g) at STP or 1 mol of H<sub>2</sub>(g) at 100 °C and 0.5 atm, (b) 1 mol of H<sub>2</sub>O(s) at 0 °C or 1 mol of H<sub>2</sub>O(l) at 25 °C, (c) 1 mol of H<sub>2</sub>(g) at STP or 1 mol of SO<sub>2</sub>(g) at STP, (d) 1 mol of N<sub>2</sub>O<sub>4</sub>(g) at STP or 2 mol of NO<sub>2</sub>(g) at STP.

**Answers:** (a) 1 mol of H<sub>2</sub>(g) at 100 °C and 0.5 atm, (b) 1 mol of H<sub>2</sub>O(l) at 25 °C, (c) 1 mol of SO<sub>2</sub>(g) at STP, (d) 2 mol of NO<sub>2</sub>(g) at STP

## Chemistry and Life

### ENTROPY AND LIFE

The ginkgo leaf shown in Figure 19.12(a) reveals beautiful patterns of form and color. Both plant systems and animal systems, including those of humans, are incredibly complex structures in which a host of substances come together in organized ways to form cells, tissue, organ systems, and so on. These various components must operate in synchrony for the organism as a whole to be viable. If even one key system strays far from its optimal state, the organism as a whole may die.

To make a living system from its component molecules—such as a ginkgo leaf from sugar molecules, cellulose molecules, and the other substances present in the leaf—requires a very large reduction in entropy. It would seem, then, that living systems might violate the second law of thermodynamics. They seem spontaneously to become more, not less, organized as they develop. To get the full picture, however, we must take into account the surroundings.

We know that a system can move toward lower entropy if we do work on it. (That is, if we supply energy to the system in a very specific way.) When we do work on a gas, for example, by compressing it isothermally, the entropy of the gas is lowered. The energy for the work done is provided by the surroundings, and in the process the net entropy change in the universe is positive.

The striking thing about living systems is that they are organized to recruit energy from their surroundings spontaneously. Some single-celled organisms, called *autotrophs*, capture energy from sunlight and store it in molecules such as sugars and fats [Figure 19.12(b)]. Others, called *heterotrophs*, absorb food molecules from their surroundings and then break down the molecules to provide needed energy. Whatever their mode of existence, however, living systems gain their order at the expense of the surroundings. Each cell exists at the expense of an increase in the entropy of the universe.

▲ **Figure 19.12 Entropy and life.** (a) This ginkgo leaf represents a highly organized living system. (b) Cyanobacteria absorb light energy and utilize it to synthesize the substances needed for growth.

► **Figure 19.13** A perfectly ordered crystalline solid at and above 0 K.

At absolute zero (left), all lattice units are in their lattice sites, devoid of thermal motion. As the temperature rises above 0 K (right), the atoms or molecules gain energy and their vibrational motion increases.

### The Third Law of Thermodynamics

If we decrease the thermal energy of a system by lowering the temperature, the energy stored in translational, vibrational, and rotational forms of motion decreases. As less energy is stored, the entropy of the system decreases. If we keep lowering the temperature, do we reach a state in which these motions are essentially shut down, a point described by a single microstate? This question is addressed by the **third law of thermodynamics**, which states that *the entropy of a pure crystalline substance at absolute zero is zero:  $S(0 \text{ K}) = 0$* .

Figure 19.13▲ shows schematically a pure crystalline solid. At absolute zero all the units of the lattice have no thermal motion. There is, therefore, only one microstate. As a result  $S = k \ln W = k \ln 1 = 0$ . As the temperature is increased from absolute zero, the atoms or molecules in the crystal gain energy in the form of vibrational motion about their lattice positions. Thus, the degrees of freedom of the crystal increase. The entropy of the lattice therefore increases with temperature because vibrational motion causes the atoms or molecules to have a greater number of accessible microstates.

What happens to the entropy of the substance as we continue to heat it? Figure 19.14◀ is a plot of how the entropy of a typical substance varies with temperature. We see that the entropy of the solid continues to increase steadily with increasing temperature up to the melting point of the solid. When the solid melts, the bonds holding the atoms or molecules are broken and the particles are free to move about the entire volume of the substance. The added degrees of freedom for the individual molecules allow greater dispersal of the substance's energy thereby increasing its entropy. We therefore see a sharp increase in the entropy at the melting point. After all the solid has melted to liquid, the temperature again increases and with it, the entropy.

At the boiling point of the liquid, another abrupt increase in entropy occurs. We can understand this increase as resulting from the increased volume in which the molecules may be found. When the gas is heated further, the entropy increases steadily as more energy is stored in the translational motion of the gas molecules. At higher temperatures, the distribution of molecular speeds is spread out toward higher values. ∞ (Figure 10.18) More of the molecules have speeds that differ greatly from the most probable value. The expansion of the range of speeds of the gas molecules leads to an increased entropy.

The general conclusions we reach in examining Figure 19.14 are consistent with what we noted earlier: Entropy generally increases with increasing temperature because the increased motional energy can be dispersed in more ways. Further, the entropies of the phases of a given substance follow the order  $S_{\text{solid}} < S_{\text{liquid}} < S_{\text{gas}}$ . This ordering fits in nicely with our picture of the number of microstates available to solids, liquids, and gases.

▲ **Figure 19.14** Entropy as a function of temperature. Entropy increases as the temperature of a crystalline solid is increased from absolute zero. The vertical jumps in entropy correspond to phase changes.

## GIVE IT SOME THOUGHT

If you are told that the entropy of a certain system is zero, what do you know about the system?

## 19.4 ENTROPY CHANGES IN CHEMICAL REACTIONS

In Section 5.5 we discussed how calorimetry can be used to measure  $\Delta H$  for chemical reactions. No comparable, easy method exists for measuring  $\Delta S$  for a reaction. By using experimental measurements of the variation of heat capacity with temperature, however, we can determine the absolute value of the entropy,  $S$ , for many substances at any temperature. (The theory and the methods used for these measurements and calculations are beyond the scope of this text.) Absolute entropies are based on the reference point of zero entropy for perfect crystalline solids at 0 K (the third law). Entropies are usually tabulated as molar quantities, in units of joules per mole-kelvin (J/mol·K).

The molar entropy values of substances in their standard states are known as **standard molar entropies** and are denoted  $S^\circ$ . The standard state for any substance is defined as the pure substance at 1 atm pressure.\* Table 19.2 lists the values of  $S^\circ$  for several substances at 298 K; Appendix C gives a more extensive list.

We can make several observations about the  $S^\circ$  values in Table 19.2:

1. Unlike enthalpies of formation, the standard molar entropies of elements at the reference temperature of 298 K are *not* zero.
2. The standard molar entropies of gases are greater than those of liquids and solids, consistent with our interpretation of experimental observations, as represented in Figure 19.14
3. Standard molar entropies generally increase with increasing molar mass. [Compare Li(s), Na(s), and K(s).]
4. Standard molar entropies generally increase with an increasing number of atoms in the formula of a substance.

Point 4 is related to molecular motion (Section 19.3). In general, the number of degrees of freedom for a molecule increases with increasing number of atoms, and thus the number of accessible microstates also increases. Figure 19.15 compares the standard molar entropies of three hydrocarbons. Notice how the entropy increases as the number of atoms in the molecule increases.

The entropy change in a chemical reaction equals the sum of the entropies of the products less the sum of the entropies of the reactants:

$$\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants}) \quad [19.8]$$

As in Equation 5.31, the coefficients  $n$  and  $m$  are the coefficients in the chemical equation, as illustrated in Sample Exercise 19.5.

TABLE 19.2 ■ Standard Molar Entropies of Selected Substances at 298 K

Substance	$S^\circ$ , J/mol·K
<b>Gases</b>	
H <sub>2</sub> (g)	130.6
N <sub>2</sub> (g)	191.5
O <sub>2</sub> (g)	205.0
H <sub>2</sub> O(g)	188.8
NH <sub>3</sub> (g)	192.5
CH <sub>3</sub> OH(g)	237.6
C <sub>6</sub> H <sub>6</sub> (g)	269.2
<b>Liquids</b>	
H <sub>2</sub> O(l)	69.9
CH <sub>3</sub> OH(l)	126.8
C <sub>6</sub> H <sub>6</sub> (l)	172.8
<b>Solids</b>	
Li(s)	29.1
Na(s)	51.4
K(s)	64.7
Fe(s)	27.23
FeCl <sub>3</sub> (s)	142.3
NaCl(s)	72.3

▼ **Figure 19.15 Molar entropies.** In general, the more complex a molecule (that is, the greater the number of atoms present), the greater the molar entropy of the substance, as illustrated here by the molar entropies of three simple hydrocarbons.

\*The standard pressure used in thermodynamics is no longer 1 atm but is based on the SI unit for pressure, the pascal (Pa). The standard pressure is  $10^5 \text{ Pa}$ , a quantity known as a bar:  $1 \text{ bar} = 10^5 \text{ Pa} = 0.987 \text{ atm}$ . Because 1 bar differs from 1 atm by only 1.3%, we will continue to refer to the standard pressure as 1 atm.

**SAMPLE EXERCISE 19.5** | Calculating  $\Delta S$  from Tabulated Entropies

Calculate  $\Delta S^\circ$  for the synthesis of ammonia from  $N_2(g)$  and  $H_2(g)$  at 298 K:

**SOLUTION**

**Analyze:** We are asked to calculate the entropy change for the synthesis of  $NH_3(g)$  from its constituent elements.

**Plan:** We can make this calculation using Equation 19.8 and the standard molar entropy values for the reactants and the products that are given in Table 19.2 and in Appendix C.

**Solve:** Using Equation 19.8, we have  $\Delta S^\circ = 2S^\circ(NH_3) - [S^\circ(N_2) + 3S^\circ(H_2)]$

Substituting the appropriate  $S^\circ$  values from Table 19.2 yields  $\Delta S^\circ = (2 \text{ mol})(192.5 \text{ J/mol}\cdot\text{K}) - [(1 \text{ mol})(191.5 \text{ J/mol}\cdot\text{K}) + (3 \text{ mol})(130.6 \text{ J/mol}\cdot\text{K})] = -198.3 \text{ J/K}$

**Check:** The value for  $\Delta S^\circ$  is negative, in agreement with our qualitative prediction based on the decrease in the number of molecules of gas during the reaction.

**PRACTICE EXERCISE**

Using the standard entropies in Appendix C, calculate the standard entropy change,  $\Delta S^\circ$ , for the following reaction at 298 K:

*Answer:* 180.39 J/K

## Entropy Changes in the Surroundings

We can use tabulated absolute entropy values to calculate the standard entropy change in a system, such as a chemical reaction, as just described. But what about the entropy change in the surroundings? We encountered this situation in Section 19.2, but it is good to revisit it now that we are examining chemical reactions.

We should recognize that the surroundings serve essentially as a large, constant-temperature heat source (or heat sink if the heat flows from the system to the surroundings). The change in entropy of the surroundings will depend on how much heat is absorbed or given off by the system. For an isothermal process, the entropy change of the surroundings is given by

$$\Delta S_{\text{surr}} = \frac{-q_{\text{sys}}}{T}$$

For a reaction occurring at constant pressure,  $q_{\text{sys}}$  is simply the enthalpy change for the reaction,  $\Delta H$ . Thus, we can write

$$\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T} \quad [19.9]$$

For the reaction in Sample Exercise 19.5, the formation of ammonia from  $H_2(g)$  and  $N_2(g)$  at 298 K,  $q_{\text{sys}}$  is the enthalpy change for reaction under standard conditions,  $\Delta H^\circ$ . (Section 5.7) Using the procedures described in Section 5.7, we have

$$\begin{aligned} \Delta H_{\text{rxn}}^\circ &= 2\Delta H_f^\circ[NH_3(g)] - 3\Delta H_f^\circ[H_2(g)] - \Delta H_f^\circ[N_2(g)] \\ &= 2(-46.19 \text{ kJ}) - 3(0 \text{ kJ}) - (0 \text{ kJ}) = -92.38 \text{ kJ} \end{aligned}$$

Thus at 298 K the formation of ammonia from  $H_2(g)$  and  $N_2(g)$  is exothermic. Absorption of the heat given off by the system results in an increase in the entropy of the surroundings:

$$\Delta S_{\text{surr}}^\circ = \frac{92.38 \text{ kJ}}{298 \text{ K}} = 0.310 \text{ kJ/K} = 310 \text{ J/K}$$

Notice that the magnitude of the entropy gained by the surroundings is greater than that lost by the system (as calculated in Sample Exercise 19.5):

$$\Delta S_{\text{univ}}^{\circ} = \Delta S_{\text{sys}}^{\circ} + \Delta S_{\text{surr}}^{\circ} = -198.3 \text{ J/K} + 310 \text{ J/K} = 112 \text{ J/K}$$

Because  $\Delta S_{\text{univ}}^{\circ}$  is positive for any spontaneous reaction, this calculation indicates that when  $\text{NH}_3(\text{g})$ ,  $\text{H}_2(\text{g})$ , and  $\text{N}_2(\text{g})$  are together at 298 K in their standard states (each at 1 atm pressure), the reaction system will move spontaneously toward formation of  $\text{NH}_3(\text{g})$ . Keep in mind that while the thermodynamic calculations indicate that formation of ammonia is spontaneous, they do not tell us anything about the rate at which ammonia is formed. Establishing equilibrium in this system within a reasonable period requires a catalyst, as discussed in Section 15.7.

### GIVE IT SOME THOUGHT

If a process is exothermic, does the entropy of the surroundings (1) always increase, (2) always decrease, or (3) sometimes increase and sometimes decrease, depending on the process?

## 19.5 GIBBS FREE ENERGY

We have seen examples of endothermic processes that are spontaneous, such as the dissolution of ammonium nitrate in water.  $\infty$  (Section 13.1) We learned in our discussion of the solution process that a spontaneous, endothermic process must be accompanied by an increase in the entropy of the system. However, we have also encountered processes that are spontaneous and yet proceed with a decrease in the entropy of the system, such as the highly exothermic formation of sodium chloride from its constituent elements.  $\infty$  (Section 8.2) Spontaneous processes that result in a decrease in the system's entropy are always exothermic. Thus, the spontaneity of a reaction seems to involve two thermodynamic concepts, enthalpy and entropy.

There should be a way to use  $\Delta H$  and  $\Delta S$  to predict whether a given reaction occurring at constant temperature and pressure will be spontaneous. The means for doing so was first developed by the American mathematician J. Willard Gibbs (1839–1903). Gibbs (Figure 19.16▶) proposed a new state function, now called the **Gibbs free energy** (or just **free energy**). The Gibbs free energy,  $G$ , of a state is defined as

$$G = H - TS \quad [19.10]$$

where  $T$  is the absolute temperature. For a process occurring at constant temperature, the change in free energy of the system,  $\Delta G$ , is given by the expression

$$\Delta G = \Delta H - T\Delta S \quad [19.11]$$

Under standard conditions, this equation becomes

$$\Delta G^{\circ} = \Delta H^{\circ} - T\Delta S^{\circ} \quad [19.12]$$

To see how the state function  $G$  relates to reaction spontaneity, recall that for a reaction occurring at constant temperature and pressure

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = \Delta S_{\text{sys}} + \left( \frac{-\Delta H_{\text{sys}}}{T} \right)$$

Multiplying both sides by  $(-T)$  gives us

$$-T\Delta S_{\text{univ}} = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} \quad [19.13]$$

▲ **Figure 19.16 Josiah Willard Gibbs (1839–1903).** Gibbs was the first person to be awarded a Ph.D. in science from an American university (Yale, 1863). From 1871 until his death, he held the chair of mathematical physics at Yale. He developed much of the theoretical foundation that led to the development of chemical thermodynamics.

**▲ Figure 19.17 Potential energy and free energy.** An analogy is shown between the gravitational potential-energy change of a boulder rolling down a hill (a) and the free-energy change in a spontaneous reaction (b). The equilibrium position in (a) is given by the minimum gravitational potential energy available to the system. The equilibrium position in (b) is given by the minimum free energy available to the system.

Comparing Equation 19.13 with Equation 19.11, we see that the free-energy change in a process occurring at constant temperature and pressure,  $\Delta G$ , is equal to  $-T\Delta S_{\text{univ}}$ . We know that for spontaneous processes,  $\Delta S_{\text{univ}}$  is always positive, and therefore  $-T\Delta S_{\text{univ}}$  will be negative. Thus, the sign of  $\Delta G$  provides us with extremely valuable information about the spontaneity of processes that occur at constant temperature and pressure. If both  $T$  and  $P$  are constant, the relationship between the sign of  $\Delta G$  and the spontaneity of a reaction is as follows:

1. If  $\Delta G$  is negative, the reaction is spontaneous in the forward direction.
2. If  $\Delta G$  is zero, the reaction is at equilibrium.
3. If  $\Delta G$  is positive, the reaction in the forward direction is nonspontaneous; work must be supplied from the surroundings to make it occur. However, the reverse reaction will be spontaneous.

It is more convenient to use  $\Delta G$  as a criterion for spontaneity than to use  $\Delta S_{\text{univ}}$ , because  $\Delta G$  relates to the system alone and avoids the complication of having to examine the surroundings.

An analogy is often drawn between the free-energy change during a spontaneous reaction and the potential-energy change when a boulder rolls down a hill. Potential energy in a gravitational field “drives” the boulder until it reaches a state of minimum potential energy in the valley [Figure 19.17(a)]. Similarly, the free energy of a chemical system decreases until it reaches a minimum value [Figure 19.17(b)]. When this minimum is reached, a state of equilibrium exists. *In any spontaneous process at constant temperature and pressure, the free energy always decreases.*

As a specific illustration of these ideas, let’s return to the Haber process for the synthesis of ammonia from nitrogen and hydrogen, which we discussed extensively in Chapter 15:

Imagine that we have a reaction vessel that allows us to maintain a constant temperature and pressure and that we have a catalyst that allows the reaction to proceed at a reasonable rate. What will happen if we charge the vessel with a certain number of moles of  $\text{N}_2$  and three times that number of moles of  $\text{H}_2$ ? As we saw in Figure 15.3(a), the  $\text{N}_2$  and  $\text{H}_2$  will react spontaneously to form  $\text{NH}_3$  until equilibrium is achieved. Similarly, Figure 15.3(b) demonstrates that if we charge the vessel with pure  $\text{NH}_3$ , it will decompose spontaneously to form  $\text{N}_2$  and  $\text{H}_2$  until equilibrium is reached. In each case the free energy of the system is lowered on the way to equilibrium, which represents a minimum in the free energy. We illustrate these cases in Figure 19.18.

### GIVE IT SOME THOUGHT

Give the criterion for spontaneity first in terms of entropy and then in terms of free energy.

This is a good time to remind ourselves of the significance of the reaction quotient,  $Q$ , for a system that is not at equilibrium.  $\square$  (Section 15.6) Recall that when  $Q < K$ , there is an excess of reactants relative to products. The reaction will proceed spontaneously in the forward direction to reach equilibrium. When  $Q > K$ , the reaction will proceed spontaneously in the reverse direction. At equilibrium  $Q = K$ . We have illustrated these points in Figure 19.18. In Section 19.7 we will see how to use the value of  $Q$  to calculate the value of  $\Delta G$  for systems that are not at equilibrium.

◀ **Figure 19.18 Free energy and equilibrium.** In the reaction  $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \rightleftharpoons 2\text{NH}_3(\text{g})$ , if the reaction mixture has too much  $\text{N}_2$  and  $\text{H}_2$  relative to  $\text{NH}_3$  (left), the equilibrium lies too far to the left ( $Q < K$ ) and  $\text{NH}_3$  forms spontaneously. If there is too much  $\text{NH}_3$  in the mixture (right), the equilibrium lies too far to the right ( $Q > K$ ) and the  $\text{NH}_3$  decomposes spontaneously into  $\text{N}_2$  and  $\text{H}_2$ . Both of these spontaneous processes are “downhill” in free energy. At equilibrium (center),  $Q = K$  and the free energy is at a minimum ( $\Delta G = 0$ ).

### SAMPLE EXERCISE 19.6 | Calculating Free-Energy Change from $\Delta H^\circ$ , $T$ , and $\Delta S^\circ$

Calculate the standard free energy change for the formation of  $\text{NO}(\text{g})$  from  $\text{N}_2(\text{g})$  and  $\text{O}_2(\text{g})$  at 298 K:

given that  $\Delta H^\circ = 180.7 \text{ kJ}$  and  $\Delta S^\circ = 24.7 \text{ J/K}$ . Is the reaction spontaneous under these circumstances?

#### SOLUTION

**Analyze:** We are asked to calculate  $\Delta G^\circ$  for the indicated reaction (given  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $T$ ) and to predict whether the reaction is spontaneous under standard conditions at 298 K.

**Plan:** To calculate  $\Delta G^\circ$ , we use Equation 19.12,  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ . To determine whether the reaction is spontaneous under standard conditions, we look at the sign of  $\Delta G^\circ$ .

**Solve:**

$$\begin{aligned} \Delta G^\circ &= \Delta H^\circ - T\Delta S^\circ \\ &= 180.7 \text{ kJ} - (298 \text{ K})(24.7 \text{ J/K}) \left( \frac{1 \text{ kJ}}{10^3 \text{ J}} \right) \\ &= 180.7 \text{ kJ} - 7.4 \text{ kJ} \\ &= 173.3 \text{ kJ} \end{aligned}$$

Because  $\Delta G^\circ$  is positive, the reaction is not spontaneous under standard conditions at 298 K.

**Comment:** Notice that we had to convert the units of the  $T\Delta S^\circ$  term to kJ so that they could be added to the  $\Delta H^\circ$  term, whose units are kJ.

#### PRACTICE EXERCISE

A particular reaction has  $\Delta H^\circ = 24.6 \text{ kJ}$  and  $\Delta S^\circ = 132 \text{ J/K}$  at 298 K. Calculate  $\Delta G^\circ$ . Is the reaction spontaneous under these conditions?

**Answer:**  $\Delta G^\circ = -14.7 \text{ kJ}$ ; the reaction is spontaneous.

**TABLE 19.3** Conventions Used in Establishing Standard Free Energies

State of Matter	Standard State
Solid	Pure solid
Liquid	Pure liquid
Gas	1 atm pressure
Solution	1 M concentration
Elements	Standard free energy of formation of an element in its standard state is defined as zero

## Standard Free Energy of Formation

Free energy is a state function, like enthalpy. We can tabulate **standard free energies of formation** for substances, just as we can tabulate standard enthalpies of formation.  $\infty$  (Section 5.7) It is important to remember that standard values for these functions imply a particular set of conditions, or standard states. The standard state for gaseous substances is 1 atm pressure. For solid substances, the standard state is the pure solid; for liquids, the pure liquid. For substances in solution, the standard state is normally a concentration of 1 M. (In very accurate work it may be necessary to make certain corrections, but we need not worry about these.) The temperature usually chosen for purposes of tabulating data is 25 °C, but we will calculate  $\Delta G^\circ$  at other temperatures as well. Just as for the standard heats of formation, the free energies of elements in their standard states are set to zero. This arbitrary choice of a reference point has no effect on the quantity in which we are interested, namely, the *difference* in free energy between reactants and products. The rules about standard states are summarized in Table 19.3. A listing of standard free energies of formation, denoted  $\Delta G_f^\circ$ , appears in Appendix C.

### GIVE IT SOME THOUGHT

What does the superscript  $^\circ$  indicate when associated with a thermodynamic quantity, as in  $\Delta H^\circ$ ,  $\Delta S^\circ$ , or  $\Delta G^\circ$ ?

The standard free energies of formation are useful in calculating the *standard free-energy change* for chemical processes. The procedure is analogous to the calculation of  $\Delta H^\circ$  (Equation 5.31) and  $\Delta S^\circ$  (Equation 19.8):

$$\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants}) \quad [19.14]$$

## A Closer Look

### WHAT'S "FREE" ABOUT FREE ENERGY?

The Gibbs free energy is a remarkable thermodynamic quantity. Because so many chemical reactions are carried out under conditions of near-constant pressure and temperature, chemists, biochemists, and engineers use the sign and magnitude of  $\Delta G$  as exceptionally useful tools in the design and implementation of chemical and biochemical reactions. We will see examples of the usefulness of  $\Delta G$  throughout the remainder of this chapter and this text. But what is "free" about free energy?

We have seen that we can use the sign of  $\Delta G$  to conclude whether a reaction is spontaneous, nonspontaneous, or at equilibrium. The magnitude of  $\Delta G$  is also significant. A reaction for which  $\Delta G$  is large and negative, such as the burning of gasoline, is much more capable of doing work on the surroundings than is a reaction for which  $\Delta G$  is small and negative, such as ice melting at room temperature. In fact, thermodynamics tells us that *the change in free energy for a process,  $\Delta G$ , equals the maximum useful work that can be done by the system on its surroundings in a spontaneous process occurring at constant temperature and pressure:*

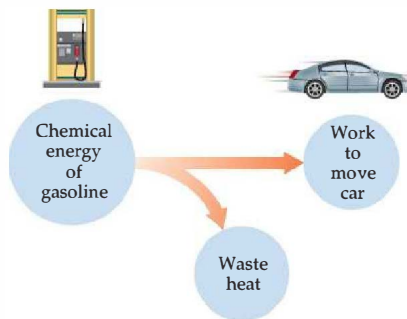

$$\Delta G = -w_{\max} \quad [19.15]$$

In other words,  $\Delta G$  gives the theoretical limit to how much work can be done by a process. This relationship explains why  $\Delta G$  is called the *free* energy. It is the portion of the energy change of a spontaneous reaction that is free to do useful work. The remainder of the energy enters the environment as heat.

For example, when we burn gasoline to move a car, only part of the energy of the gasoline is used to drive the car forward, performing useful work. The rest of the energy is

dissipated to the surroundings as heat, accomplishing no useful work, as illustrated in Figure 19.19. The efficiency of energy conversion is given by the ratio of the work accomplished compared to the total energy used.

For processes that are not spontaneous ( $\Delta G > 0$ ), the free-energy change is a measure of the *minimum* amount of work that must be done to cause the process to occur. In actual cases we always need to do more than this theoretical minimum amount because of the inefficiencies in the way the changes occur.

**▲ Figure 19.19 Energy conversion.** All conversions of energy are accompanied by production of heat, which enters the surroundings without accomplishing useful work.

**SAMPLE EXERCISE 19.7** | Calculating Standard Free-Energy Change from Free Energies of Formation

(a) Use data from Appendix C to calculate the standard free-energy change for the following reaction at 298 K:

(b) What is  $\Delta G^\circ$  for the reverse of the above reaction?

**SOLUTION**

**Analyze:** We are asked to calculate the free-energy change for the indicated reaction and then to determine the free-energy change of its reverse.

**Plan:** To accomplish our task, we look up the free-energy values for the products and reactants and use Equation 19.14: We multiply the molar quantities by the coefficients in the balanced equation, and subtract the total for the reactants from that for the products.

**Solve:**

(a)  $\text{Cl}_2(\text{g})$  is in its standard state, so  $\Delta G_f^\circ$  is zero for this reactant.  $\text{P}_4(\text{g})$ , however, is not in its standard state, so  $\Delta G_f^\circ$  is not zero for this reactant. From the balanced equation and using Appendix C, we have:

$$\begin{aligned} \Delta G_{rxn}^\circ &= 4 \Delta G_f^\circ[\text{PCl}_3(\text{g})] - \Delta G_f^\circ[\text{P}_4(\text{g})] - 6 \Delta G_f^\circ[\text{Cl}_2(\text{g})] \\ &= (4 \text{ mol})(-269.6 \text{ kJ/mol}) - (1 \text{ mol})(24.4 \text{ kJ/mol}) - 0 \\ &= -1102.8 \text{ kJ} \end{aligned}$$

The fact that  $\Delta G^\circ$  is negative tells us that a mixture of  $\text{P}_4(\text{g})$ ,  $\text{Cl}_2(\text{g})$ , and  $\text{PCl}_3(\text{g})$  at 25 °C, each present at a partial pressure of 1 atm, would react spontaneously in the forward direction to form more  $\text{PCl}_3$ . Remember, however, that the value of  $\Delta G^\circ$  tells us nothing about the rate at which the reaction occurs.

(b) Remember that  $\Delta G = G(\text{products}) - G(\text{reactants})$ . If we reverse the reaction, we reverse the roles of the reactants and products. Thus, reversing the reaction changes the sign of  $\Delta G$ , just as reversing the reaction changes the sign of  $\Delta H$  (Section 5.4). Hence, using the result from part (a):

**PRACTICE EXERCISE**

By using data from Appendix C, calculate  $\Delta G^\circ$  at 298 K for the combustion of methane:

**Answer:**  $-800.7 \text{ kJ}$

**SAMPLE EXERCISE 19.8** | Estimating and Calculating  $\Delta G^\circ$ 

In Section 5.7 we used Hess's law to calculate  $\Delta H^\circ$  for the combustion of propane gas at 298 K:

(a) Without using data from Appendix C, predict whether  $\Delta G^\circ$  for this reaction is more negative or less negative than  $\Delta H^\circ$ . (b) Use data from Appendix C to calculate the standard free-energy change for the reaction at 298 K. Is your prediction from part (a) correct?

**SOLUTION**

**Analyze:** In part (a) we must predict the value for  $\Delta G^\circ$  relative to that for  $\Delta H^\circ$  on the basis of the balanced equation for the reaction. In part (b) we must calculate the value for  $\Delta G^\circ$  and compare with our qualitative prediction.

**Plan:** The free-energy change incorporates both the change in enthalpy and the change in entropy for the reaction (Equation 19.11), so under standard conditions:

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

To determine whether  $\Delta G^\circ$  is more negative or less negative than  $\Delta H^\circ$ , we need to determine the sign of the term  $T\Delta S^\circ$ .  $T$  is the absolute temperature, 298 K, so it is a positive number. We can predict the sign of  $\Delta S^\circ$  by looking at the reaction.

**Solve:**

(a) We see that the reactants consist of six molecules of gas, and the products consist of three molecules of gas and four molecules of liquid. Thus, the number of molecules of gas has decreased significantly during the reaction. By using the general rules we discussed in Section 19.3, we would expect a decrease in the number of gas molecules to lead to a decrease in the entropy of the system—the products have fewer accessible microstates than the reactants. We therefore expect  $\Delta S^\circ$  and therefore  $T\Delta S^\circ$  to be negative numbers. Because we are subtracting  $T\Delta S^\circ$ , which is a negative number, we would predict that  $\Delta G^\circ$  is *less negative* than  $\Delta H^\circ$ .

(b) Using Equation 19.14 and values from Appendix C, we can calculate the value of  $\Delta G^\circ$

$$\begin{aligned}\Delta G^\circ &= 3\Delta G_f^\circ[\text{CO}_2(\text{g})] + 4\Delta G_f^\circ[\text{H}_2\text{O}(\text{l})] - \Delta G_f^\circ[\text{C}_3\text{H}_8(\text{g})] - 5\Delta G_f^\circ[\text{O}_2(\text{g})] \\ &= 3 \text{ mol}(-394.4 \text{ kJ/mol}) + 4 \text{ mol}(-237.13 \text{ kJ/mol}) - \\ &\quad 1 \text{ mol}(-23.47 \text{ kJ/mol}) - 5 \text{ mol}(0 \text{ kJ/mol}) = -2108 \text{ kJ}\end{aligned}$$

Notice that we have been careful to use the value of  $\Delta G_f^\circ$  for  $\text{H}_2\text{O}(\text{l})$ , as in the calculation of  $\Delta H$  values, the phases of the reactants and products are important. As we predicted,  $\Delta G^\circ$  is less negative than  $\Delta H^\circ$  because of the decrease in entropy during the reaction.

**PRACTICE EXERCISE**

Consider the combustion of propane to form  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$  at 298 K:  $\text{C}_3\text{H}_8(\text{g}) + 5 \text{ O}_2(\text{g}) \longrightarrow 3 \text{ CO}_2(\text{g}) + 4 \text{ H}_2\text{O}(\text{g})$ . Would you expect  $\Delta G^\circ$  to be more negative or less negative than  $\Delta H^\circ$ ?

*Answer:* more negative

## 19.6 FREE ENERGY AND TEMPERATURE

We have seen that tabulations of  $\Delta G_f^\circ$ , such as those in Appendix C, make it possible to calculate  $\Delta G^\circ$  for reactions at the standard temperature of 25°C. However, we are often interested in examining reactions at other temperatures. How is the change in free energy affected by the change in temperature? Let's look again at Equation 19.11:

$$\Delta G = \Delta H - T\Delta S = \underset{\substack{\text{Enthalpy} \\ \text{term}}}{\Delta H} + \underset{\substack{\text{Entropy} \\ \text{term}}}{(-T\Delta S)}$$

Notice that we have written the expression for  $\Delta G$  as a sum of two contributions, an enthalpy term,  $\Delta H$ , and an entropy term,  $-T\Delta S$ . Because the value of  $-T\Delta S$  depends directly on the absolute temperature  $T$ ,  $\Delta G$  will vary with temperature.  $T$  is a positive number at all temperatures other than absolute zero. We know that the enthalpy term,  $\Delta H$ , can be positive or negative. The entropy term,  $-T\Delta S$ , can also be positive or negative. When  $\Delta S$  is positive, which means that the final state has greater randomness (a greater number of microstates) than the initial state, the term  $-T\Delta S$  is negative. When  $\Delta S$  is negative, the term  $-T\Delta S$  is positive.

The sign of  $\Delta G$ , which tells us whether a process is spontaneous, will depend on the signs and magnitudes of  $\Delta H$  and  $-T\Delta S$ . When both  $\Delta H$  and  $-T\Delta S$  are negative,  $\Delta G$  will always be negative and the process will be spontaneous at all temperatures. Likewise, when both  $\Delta H$  and  $-T\Delta S$  are positive,  $\Delta G$  will always be positive and the process will be nonspontaneous at all temperatures (the reverse process will be spontaneous at all temperatures). When  $\Delta H$  and  $-T\Delta S$  have opposite signs, however, the sign of  $\Delta G$  will depend on the magnitudes of these two terms. In these instances temperature is an important consideration. Generally,  $\Delta H$  and  $\Delta S$  change very little with temperature.

However, the value of  $T$  directly affects the magnitude of  $-T\Delta S$ . As the temperature increases, the magnitude of the term  $-T\Delta S$  increases and it will become relatively more important in determining the sign and magnitude of  $\Delta G$ .

For example, let's consider once more the melting of ice to liquid water at 1 atm pressure:

This process is endothermic, which means that  $\Delta H$  is positive. We also know that the entropy increases during this process, so  $\Delta S$  is positive and  $-T\Delta S$  is negative. At temperatures below  $0^\circ\text{C}$  (273 K) the magnitude of  $\Delta H$  is greater than that of  $-T\Delta S$ . Hence, the positive enthalpy term dominates, leading to a positive value for  $\Delta G$ . The positive value of  $\Delta G$  means that the melting of ice is not spontaneous at  $T < 0^\circ\text{C}$ ; rather, the reverse process, the freezing of liquid water into ice, is spontaneous at these temperatures.

What happens at temperatures greater than  $0^\circ\text{C}$ ? As the temperature increases, so does the magnitude of the entropy term  $-T\Delta S$ . When  $T > 0^\circ\text{C}$ , the magnitude of  $-T\Delta S$  is greater than the magnitude of  $\Delta H$ . At these temperatures the negative entropy term dominates, which leads to a negative value for  $\Delta G$ . The negative value of  $\Delta G$  tells us that the melting of ice is spontaneous at  $T > 0^\circ\text{C}$ . At the normal melting point of water,  $T = 0^\circ\text{C}$ , the two phases are in equilibrium. Recall that  $\Delta G = 0$  at equilibrium; at  $T = 0^\circ\text{C}$ ,  $\Delta H$  and  $-T\Delta S$ , are equal in magnitude and opposite in sign, so they cancel one another and give  $\Delta G = 0$ .

### GIVE IT SOME THOUGHT

The normal boiling point of benzene is  $80^\circ\text{C}$ . At  $100^\circ\text{C}$  and 1 atm, which term is greater for the vaporization of benzene,  $\Delta H$  or  $T\Delta S$ ?

The possible situations for the relative signs of  $\Delta H$  and  $\Delta S$  are given in Table 19.4, along with examples of each. By applying the concepts we have developed for predicting entropy changes, we often can predict how  $\Delta G$  will change with temperature.

Our discussion of the temperature dependence of  $\Delta G$  is also relevant to standard free-energy changes. As we saw earlier in Equation 19.12, we can calculate  $\Delta G^\circ$  from  $\Delta H^\circ$  and  $T\Delta S^\circ$ :  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ . We can readily calculate the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  at 298 K from the data tabulated in Appendix C. If we assume that the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature, we can then use Equation 19.12 to estimate the value of  $\Delta G^\circ$  at temperatures other than 298 K.

TABLE 19.4 ■ Effect of Temperature on the Spontaneity of Reactions

$\Delta H$	$\Delta S$	$-T\Delta S$	$\Delta G = \Delta H - T\Delta S$	Reaction Characteristics	Example
–	+	–	–	Spontaneous at all temperatures	$2\text{O}_3(g) \longrightarrow 3\text{O}_2(g)$
+	–	+	+	Nonspontaneous at all temperatures	$3\text{O}_2(g) \longrightarrow 2\text{O}_3(g)$
–	–	+	+ or –	Spontaneous at low $T$ ; nonspontaneous at high $T$	$\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(s)$
+	+	–	+ or –	Spontaneous at high $T$ ; nonspontaneous at low $T$	$\text{H}_2\text{O}(s) \longrightarrow \text{H}_2\text{O}(l)$

### SAMPLE EXERCISE 19.9 Determining the Effect of Temperature on Spontaneity

The Haber process for the production of ammonia involves the equilibrium

Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  for this reaction do not change with temperature. (a) Predict the direction in which  $\Delta G^\circ$  for this reaction changes with increasing temperature. (b) Calculate the values of  $\Delta G^\circ$  for the reaction at 25 °C and 500 °C.

#### SOLUTION

**Analyze:** In part (a) we are asked to predict the direction in which  $\Delta G^\circ$  for the ammonia synthesis reaction changes as temperature increases. In part (b) we need to determine  $\Delta G^\circ$  for the reaction at two different temperatures.

**Plan:** In part (a) we can make this prediction by determining the sign of  $\Delta S$  for the reaction and then using that information to analyze Equation 19.12. In part (b) we need to calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  for the reaction by using the data in Appendix C. We can then use Equation 19.12 to calculate  $\Delta G^\circ$ .

#### Solve:

(a) Equation 19.12 tells us that  $\Delta G^\circ$  is the sum of the enthalpy term  $\Delta H^\circ$  and the entropy term  $-T\Delta S^\circ$ . The temperature dependence of  $\Delta G^\circ$  comes from the entropy term. We expect  $\Delta S^\circ$  for this reaction to be negative because the number of molecules of gas is smaller in the products. Because  $\Delta S^\circ$  is negative, the term  $-T\Delta S^\circ$  is positive and grows larger with increasing temperature. As a result,  $\Delta G^\circ$  becomes less negative (or more positive) with increasing temperature. Thus, the driving force for the production of  $\text{NH}_3$  becomes smaller with increasing temperature.

(b) We calculated the value of  $\Delta H^\circ$  in Sample Exercise 15.14, and the value of  $\Delta S^\circ$  was determined in Sample Exercise 19.5:  $\Delta H^\circ = -92.38 \text{ kJ}$  and  $\Delta S^\circ = -198.3 \text{ J/K}$ . If we assume that these values do not change with temperature, we can calculate  $\Delta G^\circ$  at any temperature by using Equation 19.12. At  $T = 298 \text{ K}$  we have:

$$\begin{aligned} \Delta G^\circ &= -92.38 \text{ kJ} - (298 \text{ K})(-198.3 \text{ J/K})\left(\frac{1 \text{ kJ}}{1000 \text{ J}}\right) \\ &= -92.38 \text{ kJ} + 59.1 \text{ kJ} = -33.3 \text{ kJ} \end{aligned}$$

At  $T = 500 + 273 = 773 \text{ K}$  we have

$$\begin{aligned} \Delta G^\circ &= -92.38 \text{ kJ} - (773 \text{ K})\left(-198.3 \frac{\text{J}}{\text{K}}\right)\left(\frac{1 \text{ kJ}}{1000 \text{ J}}\right) \\ &= -92.38 \text{ kJ} + 153 \text{ kJ} = 61 \text{ kJ} \end{aligned}$$

Notice that we have been careful to convert  $-T\Delta S^\circ$  into units of kJ so that it can be added to  $\Delta H^\circ$ , which has units of kJ.

**Comment:** Increasing the temperature from 298 K to 773 K changes  $\Delta G^\circ$  from  $-33.3 \text{ kJ}$  to  $+61 \text{ kJ}$ . Of course, the result at 773 K depends on the assumption that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature. In fact, these values do change slightly with temperature. Nevertheless, the result at 773 K should be a reasonable approximation. The positive increase in  $\Delta G^\circ$  with increasing  $T$  agrees with our prediction in part (a) of this exercise. Our result indicates that a mixture of  $\text{N}_2(\text{g})$ ,  $\text{H}_2(\text{g})$ , and  $\text{NH}_3(\text{g})$ , each present at a partial pressure of 1 atm, will react spontaneously at 298 K to form more  $\text{NH}_3(\text{g})$ . In contrast, at 773 K the positive value of  $\Delta G^\circ$  tells us that the reverse reaction is spontaneous. Thus, when the mixture of three gases, each at a partial pressure of 1 atm, is heated to 773 K, some of the  $\text{NH}_3(\text{g})$  spontaneously decomposes into  $\text{N}_2(\text{g})$  and  $\text{H}_2(\text{g})$ .

#### PRACTICE EXERCISE

(a) Using standard enthalpies of formation and standard entropies in Appendix C, calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  at 298 K for the following reaction:  $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{SO}_3(\text{g})$ . (b) Using the values obtained in part (a), estimate  $\Delta G^\circ$  at 400 K.

**Answers:** (a)  $\Delta H^\circ = -196.6 \text{ kJ}$ ,  $\Delta S^\circ = -189.6 \text{ J/K}$ ; (b)  $\Delta G^\circ = -120.8 \text{ kJ}$

## 19.7 FREE ENERGY AND THE EQUILIBRIUM CONSTANT

In Section 19.5 we saw a special relationship between  $\Delta G$  and equilibrium: For a system at equilibrium,  $\Delta G = 0$ . We have also seen how we can use tabulated thermodynamic data, such as those in Appendix C, to calculate values of the standard free-energy change,  $\Delta G^\circ$ . In this final section of this chapter, we will

learn two more ways in which we can use free energy as a powerful tool in our analysis of chemical reactions. First, we will learn how to use the value of  $\Delta G^\circ$  to calculate the value of  $\Delta G$  under *nonstandard* conditions. Second, we will see how we can directly relate the value of  $\Delta G^\circ$  for a reaction to the value of the equilibrium constant for the reaction.

The set of standard conditions for which  $\Delta G^\circ$  values pertain are given in Table 19.3. Most chemical reactions occur under nonstandard conditions. For any chemical process the general relationship between the standard free-energy change,  $\Delta G^\circ$ , and the free-energy change under any other conditions,  $\Delta G$ , is given by the expression

$$\Delta G = \Delta G^\circ + RT \ln Q \quad [19.16]$$

In this equation  $R$  is the ideal-gas constant,  $8.314 \text{ J/mol}\cdot\text{K}$ ,  $T$  is the absolute temperature; and  $Q$  is the reaction quotient that corresponds to the particular reaction mixture of interest.  $\infty$  (Section 15.6) Recall that the expression for  $Q$  is identical to the equilibrium-constant expression except that the reactants and products need not necessarily be at equilibrium.

Under standard conditions the concentrations of all the reactants and products are equal to 1. Thus, under standard conditions  $Q = 1$  and therefore  $\ln Q = 0$ . We see that Equation 19.16 therefore reduces to  $\Delta G = \Delta G^\circ$  under standard conditions, as it should.

### SAMPLE EXERCISE 19.10 | Relating $\Delta G$ to a Phase Change at Equilibrium

As we saw in Section 11.5, the *normal boiling point* is the temperature at which a pure liquid is in equilibrium with its vapor at a pressure of 1 atm. (a) Write the chemical equation that defines the normal boiling point of liquid carbon tetrachloride,  $\text{CCl}_4(l)$ . (b) What is the value of  $\Delta G^\circ$  for the equilibrium in part (a)? (c) Use thermodynamic data in Appendix C and Equation 19.12 to estimate the normal boiling point of  $\text{CCl}_4$ .

#### SOLUTION

**Analyze:** (a) We must write a chemical equation that describes the physical equilibrium between liquid and gaseous  $\text{CCl}_4$  at the normal boiling point. (b) We must determine the value of  $\Delta G^\circ$  for  $\text{CCl}_4$ , in equilibrium with its vapor at the normal boiling point. (c) We must estimate the normal boiling point of  $\text{CCl}_4$ , based on available thermodynamic data.

**Plan:** (a) The chemical equation will merely show the change of state of  $\text{CCl}_4$  from liquid to solid. (b) We need to analyze Equation 19.16 at equilibrium ( $\Delta G = 0$ ). (c) We can use Equation 19.12 to calculate  $T$  when  $\Delta G = 0$ .

**Solve:** (a) The normal boiling point of  $\text{CCl}_4$  is the temperature at which pure liquid  $\text{CCl}_4$  is in equilibrium with its vapor at a pressure of 1 atm:

(b) At equilibrium  $\Delta G = 0$ . In any normal boiling-point equilibrium both the liquid and the vapor are in their standard states (Table 19.2). Consequently,  $Q = 1$ ,  $\ln Q = 0$ , and  $\Delta G = \Delta G^\circ$  for this process. Thus, we conclude that  $\Delta G^\circ = 0$  for the equilibrium involved in the normal boiling point of any liquid. We would also find that  $\Delta G^\circ = 0$  for the equilibria relevant to normal melting points and normal sublimation points of solids.

(c) Combining Equation 19.12 with the result from part (b), we see that the equality at the normal boiling point,  $T_b$ , of  $\text{CCl}_4(l)$  or any other pure liquid is

$$\Delta G^\circ = \Delta H^\circ - T_b \Delta S^\circ = 0$$

Solving the equation for  $T_b$ , we obtain

$$T_b = \Delta H^\circ / \Delta S^\circ$$

Strictly speaking, we would need the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  for the equilibrium between  $\text{CCl}_4(l)$  and  $\text{CCl}_4(g)$  at the normal boiling point to do this calculation. However, we can *estimate* the boiling point by using the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  for  $\text{CCl}_4$  at 298 K, which we can obtain from the data in Appendix C and Equations 5.31 and 19.8:

$$\Delta H^\circ = (1 \text{ mol})(-106.7 \text{ kJ/mol}) - (1 \text{ mol})(-139.3 \text{ kJ/mol}) = +32.6 \text{ kJ}$$

$$\Delta S^\circ = (1 \text{ mol})(309.4 \text{ J/mol}\cdot\text{K}) - (1 \text{ mol})(214.4 \text{ J/mol}\cdot\text{K}) = +95.0 \text{ J/K}$$

Notice that, as expected, the process is endothermic ( $\Delta H > 0$ ) and produces a gas in which energy can be more spread out ( $\Delta S > 0$ ). We can now use these values to estimate  $T_b$  for  $\text{CCl}_4(l)$ :

$$T_b = \frac{\Delta H^\circ}{\Delta S^\circ} = \left( \frac{32.6 \text{ kJ}}{95.0 \text{ J/K}} \right) \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) = 343 \text{ K} = 70^\circ \text{ C}$$

Note also that we have used the conversion factor between J and kJ to make sure that the units of  $\Delta H^\circ$  and  $\Delta S^\circ$  match.

**Check:** The experimental normal boiling point of  $\text{CCl}_4(l)$  is  $76.5^\circ\text{C}$ . The small deviation of our estimate from the experimental value is due to the assumption that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature.

### PRACTICE EXERCISE

Use data in Appendix C to estimate the normal boiling point, in K, for elemental bromine,  $\text{Br}_2(l)$ . (The experimental value is given in Table 11.3.)

**Answer:** 330 K

When the concentrations of reactants and products are nonstandard, we must calculate the value of  $Q$  to determine the value of  $\Delta G$ . We illustrate how this is done in Sample Exercise 19.11. At this stage in our discussion, it becomes important to note the units associated with  $Q$  in Equation 19.16. The convention used for standard states imposes itself into the way  $Q$  is expressed: In Equation 19.16 the concentrations of gases are always expressed by their partial pressures in atmospheres, and solutes are expressed by their concentrations in molarity.

### SAMPLE EXERCISE 19.11 | Calculating the Free-Energy Change under Nonstandard Conditions

We will continue to explore the Haber process for the synthesis of ammonia:

Calculate  $\Delta G$  at 298 K for a reaction mixture that consists of 1.0 atm  $\text{N}_2$ , 3.0 atm  $\text{H}_2$ , and 0.50 atm  $\text{NH}_3$ .

#### SOLUTION

**Analyze:** We are asked to calculate  $\Delta G$  under nonstandard conditions.

**Plan:** We can use Equation 19.16 to calculate  $\Delta G$ . Doing so requires that we calculate the value of the reaction quotient  $Q$  for the specified partial pressures of the gases and evaluate  $\Delta G^\circ$ , using a table of standard free energies of formation.

**Solve:** Solving for the reaction quotient gives:

$$Q = \frac{P_{\text{NH}_3}^2}{P_{\text{N}_2} P_{\text{H}_2}^3} = \frac{(0.50)^2}{(1.0)(3.0)^3} = 9.3 \times 10^{-3}$$

In Sample Exercise 19.9 we calculated  $\Delta G^\circ = -33.3 \text{ kJ}$  for this reaction. We will have to change the units of this quantity in applying Equation 19.16, however. For the units in Equation 19.16 to work out, we will use kJ/mol as our units for  $\Delta G^\circ$ , where “per mole” means “per mole of the reaction as written.” Thus,  $\Delta G^\circ = -33.3 \text{ kJ/mol}$  implies per 1 mol of  $\text{N}_2$ , per 3 mol of  $\text{H}_2$ , and per 2 mol of  $\text{NH}_3$ .

We can now use Equation 19.16 to calculate  $\Delta G$  for these nonstandard conditions:

$$\begin{aligned} \Delta G &= \Delta G^\circ + RT \ln Q \\ &= (-33.3 \text{ kJ/mol}) + (8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})(1 \text{ kJ}/1000 \text{ J}) \ln(9.3 \times 10^{-3}) \\ &= (-33.3 \text{ kJ/mol}) + (-11.6 \text{ kJ/mol}) = -44.9 \text{ kJ/mol} \end{aligned}$$

**Comment:** We see that  $\Delta G$  becomes more negative, changing from  $-33.3 \text{ kJ/mol}$  to  $-44.9 \text{ kJ/mol}$ , as the pressures of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  are changed from 1.0 atm each (standard conditions,  $\Delta G^\circ$ ) to 1.0 atm, 3.0 atm, and 0.50 atm, respectively. The larger negative value for  $\Delta G$  indicates a larger “driving force” to produce  $\text{NH}_3$ .

We would have made the same prediction based on Le Châtelier’s principle.  $\rightleftharpoons$  (Section 15.7) Relative to standard conditions, we have increased the pressure of a reactant ( $\text{H}_2$ ) and decreased the pressure of the product ( $\text{NH}_3$ ). Le Châtelier’s principle predicts that both of these changes should shift the reaction more to the product side, thereby forming more  $\text{NH}_3$ .

### PRACTICE EXERCISE

Calculate  $\Delta G$  at 298 K for the reaction of nitrogen and hydrogen to form ammonia if the reaction mixture consists of 0.50 atm  $\text{N}_2$ , 0.75 atm  $\text{H}_2$ , and 2.0 atm  $\text{NH}_3$ .

**Answer:**  $-26.0 \text{ kJ/mol}$

We can now use Equation 19.16 to derive the relationship between  $\Delta G^\circ$  and the equilibrium constant,  $K$ . At equilibrium  $\Delta G = 0$ . Further, recall that the reaction quotient,  $Q$ , equals the equilibrium constant,  $K$ , when the system is at equilibrium. Thus, at equilibrium, Equation 19.16 transforms as follows:

$$\begin{aligned}\Delta G &= \Delta G^\circ + RT \ln Q \\ 0 &= \Delta G^\circ + RT \ln K \\ \Delta G^\circ &= -RT \ln K\end{aligned}\quad [19.17]$$

Equation 19.17 also allows us to calculate the value of  $K$  if we know the value of  $\Delta G^\circ$ . If we solve the equation for  $K$ , we obtain

$$K = e^{-\Delta G^\circ/RT}\quad [19.18]$$

As we pointed out in discussing Equation 19.16, some care is necessary in the choice of units. Thus, in Equations 19.17 and 19.18 we again express  $\Delta G^\circ$  in kJ/mol. For the reactants and products in the equilibrium-constant expression, we use the following conventions: Gas pressures are given in atm; solution concentrations are given in moles per liter (molarity); and solids, liquids, and solvents do not appear in the expression.  $\infty$  (Section 15.4) Thus, for gas-phase reactions the equilibrium constant is  $K_p$ , whereas for reactions in solution it is  $K_c$ .  $\infty$  (Section 15.2)

From Equation 19.17 we can see that if  $\Delta G^\circ$  is negative, then  $\ln K$  must be positive. A positive value for  $\ln K$  means  $K > 1$ . Therefore, the more negative  $\Delta G^\circ$  is, the larger the equilibrium constant,  $K$ . Conversely, if  $\Delta G^\circ$  is positive, then  $\ln K$  is negative, which means that  $K < 1$ . Table 19.5  $\blacktriangleright$  summarizes these conclusions by comparing  $\Delta G^\circ$  and  $K$  for both positive and negative values of  $\Delta G^\circ$ .

**TABLE 19.5** Relationship between  $\Delta G^\circ$  and  $K$  at 298 K

$\Delta G^\circ$ , kJ/mol	$K$
+200	$8.7 \times 10^{-36}$
+100	$3.0 \times 10^{-18}$
+50	$1.7 \times 10^{-9}$
+10	$1.8 \times 10^{-2}$
+1.0	$6.7 \times 10^{-1}$
0	1.0
-1.0	1.5
-10	$5.7 \times 10^1$
-50	$5.8 \times 10^8$
-100	$3.4 \times 10^{17}$
-200	$1.1 \times 10^{35}$

### SAMPLE EXERCISE 19.12 | Calculating an Equilibrium Constant from $\Delta G^\circ$

Use standard free energies of formation to calculate the equilibrium constant,  $K$ , at 25 °C for the reaction involved in the Haber process:

The standard free-energy change for this reaction was calculated in Sample Exercise 19.9:  $\Delta G^\circ = -33.3 \text{ kJ/mol} = -33,300 \text{ J/mol}$ .

#### SOLUTION

**Analyze:** We are asked to calculate  $K$  for a reaction, given  $\Delta G^\circ$ .

**Plan:** We can use Equation 19.18 to evaluate the equilibrium constant, which in this case takes the form

$$K = \frac{P_{\text{NH}_3}^2}{P_{\text{N}_2} P_{\text{H}_2}^3}$$

In this expression the gas pressures are expressed in atmospheres. (Remember that we use kJ/mol as the units of  $\Delta G^\circ$  when using Equations 19.16, 19.17, or 19.18.)

**Solve:** Solving Equation 19.17 for the exponent  $-\Delta G^\circ/RT$ , we have

$$\frac{-\Delta G^\circ}{RT} = \frac{-(-33,300 \text{ J/mol})}{(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})} = 13.4$$

We insert this value into Equation 19.18 to obtain  $K$ :

$$K = e^{-\Delta G^\circ/RT} = e^{13.4} = 7 \times 10^5$$

**Comment:** This is a large equilibrium constant, which indicates that the product,  $\text{NH}_3$ , is greatly favored in the equilibrium mixture at 25 °C. The equilibrium constants for temperatures in the range of 300 °C to 600 °C, given in Table 15.2, are much smaller than the value at 25 °C. Clearly, a low-temperature equilibrium favors the production of ammonia more than a high-temperature one. Nevertheless, the Haber process is carried out at high temperatures because the reaction is extremely slow at room temperature.

**Remember:** Thermodynamics can tell us the direction and extent of a reaction, but tells us nothing about the rate at which it will occur. If a catalyst were found that would permit the reaction to proceed at a rapid rate at room temperature, high pressures would not be needed to force the equilibrium toward  $\text{NH}_3$ .

### PRACTICE EXERCISE

Use data from Appendix C to calculate the standard free-energy change,  $\Delta G^\circ$ , and the equilibrium constant,  $K$ , at 298 K for the reaction  $\text{H}_2(\text{g}) + \text{Br}_2(\text{l}) \rightleftharpoons 2 \text{HBr}(\text{g})$ .

**Answer:**  $\Delta G^\circ = -106.4 \text{ kJ/mol}$ ,  $K = 4 \times 10^{18}$

Many desirable chemical reactions, including a large number that are central to living systems, are nonspontaneous as written. For example, consider the extraction of copper metal from the mineral *chalcocite*, which contains  $\text{Cu}_2\text{S}$ . The decomposition of  $\text{Cu}_2\text{S}$  to its elements is nonspontaneous:

Because  $\Delta G^\circ$  is very positive, we cannot obtain  $\text{Cu}(s)$  directly via this reaction. Instead, we must find some way to “do work” on the reaction to force it to occur as we wish. We can do this by coupling the reaction to another one so that the overall reaction is spontaneous. For example, we can envision the  $\text{S}(s)$  reacting with  $\text{O}_2(g)$  to form  $\text{SO}_2(g)$ :

By coupling these reactions, we can extract much of the copper metal via a spontaneous reaction:

In essence, we have used the spontaneous reaction of  $\text{S}(s)$  with  $\text{O}_2(g)$  to provide the free energy needed to extract the copper metal from the mineral.

Biological systems employ the same principle of using spontaneous reactions to drive nonspontaneous ones. Many of the biochemical reactions that are essential for the formation and maintenance of highly ordered biological structures are not spontaneous. These necessary reactions are made to

occur by coupling them with spontaneous reactions that release energy. The metabolism of food is the usual source of the free energy needed to do the work of maintaining biological systems. For example, complete oxidation of the sugar *glucose*,  $\text{C}_6\text{H}_{12}\text{O}_6$ , to  $\text{CO}_2$  and  $\text{H}_2\text{O}$  yields substantial free energy:

This energy can be used to drive nonspontaneous reactions in the body. However, a means is necessary to transport the energy released by glucose metabolism to the reactions that require energy. One way, shown in Figure 19.20, involves the interconversion of adenosine triphosphate (ATP) and adenosine diphosphate (ADP), molecules that are related to the building blocks of nucleic acids. The conversion of ATP to ADP releases free energy ( $\Delta G^\circ = -30.5 \text{ kJ}$ ) that can be used to drive other reactions.

In the human body the metabolism of glucose occurs via a complex series of reactions, most of which release free energy. The free energy released during these steps is used in part to reconvert lower-energy ADP back to higher-energy ATP. Thus, the ATP–ADP interconversions are used to store energy during metabolism and to release it as needed to drive nonspontaneous reactions in the body. If you take a course in biochemistry, you will have the opportunity to learn more about the remarkable sequence of reactions used to transport free energy throughout the human body.

**Related Exercises:** 19.94 and 19.95

**▲ Figure 19.20 Free energy and cell metabolism.** This schematic representation shows part of the free-energy changes that occur in cell metabolism. The oxidation of glucose to  $\text{CO}_2$  and  $\text{H}_2\text{O}$  produces free energy that is then used to convert ADP into the more energetic ATP. The ATP is then used, as needed, as an energy source to convert simple molecules into more complex cell constituents. When it releases its stored free energy, ATP is converted back into ADP.

**SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

Consider the simple salts NaCl(s) and AgCl(s). We will examine the equilibria in which these salts dissolve in water to form aqueous solutions of ions:

(a) Calculate the value of  $\Delta G^\circ$  at 298 K for each of the preceding reactions. (b) The two values from part (a) are very different. Is this difference primarily due to the enthalpy term or the entropy term of the standard free-energy change? (c) Use the values of  $\Delta G^\circ$  to calculate the  $K_{sp}$  values for the two salts at 298 K. (d) Sodium chloride is considered a soluble salt, whereas silver chloride is considered insoluble. Are these descriptions consistent with the answers to part (c)? (e) How will  $\Delta G^\circ$  for the solution process of these salts change with increasing  $T$ ? What effect should this change have on the solubility of the salts?

**SOLUTION**

(a) We will use Equation 19.14 along with  $\Delta G_f^\circ$  values from Appendix C to calculate the  $\Delta G_{\text{soln}}^\circ$  values for each equilibrium. (As we did in Section 13.1, we use the subscript “soln” to indicate that these are thermodynamic quantities for the formation of a solution.) We find

$$\begin{aligned}\Delta G_{\text{soln}}^\circ(\text{NaCl}) &= (-261.9 \text{ kJ/mol}) + (-131.2 \text{ kJ/mol}) - (-384.0 \text{ kJ/mol}) \\ &= -9.1 \text{ kJ/mol}\end{aligned}$$

$$\begin{aligned}\Delta G_{\text{soln}}^\circ(\text{AgCl}) &= (+77.11 \text{ kJ/mol}) + (-131.2 \text{ kJ/mol}) - (-109.70 \text{ kJ/mol}) \\ &= +55.6 \text{ kJ/mol}\end{aligned}$$

(b) We can write  $\Delta G_{\text{soln}}^\circ$  as the sum of an enthalpy term,  $\Delta H_{\text{soln}}^\circ$ , and an entropy term,  $-T\Delta S_{\text{soln}}^\circ$ :  $\Delta G_{\text{soln}}^\circ = \Delta H_{\text{soln}}^\circ + (-T\Delta S_{\text{soln}}^\circ)$ . We can calculate the values of  $\Delta H_{\text{soln}}^\circ$  and  $\Delta S_{\text{soln}}^\circ$  by using Equations 5.31 and 19.8. We can then calculate  $-T\Delta S_{\text{soln}}^\circ$  at  $T = 298\text{K}$ . All these calculations are now familiar to us. The results are summarized in the following table:

Salt	$\Delta H_{\text{soln}}^\circ$	$\Delta S_{\text{soln}}^\circ$	$-T\Delta S_{\text{soln}}^\circ$
NaCl	+3.6 kJ/mol	+43.2 J/mol-K	-12.9 kJ/mol
AgCl	+65.7 kJ/mol	+34.3 J/mol-K	-10.2 kJ/mol

The entropy terms for the solution of the two salts are very similar. That seems sensible because each solution process should lead to a similar increase in randomness as the salt dissolves, forming hydrated ions.  $\infty$  (Section 13.1) In contrast, we see a very large difference in the enthalpy term for the solution of the two salts. The difference in the values of  $\Delta G_{\text{soln}}^\circ$  is dominated by the difference in the values of  $\Delta H_{\text{soln}}^\circ$ .

(c) The solubility product,  $K_{sp}$ , is the equilibrium constant for the solution process.  $\infty$  (Section 17.4) As such, we can relate  $K_{sp}$  directly to  $\Delta G_{\text{soln}}^\circ$  by using Equation 19.18:

$$K_{sp} = e^{-\Delta G_{\text{soln}}^\circ/RT}$$

We can calculate the  $K_{sp}$  values in the same way we applied Equation 19.18 in Sample Exercise 19.12. We use the  $\Delta G_{\text{soln}}^\circ$  values we obtained in part (a), remembering to convert them from kJ/mol to J/mol:

$$\text{NaCl: } K_{sp} = [\text{Na}^+(aq)][\text{Cl}^-(aq)] = e^{-(-9100)/(8.314)(298)} = e^{+3.7} = 40$$

$$\text{AgCl: } K_{sp} = [\text{Ag}^+(aq)][\text{Cl}^-(aq)] = e^{-(+55,600)/(8.314)(298)} = e^{-22.4} = 1.9 \times 10^{-10}$$

The value calculated for the  $K_{sp}$  of AgCl is very close to that listed in Appendix D.

(d) A soluble salt is one that dissolves appreciably in water.  $\infty$  (Section 4.2) The  $K_{sp}$  value for NaCl is greater than 1, indicating that NaCl dissolves to a great extent. The  $K_{sp}$  value for AgCl is very small, indicating that very little dissolves in water. Silver chloride should indeed be considered an insoluble salt.

(e) As we expect, the solution process has a positive value of  $\Delta S$  for both salts (see the table in part b). As such, the entropy term of the free-energy change,  $-T\Delta S_{\text{soln}}^\circ$ , is negative. If we assume that  $\Delta H_{\text{soln}}^\circ$  and  $\Delta S_{\text{soln}}^\circ$  do not change much with temperature, then an increase in  $T$  will serve to make  $\Delta G_{\text{soln}}^\circ$  more negative. Thus, the driving force for dissolution of the salts will increase with increasing  $T$ , and we therefore expect the solubility of the salts to increase with increasing  $T$ . In Figure 13.17 we see that the solubility of NaCl (and that of nearly any salt) increases with increasing temperature.  $\infty$  (Section 13.3)

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Section 19.1** Most reactions and chemical processes have an inherent directionality: They are **spontaneous** in one direction and nonspontaneous in the reverse direction. The spontaneity of a process is related to the thermodynamic path the system takes from the initial state to the final state. In a **reversible process**, both the system and its surroundings can be restored to their original state by exactly reversing the change. In an **irreversible process** the system cannot return to its original state without there being a permanent change in the surroundings. Any spontaneous process is irreversible. A process that occurs at a constant temperature is said to be **isothermal**.

**Section 19.2** The spontaneous nature of processes is related to a thermodynamic state function called **entropy**, denoted  $S$ . For a process that occurs at constant temperature, the entropy change of the system is given by the heat absorbed by the system along a reversible path, divided by the temperature:  $\Delta S = q_{\text{rev}}/T$ . The way entropy controls the spontaneity of processes is given by the **second law of thermodynamics**, which governs the change in the entropy of the universe,  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$ . The second law states that in a reversible process  $\Delta S_{\text{univ}} = 0$ ; in an irreversible (spontaneous) process  $\Delta S_{\text{univ}} > 0$ . Entropy values are usually expressed in units of joules per kelvin, J/K.

**Section 19.3** Molecules can undergo three kinds of motion: In **translational motion** the entire molecule moves in space. Molecules can also undergo **vibrational motion**, in which the atoms of the molecule move toward and away from one another in periodic fashion, and **rotational motion**, in which the entire molecule spins like a top. A particular combination of motions and locations of the atoms and molecules of a system at a particular instant is called a **microstate**. Entropy is a measure of the number of microstates,  $W$ , over which the energy of the system is distributed:  $S = k \ln W$ . The number of available microstates, and therefore the entropy, increases with an increase in volume, temperature, or motion of molecules because any of these changes increases the possible motions and locations of the molecules. As a result, entropy generally increases when liquids or solutions are formed from solids, gases are formed from either solids or liquids, or the number of molecules of gas increases during a chemical reaction. The **third law of**

**thermodynamics** states that the entropy of a pure crystalline solid at 0 K is zero.

**Section 19.4** The third law allows us to assign entropy values for substances at different temperatures. Under standard conditions the entropy of a mole of a substance is called its **standard molar entropy**, denoted  $S^\circ$ . From tabulated values of  $S^\circ$ , we can calculate the entropy change for any process under standard conditions. For an isothermal process, the entropy change in the surroundings is equal to  $-\Delta H/T$ .

**Section 19.5** The **Gibbs free energy** (or just **free energy**),  $G$ , is a thermodynamic state function that combines the two state functions enthalpy and entropy:  $G = H - TS$ . For processes that occur at constant temperature,  $\Delta G = \Delta H - T\Delta S$ . For a process occurring at constant temperature and pressure, the sign of  $\Delta G$  relates to the spontaneity of the process. When  $\Delta G$  is negative, the process is spontaneous. When  $\Delta G$  is positive, the process is nonspontaneous but the reverse process is spontaneous. At equilibrium the process is reversible and  $\Delta G$  is zero. The free energy is also a measure of the maximum useful work that can be performed by a system in a spontaneous process. The standard free-energy change,  $\Delta G^\circ$ , for any process can be calculated from tabulations of **standard free energies of formation**,  $\Delta G_f^\circ$ , which are defined in a fashion analogous to standard enthalpies of formation,  $\Delta H_f^\circ$ . The value of  $\Delta G_f^\circ$  for a pure element in its standard state is defined to be zero.

**Sections 19.6 and 19.7** The values of  $\Delta H$  and  $\Delta S$  generally do not vary much with temperature. Therefore, the dependence of  $\Delta G$  with temperature is governed mainly by the value of  $T$  in the expression  $\Delta G = \Delta H - T\Delta S$ . The entropy term  $-T\Delta S$  has the greater effect on the temperature dependence of  $\Delta G$  and, hence, on the spontaneity of the process. For example, a process for which  $\Delta H > 0$  and  $\Delta S > 0$ , such as the melting of ice, can be nonspontaneous ( $\Delta G > 0$ ) at low temperatures and spontaneous ( $\Delta G < 0$ ) at higher temperatures. Under nonstandard conditions  $\Delta G$  is related to  $\Delta G^\circ$  and the value of the reaction quotient,  $Q$ :  $\Delta G = \Delta G^\circ + RT \ln Q$ . At equilibrium ( $\Delta G = 0, Q = K$ ),  $\Delta G^\circ = -RT \ln K$ . Thus, the standard free-energy change is directly related to the equilibrium constant for the reaction. This relationship expresses the temperature dependence of equilibrium constants.

## KEY SKILLS

- Understand the meaning of *spontaneous process*, *reversible process*, *irreversible process*, and *isothermal process*.
- State the second law of thermodynamics.
- Describe the kinds of molecular motion that a molecule can possess.

- Explain how the entropy of a system is related to the number of accessible microstates.
- Predict the sign of  $\Delta S$  for physical and chemical processes.
- State the third law of thermodynamics.
- Calculate standard entropy changes for a system from standard molar entropies.
- Calculate entropy changes in the surroundings for isothermal processes.
- Calculate the Gibbs free energy from the enthalpy change and entropy change at a given temperature.
- Use free energy changes to predict whether reactions are spontaneous.
- Calculate standard free energy changes using standard free energies of formation.
- Predict the effect of temperature on spontaneity given  $\Delta H$  and  $\Delta S$ .
- Calculate  $\Delta G$  under nonstandard conditions.
- Relate  $\Delta G^\circ$  and equilibrium constant.

## KEY EQUATIONS

$$\Delta S = \frac{q_{\text{rev}}}{T} \quad (\text{constant } T) \quad [19.2]$$

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0 \quad [19.4]$$

$$S = k \ln W \quad [19.5]$$

$$\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants}) \quad [19.8]$$

$$\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T} \quad [19.9]$$

$$\Delta G = \Delta H - T\Delta S \quad [19.11]$$

$$\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants}) \quad [19.14]$$

$$\Delta G = -w_{\text{max}} \quad [19.15]$$

$$\Delta G = \Delta G^\circ + RT \ln Q \quad [19.16]$$

$$\Delta G^\circ = -RT \ln K \quad [19.17]$$

Relating entropy change to the heat absorbed or released in a reversible process

The second law of thermodynamics (spontaneous process)

Relating entropy to the number of microstates

Calculating the standard entropy change from standard molar entropies

The entropy change of the surroundings for a process at constant temperature and pressure

Calculating the Gibbs free-energy change from enthalpy and entropy changes at constant temperature

Calculating the standard free-energy change from standard free energies of formation

Relating the free-energy change to the maximum work a process can perform.

Calculating free-energy change under nonstandard conditions.

Relating the standard free-energy change and the equilibrium constant.

## VISUALIZING CONCEPTS

- 19.1** Two different gases occupy two separate bulbs. Consider the process that occurs when the stopcock separating the gases is opened, assuming the gases behave ideally. (a) Draw the final (equilibrium) state. (b) Predict the signs of  $\Delta H$  and  $\Delta S$  for the process. (c) Is the process that occurs when the stopcock is opened a reversible one? (d) How does the process affect the entropy of the surroundings? [Sections 19.1 and 19.2]

- 19.2** (a) What are the signs of  $\Delta S$  and  $\Delta H$  for the process depicted to the right? (b) How might temperature affect

the sign of  $\Delta G$ ? (c) If energy can flow in and out of the system to maintain a constant temperature during the process, what can you say about the entropy change of the surroundings as a result of this process? [Sections 19.2 and 19.5]

- 19.3 Predict the sign of  $\Delta S$  accompanying this reaction. Explain your choice. [Section 19.3]

- 19.4 The diagram below shows the variation in entropy with temperature for a substance that is a gas at the highest temperature shown. (a) What processes correspond to the entropy increases along the vertical lines labeled 1 and 2 in this diagram? (b) Why is the entropy change for 2 larger than that for 1? [Section 19.3]

- 19.5 The diagram below shows how  $\Delta H$  (red line) and  $T\Delta S$  (blue line) change with temperature for a hypothetical reaction. (a) What is the significance of the point at 300 K, where  $\Delta H$  and  $T\Delta S$  are equal? (b) In what temperature range is this reaction spontaneous? [Section 19.6]

- 19.6 Consider the accompanying diagram, which represents how  $\Delta G$  for a hypothetical reaction responds to

temperature. (a) At what temperature is the system at equilibrium? (b) In what temperature range is the reaction spontaneous? (c) Is  $\Delta H$  positive or negative? (d) Is  $\Delta S$  positive or negative? [Sections 19.5 and 19.6]

- 19.7 Consider a reaction  $A_2(g) + B_2(g) \rightleftharpoons 2 AB(g)$ , with atoms of A shown in red and atoms of B shown in blue. (a) If  $K_c = 1$ , which system is at equilibrium? (b) What is the sign of  $\Delta G$  for any process in which the contents of a reaction vessel move to equilibrium? (c) Rank the boxes in order of increasing magnitude of  $\Delta G$  for the reaction. [Sections 19.5 and 19.7]

- 19.8 The diagram below shows how the free energy,  $G$ , changes during a hypothetical reaction  $A(g) + B(g) \rightarrow AB(g)$ . On the left are pure reactants, each at 1 atm, and on the right is the pure product, also at 1 atm. (a) What is the significance of the minimum in the plot? (b) What does the quantity  $x$ , shown on the right side of the diagram, represent? [Section 19.7]

## EXERCISES

### Spontaneous Processes

- 19.9 Which of the following processes are spontaneous, and which are nonspontaneous: (a) the ripening of a banana, (b) dissolution of sugar in a cup of hot coffee, (c) the reaction of nitrogen atoms to form  $N_2$  molecules at 25 °C

and 1 atm, (d) lightning, (e) formation of  $CH_4$  and  $O_2$  molecules from  $CO_2$  and  $H_2O$  at room temperature and 1 atm of pressure?

- 19.10** Which of the following processes are spontaneous: (a) the melting of ice cubes at 10 °C and 1 atm pressure; (b) separating a mixture of N<sub>2</sub> and O<sub>2</sub> into two separate samples, one that is pure N<sub>2</sub> and one that is pure O<sub>2</sub>; (c) alignment of iron filings in a magnetic field; (d) the reaction of sodium metal with chlorine gas to form sodium chloride; (e) the dissolution of HCl(g) in water to form concentrated hydrochloric acid?
- 19.11** (a) Give two examples of endothermic processes that are spontaneous. (b) Give an example of a process that is spontaneous at one temperature but nonspontaneous at a different temperature.
- 19.12** The crystalline hydrate Cd(NO<sub>3</sub>)<sub>2</sub> · 4H<sub>2</sub>O(s) loses water when placed in a large, closed, dry vessel:  

$$\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}(\text{s}) \longrightarrow \text{Cd}(\text{NO}_3)_2(\text{s}) + 4\text{H}_2\text{O}(\text{g})$$
 This process occurs even though it is endothermic; that is,  $\Delta H$  is positive. Is this process an exception to Bertholet's generalization? Explain.
- 19.13** Consider the vaporization of liquid water to steam at a pressure of 1 atm. (a) Is this process endothermic or exothermic? (b) In what temperature range is it a spontaneous process? (c) In what temperature range is it a nonspontaneous process? (d) At what temperature are the two phases in equilibrium?
- 19.14** The normal freezing point of 1-propanol (C<sub>3</sub>H<sub>8</sub>O) is -127 °C. (a) Is the freezing of 1-propanol an endothermic or exothermic process? (b) In what temperature range is the freezing of 1-propanol a spontaneous process? (c) In what temperature range is it a nonspontaneous process? (d) Is there any temperature at which liquid and solid 1-propanol are in equilibrium? Explain.
- 19.15** (a) What is special about a *reversible* process? (b) Suppose a reversible process is reversed, restoring the system to its original state. What can be said about the surroundings after the process is reversed? (c) Under what circumstances will the vaporization of water to steam be a reversible process? (d) Are any of the processes that occur in the world around us reversible in nature? Explain.
- 19.16** (a) What is meant by calling a process *irreversible*? (b) After an irreversible process the system is restored to its original state. What can be said about the condition of the surroundings after the system is restored to its original state? (c) Under what conditions will the condensation of a liquid be an irreversible process?
- 19.17** Consider a process in which an ideal gas changes from state 1 to state 2 in such a way that its temperature changes from 300 K to 200 K. (a) Describe how this change might be carried out while keeping the volume of the gas constant. (b) Describe how it might be carried out while keeping the pressure of the gas constant. (c) Does the change in  $\Delta E$  depend on the particular pathway taken to carry out this change of state? Explain.
- 19.18** A system goes from state 1 to state 2 and back to state 1. (a) What is the relationship between the value of  $\Delta E$  for going from state 1 to state 2 to that for going from state 2 back to state 1? (b) Without further information, can you conclude anything about the amount of heat transferred to the system as it goes from state 1 to state 2 as compared to that upon going from state 2 back to state 1? (c) Suppose the changes in state are reversible processes. Can you conclude anything about the work done by the system upon going from state 1 to state 2 as compared to that upon going from state 2 back to state 1?
- 19.19** Consider a system consisting of an ice cube. (a) Under what conditions can the ice cube melt reversibly? (b) If the ice cube melts reversibly, is  $\Delta E$  zero for the process? Explain.
- 19.20** Consider what happens when a sample of the explosive TNT (Section 8.8: "Chemistry Put to Work: Explosives and Alfred Nobel") is detonated. (a) Is the detonation a spontaneous process? (b) What is the sign of  $q$  for this process? (c) Can you determine whether  $w$  is positive, negative, or zero for the process? Explain. (d) Can you determine the sign of  $\Delta E$  for the process? Explain.

## Entropy and the Second Law of Thermodynamics

- 19.21** (a) How can we calculate  $\Delta S$  for an isothermal process? (b) Does  $\Delta S$  for a process depend on the path taken from the initial to the final state of the system? Explain.
- 19.22** Suppose we vaporize a mole of liquid water at 25 °C and another mole of water at 100 °C. (a) Assuming that the enthalpy of vaporization of water does not change much between 25 °C and 100 °C, which process involves the larger change in entropy? (b) Does the entropy change in either process depend on whether we carry out the process reversibly or not? Explain.
- 19.23** The normal boiling point of methanol (CH<sub>3</sub>OH) is 64.7 °C, and its molar enthalpy of vaporization is  $\Delta H_{\text{vap}} = 71.8$  kJ/mol. (a) When CH<sub>3</sub>OH(l) boils at its normal boiling point, does its entropy increase or decrease? (b) Calculate the value of  $\Delta S$  when 1.00 mol of CH<sub>3</sub>OH(l) is vaporized at 64.7 °C.
- 19.24** The element cesium (Cs) freezes at 28.4 °C, and its molar enthalpy of fusion is  $\Delta H_{\text{fus}} = 2.09$  kJ/mol. (a) When molten cesium solidifies to Cs(s) at its normal melting point, is  $\Delta S$  positive or negative? (b) Calculate the value of  $\Delta S$  when 15.0 g of Cs(l) solidifies at 28.4 °C.
- 19.25** (a) Express the second law of thermodynamics in words. (b) If the entropy of the system increases during a reversible process, what can you say about the entropy change of the surroundings? (c) In a certain spontaneous process the system undergoes an entropy change,  $\Delta S = 42$  J/K. What can you conclude about  $\Delta S_{\text{surr}}$ ?

- 19.26 (a) Express the second law of thermodynamics as a mathematical equation. (b) In a particular spontaneous process the entropy of the system decreases. What can you conclude about the sign and magnitude of  $\Delta S_{\text{surr}}$ ? (c) During a certain reversible process, the surroundings undergo an entropy change,  $\Delta S_{\text{surr}} = -78 \text{ J/K}$ . What is the entropy change of the system for this process?
- 19.27 The volume of 0.100 mol of helium gas at 27 °C is increased isothermally from 2.00 L to 5.00 L. Assuming the gas to be ideal, calculate the entropy change for the process.
- 19.28 The pressure on 0.850 mol of neon gas is increased from 1.25 atm to 2.75 atm at 100 °C. Assuming the gas to be ideal, calculate  $\Delta S$  for this process.

## The Molecular Interpretation of Entropy

- 19.29 How would each of the following changes affect the number of microstates available to a system: (a) increase in temperature, (b) decrease in volume, (c) change of state from liquid to gas?
- 19.30 (a) Using the heat of vaporization in Appendix B, calculate the entropy change for the vaporization of water at 25 °C and at 100 °C. (b) From your knowledge of microstates and the structure of liquid water, explain the difference in these two values.
- 19.31 (a) What do you expect for the sign of  $\Delta S$  in a chemical reaction in which two moles of gaseous reactants are converted to three moles of gaseous products? (b) For which of the processes in Exercise 19.9 does the entropy of the system increase?
- 19.32 (a) In a chemical reaction two gases combine to form a solid. What do you expect for the sign of  $\Delta S$ ? (b) How does the entropy of the system change in the processes described in Exercise 19.10?
- 19.33 How does the entropy of the system change when (a) a solid melts, (b) a gas liquefies, (c) a solid sublimates?
- 19.34 How does the entropy of the system change when (a) the temperature of the system increases, (b) the volume of a gas increases, (c) equal volumes of ethanol and water are mixed to form a solution.
- 19.35 (a) State the third law of thermodynamics. (b) Distinguish between translational motion, vibrational motion, and rotational motion of a molecule. (c) Illustrate these three kinds of motion with sketches for the HCl molecule.
- 19.36 (a) The energy of a gas is increased by heating it. Using  $\text{CO}_2$  as an example, illustrate the different ways in which additional energy can be distributed among the molecules of the gas. (b) You are told that the number of microstates for a system increases. What does this tell you about the entropy of the system?
- 19.37 (a) Using Figure 19.14 as a model, sketch how the entropy of water changes as it is heated from  $-50 \text{ }^\circ\text{C}$  to  $110 \text{ }^\circ\text{C}$  at sea level. Show the temperatures at which there are vertical increases in entropy. (b) Which process has the larger entropy change: melting ice or boiling water? Explain.
- 19.38 Propanol ( $\text{C}_3\text{H}_7\text{OH}$ ) melts at  $-126.5 \text{ }^\circ\text{C}$  and boils at  $97.4 \text{ }^\circ\text{C}$ . Draw a qualitative sketch of how the entropy changes as propanol vapor at  $150 \text{ }^\circ\text{C}$  and 1 atm is cooled to solid propanol at  $-150 \text{ }^\circ\text{C}$  and 1 atm.
- 19.39 For each of the following pairs, choose the substance with the higher entropy per mole at a given temperature: (a) Ar(l) or Ar(g), (b) He(g) at 3 atm pressure or He(g) at 1.5 atm pressure, (c) 1 mol of Ne(g) in 15.0 L or 1 mol of Ne(g) in 1.50 L, (d)  $\text{CO}_2(\text{g})$  or  $\text{CO}_2(\text{s})$ .
- 19.40 For each of the following pairs, indicate which substance possesses the larger standard entropy: (a) 1 mol of  $\text{P}_4(\text{g})$  at  $300 \text{ }^\circ\text{C}$ , 0.01 atm, or 1 mol of  $\text{As}_4(\text{g})$  at  $300 \text{ }^\circ\text{C}$ , 0.01 atm; (b) 1 mol of  $\text{H}_2\text{O}(\text{g})$  at  $100 \text{ }^\circ\text{C}$ , 1 atm, or 1 mol of  $\text{H}_2\text{O}(\text{l})$  at  $100 \text{ }^\circ\text{C}$ , 1 atm; (c) 0.5 mol of  $\text{N}_2(\text{g})$  at 298 K, 20-L volume, or 0.5 mol  $\text{CH}_4(\text{g})$  at 298 K, 20-L volume; (d) 100 g  $\text{Na}_2\text{SO}_4(\text{s})$  at  $30 \text{ }^\circ\text{C}$  or 100 g  $\text{Na}_2\text{SO}_4(\text{aq})$  at  $30 \text{ }^\circ\text{C}$ .
- 19.41 Predict the sign of the entropy change of the system for each of the following reactions:
- (a)  $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{SO}_3(\text{g})$   
 (b)  $\text{Ba}(\text{OH})_2(\text{s}) \longrightarrow \text{BaO}(\text{s}) + \text{H}_2\text{O}(\text{g})$   
 (c)  $\text{CO}(\text{g}) + 2 \text{H}_2(\text{g}) \longrightarrow \text{CH}_3\text{OH}(\text{l})$   
 (d)  $\text{FeCl}_2(\text{s}) + \text{H}_2(\text{g}) \longrightarrow \text{Fe}(\text{s}) + 2 \text{HCl}(\text{g})$
- 19.42 Predict the sign of  $\Delta S_{\text{sys}}$  for each of the following processes: (a) Gaseous Ar is liquefied at 80 K. (b) Gaseous  $\text{N}_2\text{O}_4$  dissociates to form gaseous  $\text{NO}_2$ . (c) Solid potassium reacts with gaseous  $\text{O}_2$  to form solid potassium superoxide,  $\text{KO}_2$ . (d) Lead bromide precipitates upon mixing  $\text{Pb}(\text{NO}_3)_2(\text{aq})$  and  $\text{KBr}(\text{aq})$ .

## Entropy Changes in Chemical Reactions

- 19.43 In each of the following pairs, which compound would you expect to have the higher standard molar entropy: (a)  $\text{C}_2\text{H}_2(\text{g})$  or  $\text{C}_2\text{H}_6(\text{g})$ ; (b)  $\text{CO}_2(\text{g})$  or  $\text{CO}(\text{g})$ ? Explain.
- 19.44 Cyclopropane and propylene isomers both have the formula  $\text{C}_3\text{H}_6$ . Based on the molecular structures shown, which of these isomers would you expect to have the higher standard molar entropy at 25 °C?

- 19.45** Use Appendix C to compare the standard entropies at 25 °C for the following pairs of substances: (a) Sc(s) and Sc(g); (b) NH<sub>3</sub>(g) and NH<sub>3</sub>(aq); (c) 1 mol P<sub>4</sub>(g) and 2 mol P<sub>2</sub>(g); (d) C(graphite) and C(diamond). In each case explain the difference in the entropy values.
- 19.46** Using Appendix C, compare the standard entropies at 25 °C for the following pairs of substances: (a) CuO(s) and Cu<sub>2</sub>O(s); (b) 1 mol N<sub>2</sub>O<sub>4</sub>(g) and 2 mol NO<sub>2</sub>(g); (c) SiO<sub>2</sub>(s) and CO<sub>2</sub>(g); (d) CO(g) and CO<sub>2</sub>(g). For each pair, explain the difference in the entropy values.
- [19.47]** The standard entropies at 298 K for certain of the group 4A elements are as follows: C(s, diamond) = 2.43 J/mol-K; Si(s) = 18.81 J/mol-K; Ge(s) = 31.09 J/mol-K; and Sn(s) = 51.18 J/mol-K. All but Sn have the diamond structure. How do you account for the trend in the S° values?
- [19.48]** Three of the forms of elemental carbon are graphite, diamond, and buckminsterfullerene. The entropies at 298 K for graphite and diamond are listed in Appendix C.

## Gibbs Free Energy

- 19.51** (a) For a process that occurs at constant temperature, express the change in Gibbs free energy in terms of changes in the enthalpy and entropy of the system. (b) For a certain process that occurs at constant *T* and *P*, the value of Δ*G* is positive. What can you conclude? (c) What is the relationship between Δ*G* for a process and the rate at which it occurs?
- 19.52** (a) What is the meaning of the standard free-energy change, Δ*G*°, as compared with Δ*G*? (b) For any process that occurs at constant temperature and pressure, what is the significance of Δ*G* = 0? (c) For a certain process, Δ*G* is large and negative. Does this mean that the process necessarily occurs rapidly?
- 19.53** For a certain chemical reaction, Δ*H*° = -35.4 kJ and Δ*S*° = -85.5 J/K. (a) Is the reaction exothermic or endothermic? (b) Does the reaction lead to an increase or decrease in the randomness or disorder of the system? (c) Calculate Δ*G*° for the reaction at 298 K. (d) Is the reaction spontaneous at 298 K under standard conditions?
- 19.54** A certain reaction has Δ*H*° = -19.5 kJ and Δ*S*° = +42.7 J/K. (a) Is the reaction exothermic or endothermic? (b) Does the reaction lead to an increase or decrease in the randomness or disorder of the system? (c) Calculate Δ*G*° for the reaction at 298 K. (d) Is the reaction spontaneous at 298 K under standard conditions?
- 19.55** Using data in Appendix C, calculate Δ*H*°, Δ*S*°, and Δ*G*° at 298 K for each of the following reactions. In each case show that Δ*G*° = Δ*H*° - *T*Δ*S*°.
- (a) H<sub>2</sub>(g) + F<sub>2</sub>(g) → 2 HF(g)  
 (b) C(s, graphite) + 2 Cl<sub>2</sub>(g) → CCl<sub>4</sub>(g)  
 (c) 2 PCl<sub>3</sub>(g) + O<sub>2</sub>(g) → 2 POCl<sub>3</sub>(g)  
 (d) 2 CH<sub>3</sub>OH(g) + H<sub>2</sub>(g) → C<sub>2</sub>H<sub>6</sub>(g) + 2 H<sub>2</sub>O(g)
- (a) Account for the difference in the S° values of graphite and diamond in light of their structures (Figure 11.41). (b) What would you expect for the S° value of buckminsterfullerene (Figure 11.43) relative to the values for graphite and diamond? Explain.
- 19.49** Using S° values from Appendix C, calculate Δ*S*° values for the following reactions. In each case account for the sign of Δ*S*°.
- (a) C<sub>2</sub>H<sub>4</sub>(g) + H<sub>2</sub>(g) → C<sub>2</sub>H<sub>6</sub>(g)  
 (b) N<sub>2</sub>O<sub>4</sub>(g) → 2 NO<sub>2</sub>(g)  
 (c) Be(OH)<sub>2</sub>(s) → BeO(s) + H<sub>2</sub>O(g)  
 (d) 2 CH<sub>3</sub>OH(g) + 3 O<sub>2</sub>(g) → 2 CO<sub>2</sub>(g) + 4 H<sub>2</sub>O(g)
- 19.50** Calculate Δ*S*° values for the following reactions by using tabulated S° values from Appendix C. In each case explain the sign of Δ*S*°.
- (a) N<sub>2</sub>H<sub>4</sub>(g) + H<sub>2</sub>(g) → 2 NH<sub>3</sub>(g)  
 (b) K(s) + O<sub>2</sub>(g) → KO<sub>2</sub>(s)  
 (c) Mg(OH)<sub>2</sub>(s) + 2 HCl(g) → MgCl<sub>2</sub>(s) + 2 H<sub>2</sub>O(l)  
 (d) CO(g) + 2 H<sub>2</sub>(g) → CH<sub>3</sub>OH(g)
- 19.56** Use data in Appendix C to calculate Δ*H*°, Δ*S*°, and Δ*G*° at 25 °C for each of the following reactions. In each case show that Δ*G*° = Δ*H*° - *T*Δ*S*°.
- (a) 2 Cr(s) + 3 Br<sub>2</sub>(g) → 2 CrBr<sub>3</sub>(s)  
 (b) BaCO<sub>3</sub>(s) → BaO(s) + CO<sub>2</sub>(g)  
 (c) 2 P(s) + 10 HF(g) → 2 PF<sub>5</sub>(g) + 5 H<sub>2</sub>(g)  
 (d) K(s) + O<sub>2</sub>(g) → KO<sub>2</sub>(s)
- 19.57** Using data from Appendix C, calculate Δ*G*° for the following reactions. Indicate whether each reaction is spontaneous under standard conditions.
- (a) 2 SO<sub>2</sub>(g) + O<sub>2</sub>(g) → 2 SO<sub>3</sub>(g)  
 (b) NO<sub>2</sub>(g) + N<sub>2</sub>O(g) → 3 NO(g)  
 (c) 6 Cl<sub>2</sub>(g) + 2 Fe<sub>2</sub>O<sub>3</sub>(s) → 4 FeCl<sub>3</sub>(s) + 3 O<sub>2</sub>(g)  
 (d) SO<sub>2</sub>(g) + 2 H<sub>2</sub>(g) → S(s) + 2 H<sub>2</sub>O(g)
- 19.58** Using data from Appendix C, calculate the change in Gibbs free energy for each of the following reactions. In each case indicate whether the reaction is spontaneous under standard conditions.
- (a) H<sub>2</sub>(g) + Cl<sub>2</sub>(g) → 2 HCl(g)  
 (b) MgCl<sub>2</sub>(s) + H<sub>2</sub>O(l) → MgO(s) + 2 HCl(g)  
 (c) 2 NH<sub>3</sub>(g) → N<sub>2</sub>H<sub>4</sub>(g) + H<sub>2</sub>(g)  
 (d) 2 NOCl(g) → 2 NO(g) + Cl<sub>2</sub>(g)
- 19.59** Cyclohexane (C<sub>6</sub>H<sub>12</sub>) is a liquid hydrocarbon at room temperature. (a) Write a balanced equation for the combustion of C<sub>6</sub>H<sub>12</sub>(l) to form CO<sub>2</sub>(g) and H<sub>2</sub>O(l). (b) Without using thermochemical data, predict whether Δ*G*° for this reaction is more negative or less negative than Δ*H*°.

19.60 Sulfur dioxide reacts with strontium oxide as follows:

(a) Without using thermochemical data, predict whether  $\Delta G^\circ$  for this reaction is more negative or less negative than  $\Delta H^\circ$ . (b) If you had only standard enthalpy data for this reaction, how would you go about making a rough estimate of the value of  $\Delta G^\circ$  at 298 K, using data from Appendix C on other substances?

19.61 Classify each of the following reactions as one of the four possible types summarized in Table 19.4:

19.62 From the values given for  $\Delta H^\circ$  and  $\Delta S^\circ$ , calculate  $\Delta G^\circ$  for each of the following reactions at 298 K. If the reaction is not spontaneous under standard conditions at 298 K, at what temperature (if any) would the reaction become spontaneous?

19.63 A particular reaction is spontaneous at 450 K. The enthalpy change for the reaction is +34.5 kJ. What can you conclude about the sign and magnitude of  $\Delta S$  for the reaction?

19.64 A certain reaction is nonspontaneous at  $-25^\circ \text{C}$ . The entropy change for the reaction is 95 J/K. What can you conclude about the sign and magnitude of  $\Delta H$ ?

19.65 For a particular reaction,  $\Delta H = -32 \text{ kJ}$  and  $\Delta S = -98 \text{ J/K}$ . Assume that  $\Delta H$  and  $\Delta S$  do not vary with temperature. (a) At what temperature will the reaction have  $\Delta G = 0$ ? (b) If  $T$  is increased from that in part (a), will the reaction be spontaneous or nonspontaneous?

19.66 Reactions in which a substance decomposes by losing CO are called *decarbonylation* reactions. The decarbonylation of acetic acid proceeds as follows:

By using data from Appendix C, calculate the minimum temperature at which this process will be spontaneous under standard conditions. Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not vary with temperature.

19.67 Consider the following reaction between oxides of nitrogen:

(a) Use data in Appendix C to predict how  $\Delta G^\circ$  for the reaction varies with increasing temperature. (b) Calculate  $\Delta G^\circ$  at 800 K, assuming that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature. Under standard conditions is the reaction spontaneous at 800 K? (c) Calculate  $\Delta G^\circ$  at 1000 K. Is the reaction spontaneous under standard conditions at this temperature?

19.68 Methanol ( $\text{CH}_3\text{OH}$ ) can be made by the controlled oxidation of methane:

(a) Use data in Appendix C to calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  for this reaction. (b) How is  $\Delta G^\circ$  for the reaction expected to vary with increasing temperature? (c) Calculate  $\Delta G^\circ$  at 298 K. Under standard conditions, is the reaction spontaneous at this temperature? (d) Is there a temperature at which the reaction would be at equilibrium under standard conditions and that is low enough so that the compounds involved are likely to be stable?

19.69 (a) Use data in Appendix C to estimate the boiling point of benzene,  $\text{C}_6\text{H}_6(\text{l})$ . (b) Use a reference source, such as the *CRC Handbook of Chemistry and Physics*, to find the experimental boiling point of benzene. How do you explain any deviation between your answer in part (a) and the experimental value?

19.70 (a) Using data in Appendix C, estimate the temperature at which the free-energy change for the transformation from  $\text{I}_2(\text{s})$  to  $\text{I}_2(\text{g})$  is zero. What assumptions must you make in arriving at this estimate? (b) Use a reference source, such as WebElements ([www.webelements.com](http://www.webelements.com)), to find the experimental melting and boiling points of  $\text{I}_2$ . (c) Which of the values in part (b) is closer to the value you obtained in part (a)? Can you explain why this is so?

19.71 Acetylene gas,  $\text{C}_2\text{H}_2(\text{g})$ , is used in welding. (a) Write a balanced equation for the combustion of acetylene gas to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ . (b) How much heat is produced in burning 1 mol of  $\text{C}_2\text{H}_2$  under standard conditions if both reactants and products are brought to 298 K? (c) What is the maximum amount of useful work that can be accomplished under standard conditions by this reaction?

19.72 (a) How much heat is produced in burning 1 mol of ethane ( $\text{C}_2\text{H}_6$ ) under standard conditions if reactants and products are brought to 298 K and  $\text{H}_2\text{O}(\text{l})$  is formed? (b) What is the maximum amount of useful work that can be accomplished under standard conditions by this system?

## Free Energy and Equilibrium

19.73 Explain qualitatively how  $\Delta G$  changes for each of the following reactions as the partial pressure of  $\text{O}_2$  is increased:

19.74 Indicate whether  $\Delta G$  increases, decreases, or does not change when the partial pressure of  $\text{H}_2$  is increased in each of the following reactions:

19.75 Consider the reaction  $2 \text{NO}_2(\text{g}) \longrightarrow \text{N}_2\text{O}_4(\text{g})$ . (a) Using data from Appendix C, calculate  $\Delta G^\circ$  at 298 K. (b) Calculate  $\Delta G$  at 298 K if the partial pressures of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  are 0.40 atm and 1.60 atm, respectively.

- 19.76 Consider the reaction  $6\text{H}_2(\text{g}) + \text{P}_4(\text{g}) \longrightarrow 4\text{PH}_3(\text{g})$ .  
 (a) Using data from Appendix C, calculate  $\Delta G^\circ$  at 298 K.  
 (b) Calculate  $\Delta G$  at 298 K if the reaction mixture consists of 8.0 atm of  $\text{H}_2$ , 0.050 atm of  $\text{P}_4$ , and 0.22 atm of  $\text{PH}_3$ .

19.77 Use data from Appendix C to calculate the equilibrium constant,  $K$ , at 298 K for each of the following reactions:

- (a)  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2\text{HI}(\text{g})$   
 (b)  $\text{C}_2\text{H}_5\text{OH}(\text{g}) \rightleftharpoons \text{C}_2\text{H}_4(\text{g}) + \text{H}_2\text{O}(\text{g})$   
 (c)  $3\text{C}_2\text{H}_2(\text{g}) \rightleftharpoons \text{C}_6\text{H}_6(\text{g})$

19.78 Write the equilibrium-constant expression and calculate the value of the equilibrium constant for each of the following reactions at 298 K, using data from Appendix C:

- (a)  $\text{NaHCO}_3(\text{s}) \rightleftharpoons \text{NaOH}(\text{s}) + \text{CO}_2(\text{g})$   
 (b)  $2\text{HBr}(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2\text{HCl}(\text{g}) + \text{Br}_2(\text{g})$   
 (c)  $2\text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2\text{SO}_3(\text{g})$

19.79 Consider the decomposition of barium carbonate:

Using data from Appendix C, calculate the equilibrium pressure of  $\text{CO}_2$  at (a) 298 K and (b) 1100 K.

19.80 Consider the following reaction:

Using data in Appendix C, calculate the equilibrium pressure of  $\text{CO}_2$  in the system at (a) 400 °C and (b) 180 °C.

19.81 The value of  $K_a$  for nitrous acid ( $\text{HNO}_2$ ) at 25 °C is given in Appendix D. (a) Write the chemical equation for the equilibrium that corresponds to  $K_a$ . (b) By using the value of  $K_a$ , calculate  $\Delta G^\circ$  for the dissociation of nitrous acid in aqueous solution. (c) What is the value of  $\Delta G$  at equilibrium? (d) What is the value of  $\Delta G$  when  $[\text{H}^+] = 5.0 \times 10^{-2}\text{ M}$ ,  $[\text{NO}_2^-] = 6.0 \times 10^{-4}\text{ M}$ , and  $[\text{HNO}_2] = 0.20\text{ M}$ ?

19.82 The  $K_b$  for methylamine ( $\text{CH}_3\text{NH}_2$ ) at 25 °C is given in Appendix D. (a) Write the chemical equation for the equilibrium that corresponds to  $K_b$ . (b) By using the value of  $K_b$ , calculate  $\Delta G^\circ$  for the equilibrium in part (a). (c) What is the value of  $\Delta G$  at equilibrium? (d) What is the value of  $\Delta G$  when  $[\text{CH}_3\text{NH}_3^+] = [\text{H}^+] = 1.5 \times 10^{-8}\text{ M}$ ,  $[\text{CH}_3\text{NH}_2] = 5.5 \times 10^{-4}\text{ M}$ , and  $[\text{CH}_3\text{NH}_2] = 0.120\text{ M}$ ?

## ADDITIONAL EXERCISES

19.83 Indicate whether each of the following statements is true or false. If it is false, correct it. (a) The feasibility of manufacturing  $\text{NH}_3$  from  $\text{N}_2$  and  $\text{H}_2$  depends entirely on the value of  $\Delta H$  for the process  $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \longrightarrow 2\text{NH}_3(\text{g})$ . (b) The reaction of  $\text{Na}(\text{s})$  with  $\text{Cl}_2(\text{g})$  to form  $\text{NaCl}(\text{s})$  is a spontaneous process. (c) A spontaneous process can in principle be conducted reversibly. (d) Spontaneous processes in general require that work be done to force them to proceed. (e) Spontaneous processes are those that are exothermic and that lead to a higher degree of order in the system.

19.84 For each of the following processes, indicate whether the signs of  $\Delta S$  and  $\Delta H$  are expected to be positive, negative, or about zero. (a) A solid sublimes. (b) The temperature of a sample of  $\text{Co}(\text{s})$  is lowered from 60 °C to 25 °C. (c) Ethyl alcohol evaporates from a beaker. (d) A diatomic molecule dissociates into atoms. (e) A piece of charcoal is combusted to form  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ .

19.85 The reaction  $2\text{Mg}(\text{s}) + \text{O}_2(\text{g}) \longrightarrow 2\text{MgO}(\text{s})$  is highly spontaneous and has a negative value for  $\Delta S^\circ$ . The second law of thermodynamics states that in any spontaneous process there is always an increase in the entropy of the universe. Is there an inconsistency between the above reaction and the second law?

19.86 Ammonium nitrate dissolves spontaneously and endothermally in water at room temperature. What can you deduce about the sign of  $\Delta S$  for this solution process?

[19.87] *Trouton's rule* states that for many liquids at their normal boiling points, the standard molar entropy of vaporization is about 88 J/mol·K. (a) Estimate the normal boiling point of bromine,  $\text{Br}_2$ , by determining  $\Delta H_{\text{vap}}^\circ$  for  $\text{Br}_2$  using data from Appendix C. Assume that  $\Delta H_{\text{vap}}^\circ$  remains constant with temperature and that Trouton's rule holds. (b) Look up the normal boiling point of  $\text{Br}_2$  in a chemistry handbook or at the WebElements web site ([www.webelements.com](http://www.webelements.com)).

[19.88] For the majority of the compounds listed in Appendix C, the value of  $\Delta G_f^\circ$  is more positive (or less negative) than the value of  $\Delta H_f^\circ$ . (a) Explain this observation, using  $\text{NH}_3(\text{g})$ ,  $\text{CCl}_4(\text{l})$ , and  $\text{KNO}_3(\text{s})$  as examples. (b) An exception to this observation is  $\text{CO}(\text{g})$ . Explain the trend in the  $\Delta H_f^\circ$  and  $\Delta G_f^\circ$  values for this molecule.

19.89 Consider the following three reactions:

- (i)  $\text{Ti}(\text{s}) + 2\text{Cl}_2(\text{g}) \longrightarrow \text{TiCl}_4(\text{g})$   
 (ii)  $\text{C}_2\text{H}_6(\text{g}) + 7\text{Cl}_2(\text{g}) \longrightarrow 2\text{CCl}_4(\text{g}) + 6\text{HCl}(\text{g})$   
 (iii)  $\text{BaO}(\text{s}) + \text{CO}_2(\text{g}) \longrightarrow \text{BaCO}_3(\text{s})$

(a) For each of the reactions, use data in Appendix C to calculate  $\Delta H^\circ$ ,  $\Delta G^\circ$ , and  $\Delta S^\circ$  at 25 °C. (b) Which of these reactions are spontaneous under standard conditions at 25 °C? (c) For each of the reactions, predict the manner in which the change in free energy varies with an increase in temperature.

19.90 Using the data in Appendix C and given the pressures listed, calculate  $\Delta G$  for each of the following reactions:

- (a)  $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \longrightarrow 2\text{NH}_3(\text{g})$   
 $P_{\text{N}_2} = 2.6\text{ atm}$ ,  $P_{\text{H}_2} = 5.9\text{ atm}$ ,  $P_{\text{NH}_3} = 1.2\text{ atm}$   
 (b)  $2\text{N}_2\text{H}_4(\text{g}) + 2\text{NO}_2(\text{g}) \longrightarrow 3\text{N}_2(\text{g}) + 4\text{H}_2\text{O}(\text{g})$   
 $P_{\text{N}_2\text{H}_4} = P_{\text{NO}_2} = 5.0 \times 10^{-2}\text{ atm}$ ,  $P_{\text{N}_2} = 0.5\text{ atm}$ ,  
 $P_{\text{H}_2\text{O}} = 0.3\text{ atm}$   
 (c)  $\text{N}_2\text{H}_4(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 2\text{H}_2(\text{g})$   
 $P_{\text{N}_2\text{H}_4} = 0.5\text{ atm}$ ,  $P_{\text{N}_2} = 1.5\text{ atm}$ ,  $P_{\text{H}_2} = 2.5\text{ atm}$

19.91 (a) For each of the following reactions, predict the sign of  $\Delta H^\circ$  and  $\Delta S^\circ$  and discuss briefly how these factors determine the magnitude of  $K$ . (b) Based on your general chemical knowledge, predict which of these reactions will have  $K > 0$ . (c) In each case indicate whether  $K$  should increase or decrease with increasing temperature.

- (i)  $2\text{Mg}(\text{s}) + \text{O}_2(\text{g}) \rightleftharpoons 2\text{MgO}(\text{s})$   
 (ii)  $2\text{KI}(\text{s}) \rightleftharpoons 2\text{K}(\text{g}) + \text{I}_2(\text{g})$   
 (iii)  $\text{Na}_2(\text{g}) \rightleftharpoons 2\text{Na}(\text{g})$   
 (iv)  $2\text{V}_2\text{O}_5(\text{s}) \rightleftharpoons 4\text{V}(\text{s}) + 5\text{O}_2(\text{g})$

**19.92** Acetic acid can be manufactured by combining methanol with carbon monoxide, an example of a *carbonylation* reaction:

(a) Calculate the equilibrium constant for the reaction at 25 °C. (b) Industrially, this reaction is run at temperatures above 25 °C. Will an increase in temperature produce an increase or decrease in the mole fraction of acetic acid at equilibrium? Why are elevated temperatures used? (c) At what temperature will this reaction have an equilibrium constant equal to 1? (You may assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  are temperature independent, and you may ignore any phase changes that might occur.)

**19.93** The oxidation of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in body tissue produces  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . In contrast, anaerobic decomposition, which occurs during fermentation, produces ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) and  $\text{CO}_2$ . (a) Using data given in Appendix C, compare the equilibrium constants for the following reactions:

(b) Compare the maximum work that can be obtained from these processes under standard conditions.

**[19.94]** The conversion of natural gas, which is mostly methane, into products that contain two or more carbon atoms, such as ethane ( $\text{C}_2\text{H}_6$ ), is a very important industrial chemical process. In principle, methane can be converted into ethane and hydrogen:

In practice, this reaction is carried out in the presence of oxygen:

(a) Using the data in Appendix C, calculate  $K$  for these reactions at 25 °C and 500 °C. (b) Is the difference in  $\Delta G^\circ$  for the two reactions due primarily to the enthalpy term ( $\Delta H$ ) or the entropy term ( $-T\Delta S$ )? (c) Explain how the preceding reactions are an example of driving a non-spontaneous reaction, as discussed in the “Chemistry and Life” box in Section 19.7. (d) The reaction of  $\text{CH}_4$  and  $\text{O}_2$  to form  $\text{C}_2\text{H}_6$  and  $\text{H}_2\text{O}$  must be carried out carefully to avoid a competing reaction. What is the most likely competing reaction?

**[19.95]** Cells use the hydrolysis of adenosine triphosphate (ATP) as a source of energy (Figure 19.20). The conversion of ATP to ADP has a standard free-energy change of  $-30.5 \text{ kJ/mol}$ . If all the free energy from the metabolism of glucose,

goes into the conversion of ADP to ATP, how many moles of ATP can be produced for each mole of glucose?

**[19.96]** The potassium-ion concentration in blood plasma is about  $5.0 \times 10^{-3} \text{ M}$ , whereas the concentration in muscle-cell fluid is much greater (0.15 M). The plasma and intracellular fluid are separated by the cell membrane, which we assume is permeable only to  $\text{K}^+$ . (a) What is  $\Delta G$  for the transfer of 1 mol of  $\text{K}^+$  from blood plasma to the cellular fluid at body temperature 37 °C? (b) What is the minimum amount of work that must be used to transfer this  $\text{K}^+$ ?

**[19.97]** The relationship between the temperature of a reaction, its standard enthalpy change, and the equilibrium constant at that temperature can be expressed as the following linear equation:

$$\ln K = \frac{-\Delta H^\circ}{RT} + \text{constant}$$

(a) Explain how this equation can be used to determine  $\Delta H^\circ$  experimentally from the equilibrium constants at several different temperatures. (b) Derive the preceding equation using relationships given in this chapter. To what is the constant equal?

**[19.98]** One way to derive Equation 19.3 depends on the observation that at constant  $T$  the number of ways,  $W$ , of arranging  $m$  ideal-gas particles in a volume  $V$  is proportional to the volume raised to the  $m$  power:

$$W \propto V^m$$

Use this relationship and Boltzmann’s relationship between entropy and number of arrangements (Equation 19.5) to derive the equation for the entropy change for the isothermal expansion or compression of  $n$  moles of an ideal gas.

**[19.99]** About 86% of the world’s electrical energy is produced by using steam turbines, a form of heat engine. In his analysis of an ideal heat engine, Sadi Carnot concluded that the maximum possible efficiency is defined by the total work that could be done by the engine, divided by the quantity of heat available to do the work (for example from hot steam produced by combustion of a fuel such as coal or methane). This efficiency is given by the ratio  $(T_{\text{high}} - T_{\text{low}})/T_{\text{high}}$ , where  $T_{\text{high}}$  is the temperature of the heat going into the engine and  $T_{\text{low}}$  is that of the heat leaving the engine. (a) What is the maximum possible efficiency of a heat engine operating between an input temperature of 700 K and an exit temperature of 288 K? (b) Why is it important that electrical power plants be located near bodies of relatively cool water? (c) Under what conditions could a heat engine operate at or near 100% efficiency? (d) It is often said that if the energy of combustion of a fuel such as methane were captured in an electrical fuel cell instead of by burning the fuel in a heat engine, a greater fraction of the energy could be put to useful work. Make a qualitative drawing like that in Figure 5.10 that illustrates the fact that in principle the fuel cell route will produce more useful work than the heat engine route from combustion of methane.

## INTEGRATIVE EXERCISES

**19.100** Most liquids follow Trouton’s rule, which states that the molar entropy of vaporization lies in the range of  $88 \pm 5 \text{ J/mol}\cdot\text{K}$ . The normal boiling points and enthalpies of vaporization of several organic liquids are as follows:

Substance	Normal Boiling Point (°C)	$\Delta H_{\text{vap}}$ (kJ/mol)
Acetone, $(\text{CH}_3)_2\text{CO}$	56.1	29.1
Dimethyl ether, $(\text{CH}_3)_2\text{O}$	-24.8	21.5
Ethanol, $\text{C}_2\text{H}_5\text{OH}$	78.4	38.6
Octane, $\text{C}_8\text{H}_{18}$	125.6	34.4
Pyridine, $\text{C}_5\text{H}_5\text{N}$	115.3	35.1

(a) Calculate  $\Delta S_{\text{vap}}$  for each of the liquids. Do all of the liquids obey Trouton's rule? (b) With reference to intermolecular forces (Section 11.2), can you explain any exceptions to the rule? (c) Would you expect water to obey Trouton's rule? By using data in Appendix B, check the accuracy of your conclusion. (d) Chlorobenzene ( $\text{C}_6\text{H}_5\text{Cl}$ ) boils at  $131.8^\circ\text{C}$ . Use Trouton's rule to estimate  $\Delta H_{\text{vap}}$  for this substance.

**19.101** Consider the polymerization of ethylene to polyethylene.  $\rightleftharpoons$  (Section 12.6) (a) What would you predict for the sign of the entropy change during polymerization ( $\Delta S_{\text{poly}}$ )? Explain your reasoning. (b) The polymerization of ethylene is a spontaneous process at room temperature. What can you conclude about the enthalpy change during polymerization ( $\Delta H_{\text{poly}}$ )? (c) Use average bond enthalpies (Table 8.4) to estimate the value of  $\Delta H_{\text{poly}}$  per ethylene monomer added. (d) Polyethylene is an *addition polymer*. By comparison, Nylon 66 is a *condensation polymer*. How would you expect  $\Delta S_{\text{poly}}$  for a condensation polymer to compare to that for an addition polymer? Explain.

**19.102** In chemical kinetics the *entropy of activation* is the entropy change for the process in which the reactants reach the activated complex. The entropy of activation for bimolecular processes is usually negative. Explain this observation with reference to Figure 14.15.

**19.103** The following processes were all discussed in Chapter 18, "Chemistry of the Environment." Estimate whether the entropy of the system increases or decreases during each process: (a) photodissociation of  $\text{O}_2(\text{g})$ , (b) formation of ozone from oxygen molecules and oxygen atoms, (c) diffusion of CFCs into the stratosphere, (d) desalination of water by reverse osmosis.

**19.104** Carbon disulfide ( $\text{CS}_2$ ) is a toxic, highly flammable substance. The following thermodynamic data are available for  $\text{CS}_2(\text{l})$  and  $\text{CS}_2(\text{g})$  at 298 K:

	$\Delta H_f^\circ$ (kJ/mol)	$\Delta G_f^\circ$ (kJ/mol)
$\text{CS}_2(\text{l})$	89.7	65.3
$\text{CS}_2(\text{g})$	117.4	67.2

(a) Draw the Lewis structure of the molecule. What do you predict for the bond order of the C—S bonds? (b) Use the VSEPR method to predict the structure of the  $\text{CS}_2$  molecule. (c) Liquid  $\text{CS}_2$  burns in  $\text{O}_2$  with a blue flame, forming  $\text{CO}_2(\text{g})$  and  $\text{SO}_2(\text{g})$ . Write a balanced equation for this reaction. (d) Using the data in the preceding table and in Appendix C, calculate  $\Delta H^\circ$  and  $\Delta G^\circ$  for the reaction in part (c). Is the reaction exothermic? Is it spontaneous at 298 K? (e) Use the data in the preceding table to calculate  $\Delta S^\circ$  at 298 K for the vaporization of  $\text{CS}_2(\text{l})$ . Is the sign of  $\Delta S^\circ$  as you would expect for a vaporization? (f) Using data in the preceding table and your answer to part (e), estimate the boiling point of  $\text{CS}_2(\text{l})$ . Do you predict that the substance will be a liquid or a gas at 298 K and 1 atm?

**[19.105]** The following data compare the standard enthalpies and free energies of formation of some crystalline ionic substances and aqueous solutions of the substances:

Substance	$\Delta H_f^\circ$ (kJ/mol)	$\Delta G_f^\circ$ (kJ/mol)
$\text{AgNO}_3(\text{s})$	-124.4	-33.4
$\text{AgNO}_3(\text{aq})$	-101.7	-34.2
$\text{MgSO}_4(\text{s})$	-1283.7	-1169.6
$\text{MgSO}_4(\text{aq})$	-1374.8	-1198.4

(a) Write the formation reaction for  $\text{AgNO}_3(\text{s})$ . Based on this reaction, do you expect the entropy of the system to increase or decrease upon the formation of  $\text{AgNO}_3(\text{s})$ ? (b) Use  $\Delta H_f^\circ$  and  $\Delta G_f^\circ$  of  $\text{AgNO}_3(\text{s})$  to determine the entropy change upon formation of the substance. Is your answer consistent with your reasoning in part (a)? (c) Is dissolving  $\text{AgNO}_3$  in water an exothermic or endothermic process? What about dissolving  $\text{MgSO}_4$  in water? (d) For both  $\text{AgNO}_3$  and  $\text{MgSO}_4$ , use the data to calculate the entropy change when the solid is dissolved in water. (e) Discuss the results from part (d) with reference to material presented in this chapter and in the second "Closer Look" box in Section 13.5.

**[19.106]** Consider the following equilibrium:

Thermodynamic data on these gases are given in Appendix C. You may assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not vary with temperature. (a) At what temperature will an equilibrium mixture contain equal amounts of the two gases? (b) At what temperature will an equilibrium mixture of 1 atm total pressure contain twice as much  $\text{NO}_2$  as  $\text{N}_2\text{O}_4$ ? (c) At what temperature will an equilibrium mixture of 10 atm total pressure contain twice as much  $\text{NO}_2$  as  $\text{N}_2\text{O}_4$ ? (d) Rationalize the results from parts (b) and (c) by using Le Châtelier's principle.  $\rightleftharpoons$  (Section 15.7)

**[19.107]** The reaction

is the basis of a suggested method for removal of  $\text{SO}_2$  from power-plant stack gases. The standard free energy of each substance is given in Appendix C. (a) What is the equilibrium constant for the reaction at 298 K? (b) In principle, is this reaction a feasible method of removing  $\text{SO}_2$ ? (c) If  $P_{\text{SO}_2} = P_{\text{H}_2\text{S}}$  and the vapor pressure of water is 25 torr, calculate the equilibrium  $\text{SO}_2$  pressure in the system at 298 K. (d) Would you expect the process to be more or less effective at higher temperatures?

**19.108** When most elastomeric polymers (e.g., a rubber band) are stretched, the molecules become more ordered, as illustrated here:

Suppose you stretch a rubber band. (a) Do you expect the entropy of the system to increase or decrease? (b) If the rubber band were stretched isothermally, would heat need to be absorbed or emitted to maintain constant temperature?

CHAPTER

20

ELECTROCHEMISTRY

A VARIETY OF BATTERIES of different sizes, composition, and voltages.

## WHAT'S AHEAD

---

- 20.1 Oxidation States and Oxidation-Reduction Reactions**  
We briefly review oxidation states and *oxidation-reduction (redox) reactions*.
- 20.2 Balancing Oxidation-Reduction Equations**  
We learn how to balance redox equations using the method of *half-reactions*.
- 20.3 Voltaic Cells**  
We next consider *voltaic cells*, which produce electricity from spontaneous redox reactions. In these cells, solid electrodes serve as the surfaces at which oxidation and reduction reactions take place. The electrode where oxidation occurs is the *anode*, and the electrode where reduction occurs is the *cathode*.
- 20.4 Cell EMF under Standard Conditions**  
We see that one of the important characteristics of a voltaic cell is its *emf*, or voltage, which is the difference in the electrical potentials at the two electrodes. Electrode potentials are tabulated for reduction half-reactions under standard conditions (*standard reduction potentials*). They are used to calculate cell voltages, to determine the relative strengths of oxidizing agents and reducing agents, and to predict whether particular redox reactions are spontaneous.
- 20.5 Free Energy and Redox Reactions**  
We relate the Gibbs free energy,  $\Delta G^\circ$ , to the emf of an electrochemical cell.
- 20.6 Cell EMF under Nonstandard Conditions**  
We can calculate the voltage of cells that run under nonstandard conditions by using standard voltages and the Nernst equation.
- 20.7 Batteries and Fuel Cells**  
We describe batteries and fuel cells, which are commercially important energy sources based on electrochemical reactions.
- 20.8 Corrosion**  
Next, we discuss *corrosion*, a spontaneous electrochemical process involving metals.
- 20.9 Electrolysis**  
Finally, we focus on nonspontaneous redox reactions, examining *electrolytic cells*, which use electricity to perform chemical reactions.

**WE ARE SURROUNDED BY AN AMAZING ARRAY** of portable electronic gadgets including cell phones, portable music players, laptop computers, and gaming devices. In the absence of batteries, however, all of today's wirelessly connected electronic gadgetry would be nothing more than extra weight.

Thus, a variety of batteries of different sizes, compositions, and voltages have been developed, as shown in the chapter-opening photograph. Considerable research is in progress to develop new batteries with more power, faster recharging ability, lighter weight, or cheaper price. For example, in an effort to develop a battery that lasts long enough for all-day computing, battery makers are trying to increase the capacity of batteries without increasing their mass. At the heart of such development is the utilization of oxidation-reduction (redox) reactions, which are the chemical reactions that power batteries.

Redox reactions are among the most common and important chemical reactions. They are involved in the operation of batteries and in a wide variety of important natural processes, including the rusting of iron, the browning of

foods, and the respiration of animals. As we discussed in Chapter 4, *oxidation* refers to the loss of electrons, and *reduction* refers to the gain of electrons.  $\rightleftharpoons$  (Section 4.4) Thus, oxidation-reduction reactions occur when electrons are transferred from an atom that is oxidized to an atom that is reduced.

The examples of redox reactions that we have cited in this introduction are all spontaneous processes. We can also use electrical energy to make certain nonspontaneous redox reactions occur. A common example is electroplating, in which layers of one metal are coated onto another by the application of a voltage. **Electrochemistry** is the study of the relationships between electricity and chemical reactions. It includes the study of both spontaneous and nonspontaneous processes.

## 20.1 OXIDATION STATES AND OXIDATION-REDUCTION REACTIONS

How do we determine whether a given chemical reaction is an oxidation-reduction reaction? We can do so by keeping track of the *oxidation numbers* (*oxidation states*) of all the elements involved in the reaction.  $\rightleftharpoons$  (Section 4.4) This procedure identifies whether any elements are changing oxidation state. For example, consider the reaction that occurs when zinc metal is added to a strong acid (Figure 20.1  $\blacktriangledown$ ):

The reaction proceeds spontaneously and produces energy in the form of heat. The chemical equation for this reaction can be written as

**► Figure 20.1 Redox reaction in acidic solution.** The addition of zinc metal to hydrochloric acid leads to a spontaneous oxidation-reduction reaction: Zinc metal is oxidized to  $\text{Zn}^{2+}(aq)$ , and  $\text{H}^+(aq)$  is reduced to  $\text{H}_2(g)$ , which produces the vigorous bubbling.

By writing the oxidation number of each element above or below the equation, we can see how the oxidation numbers change. The oxidation number of Zn changes from 0 to +2, and that of H changes from +1 to 0. Thus, this is an oxidation-reduction reaction. Electrons are transferred from zinc atoms to hydrogen ions, and therefore Zn is oxidized and  $H^+$  is reduced.

In a reaction such as Equation 20.2, a clear transfer of electrons occurs. Zinc loses electrons as  $Zn(s)$  is converted to  $Zn^{2+}(aq)$ , and hydrogen gains electrons as  $H^+(aq)$  is turned into  $H_2(g)$ . In some reactions, however, the oxidation numbers change, but we cannot say that any substance literally gains or loses electrons. For example, consider the combustion of hydrogen gas:

In this reaction, hydrogen is oxidized from the 0 to the +1 oxidation state and oxygen is reduced from the 0 to the -2 oxidation state. Therefore, Equation 20.3 is an oxidation-reduction reaction. Water is not an ionic substance, however, and so there is not a complete transfer of electrons from hydrogen to oxygen as water is formed. Using oxidation states, therefore, is a convenient form of “bookkeeping,” but you should not generally equate the oxidation state of an atom with its actual charge in a chemical compound.  $\infty$  (Section 8.5 “A Closer Look: Oxidation Numbers, Formal Charges, and Actual Partial Charges”)

### GIVE IT SOME THOUGHT

What are the oxidation numbers, or states, of the elements in the nitrite ion,  $\text{NO}_2^-$ ?

In any redox reaction, both oxidation and reduction must occur. In other words, if one substance is oxidized, then another must be reduced: The electrons formally have to go from one place to another. The substance that makes it possible for another substance to be oxidized is called either the **oxidizing agent** or the **oxidant**. The oxidizing agent removes electrons from another substance by acquiring them itself; thus, the oxidizing agent is itself reduced. Similarly, a **reducing agent**, or **reductant**, is a substance that gives up electrons, thereby causing another substance to be reduced. The reducing agent is therefore oxidized in the process. In Equation 20.2,  $H^+(aq)$  is the oxidizing agent and  $Zn(s)$  is the reducing agent.

#### SAMPLE EXERCISE 20.1 | Identifying Oxidizing and Reducing Agents

The nickel-cadmium (nicad) battery, a rechargeable “dry cell” used in battery-operated devices, uses the following redox reaction to generate electricity:

Identify the substances that are oxidized and reduced, and indicate which is the oxidizing agent and which is the reducing agent.

#### SOLUTION

**Analyze:** We are given a redox equation and asked to identify the substance oxidized and the substance reduced and to label one as the oxidizing agent and the other as the reducing agent.

**Plan:** First, we assign oxidation states, or numbers, to all the atoms in the reaction and determine the elements that are changing oxidation state. Second, we apply the definitions of oxidation and reduction.

Cd increases in oxidation state from 0 to +2, and Ni decreases from +4 to +2.

Because the Cd atom increases in oxidation state, it is oxidized (loses electrons) and therefore serves as the reducing agent. The Ni atom decreases in oxidation state as  $\text{NiO}_2$  is converted into  $\text{Ni(OH)}_2$ . Thus,  $\text{NiO}_2$  is reduced (gains electrons) and therefore serves as the oxidizing agent.

**Comment:** A common mnemonic for remembering oxidation and reduction is “LEO the lion says GER”: losing electrons is oxidation; gaining electrons is reduction.

### ■ PRACTICE EXERCISE

Identify the oxidizing and reducing agents in the oxidation-reduction reaction

*Answer:*  $\text{Al}(s)$  is the reducing agent;  $\text{MnO}_4^-(aq)$  is the oxidizing agent.

## 20.2 BALANCING OXIDATION-REDUCTION EQUATIONS

Whenever we balance a chemical equation, we must obey the law of conservation of mass: The amount of each element must be the same on both sides of the equation. (Atoms are neither created nor destroyed in any chemical reaction.) As we balance oxidation-reduction reactions, there is an additional requirement: The gains and losses of electrons must be balanced. In other words, if a substance loses a certain number of electrons during a reaction, then another substance must gain that same number of electrons. (Electrons are neither created nor destroyed in any chemical reaction.)

In many simple chemical reactions, such as Equation 20.2, balancing the electrons is handled “automatically”; we can balance the equation without explicitly considering the transfer of electrons. Many redox reactions are more complex than Equation 20.2, however, and cannot be balanced easily without taking into account the number of electrons lost and gained in the course of the reaction. In this section we examine the method of half reactions, which is a systematic procedure for balancing redox equations.

### Half-Reactions

Although oxidation and reduction must take place simultaneously, it is often convenient to consider them as separate processes. For example, the oxidation of  $\text{Sn}^{2+}$  by  $\text{Fe}^{3+}$ :

can be considered to consist of two processes: (1) the oxidation of  $\text{Sn}^{2+}$  (Equation 20.4) and (2) the reduction of  $\text{Fe}^{3+}$  (Equation 20.5):

Notice that electrons are shown as products in the oxidation process, whereas electrons are shown as reactants in the reduction process.

Equations that show either oxidation or reduction alone, such as Equations 20.4 and 20.5, are called **half-reactions**. In the overall redox reaction, the number of electrons lost in the oxidation half-reaction must equal the number of electrons gained in the reduction half-reaction. When this condition is met and each half-reaction is balanced, the electrons on the two sides cancel when the two half-reactions are added to give the overall balanced oxidation-reduction equation.

### Balancing Equations by the Method of Half-Reactions

The use of half-reactions provides a general method for balancing oxidation-reduction equations. We usually begin with a “skeleton” ionic equation that shows only the substances undergoing oxidation and reduction. In such cases,

we usually do not need to assign oxidation numbers unless we are unsure whether the reaction actually involves oxidation-reduction. We will find that  $\text{H}^+$  (for acidic solutions),  $\text{OH}^-$  (for basic solutions), and  $\text{H}_2\text{O}$  are often involved as reactants or products in redox reactions. Unless  $\text{H}^+$ ,  $\text{OH}^-$ , or  $\text{H}_2\text{O}$  are being oxidized or reduced, they do not appear in the skeleton equation. Their presence, however, can be deduced during the course of balancing the equation.

For balancing a redox reaction that occurs in acidic aqueous solution, the procedure is as follows:

1. Divide the equation into two half-reactions, one for oxidation and the other for reduction.
2. Balance each half-reaction.
  - (a) First, balance the elements other than H and O.
  - (b) Next, balance the O atoms by adding  $\text{H}_2\text{O}$  as needed.
  - (c) Then, balance the H atoms by adding  $\text{H}^+$  as needed.
  - (d) Finally, balance the charge by adding  $e^-$  as needed.
3. Multiply the half-reactions by integers, if necessary, so that the number of electrons lost in one half-reaction equals the number of electrons gained in the other.
4. Add the two half-reactions and, if possible, simplify by canceling species appearing on both sides of the combined equation.
5. Check to make sure that atoms and charges are balanced.

As an example, let's consider the reaction between permanganate ion ( $\text{MnO}_4^-$ ) and oxalate ion ( $\text{C}_2\text{O}_4^{2-}$ ) in acidic aqueous solution. When  $\text{MnO}_4^-$  is added to an acidified solution of  $\text{C}_2\text{O}_4^{2-}$ , the deep purple color of the  $\text{MnO}_4^-$  ion fades, as illustrated in Figure 20.2. Bubbles of  $\text{CO}_2$  form, and the solution takes on the pale pink color of  $\text{Mn}^{2+}$ . We can therefore write the skeleton equation as

Experiments show that  $\text{H}^+$  is consumed and  $\text{H}_2\text{O}$  is produced in the reaction. We will see that their involvement in the reaction is deduced in the course of balancing the equation.

To complete and balance this equation, we first write the two half-reactions (step 1). One half-reaction must have Mn on both sides of the arrow, and the other must have C on both sides of the arrow:

◀ **Figure 20.2** Titration of an acidic solution of  $\text{Na}_2\text{C}_2\text{O}_4$  with  $\text{KMnO}_4(aq)$ . (a) As it moves from the buret to the reaction flask, the deep purple  $\text{MnO}_4^-$  is rapidly reduced to extremely pale pink  $\text{Mn}^{2+}$  by  $\text{C}_2\text{O}_4^{2-}$ . (b) Once all the  $\text{C}_2\text{O}_4^{2-}$  in the flask has been consumed, any  $\text{MnO}_4^-$  added to the flask retains its purple color, and the end point corresponds to the faintest discernible purple color in the solution. (c) Beyond the end point the solution in the flask becomes deep purple because of excess  $\text{MnO}_4^-$ .

**SAMPLE EXERCISE 20.2** | Balancing Redox Equations in Acidic Solution

Complete and balance this equation by the method of half-reactions:

**SOLUTION**

**Analyze:** We are given an incomplete, unbalanced (skeleton) equation for a redox reaction occurring in acidic solution and asked to complete and balance it.

**Plan:** We use the half-reaction procedure we just learned.

**Solve: Step 1:** We divide the equation into two half-reactions:

**Step 2:** We balance each half-reaction. In the first half-reaction the presence of one  $\text{Cr}_2\text{O}_7^{2-}$  among the reactants requires two  $\text{Cr}^{3+}$  among the products. The seven oxygen atoms in  $\text{Cr}_2\text{O}_7^{2-}$  are balanced by adding seven  $\text{H}_2\text{O}$  to the products. The 14 hydrogen atoms in 7  $\text{H}_2\text{O}$  are then balanced by adding 14  $\text{H}^+$  to the reactants:

We then balance the charge by adding electrons to the left side of the equation so that the total charge is the same on the two sides:

We can check this result by looking at the oxidation state changes. Each chromium atom goes from +6 to +3, gaining three electrons, and therefore the two Cr atoms in  $\text{Cr}_2\text{O}_7^{2-}$  gains six electrons, in agreement with our half-reaction.

In the second half-reaction, two  $\text{Cl}^-$  are required to balance one  $\text{Cl}_2$ :

We add two electrons to the right side to attain charge balance:

This result agrees with the oxidation state changes. Each chlorine atom goes from  $-1$  to  $0$ , losing one electron, and therefore the two chlorine atoms lose two electrons.

**Step 3:** We equalize the number of electrons transferred in the two half-reactions. To do so, we multiply the Cl half-reaction by 3 so that the number of electrons gained in the Cr half-reaction (6) equals the number lost in the Cl half-reaction, allowing the electrons to cancel when the half-reactions are added:

**Step 4:** The equations are added to give the balanced equation:

**Step 5:** There are equal numbers of atoms of each kind on the two sides of the equation (14 H, 2 Cr, 7 O, 6 Cl). In addition, the charge is the same on the two sides (6+). Thus, the equation is balanced.

**PRACTICE EXERCISE**

Complete and balance the following equations using the method of half-reactions. Both reactions occur in acidic solution.

**Balancing Equations for Reactions Occurring in Basic Solution**

If a redox reaction occurs in basic solution, the equation must be completed by using  $\text{OH}^-$  and  $\text{H}_2\text{O}$  rather than  $\text{H}^+$  and  $\text{H}_2\text{O}$ . One way to balance these reactions is to balance the half-reactions initially as if they occurred in acidic solution. Then, count the  $\text{H}^+$  in each half-reaction, and add the same number of  $\text{OH}^-$  to each side of the half-reaction. This way the reaction is still mass-balanced because you are adding the same thing to both sides. In essence, what you are doing is

“neutralizing” the protons to form water ( $\text{H}^+ + \text{OH}^- \longrightarrow \text{H}_2\text{O}$ ) on the side containing  $\text{H}^+$ , and the other side ends up with the  $\text{OH}^-$ . The resulting water molecules can be canceled as needed. This procedure is shown in Sample Exercise 20.3.

### SAMPLE EXERCISE 20.3 | Balancing Redox Equations in Basic Solution

Complete and balance this equation for a redox reaction that takes place in basic solution:

#### SOLUTION

**Analyze:** We are given an incomplete equation for a basic redox reaction and asked to balance it.

**Plan:** We go through the first steps of our procedure as if the reaction were occurring in acidic solution. We then add the appropriate number of  $\text{OH}^-$  ions to each side of the equation, combining  $\text{H}^+$  and  $\text{OH}^-$  to form  $\text{H}_2\text{O}$ . We complete the process by simplifying the equation.

**Solve:** **Step 1:** We write the incomplete, unbalanced half-reactions:

**Step 2:** We balance each half-reaction as if it took place in acidic solution. The  $\text{H}^+$  ions are set in red for emphasis:

Now we need to take into account that the reaction occurs in basic solution, adding  $\text{OH}^-$  to both sides of both half-reactions to neutralize  $\text{H}^+$ . The  $\text{OH}^-$  ions are set in blue for emphasis.

We now “neutralize”  $\text{H}^+$  and  $\text{OH}^-$  by forming  $\text{H}_2\text{O}$  when they are on the same side of either half-reaction:

Next, we cancel water molecules that appear as both reactants and products:

Both half-reactions are now balanced. You can check the atoms and the overall charge.

**Step 3:** Now we multiply the cyanide half-reaction through by 3, which will give 6 electrons on the product side; and multiply the permanganate half-reaction through by 2, which will give 6 electrons on the reactant side:

**Step 4:** Now we can add the two half-reactions together and simplify by canceling species that appear as both reactants and products:

**Step 5:** Check that the atoms and charges are balanced.

There are 3 C, 3 N, 2 H, 9 O, 2 Mn, and a charge of 5<sup>-</sup> on both sides of the equation.

#### PRACTICE EXERCISE

Complete and balance the following equations for oxidation-reduction reactions that occur in basic solution:

## 20.3 VOLTAIC CELLS

The energy released in a spontaneous redox reaction can be used to perform electrical work. This task is accomplished through a **voltaic** (or **galvanic**) cell, a device in which the transfer of electrons takes place through an external pathway rather than directly between reactants.

One such spontaneous reaction occurs when a strip of zinc is placed in contact with a solution containing  $\text{Cu}^{2+}$ . As the reaction proceeds, the blue color of  $\text{Cu}^{2+}(\text{aq})$  ions fades, and copper metal deposits on the zinc. At the same time, the zinc begins to dissolve. These transformations are shown in Figure 20.3 ▼ and are summarized by the equation

▲ **Figure 20.3** A spontaneous oxidation-reduction reaction.

▲ **Figure 20.4** A voltaic cell based on the reaction in Equation 20.7. The left compartment contains 1 M  $\text{CuSO}_4$  and a copper electrode. The one on the right contains 1 M  $\text{ZnSO}_4$  and a zinc electrode. The solutions are connected by a porous glass disc, which permits contact of the two solutions. The metal electrodes are connected through a voltmeter, which reads the potential of the cell, 1.10 V.

Figure 20.4 ◀ shows a voltaic cell that uses the redox reaction between Zn and  $\text{Cu}^{2+}$  given in Equation 20.7. Although the setup shown in Figure 20.4 is more complex than that in Figure 20.3, the reaction is the same in both cases. The significant difference is that the Zn metal and  $\text{Cu}^{2+}(\text{aq})$  are not in direct contact in the voltaic cell. Instead, the Zn metal is in contact with  $\text{Zn}^{2+}(\text{aq})$  in one compartment of the cell, and Cu metal is in contact with  $\text{Cu}^{2+}(\text{aq})$  in another compartment. Consequently, the reduction of the  $\text{Cu}^{2+}$  can occur only by a flow of electrons through an external circuit, namely, the wire that connects the Zn and Cu strips. In other words, by physically separating the reduction half of a redox reaction from the oxidation half, we create a flow of electrons through an external circuit. The electron flow can be used to accomplish electrical work.

The two solid metals that are connected by the external circuit are called *electrodes*. By definition, the electrode at which oxidation occurs is called the **anode**; the electrode at which reduction occurs is called the **cathode**.\* The electrodes can be made of materials that participate in the reaction, as in the present example. Over the course of the reaction, the Zn electrode will gradually disappear and the copper electrode will gain mass. More typically, the electrodes are made of a conducting material, such as platinum or graphite, that does not gain or lose mass during the reaction but serves as a surface at which electrons are transferred.

Each of the two compartments of a voltaic cell is called a *half-cell*. One half-cell is the site of the oxidation half-reaction, and the other is the site of the reduction half-reaction. In our present example Zn is oxidized and  $\text{Cu}^{2+}$  is reduced:

Electrons become available as zinc metal is oxidized at the anode. They flow through the external circuit to the cathode, where they are consumed as  $\text{Cu}^{2+}(\text{aq})$  is reduced. Because Zn(s) is oxidized in the cell, the zinc electrode loses mass, and the concentration of the  $\text{Zn}^{2+}$  solution increases as the cell operates. Similarly, the Cu electrode gains mass, and the  $\text{Cu}^{2+}$  solution becomes less concentrated as  $\text{Cu}^{2+}$  is reduced to Cu(s).

For a voltaic cell to work, the solutions in the two half-cells must remain electrically neutral. As Zn is oxidized in the anode compartment,  $\text{Zn}^{2+}$  ions enter the solution. Thus, there must be some means for positive ions to migrate out of the anode compartment and for negative ions to migrate in to keep the solution electrically neutral. Similarly, the reduction of  $\text{Cu}^{2+}$  at the cathode removes positive charge from the solution, leaving an excess of negative charge in that half-cell. Thus, positive ions must migrate into the compartment and negative ions must migrate out. In fact, no measurable electron flow will occur between electrodes unless a means is provided for ions to migrate through the solution from one electrode compartment to the other, thereby completing the circuit.

▲ **Figure 20.5** A voltaic cell that uses a salt bridge to complete the electrical circuit.

\*To help remember these definitions, note that anode and oxidation both begin with a vowel, and cathode and reduction both begin with a consonant.

not pour out when the U-tube is inverted. As oxidation and reduction proceed at the electrodes, ions from the salt bridge migrate to neutralize charge in the cell compartments. Whatever means is used to allow ions to migrate between half-cells, *anions always migrate toward the anode and cations toward the cathode.*

### GIVE IT SOME THOUGHT

Why do anions in a salt bridge migrate toward the anode?

Figure 20.6 summarizes the relationships among the anode, the cathode, the chemical process occurring in a voltaic cell, the direction of migration of ions in solution, and the motion of electrons between electrodes in the external circuit. Notice in particular that *in any voltaic cell the electrons flow from the anode through the external circuit to the cathode.* Because the negatively charged electrons flow from the anode to the cathode, the anode in a voltaic cell is labeled with a negative sign and the cathode with a positive sign; we can envision the electrons as being attracted to the positive cathode from the negative anode through the external circuit.

**▲ Figure 20.6** A summary of the terminology used to describe voltaic cells. Oxidation occurs at the anode; reduction occurs at the cathode. The electrons flow spontaneously from the negative anode to the positive cathode. The movement of ions in solution completes the electrical circuit. Anions move toward the anode, whereas cations move toward the cathode. The cell compartments can be separated by either a porous glass barrier (as in Figure 20.4) or by a salt bridge (as in Figure 20.5).

### SAMPLE EXERCISE 20.4 | Describing a Voltaic Cell

The oxidation-reduction reaction

is spontaneous. A solution containing  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  is poured into one beaker, and a solution of KI is poured into another. A salt bridge is used to join the beakers. A metallic conductor that will not react with either solution (such as platinum foil) is suspended in each solution, and the two conductors are connected with wires through a voltmeter or some other device to detect an electric current. The resultant voltaic cell generates an electric current. Indicate the reaction occurring at the anode, the reaction at the cathode, the direction of electron migration, the direction of ion migration, and the signs of the electrodes.

### SOLUTION

**Analyze:** We are given the equation for a spontaneous reaction that takes place in a voltaic cell and a description of how the cell is constructed. We are asked to write the half-reactions occurring at the anode and at the cathode, as well as the directions of electron and ion movements and the signs assigned to the electrodes.

**Plan:** Our first step is to divide the chemical equation into half-reactions so that we can identify the oxidation and the reduction processes. We then use the definitions of anode and cathode and the other terminology summarized in Figure 20.6.

**Solve:** In one half-reaction,  $\text{Cr}_2\text{O}_7^{2-}(\text{aq})$  is converted into  $\text{Cr}^{3+}(\text{aq})$ . Starting with these ions and then completing and balancing the half-reaction, we have

In the other half-reaction,  $\text{I}^-(\text{aq})$  is converted to  $\text{I}_2(\text{s})$ :

Now we can use the summary in Figure 20.6 to help us describe the voltaic cell. The first half-reaction is the reduction process (electrons on the reactant side of the equation). By definition, the reduction process occurs at the cathode. The second half-reaction is the oxidation process (electrons on the product side of the equation), which occurs at the anode.

The  $\text{I}^-$  ions are the source of electrons, and the  $\text{Cr}_2\text{O}_7^{2-}$  ions accept the electrons. Hence, the electrons flow through the external circuit from the electrode immersed in the KI solution (the anode) to the electrode immersed in the  $\text{K}_2\text{Cr}_2\text{O}_7\text{-H}_2\text{SO}_4$  solution (the cathode). The electrodes themselves do not react in any way; they merely provide a means of transferring electrons from or to the solutions. The cations move through the solutions toward the cathode, and the anions move toward the anode. The anode (from which the electrons move) is the negative electrode, and the cathode (toward which the electrons move) is the positive electrode.

▼ **Figure 20.7 Atomic-level depiction of the Zn(s)-Cu<sup>2+</sup>(aq) reaction.** The water molecules and anions in the solution are not shown. (a) A Cu<sup>2+</sup> ion comes in contact with the surface of the Zn strip and gains two electrons from a Zn atom; the Cu<sup>2+</sup> ion is reduced, and the Zn atom is oxidized. (b) The resulting Zn<sup>2+</sup> ion enters the solution, and the Cu atom remains deposited on the strip.

▼ **Figure 20.8 Atomic-level depiction of the voltaic cell in Figure 20.5.** At the anode a Zn atom loses two electrons and becomes a Zn<sup>2+</sup> ion; the Zn atom is oxidized. The electrons travel through the external circuit to the cathode. At the cathode a Cu<sup>2+</sup> ion gains the two electrons, forming a Cu atom; the Cu<sup>2+</sup> ion is reduced. Ions migrate through the porous barrier to maintain charge balance between the compartments.

### PRACTICE EXERCISE

The two half-reactions in a voltaic cell are

(a) Indicate which reaction occurs at the anode and which at the cathode. (b) Which electrode is consumed in the cell reaction? (c) Which electrode is positive?

**Answers:** (a) The first reaction occurs at the anode and the second reaction at the cathode. (b) The anode (Zn) is consumed in the cell reaction. (c) The cathode is positive.

### A Molecular View of Electrode Processes

To better understand the relationship between voltaic cells and spontaneous redox reactions, let's look at what happens at the atomic or molecular level. The actual processes involved in the transfer of electrons are quite complex; nevertheless, we can learn much by examining these processes in a simplified way.

Consider the spontaneous reaction between Zn(s) and Cu<sup>2+</sup>(aq), in which Zn(s) is oxidized to Zn<sup>2+</sup>(aq)

and Cu<sup>2+</sup>(aq) is reduced to Cu(s), as shown in Figure 20.3. Figure 20.7 ◀ shows a schematic diagram of these processes at the atomic level. We can envision a Cu<sup>2+</sup> ion coming into contact with the strip of Zn metal, as in Figure 20.7(a). Two electrons are transferred from a Zn atom to the Cu<sup>2+</sup> ion, leading to a Zn<sup>2+</sup> ion and a Cu atom. The Zn<sup>2+</sup> ion migrates away into the aqueous solution while the Cu atom remains deposited on the metal strip [Figure 20.7(b)]. As the reaction proceeds, we produce more and more Cu(s) and deplete the Cu<sup>2+</sup>(aq).

### GIVE IT SOME THOUGHT

What happens to the surface Zn atoms as they lose electrons?

The voltaic cell in Figure 20.5 is also based on the oxidation of Zn(s) and the reduction of Cu<sup>2+</sup>(aq). In this case, however, the electrons are not transferred directly from one reacting species to the other. As shown in Figure 20.8 ◀, a Zn atom at the surface of the anode “loses” two electrons and becomes a Zn<sup>2+</sup>(aq) ion in the anode compartment. We envision the two electrons traveling from the anode through the wire to the cathode. At the surface of the cathode, a Cu<sup>2+</sup> ion from the solution gains the two electrons to form a Cu atom, which is deposited on the cathode.

The redox reaction between Zn and Cu<sup>2+</sup> is spontaneous regardless of whether they react directly or in the separate compartments of a voltaic cell. In each case the overall reaction is the same—only the path by which the electrons are transferred from the Zn atom to a Cu<sup>2+</sup> ion is different.

## 20.4 CELL EMF UNDER STANDARD CONDITIONS

Why do electrons transfer spontaneously from a Zn atom to a  $\text{Cu}^{2+}$  ion, either directly as in the reaction of Figure 20.3 or through an external circuit as in the voltaic cell of Figure 20.4? In a simple sense, we can compare the electron flow to the flow of water in a waterfall (Figure 20.9). Water flows spontaneously over a waterfall because of a difference in potential energy between the top of the falls and the stream below.  $\infty$  (Section 5.1) In a similar fashion, electrons flow from the anode of a voltaic cell to the cathode because of a difference in potential energy. The potential energy of electrons is higher in the anode than in the cathode, and they spontaneously flow through an external circuit from the anode to the cathode. That is, electrons flow spontaneously toward the electrode with the more positive electrical potential.

The difference in potential energy per electrical charge (the *potential difference*) between two electrodes is measured in units of volts. One volt (V) is the potential difference required to impart 1 joule (J) of energy to a charge of 1 coulomb (C).

$$1 \text{ V} = 1 \frac{\text{J}}{\text{C}}$$

Recall that one electron has a charge of  $1.60 \times 10^{-19} \text{ C}$ .  $\infty$  (Section 2.2)

The potential difference between the two electrodes of a voltaic cell provides the driving force that pushes electrons through the external circuit. Therefore, we call this potential difference the **electromotive** (“causing electron motion”) **force**, or **emf**. The emf of a cell, denoted  $E_{\text{cell}}$ , is also called the **cell potential**. Because  $E_{\text{cell}}$  is measured in volts, we often refer to it as the *cell voltage*. For any cell reaction that proceeds spontaneously, such as that in a voltaic cell, the cell potential will be *positive*.

The emf of a particular voltaic cell depends on the specific reactions that occur at the cathode and anode, the concentrations of reactants and products, and the temperature, which we will assume to be  $25^\circ \text{C}$  unless otherwise noted. In this section we will focus on cells that are operated at  $25^\circ \text{C}$  under *standard conditions*. Recall from Section 19.5 that standard conditions include 1 M concentrations for reactants and products in solution and 1 atm pressure for those that are gases (Table 19.3). Under standard conditions the emf is called the **standard emf**, or the **standard cell potential**, and is denoted  $E_{\text{cell}}^\circ$ . For the Zn-Cu voltaic cell in Figure 20.5, for example, the standard cell potential at  $25^\circ \text{C}$  is +1.10 V.

Recall that the superscript  $^\circ$  indicates standard-state conditions.  $\infty$  (Section 5.7)

**▲ Figure 20.9 Water analogy for electron flow.** The flow of electrons from the anode to the cathode of a voltaic cell can be likened to the flow of water over a waterfall. Water flows over the waterfall because its potential energy is lower at the bottom of the falls than at the top. Likewise, if there is an electrical connection between the anode and cathode of a voltaic cell, electrons flow from the anode to the cathode to lower their potential energy.

### GIVE IT SOME THOUGHT

If a standard cell potential is +0.85 V at  $25^\circ \text{C}$ , is the redox reaction of the cell spontaneous?

## Standard Reduction (Half-Cell) Potentials

The emf, or cell potential, of a voltaic cell,  $E_{\text{cell}}^{\circ}$ , depends on the particular cathode and anode half-cells involved. We could, in principle, tabulate the standard cell potentials for all possible cathode/anode combinations. However, it is not necessary to undertake this arduous task. Rather, we can assign a standard potential to each individual half-cell and then use these half-cell potentials to determine  $E_{\text{cell}}^{\circ}$ .

The cell potential is the difference between two electrode potentials, one associated with the cathode and the other associated with the anode. By convention, the potential associated with each electrode is chosen to be the potential for reduction to occur at that electrode. Thus, standard electrode potentials are tabulated for reduction reactions; they are **standard reduction potentials**, denoted  $E_{\text{red}}^{\circ}$ . The cell potential,  $E_{\text{cell}}^{\circ}$ , is given by the standard reduction potential of the cathode reaction,  $E_{\text{red}}^{\circ}$  (cathode), *minus* the standard reduction potential of the anode reaction,  $E_{\text{red}}^{\circ}$  (anode):

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ} (\text{cathode}) - E_{\text{red}}^{\circ} (\text{anode}) \quad [20.8]$$

For all spontaneous reactions at standard conditions,  $E_{\text{cell}}^{\circ} > 0$ .

Because every voltaic cell involves two half-cells, it is not possible to measure the standard reduction potential of a half-reaction directly. If we assign a standard reduction potential to a certain reference half-reaction, however, we can then determine the standard reduction potentials of other half-reactions relative to that reference. The reference half-reaction is the reduction of  $\text{H}^{+}(\text{aq})$  to  $\text{H}_2(\text{g})$  under standard conditions, which is assigned a standard reduction potential of exactly 0 V.

An electrode designed to produce this half-reaction is called a **standard hydrogen electrode (SHE)**, or the normal hydrogen electrode (NHE). An SHE consists of a platinum wire connected to a piece of platinum foil covered with finely divided platinum that serves as an inert surface for the reaction. The electrode is encased in a glass tube so that hydrogen gas under standard conditions (1 atm) can bubble over the platinum, and the solution contains  $\text{H}^{+}(\text{aq})$  under standard (1 M) conditions (Figure 20.10 ▼).

▲ **Figure 20.10** The standard hydrogen electrode (SHE) used as a reference electrode. (a) An SHE consists of an electrode with finely divided Pt in contact with  $\text{H}_2(\text{g})$  at 1 atm pressure and an acidic solution with  $[\text{H}^{+}] = 1 \text{ M}$ . (b) Molecular depiction of the processes that occur at the SHE. When the SHE is the cathode of a cell, two  $\text{H}^{+}$  ions each accept an electron from the Pt electrode and are reduced to H atoms. The H atoms bond together to form  $\text{H}_2$ . When the SHE is the anode of a cell, the reverse process occurs: An  $\text{H}_2$  molecule at the electrode surface loses two electrons and is oxidized to  $\text{H}^{+}$ . The  $\text{H}^{+}$  ions in solution are hydrated.

Figure 20.11 ► shows a voltaic cell using an SHE and a standard electrode. The spontaneous reaction is the one shown in Figure 20.1, namely, the oxidation of Zn and the reduction of  $\text{H}^+$ :

Notice that the  $\text{Zn}^{2+}/\text{Zn}$  electrode is the anode and the SHE is the cathode and that the cell voltage is +0.76 V. By using the defined standard reduction potential of  $\text{H}^+$  ( $E_{\text{red}}^\circ = 0$ ) and Equation 20.8, we can determine the standard reduction potential for the  $\text{Zn}^{2+}/\text{Zn}$  half-reaction:

$$\begin{aligned} E_{\text{cell}}^\circ &= E_{\text{red}}^\circ(\text{cathode}) - E_{\text{red}}^\circ(\text{anode}) \\ +0.76 \text{ V} &= 0 \text{ V} - E_{\text{red}}^\circ(\text{anode}) \end{aligned}$$

$$E_{\text{red}}^\circ(\text{anode}) = -0.76 \text{ V}$$

Thus, a standard reduction potential of  $-0.76 \text{ V}$  can be assigned to the reduction of  $\text{Zn}^{2+}$  to Zn.

We write the reaction as a reduction even though it is “running in reverse” as an oxidation in the cell in Figure 20.11. *Whenever we assign an electrical potential to a half-reaction, we write the reaction as a reduction.*

The standard reduction potentials for other half-reactions can be established from other cell potentials in a fashion analogous to that used for the  $\text{Zn}^{2+}/\text{Zn}$  half-reaction. Table 20.1 ▼ lists some standard reduction potentials; a more complete list is found in Appendix E. These standard reduction potentials, often called *half-cell potentials*, can be combined to calculate the emfs of a large variety of voltaic cells.

▲ **Figure 20.11** A voltaic cell using a standard hydrogen electrode.

**TABLE 20.1** ■ Standard Reduction Potentials in Water at 25 °C

-0.44	$\text{Fe}^{2+}(aq) + 2 e^- \longrightarrow \text{Fe}(s)$
-0.76	$\text{Zn}^{2+}(aq) + 2 e^- \longrightarrow \text{Zn}(s)$
-0.83	$2 \text{H}_2\text{O}(l) + 2 e^- \longrightarrow \text{H}_2(g) + 2 \text{OH}^-(aq)$
-1.66	$\text{Al}^{3+}(aq) + 3 e^- \longrightarrow \text{Al}(s)$
-2.71	$\text{Na}^+(aq) + e^- \longrightarrow \text{Na}(s)$
-3.05	$\text{Li}^+(aq) + e^- \longrightarrow \text{Li}(s)$

## GIVE IT SOME THOUGHT

For the half-reaction  $\text{Cl}_2(\text{g}) + 2 \text{e}^- \longrightarrow 2 \text{Cl}^-(\text{aq})$ , what are the standard conditions for the reactant and product?

Because electrical potential measures potential energy per electrical charge, standard reduction potentials are intensive properties.  $\infty$  (Section 1.3). In other words, if we increased the amount of substances in a redox reaction, we would increase both the energy and charges involved, but the ratio of energy (joules) to electrical charge (coulombs) would remain constant ( $V = J/C$ ). Thus, *changing the stoichiometric coefficient in a half-reaction does not affect the value of the standard reduction potential*. For example,  $E_{\text{red}}^\circ$  for the reduction of 10 mol  $\text{Zn}^{2+}$  is the same as that for the reduction of 1 mol  $\text{Zn}^{2+}$ :

### SAMPLE EXERCISE 20.5 | Calculating $E_{\text{red}}^\circ$ from $E_{\text{cell}}^\circ$

For the Zn-Cu<sup>2+</sup> voltaic cell shown in Figure 20.5, we have

Given that the standard reduction potential of  $\text{Zn}^{2+}$  to Zn(s) is  $-0.76 \text{V}$ , calculate the  $E_{\text{red}}^\circ$  for the reduction of  $\text{Cu}^{2+}$  to Cu:

#### SOLUTION

**Analyze:** We are given  $E_{\text{cell}}^\circ$  and  $E_{\text{red}}^\circ$  for  $\text{Zn}^{2+}$  and asked to calculate  $E_{\text{red}}^\circ$  for  $\text{Cu}^{2+}$ .

**Plan:** In the voltaic cell, Zn is oxidized and is therefore the anode. Thus, the given  $E_{\text{red}}^\circ$  for  $\text{Zn}^{2+}$  is  $E_{\text{red}}^\circ$  (anode). Because  $\text{Cu}^{2+}$  is reduced, it is in the cathode half-cell. Thus, the unknown reduction potential for  $\text{Cu}^{2+}$  is  $E_{\text{red}}^\circ$  (cathode). Knowing  $E_{\text{cell}}^\circ$  and  $E_{\text{red}}^\circ$  (anode), we can use Equation 20.8 to solve for  $E_{\text{red}}^\circ$  (cathode).

**Solve:**

$$\begin{aligned} E_{\text{cell}}^\circ &= E_{\text{red}}^\circ(\text{cathode}) - E_{\text{red}}^\circ(\text{anode}) \\ 1.10 \text{V} &= E_{\text{red}}^\circ(\text{cathode}) - (-0.76 \text{V}) \\ E_{\text{red}}^\circ(\text{cathode}) &= 1.10 \text{V} - 0.76 \text{V} = 0.34 \text{V} \end{aligned}$$

**Check:** This standard reduction potential agrees with the one listed in Table 20.1.

**Comment:** The standard reduction potential for  $\text{Cu}^{2+}$  can be represented as  $E_{\text{Cu}^{2+}}^\circ = 0.34 \text{V}$ , and that for  $\text{Zn}^{2+}$  as  $E_{\text{Zn}^{2+}}^\circ = -0.76 \text{V}$ . The subscript identifies the ion that is reduced in the reduction half-reaction.

### PRACTICE EXERCISE

A voltaic cell is based on the half-reactions

The standard emf for this cell is  $1.46 \text{V}$ . Using the data in Table 20.1, calculate  $E_{\text{red}}^\circ$  for the reduction of  $\text{In}^{3+}$  to  $\text{In}^+$ .

**Answer:**  $-0.40 \text{V}$

### SAMPLE EXERCISE 20.6 | Calculating $E_{\text{cell}}^\circ$ from $E_{\text{red}}^\circ$

Using the standard reduction potentials listed in Table 20.1, calculate the standard emf for the voltaic cell described in Sample Exercise 20.4, which is based on the reaction

#### SOLUTION

**Analyze:** We are given the equation for a redox reaction and asked to use data in Table 20.1 to calculate the standard emf (standard potential) for the associated voltaic cell.

**Plan:** Our first step is to identify the half-reactions that occur at the cathode and the anode, which we did in Sample Exercise 20.4. Then we can use data from Table 20.1 and Equation 20.8 to calculate the standard emf.

**Solve:** The half-reactions are

According to Table 20.1, the standard reduction potential for the reduction of  $\text{Cr}_2\text{O}_7^{2-}$  to  $\text{Cr}^{3+}$  is +1.33 V, and the standard reduction potential for the reduction of  $\text{I}_2$  to  $\text{I}^-$  (the reverse of the oxidation half-reaction) is +0.54 V. We then use these values in Equation 20.8.

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = 1.33 \text{ V} - 0.54 \text{ V} = 0.79 \text{ V}$$

Although we must multiply the iodide half-reaction at the anode by 3 to obtain a balanced equation for the reaction, the value of  $E_{\text{red}}^{\circ}$  is *not* multiplied by 3. As we have noted, the standard reduction potential is an intensive property, so it is independent of the specific stoichiometric coefficients.

**Check:** The cell potential, 0.79 V, is a positive number. As noted earlier, a voltaic cell must have a positive emf in order to operate.

### PRACTICE EXERCISE

Using data in Table 20.1, calculate the standard emf for a cell that employs the following overall cell reaction:

**Answer:**  $0.54 \text{ V} - (-1.66 \text{ V}) = 2.20 \text{ V}$

For each of the half-cells in a voltaic cell, the standard reduction potential provides a measure of the driving force for reduction to occur: *The more positive the value of  $E_{\text{red}}^{\circ}$ , the greater the driving force for reduction under standard conditions.* In any voltaic cell operating under standard conditions, the reaction at the cathode has a more positive value of  $E_{\text{red}}^{\circ}$  than does the reaction at the anode.

Equation 20.8, which indicates that the standard cell potential is the difference between the standard reduction potential of the cathode and the standard reduction potential of the anode, is illustrated graphically in Figure 20.12. The standard reduction potentials of the cathode and anode are shown on a scale. The more positive  $E_{\text{red}}^{\circ}$  value identifies the cathode, and the difference between the two standard reduction potentials is the standard cell potential. Figure 20.13 shows the specific values of  $E_{\text{red}}^{\circ}$  for the two half-reactions in the Zn-Cu voltaic cell illustrated in Figure 20.5.

### GIVE IT SOME THOUGHT

Is the following statement true or false? The smaller the difference is between the standard reduction potentials of the cathode and anode, the smaller the driving force for the overall redox reaction.

### SAMPLE EXERCISE 20.7 Determining Half-Reactions at Electrodes and Calculating Cell EMF

A voltaic cell is based on the following two standard half-reactions:

By using the data in Appendix E, determine (a) the half-reactions that occur at the cathode and the anode, and (b) the standard cell potential.

### SOLUTION

**Analyze:** We have to look up  $E_{\text{red}}^{\circ}$  for two half-reactions and use these values to predict the cathode and anode of the cell and to calculate its standard cell potential,  $E_{\text{cell}}^{\circ}$ .

**Figure 20.12 Standard cell potential of a voltaic cell.** The cell potential measures the difference in the standard reduction potentials of the cathode and the anode reactions:  $E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$ . In a voltaic cell the cathode reaction is always the one that has the more positive (or less negative) value for  $E_{\text{red}}^{\circ}$ .

**Figure 20.13 Half-cell potentials.** The half-cell potentials for the voltaic cell in Figure 20.5, diagrammed in the style of Figure 20.12.

**Plan:** The cathode will have the reduction with the more positive  $E_{\text{red}}^{\circ}$  value. The anode will have the less positive  $E_{\text{red}}^{\circ}$ . To write the half-reaction at the anode, we reverse the half-reaction written for the reduction, so that the half-reaction is written as an oxidation.

**Solve:**

(a) According to Appendix E,  $E_{\text{red}}^{\circ}(\text{Cd}^{2+}/\text{Cd}) = -0.403 \text{ V}$  and  $E_{\text{red}}^{\circ}(\text{Sn}^{2+}/\text{Sn}) = -0.136 \text{ V}$ . The standard reduction potential for  $\text{Sn}^{2+}$  is more positive (less negative) than that for  $\text{Cd}^{2+}$ ; hence, the reduction of  $\text{Sn}^{2+}$  is the reaction that occurs at the cathode.

The anode reaction therefore is the loss of electrons by Cd.

(b) The cell potential is given by Equation 20.8.

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (-0.136 \text{ V}) - (-0.403 \text{ V}) = 0.267 \text{ V}$$

Notice that it is unimportant that the  $E_{\text{red}}^{\circ}$  values of both half-reactions are negative; the negative values merely indicate how these reductions compare to the reference reaction, the reduction of  $\text{H}^{+}(\text{aq})$ .

**Check:** The cell potential is positive, as it must be for a voltaic cell.

### PRACTICE EXERCISE

A voltaic cell is based on a  $\text{Co}^{2+}/\text{Co}$  half-cell and an  $\text{AgCl}/\text{Ag}$  half-cell.

(a) What half-reaction occurs at the anode? (b) What is the standard cell potential?

**Answers:** (a)  $\text{Co} \longrightarrow \text{Co}^{2+} + 2 \text{e}^{-}$ ; (b)  $+0.499 \text{ V}$

## Strengths of Oxidizing and Reducing Agents

We have thus far used the tabulation of standard reduction potentials to examine voltaic cells. We can also use  $E_{\text{red}}^{\circ}$  values to understand aqueous reaction chemistry. Recall, for example, the reaction between  $\text{Zn}(\text{s})$  and  $\text{Cu}^{2+}(\text{aq})$  shown in Figure 20.3.

Zinc metal is oxidized, and  $\text{Cu}^{2+}(\text{aq})$  is reduced in this reaction. These substances are in direct contact, however, so we are not producing usable electrical work; the direct contact essentially “short-circuits” the cell. Nevertheless, the driving force for the reaction is the same as that in a voltaic cell, as in Figure 20.5. Because the  $E_{\text{red}}^{\circ}$  value for the reduction of  $\text{Cu}^{2+}$  ( $0.34 \text{ V}$ ) is more positive than the  $E_{\text{red}}^{\circ}$  value for the reduction of  $\text{Zn}^{2+}$  ( $-0.76 \text{ V}$ ), the reduction of  $\text{Cu}^{2+}(\text{aq})$  by  $\text{Zn}(\text{s})$  is a spontaneous process.

We can generalize the relationship between the value of  $E_{\text{red}}^{\circ}$  and the spontaneity of redox reactions: *The more positive the  $E_{\text{red}}^{\circ}$  value for a half-reaction, the greater the tendency for the reactant of the half-reaction to be reduced and, therefore, to oxidize another species.* In Table 20.1, for example,  $\text{F}_2$  is the most easily reduced species, so it is the strongest oxidizing agent listed.

Among the most frequently used oxidizing agents are the halogens,  $\text{O}_2$ , and oxyanions such as  $\text{MnO}_4^{-}$ ,  $\text{Cr}_2\text{O}_7^{2-}$ , and  $\text{NO}_3^{-}$ , whose central atoms have high positive oxidation states. According to Table 20.1, all these species undergo reduction with large positive values of  $E_{\text{red}}^{\circ}$ .

Lithium ion ( $\text{Li}^{+}$ ) is the most difficult species to reduce and is therefore the poorest oxidizing agent:

Because  $\text{Li}^{+}$  is so difficult to reduce, the reverse reaction, the oxidation of  $\text{Li}(\text{s})$  to  $\text{Li}^{+}(\text{aq})$ , is a highly favorable reaction. *The half-reaction with the smallest reduction potential is most easily reversed as an oxidation.* Thus, lithium metal has a great tendency to transfer electrons to other species. In water, Li is the strongest reducing

agent among the substances listed in Table 20.1. Because Table 20.1 lists half-reactions as reductions, only the substances on the reactant side of these equations can serve as oxidizing agents; only those on the product side can serve as reducing agents.

Commonly used reducing agents include  $\text{H}_2$  and the active metals such as the alkali metals and the alkaline earth metals. Other metals whose cations have negative  $E_{\text{red}}^\circ$  values—Zn and Fe, for example—are also used as reducing agents. Solutions of reducing agents are difficult to store for extended periods because of the ubiquitous presence of  $\text{O}_2$ , a good oxidizing agent. For example, developer solutions used in film photography are mild reducing agents; they have only a limited shelf life because they are readily oxidized by  $\text{O}_2$  from the air.

The list of  $E_{\text{red}}^\circ$  values in Table 20.1 orders the ability of substances to act as oxidizing or reducing agents and is summarized in Figure 20.14. The substances that are most readily reduced (strong oxidizing agents) are the reactants on the top left of the table. Their products, on the top right of the table, are oxidized with difficulty (weak reducing agents). The substances on the bottom left of the table are reduced with difficulty, but their products are readily oxidized. This inverse relationship between oxidizing and reducing strength is similar to the inverse relationship between the strengths of conjugate acids and bases.  $\infty$  (Section 16.2 and Figure 16.4)

To help you remember the relationships between the strengths of oxidizing and reducing agents, recall the very exothermic reaction between sodium metal and chlorine gas to form sodium chloride (Figure 8.2). In this reaction  $\text{Cl}_2(\text{g})$  is reduced (it serves as a strong oxidizing agent) and  $\text{Na}(\text{s})$  is oxidized (it serves as a strong reducing agent). The products of this reaction— $\text{Na}^+$  and  $\text{Cl}^-$  ions—are very weak oxidizing and reducing agents, respectively.

**▲ Figure 20.14 Relative strengths of oxidizing agents.** The standard reduction potentials,  $E_{\text{red}}^\circ$ , listed in Table 20.1 are related to the ability of substances to serve as oxidizing or reducing agents. Species on the left side of the half-reactions can act as oxidizing agents, and those on the right side can act as reducing agents. As  $E_{\text{red}}^\circ$  becomes more positive, the species on the left become stronger and stronger oxidizing agents. As  $E_{\text{red}}^\circ$  becomes more negative, the species on the right become stronger and stronger reducing agents.

### SAMPLE EXERCISE 20.8 Determining the Relative Strengths of Oxidizing Agents

Using Table 20.1, rank the following ions in order of increasing strength as oxidizing agents:  $\text{NO}_3^-(\text{aq})$ ,  $\text{Ag}^+(\text{aq})$ ,  $\text{Cr}_2\text{O}_7^{2-}(\text{aq})$ .

#### SOLUTION

**Analyze:** We are given several ions and asked to rank their abilities to act as oxidizing agents.

**Plan:** The more readily an ion is reduced (the more positive its  $E_{\text{red}}^\circ$  value), the stronger it is as an oxidizing agent.

**Solve:** From Table 20.1, we have

Because the standard reduction potential of  $\text{Cr}_2\text{O}_7^{2-}$  is the most positive,  $\text{Cr}_2\text{O}_7^{2-}$  is the strongest oxidizing agent of the three. The rank order is  $\text{Ag}^+ < \text{NO}_3^- < \text{Cr}_2\text{O}_7^{2-}$ .

### PRACTICE EXERCISE

Using Table 20.1, rank the following species from the strongest to the weakest reducing agent:  $\text{I}^-(\text{aq})$ ,  $\text{Fe}(\text{s})$ ,  $\text{Al}(\text{s})$ .

**Answer:**  $\text{Al}(\text{s}) > \text{Fe}(\text{s}) > \text{I}^-(\text{aq})$

## 20.5 FREE ENERGY AND REDOX REACTIONS

We have observed that voltaic cells use redox reactions that proceed spontaneously. Any reaction that can occur in a voltaic cell to produce a positive emf must be spontaneous. Consequently, it is possible to decide whether a redox reaction will be spontaneous by using half-cell potentials to calculate the emf associated with it.

The following discussion will pertain to general redox reactions, not just reactions in voltaic cells. Thus, we will make Equation 20.8 more general by writing it as

$$E^\circ = E_{\text{red}}^\circ (\text{reduction process}) - E_{\text{red}}^\circ (\text{oxidation process}) \quad [20.10]$$

In modifying Equation 20.8, we have dropped the subscript “cell” to indicate that the calculated emf does not necessarily refer to a voltaic cell. Similarly, we have generalized the standard reduction potentials on the right side of the equation by referring to the reduction and oxidation processes, rather than the cathode and the anode. We can now make a general statement about the spontaneity of a reaction and its associated emf,  $E$ : *A positive value of  $E$  indicates a spontaneous process; a negative value of  $E$  indicates a nonspontaneous one. We will use  $E$  to represent the emf under nonstandard conditions and  $E^\circ$  to indicate the standard emf.*

### SAMPLE EXERCISE 20.9 | Spontaneous or Not?

Using standard reduction potentials in Table 20.1, determine whether the following reactions are spontaneous under standard conditions.

#### SOLUTION

**Analyze:** We are given two equations and must determine whether each is spontaneous.

**Plan:** To determine whether a redox reaction is spontaneous under standard conditions, we first need to write its reduction and oxidation half-reactions. We can then use the standard reduction potentials and Equation 20.10 to calculate the standard emf,  $E^\circ$ , for the reaction. If a reaction is spontaneous, its standard emf must be a positive number.

#### Solve:

(a) In this reaction Cu is oxidized to  $\text{Cu}^{2+}$  and  $\text{H}^+$  is reduced to  $\text{H}_2$ . The corresponding half-reactions and associated standard reduction potentials are

Notice that for the oxidation, we use the standard reduction potential from Table 20.1 for the reduction of  $\text{Cu}^{2+}$  to Cu. We now calculate  $E^\circ$  by using Equation 20.10:

$$\begin{aligned} E^\circ &= E_{\text{red}}^\circ (\text{reduction process}) - E_{\text{red}}^\circ (\text{oxidation process}) \\ &= (0 \text{ V}) - (0.34 \text{ V}) = -0.34 \text{ V} \end{aligned}$$

Because  $E^\circ$  is negative, the reaction is not spontaneous in the direction written. Copper metal does not react with acids in this fashion. The reverse reaction, however, is spontaneous and would have an  $E^\circ$  of +0.34 V.

$\text{Cu}^{2+}$  can be reduced by  $\text{H}_2$ .

(b) We follow a procedure analogous to that in (a):

In this case

$$E^\circ = (1.36 \text{ V}) - (0.54 \text{ V}) = +0.82 \text{ V}$$

Because the value of  $E^\circ$  is positive, this reaction is spontaneous and could be used to build a voltaic cell.

#### PRACTICE EXERCISE

Using the standard reduction potentials listed in Appendix E, determine which of the following reactions are spontaneous under standard conditions:

**Answer:** Reactions (b) and (c) are spontaneous.

We can use standard reduction potentials to understand the activity series of metals. [↔ \(Section 4.4\)](#) Recall that any metal in the activity series will be oxidized by the ions of any metal below it. We can now recognize the origin of this rule based on standard reduction potentials. The activity series, tabulated in Table 4.5, consists of the oxidation reactions of the metals, ordered from the strongest reducing agent at the top to the weakest reducing agent at the bottom. (Thus, the ordering is “flipped over” relative to that in Table 20.1.) For example, nickel lies above silver in the activity series. We therefore expect nickel to displace silver, according to the net reaction

In this reaction Ni is oxidized and  $\text{Ag}^+$  is reduced. Therefore, using data from Table 20.1, the standard emf for the reaction is

$$\begin{aligned} E^\circ &= E_{\text{red}}^\circ(\text{Ag}^+/\text{Ag}) - E_{\text{red}}^\circ(\text{Ni}^{2+}/\text{Ni}) \\ &= (+0.80 \text{ V}) - (-0.28 \text{ V}) = +1.08 \text{ V} \end{aligned}$$

The positive value of  $E^\circ$  indicates that the displacement of silver by nickel is a spontaneous process. Remember that although we multiply the silver half-reaction by 2, the reduction potential is not multiplied.

### GIVE IT SOME THOUGHT

Based on Table 4.5, which is the stronger reducing agent,  $\text{Hg}(l)$  or  $\text{Pb}(s)$ ?

### EMF and $\Delta G$

The change in the Gibbs free energy,  $\Delta G$ , is a measure of the spontaneity of a process that occurs at constant temperature and pressure. [↔ \(Section 19.5\)](#) The emf,  $E$ , of a redox reaction also indicates whether the reaction is spontaneous. The relationship between emf and the free-energy change is

$$\Delta G = -nFE \quad [20.11]$$

In this equation  $n$  is a positive number without units that represents the number of electrons transferred in the reaction. The constant  $F$  is called *Faraday's constant*, named after Michael Faraday (Figure 20.15 ▶). Faraday's constant is the quantity of electrical charge on one mole of electrons. This quantity of charge is called a *faraday* ( $F$ ).

$$1 F = 96,485 \text{ C/mol} = 96,485 \text{ J/V}\cdot\text{mol}$$

The units of  $\Delta G$  calculated by using Equation 20.11 are J/mol; as in Equation 19.16, we use “per mole” to mean “per mole of reaction as written.” [↔ \(Section 19.7\)](#)

Both  $n$  and  $F$  are positive numbers. Thus, a positive value of  $E$  in Equation 20.11 leads to a negative value of  $\Delta G$ . Remember: *A positive value of  $E$  and a negative value of  $\Delta G$  both indicate that a reaction is spontaneous.* When the reactants and products are all in their standard states, Equation 20.11 can be modified to relate  $\Delta G^\circ$  and  $E^\circ$ .

$$\Delta G^\circ = -nFE^\circ \quad [20.12]$$

Equation 20.12 is very important. It relates the standard emf,  $E^\circ$ , of an electrochemical reaction to the standard free-energy change,  $\Delta G^\circ$ , for the reaction. Because  $\Delta G^\circ$  is related to the equilibrium constant,  $K$ , for a reaction by the expression  $\Delta G^\circ = -RT \ln K$  [↔ \(Section 19.7\)](#), we can relate the standard emf to the equilibrium constant for the reaction.

▲ **Figure 20.15 Michael Faraday.** Faraday (1791–1867) was born in England, a child of a poor blacksmith. At the age of 14 he was apprenticed to a bookbinder who gave Faraday time to read and to attend lectures. In 1812 he became an assistant in Humphry Davy's laboratory at the Royal Institution. He succeeded Davy as the most famous and influential scientist in England, making an amazing number of important discoveries, including his formation of the quantitative relationships between electrical current and the extent of chemical reaction in electrochemical cells.

**SAMPLE EXERCISE 20.10** | Determining  $\Delta G^\circ$  and  $K$ 

(a) Use the standard reduction potentials listed in Table 20.1 to calculate the standard free-energy change,  $\Delta G^\circ$ , and the equilibrium constant,  $K$ , at 298 K for the reaction

(b) Suppose the reaction in part (a) was written

What are the values of  $E^\circ$ ,  $\Delta G^\circ$ , and  $K$  when the reaction is written in this way?

**SOLUTION**

**Analyze:** We are asked to determine  $\Delta G^\circ$  and  $K$  for a redox reaction, using standard reduction potentials.

**Plan:** We use the data in Table 20.1 and Equation 20.10 to determine  $E^\circ$  for the reaction and then use  $E^\circ$  in Equation 20.12 to calculate  $\Delta G^\circ$ . We will then use Equation 19.17,  $\Delta G^\circ = -RT \ln K$ , to calculate  $K$ .

**Solve:**

(a) We first calculate  $E^\circ$  by breaking the equation into two half-reactions, as we did in Sample Exercise 20.9, and then obtain  $E_{\text{red}}^\circ$  values from Table 20.1 (or Appendix E):

Even though the second half-reaction has 4 Ag, we use the  $E_{\text{red}}^\circ$  value directly from Table 20.1 because emf is an intensive property.

Using Equation 20.10, we have

$$E^\circ = (1.23 \text{ V}) - (0.80 \text{ V}) = 0.43 \text{ V}$$

The half-reactions show the transfer of four electrons. Thus, for this reaction  $n = 4$ . We now use Equation 20.12 to calculate  $\Delta G^\circ$ :

$$\begin{aligned} \Delta G^\circ &= -nFE^\circ \\ &= -(4)(96,485 \text{ J/V}\cdot\text{mol})(+0.43 \text{ V}) \\ &= -1.7 \times 10^5 \text{ J/mol} = -170 \text{ kJ/mol} \end{aligned}$$

The positive value of  $E^\circ$  leads to a negative value of  $\Delta G^\circ$ .

Now we need to calculate the equilibrium constant,  $K$ , using  $\Delta G^\circ = -RT \ln K$ . Because  $\Delta G^\circ$  is a large negative number, which means the reaction is thermodynamically very favorable, we expect  $K$  to be large.

$$\begin{aligned} \Delta G^\circ &= -RT \ln K \\ -1.7 \times 10^5 \text{ J/mol} &= -(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K}) \ln K \\ \ln K &= \frac{-1.7 \times 10^5 \text{ J/mol}}{-(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K})} \end{aligned}$$

$$\begin{aligned} \ln K &= 69 \\ K &= 9 \times 10^{29} \end{aligned}$$

$K$  is indeed very large! This means that we expect silver metal to oxidize in acidic aqueous environments, in air, to  $\text{Ag}^+$ .

Notice that the voltage calculated for the reaction was 0.43 V, which is easy to measure. Directly measuring such a large equilibrium constant by measuring reactant and product concentrations at equilibrium, on the other hand, would be very difficult.

(b) The overall equation is the same as that in part (a), multiplied by  $\frac{1}{2}$ . The half-reactions are

The values of  $E_{\text{red}}^\circ$  are the same as they were in part (a); they are not changed by multiplying the half-reactions by  $\frac{1}{2}$ . Thus,  $E^\circ$  has the same value as in part (a):

$$E^\circ = +0.43 \text{ V}$$

Notice, though, that the value of  $n$  has changed to  $n = 2$ , which is  $\frac{1}{2}$  the value in part (a). Thus,  $\Delta G^\circ$  is half as large as in part (a).

$$\Delta G^\circ = -(2)(96,485 \text{ J/V}\cdot\text{mol})(+0.43 \text{ V}) = -83 \text{ kJ/mol}$$

Now we can calculate  $K$  as before:

$$\begin{aligned} -83 \times 10^3 \text{ J/mol} &= -(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K}) \ln K \\ K &= 4 \times 10^{14} \end{aligned}$$

**Comment:**  $E^\circ$  is an *intensive* quantity, so multiplying a chemical equation by a certain factor will not affect the value of  $E^\circ$ . Multiplying an equation will change the value of  $n$ , however, and hence the value of  $\Delta G^\circ$ . The change in free energy, in units of J/mol of reaction as written, is an *extensive* quantity. The equilibrium constant is also an extensive quantity.

**PRACTICE EXERCISE**

For the reaction

(a) What is the value of  $n$ ? (b) Use the data in Appendix E to calculate  $\Delta G^\circ$ . (c) Calculate  $K$  at  $T = 298 \text{ K}$ .

**Answers:** (a) 6, (b) +87 kJ/mol, (c)  $K = 6 \times 10^{-16}$

## 20.6 CELL EMF UNDER NONSTANDARD CONDITIONS

We have seen how to calculate the emf of a cell when the reactants and products are under standard conditions. As a voltaic cell is discharged, however, the reactants of the reaction are consumed, and the products are generated, so the concentrations of these substances change. The emf progressively drops until  $E = 0$ , at which point we say the cell is “dead.” At that point the concentrations of the reactants and products cease to change; they are at equilibrium. In this section we will examine how the cell emf depends on the concentrations of the reactants and products of the cell reaction. The emf generated under nonstandard conditions can be calculated by using an equation first derived by Walther Nernst (1864–1941), a German chemist who established many of the theoretical foundations of electrochemistry.

### The Nernst Equation

The dependence of the cell emf on concentration can be obtained from the dependence of the free-energy change on concentration. ∞ (Section 19.7) Recall that the free-energy change,  $\Delta G$ , is related to the standard free-energy change,  $\Delta G^\circ$ :

$$\Delta G = \Delta G^\circ + RT \ln Q \quad [20.13]$$

The quantity  $Q$  is the reaction quotient, which has the form of the equilibrium-constant expression except that the concentrations are those that exist in the reaction mixture at a given moment. ∞ (Section 15.6)

Substituting  $\Delta G = -nFE$  (Equation 20.11) into Equation 20.13 gives

$$-nFE = -nFE^\circ + RT \ln Q$$

Solving this equation for  $E$  gives the **Nernst equation**:

$$E = E^\circ - \frac{RT}{nF} \ln Q \quad [20.14]$$

This equation is customarily expressed in terms of common (base 10) logarithms, which is related to natural logarithms by a factor of 2.303:

$$E = E^\circ - \frac{2.303 RT}{nF} \log Q \quad [20.15]$$

At  $T = 298 \text{ K}$  the quantity  $2.303 RT/F$  equals 0.0592, with units of volts (V), and so the equation simplifies to

$$E = E^\circ - \frac{0.0592 \text{ V}}{n} \log Q \quad (T = 298 \text{ K}) \quad [20.16]$$

We can use this equation to find the emf produced by a cell under nonstandard conditions or to determine the concentration of a reactant or product by measuring the emf of the cell.

To show how Equation 20.16 might be used, consider the following reaction, which we discussed earlier:

In this case  $n = 2$  (two electrons are transferred from Zn to  $\text{Cu}^{2+}$ ), and the standard emf is +1.10 V. Thus, at 298 K the Nernst equation gives

$$E = 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]} \quad [20.17]$$

Recall that pure solids are excluded from the expression for  $Q$ . ∞ (Section 15.6) According to Equation 20.17, the emf increases as  $[\text{Cu}^{2+}]$  increases and as  $[\text{Zn}^{2+}]$  decreases. For example, when  $[\text{Cu}^{2+}]$  is 5.0 M and  $[\text{Zn}^{2+}]$  is 0.050 M, we have

$$\begin{aligned} E &= 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \left( \frac{0.050}{5.0} \right) \\ &= 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} (-2.00) = 1.16 \text{ V} \end{aligned}$$

Thus, increasing the concentration of the reactant ( $\text{Cu}^{2+}$ ) and decreasing the concentration of the product ( $\text{Zn}^{2+}$ ) relative to standard conditions increases the emf of the cell ( $E = +1.16 \text{ V}$ ) relative to standard conditions ( $E^\circ = +1.10 \text{ V}$ ).

The Nernst equation helps us understand why the emf of a voltaic cell drops as the cell discharges. As reactants are converted to products, the value of  $Q$  increases, so the value of  $E$  decreases, eventually reaching  $E = 0$ . Because  $\Delta G = -nFE$  (Equation 20.11), it follows that  $\Delta G = 0$  when  $E = 0$ . Recall that a system is at equilibrium when  $\Delta G = 0$ .  $\infty$  (Section 19.7) Thus, when  $E = 0$ , the cell reaction has reached equilibrium, and no net reaction is occurring.

In general, increasing the concentration of reactants or decreasing the concentration of products increases the driving force for the reaction, resulting in a higher emf. Conversely, decreasing the concentration of reactants or increasing the concentration of products causes the emf to decrease.

### SAMPLE EXERCISE 20.11 | Voltaic Cell EMF under Nonstandard Conditions

Calculate the emf at 298 K generated by the cell described in Sample Exercise 20.4 when  $[\text{Cr}_2\text{O}_7^{2-}] = 2.0 \text{ M}$ ,  $[\text{H}^+] = 1.0 \text{ M}$ ,  $[\text{I}^-] = 1.0 \text{ M}$ , and  $[\text{Cr}^{3+}] = 1.0 \times 10^{-5} \text{ M}$ .

#### SOLUTION

**Analyze:** We are given a chemical equation for a voltaic cell and the concentrations of reactants and products under which it operates. We are asked to calculate the emf of the cell under these nonstandard conditions.

**Plan:** To calculate the emf of a cell under nonstandard conditions, we use the Nernst equation in the form of Equation 20.16.

**Solve:** We first calculate  $E^\circ$  for the cell from standard reduction potentials (Table 20.1 or Appendix E). The standard emf for this reaction was calculated in Sample Exercise 20.6:  $E^\circ = 0.79 \text{ V}$ . As you will see if you refer back to that exercise, the balanced equation shows six electrons transferred from reducing agent to oxidizing agent, so  $n = 6$ . The reaction quotient,  $Q$ , is

$$Q = \frac{[\text{Cr}^{3+}]^2}{[\text{Cr}_2\text{O}_7^{2-}][\text{H}^+]^{14}[\text{I}^-]^6} = \frac{(1.0 \times 10^{-5})^2}{(2.0)(1.0)^{14}(1.0)^6} = 5.0 \times 10^{-11}$$

Using Equation 20.16, we have

$$\begin{aligned} E &= 0.79 \text{ V} - \frac{0.0592 \text{ V}}{6} \log(5.0 \times 10^{-11}) \\ &= 0.79 \text{ V} - \frac{0.0592 \text{ V}}{6} (-10.30) \\ &= 0.79 \text{ V} + 0.10 \text{ V} = 0.89 \text{ V} \end{aligned}$$

**Check:** This result is qualitatively what we expect: Because the concentration of  $\text{Cr}_2\text{O}_7^{2-}$  (a reactant) is greater than  $1 \text{ M}$  and the concentration of  $\text{Cr}^{3+}$  (a product) is less than  $1 \text{ M}$ , the emf is greater than  $E^\circ$ .  $Q$  is about  $10^{-10}$ , so  $\log Q$  is about  $-10$ . Thus, the correction to  $E^\circ$  is about  $0.06 \times (10)/6$ , which is  $0.1$ , in agreement with the more detailed calculation.

#### PRACTICE EXERCISE

Calculate the emf generated by the cell described in the practice exercise accompanying Sample Exercise 20.6 when  $[\text{Al}^{3+}] = 4.0 \times 10^{-3} \text{ M}$  and  $[\text{I}^-] = 0.010 \text{ M}$ .

**Answer:**  $E = +2.36 \text{ V}$

### SAMPLE EXERCISE 20.12 | Calculating Concentrations in a Voltaic Cell

If the voltage of a Zn– $\text{H}^+$  cell (like that in Figure 20.11) is  $0.45 \text{ V}$  at  $25^\circ \text{C}$  when  $[\text{Zn}^{2+}] = 1.0 \text{ M}$  and  $P_{\text{H}_2} = 1.0 \text{ atm}$ , what is the concentration of  $\text{H}^+$ ?

#### SOLUTION

**Analyze:** We are given a description of a voltaic cell, its emf, and the concentrations of all reactants and products except  $\text{H}^+$ , which we are asked to calculate.

**Plan:** First, we write the equation for the cell reaction and use standard reduction potentials from Table 20.1 to calculate  $E^\circ$  for the reaction. After determining the value of  $n$  from our reaction equation, we solve the Nernst equation for  $Q$ . Finally, we use the equation for the cell reaction to write an expression for  $Q$  that contains  $[\text{H}^+]$  to determine  $[\text{H}^+]$ .

**Solve:** The cell reaction is  $\text{Zn}(s) + 2\text{H}^+(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{H}_2(g)$

The standard emf is  $E^\circ = E_{\text{red}}^\circ(\text{reduction}) - E_{\text{red}}^\circ(\text{oxidation})$

$$= 0\text{ V} - (-0.76\text{ V}) = +0.76\text{ V}$$

Because each Zn atom loses two electrons,  $n = 2$

Using Equation 20.16, we can solve for  $Q$ :  $0.45\text{ V} = 0.76\text{ V} - \frac{0.0592\text{ V}}{2} \log Q$

$$\log Q = (0.76\text{ V} - 0.45\text{ V}) \left( \frac{2}{0.0592\text{ V}} \right) = 10.5$$

$$Q = 10^{10.5} = 3 \times 10^{10}$$

$Q$  has the form of the equilibrium constant for the reaction  $Q = \frac{[\text{Zn}^{2+}]P_{\text{H}_2}}{[\text{H}^+]^2} = \frac{(1.0)(1.0)}{[\text{H}^+]^2} = 3 \times 10^{10}$

Solving for  $[\text{H}^+]$ , we have

$$[\text{H}^+]^2 = \frac{1.0}{3 \times 10^{10}} = 3 \times 10^{-11}$$

$$[\text{H}^+] = \sqrt{3 \times 10^{-11}} = 6 \times 10^{-6}\text{ M}$$

**Comment:** A voltaic cell whose cell reaction involves  $\text{H}^+$  can be used to measure  $[\text{H}^+]$  or pH. A pH meter is a specially designed voltaic cell with a voltmeter calibrated to read pH directly. [↔ \(Section 16.4\)](#)

### ■ PRACTICE EXERCISE

What is the pH of the solution in the cathode compartment of the cell pictured in Figure 20.11 when  $P_{\text{H}_2} = 1.0\text{ atm}$ ,  $[\text{Zn}^{2+}]$  in the anode compartment is  $0.10\text{ M}$ , and cell emf is  $0.542\text{ V}$ ?

**Answer:** pH = 4.23 (using data from Appendix E to obtain  $E^\circ$  to three significant figures)

## Concentration Cells

In each of the voltaic cells that we have looked at thus far, the reactive species at the anode has been different from the one at the cathode. Cell emf depends on concentration, however, so a voltaic cell can be constructed using the *same* species in both the anode and cathode compartments as long as the concentrations are different. A cell based solely on the emf generated because of a difference in a concentration is called a **concentration cell**.

A diagram of a concentration cell is shown in Figure 20.16(a)  $\blacktriangledown$ . One compartment consists of a strip of nickel metal immersed in a  $1.00\text{ M}$  solution of  $\text{Ni}^{2+}(aq)$ . The other compartment also has an Ni(s) electrode, but it is

**▲ Figure 20.16** Concentration cell based on the  $\text{Ni}^{2+}$ -Ni cell reaction. In (a) the concentrations of  $\text{Ni}^{2+}(aq)$  in the two compartments are unequal, and the cell generates an electrical current. The cell operates until the concentrations of  $\text{Ni}^{2+}(aq)$  in the two compartments become equal, (b) at which point the cell has reached equilibrium and is “dead.”

immersed in a  $1.00 \times 10^{-3} M$  solution of  $\text{Ni}^{2+}(\text{aq})$ . The two compartments are connected by a salt bridge and by an external wire running through a voltmeter. The half-cell reactions are the reverse of each other:

Although the *standard* emf for this cell is zero,  $E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (-0.28 \text{ V}) - (-0.28 \text{ V}) = 0 \text{ V}$ , the cell operates under *nonstandard* conditions because the concentration of  $\text{Ni}^{2+}(\text{aq})$  is different in the two compartments. In fact, the cell will operate until the concentrations of  $\text{Ni}^{2+}$  in both compartments are equal. Oxidation of  $\text{Ni(s)}$  occurs in the half-cell containing the more dilute solution, thereby increasing the concentration of  $\text{Ni}^{2+}(\text{aq})$ . It is therefore the anode compartment of the cell. Reduction of  $\text{Ni}^{2+}(\text{aq})$  occurs in the half-cell containing the more concentrated solution, thereby decreasing the concentration of  $\text{Ni}^{2+}(\text{aq})$ , making it the cathode compartment. The *overall* cell reaction is therefore

## Chemistry and Life

### HEARTBEATS AND ELECTROCARDIOGRAPHY

The human heart is a marvel of efficiency and dependability. In a typical day an adult's heart pumps more than 7000 L of blood through the circulatory system, usually with no maintenance required beyond a sensible diet and lifestyle. We generally think of the heart as a mechanical device, a muscle that circulates blood via regularly spaced muscular contractions. However, more than two centuries ago, two pioneers in electricity, Luigi Galvani (1729–1787) and Alessandro Volta (1745–1827), discovered that the contractions of the heart are controlled by electrical phenomena, as are nerve impulses throughout the body. The pulses of electricity that cause the heart to beat result from a remarkable combination of electrochemistry and the properties of semipermeable membranes. [∞ \(Section 13.5\)](#)

Cell walls are membranes with variable permeability with respect to a number of physiologically important ions (especially  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Ca}^{2+}$ ). The concentrations of these ions are different for the fluids inside the cells (the *intracellular fluid*, or ICF) and outside the cells (the *extracellular fluid*, or ECF). In cardiac muscle cells, for example, the concentrations of  $\text{K}^+$  in the ICF and ECF are typically about 135 millimolar (mM) and 4 mM, respectively. For  $\text{Na}^+$ , however, the concentration difference between the ICF and ECF is opposite that for  $\text{K}^+$ ; typically,  $[\text{Na}^+]_{\text{ICF}} = 10 \text{ mM}$  and  $[\text{Na}^+]_{\text{ECF}} = 145 \text{ mM}$ .

The cell membrane is initially permeable to  $\text{K}^+$  ions, but is much less so to  $\text{Na}^+$  and  $\text{Ca}^{2+}$ . The difference in concentration of  $\text{K}^+$  ions between the ICF and ECF generates a concentration cell: Even though the same ions are present on both sides of the membrane, there is a potential difference between the two fluids that we can calculate using the Nernst equation with  $E^{\circ} = 0$ . At physiological temperature (37 °C) the potential in millivolts for moving  $\text{K}^+$  from the ECF to the ICF is

$$\begin{aligned} E &= E^{\circ} - \frac{2.30 RT}{nF} \log \frac{[\text{K}^+]_{\text{ICF}}}{[\text{K}^+]_{\text{ECF}}} \\ &= 0 - (61.5 \text{ mV}) \log \left( \frac{135 \text{ mM}}{4 \text{ mM}} \right) = -94 \text{ mV} \end{aligned}$$

In essence, the interior of the cell and the ECF together serve as a voltaic cell. The negative sign for the potential indicates that work is required to move  $\text{K}^+$  into the intracellular fluid.

Changes in the relative concentrations of the ions in the ECF and ICF lead to changes in the emf of the voltaic cell. The cells of the heart that govern the rate of heart contraction are called the *pacemaker cells*. The membranes of the cells regulate the concentrations of ions in the ICF, allowing them to change in a systematic way. The concentration changes cause the emf to change in a cyclic fashion, as shown in Figure 20.17 ▶.

We can calculate the emf of a concentration cell by using the Nernst equation. For this particular cell, we see that  $n = 2$ . The expression for the reaction quotient for the overall reaction is  $Q = [\text{Ni}^{2+}]_{\text{dilute}}/[\text{Ni}^{2+}]_{\text{concentrated}}$ . Thus, the emf at 298 K is

$$\begin{aligned} E &= E^\circ - \frac{0.0592 \text{ V}}{n} \log Q \\ &= 0 - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Ni}^{2+}]_{\text{dilute}}}{[\text{Ni}^{2+}]_{\text{concentrated}}} = -\frac{0.0592 \text{ V}}{2} \log \frac{1.00 \times 10^{-3} \text{ M}}{1.00 \text{ M}} \\ &= +0.0888 \text{ V} \end{aligned}$$

This concentration cell generates an emf of nearly 0.09 V even though  $E^\circ = 0$ . The difference in concentration provides the driving force for the cell. When the concentrations in the two compartments become the same,  $Q = 1$  and  $E = 0$ .

The idea of generating a potential by a difference in concentration is the basis for the operation of pH meters (Figure 16.6). It is also a critical aspect in biology. For example, nerve cells in the brain generate a voltage across the cell membrane by having different concentrations of ions on either side of the membrane. The regulation of the heartbeat in mammals, as discussed in the “Chemistry and Life” box in this section, is another example of the importance of electrochemistry to living organisms.

▲ **Figure 20.17 Ion concentration and emf in the human heart.** Variation of the electrical potential caused by changes of ion concentrations in the pacemaker cells of the heart.

The emf cycle determines the rate at which the heart beats. If the pacemaker cells malfunction because of disease or injury, an artificial pacemaker can be surgically implanted. The artificial pacemaker is a small battery that generates the electrical pulses needed to trigger the contractions of the heart.

During the late 1800s scientists discovered that the electrical impulses that cause the contraction of the heart muscle are strong enough to be detected at the surface of the body.

▲ **Figure 20.18 A typical electrocardiogram.** An electrocardiogram (ECG) printout records the electrical events monitored by electrodes attached to the body surface. The horizontal axis is time, and the vertical displacement is the emf.

This observation formed the basis for *electrocardiography*, noninvasive monitoring of the heart by using a complex array of electrodes on the skin to measure voltage changes during heartbeats. A typical electrocardiogram is shown in Figure 20.18 ▲. It is quite striking that, although the heart’s major function is the *mechanical* pumping of blood, it is most easily monitored by using the *electrical* impulses generated by tiny voltaic cells.

**SAMPLE EXERCISE 20.13** Determining pH Using a Concentration Cell

A voltaic cell is constructed with two hydrogen electrodes. Electrode 1 has  $P_{\text{H}_2} = 1.00$  atm and an unknown concentration of  $\text{H}^+(aq)$ . Electrode 2 is a standard hydrogen electrode ( $[\text{H}^+] = 1.00$  M,  $P_{\text{H}_2} = 1.00$  atm). At 298 K the measured cell voltage is 0.211 V, and the electrical current is observed to flow from electrode 1 through the external circuit to electrode 2. Calculate  $[\text{H}^+]$  for the solution at electrode 1. What is its pH?

**SOLUTION**

**Analyze:** We are given the voltage of a concentration cell and the direction in which the current flows. We also have the concentrations of all reactants and products except for  $[\text{H}^+]$  in half-cell 1, which is our unknown.

**Plan:** We can use the Nernst equation to determine  $Q$  and then use  $Q$  to calculate the unknown concentration. Because this is a concentration cell,  $E_{\text{cell}}^\circ = 0$  V.

**Solve:** Using the Nernst equation, we have

$$0.211 \text{ V} = 0 - \frac{0.0592 \text{ V}}{2} \log Q$$

$$\log Q = -(0.211 \text{ V}) \left( \frac{2}{0.0592 \text{ V}} \right) = -7.13$$

$$Q = 10^{-7.13} = 7.4 \times 10^{-8}$$

Because electrons flow from electrode 1 to electrode 2, electrode 1 is the anode of the cell and electrode 2 is the cathode. The electrode reactions are therefore as follows, with the concentration of  $\text{H}^+(aq)$  in electrode 1 represented with the unknown  $x$ :

Thus,

$$Q = \frac{[\text{H}^+(\text{electrode 1})]^2 P_{\text{H}_2}(\text{electrode 2})}{[\text{H}^+(\text{electrode 2})]^2 P_{\text{H}_2}(\text{electrode 1})}$$

$$= \frac{x^2(1.00)}{(1.00)^2(1.00)} = x^2 = 7.4 \times 10^{-8}$$

$$x = \sqrt{7.4 \times 10^{-8}} = 2.7 \times 10^{-4}$$

At electrode 1, therefore,

$$[\text{H}^+] = 2.7 \times 10^{-4} \text{ M}$$

and the pH of the solution is

$$\text{pH} = -\log[\text{H}^+] = -\log(2.7 \times 10^{-4}) = 3.57$$

**Comment:** The concentration of  $\text{H}^+$  at electrode 1 is lower than that in electrode 2, which is why electrode 1 is the anode of the cell: The oxidation of  $\text{H}_2$  to  $\text{H}^+(aq)$  increases  $[\text{H}^+]$  at electrode 1.

**PRACTICE EXERCISE**

A concentration cell is constructed with two  $\text{Zn}(s)\text{-Zn}^{2+}(aq)$  half-cells. The first half-cell has  $[\text{Zn}^{2+}] = 1.35$  M, and the second half-cell has  $[\text{Zn}^{2+}] = 3.75 \times 10^{-4}$  M. (a) Which half-cell is the anode of the cell? (b) What is the emf of the cell?

**Answers:** (a) the second half-cell, (b) 0.105 V

**20.7 BATTERIES AND FUEL CELLS**

A **battery** is a portable, self-contained electrochemical power source that consists of one or more voltaic cells. For example, the common 1.5-V batteries used to power flashlights and many consumer electronic devices are single voltaic cells. Greater voltages can be achieved by using multiple voltaic cells in a single battery, as is the case in 12-V automotive batteries. When cells are connected in series (with the cathode of one attached to the anode of another), the battery produces a voltage that is the sum of the emfs of the individual cells. Higher emfs can also be achieved by using multiple batteries in series (Figure 20.19 ►). The electrodes of batteries are marked following the convention of Figure 20.6—the cathode is labeled with a plus sign and the anode with a minus sign.

Although any spontaneous redox reaction can serve as the basis for a voltaic cell, making a commercial battery that has specific performance characteristics can require considerable ingenuity. The substances that are oxidized at the

anode and reduced by the cathode determine the emf of a battery, and the usable life of the battery depends on the quantities of these substances packaged in the battery. Usually a barrier analogous to the porous barrier of Figure 20.6 separates the anode and the cathode compartments.

Different applications require batteries with different properties. The battery required to start a car, for example, must be capable of delivering a large electrical current for a short time period. The battery that powers a heart pacemaker, on the other hand, must be very small and capable of delivering a small but steady current over an extended time period. Some batteries are *primary* cells, meaning that they cannot be recharged. A primary cell must be discarded or recycled after its emf drops to zero. A *secondary* cell can be recharged from an external power source after its emf has dropped.

In this section we will briefly discuss some common batteries. As we do so, notice how the principles we have discussed so far in this chapter help us understand these important sources of portable electrical energy.

### Lead-Acid Battery

A 12-V lead-acid automotive battery consists of six voltaic cells in series, each producing 2 V. The cathode of each cell consists of lead dioxide ( $\text{PbO}_2$ ) packed on a metal grid. The anode of each cell is composed of lead. Both electrodes are immersed in sulfuric acid. The electrode reactions that occur during discharge are

The standard cell potential can be obtained from the standard reduction potentials in Appendix E:

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (+1.685 \text{ V}) - (-0.356 \text{ V}) = +2.041 \text{ V}$$

The reactants  $\text{Pb}$  and  $\text{PbO}_2$  serve as the electrodes. Because the reactants are solids, there is no need to separate the cell into anode and cathode compartments; the  $\text{Pb}$  and  $\text{PbO}_2$  cannot come into direct physical contact unless one electrode plate touches another. To keep the electrodes from touching, wood or glass-fiber spacers are placed between them (Figure 20.20 ▶).

Using a reaction whose reactants and products are solids has another benefit. Because solids are excluded from the reaction quotient  $Q$ , the relative amounts of  $\text{Pb}(\text{s})$ ,  $\text{PbO}_2(\text{s})$ , and  $\text{PbSO}_4(\text{s})$  have no effect on the emf of the lead storage battery, helping the battery maintain a relatively constant emf during discharge. The emf does vary somewhat with use because the concentration of  $\text{H}_2\text{SO}_4$  varies with the extent of cell discharge. As the equation for the overall cell reaction indicates,  $\text{H}_2\text{SO}_4$  is consumed during the discharge.

One advantage of a lead-acid battery is that it can be recharged. During recharging, an external source of energy is used to reverse the direction of the overall cell reaction, regenerating  $\text{Pb}(\text{s})$  and  $\text{PbO}_2(\text{s})$ .

In an automobile the alternator, driven by the engine, provides the energy necessary for recharging the battery. Recharging is possible because  $\text{PbSO}_4$  formed during discharge adheres to the electrodes. As the external source forces electrons from one electrode to another, the  $\text{PbSO}_4$  is converted to  $\text{Pb}$  at one electrode and to  $\text{PbO}_2$  at the other.

▲ **Figure 20.19** Combining batteries. When batteries are connected in series, as in most flashlights, the total emf is the sum of the individual emfs.

▲ **Figure 20.20** A 12-V automotive lead-acid battery. Each anode/cathode pair of electrodes in this schematic cutaway produces a potential of about 2 V. Six pairs of electrodes are connected in series, producing the desired battery voltage.

▲ **Figure 20.21** Cutaway view of a miniature alkaline battery.

## Alkaline Battery

The most common primary (nonrechargeable) battery is the alkaline battery. More than  $10^{10}$  alkaline batteries are produced annually. The anode of this battery consists of powdered zinc metal immobilized in a gel in contact with a concentrated solution of KOH (hence the name *alkaline* battery). The cathode is a mixture of  $\text{MnO}_2(\text{s})$  and graphite, separated from the anode by a porous fabric. The battery is sealed in a steel can to reduce the risk of leakage of the concentrated KOH. A schematic view of an alkaline battery is shown in Figure 20.21 ◀. The cell reactions are complex, but can be approximately represented as follows:

The emf of an alkaline battery is 1.55 V at room temperature. The alkaline battery provides far superior performance over the older “dry cells” that were also based on  $\text{MnO}_2$  and Zn as the electrochemically active substances.

## Nickel-Cadmium, Nickel-Metal-Hydride, and Lithium-Ion Batteries

The tremendous growth in high-power-demand portable electronic devices, such as cell phones, notebook computers, and video recorders, has increased the demand for lightweight, readily recharged batteries. One of the most common rechargeable batteries is the nickel-cadmium (nicad) battery. During discharge, cadmium metal is oxidized at the anode of the battery while nickel oxyhydroxide [ $\text{NiO}(\text{OH})(\text{s})$ ] is reduced at the cathode.

As in the lead-acid battery, the solid reaction products adhere to the electrodes, which permits the electrode reactions to be reversed during charging. A single nicad voltaic cell has an emf of 1.30 V. Nicad battery packs typically contain three or more cells in series to produce the higher emfs needed by most electronic devices.

There are drawbacks to nickel-cadmium batteries. Cadmium is a toxic heavy metal. Its use increases the weight of batteries and provides an environmental hazard—roughly 1.5 billion nickel-cadmium batteries are produced annually, and these must eventually be recycled as they lose their ability to be recharged. Some of these problems have been alleviated by the development of nickel-metal-hydride (NiMH) batteries. The cathode reaction of NiMH batteries is the same as that for nickel-cadmium batteries, but the anode reaction is very different. The anode consists of a metal *alloy*, such as  $\text{ZrNi}_2$ , that has the ability to absorb hydrogen atoms (we will discuss alloys in Section 23.6). During the oxidation at the anode, the hydrogen atoms lose electrons, and the resultant  $\text{H}^+$  ions react with  $\text{OH}^-$  ions to form  $\text{H}_2\text{O}$ , a process that is reversed during charging. The current generation of hybrid gas-electric automobiles, which are powered by both a gasoline engine and an electric motor, use NiMH batteries to store the electrical power. The batteries are recharged by the electric motor while braking. Due to the robustness of the batteries toward discharge and recharge, the batteries can last up to 8 years.

The newest rechargeable battery to receive large use in consumer electronic devices is the lithium-ion (Li-ion) battery. You will find this battery in cell phones and laptop computers. Because lithium is a very light element, Li-ion batteries achieve a greater *energy density*—the amount of energy stored per unit mass—than nickel-based batteries. The technology of Li-ion batteries is very different from that of the other batteries we have described here; it is based on the ability of  $\text{Li}^+$  ions to be inserted into and removed from certain layered solids.

For example,  $\text{Li}^+$  ions can be inserted reversibly into layers of graphite (Figure 11.41). In most commercial cells, one electrode is graphite or some other carbon-based material, and the other is usually made of lithium cobalt oxide ( $\text{LiCoO}_2$ ). When the cell is charged, cobalt ions are oxidized, and  $\text{Li}^+$  ions migrate into the graphite. During discharge, when the battery is producing electricity for use, the  $\text{Li}^+$  ions spontaneously migrate from the graphite anode to the cathode, enabling electrons to flow through the external circuit. An Li-ion battery produces a maximum voltage of 3.7 V, considerably higher than typical 1.5-V alkaline batteries.

## Hydrogen Fuel Cells

The thermal energy released by the combustion of fuels can be converted to electrical energy. The heat may convert water to steam, which drives a turbine that in turn drives a generator. Typically, a maximum of only 40% of the energy from combustion is converted to electricity; the remainder is lost as heat. The direct production of electricity from fuels by a voltaic cell could, in principle, yield a higher rate of conversion of the chemical energy of the reaction. Voltaic cells that perform this conversion using conventional fuels, such as  $\text{H}_2$  and  $\text{CH}_4$ , are called **fuel cells**. Strictly speaking, fuel cells are *not* batteries because they are not self-contained systems—the fuel must be continuously supplied to generate electricity.

The most promising fuel-cell system involves the reaction of  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$  to form  $\text{H}_2\text{O}(\text{l})$  as the only product. These cells can generate electricity twice as efficiently as the best internal combustion engine. Under acidic conditions, the electrode reactions are

The standard emf of an  $\text{H}_2\text{-O}_2$  fuel cell is +1.23 V, reflecting the large driving force for the reaction of  $\text{H}_2$  and  $\text{O}_2$  to form  $\text{H}_2\text{O}$ .

In this fuel cell (known as the PEM fuel cell, for “proton-exchange membrane”), the anode and cathode are separated by a thin polymer membrane that is permeable to protons but not to electrons. The polymer membrane, therefore, acts as a salt bridge. The electrodes are typically made from graphite. A PEM cell operates at a temperature of around 80 °C. At this low temperature the electrochemical reactions would normally occur very slowly, and so a thin layer of platinum on each electrode catalyzes the reactions.

Under basic conditions the electrode reactions in the hydrogen fuel cell are

NASA has used this basic hydrogen fuel cell as the energy source for its spacecraft. Liquid hydrogen and oxygen are stored as fuel, and water, the product of the reaction, is drunk by the spacecraft crew.

A schematic drawing of a low-temperature  $\text{H}_2\text{-O}_2$  fuel cell is shown in Figure 20.22. This technology is the basis for fuel cell–powered vehicles that are under study by major automobile manufacturers. Currently a great deal of research is going into improving fuel cells. Much effort is being directed toward developing fuel cells that use conventional fuels such as hydrocarbons and alcohols, which are not as difficult to handle and distribute as hydrogen gas.

▼ **Figure 20.22** A low-temperature  $\text{H}_2\text{-O}_2$  fuel cell. The porous membrane allows the  $\text{H}^+$  ions generated by the oxidation of  $\text{H}_2$  at the anode to migrate to the cathode, where  $\text{H}_2\text{O}$  is formed.

## Chemistry Put to Work

## DIRECT METHANOL FUEL CELLS

While the hydrogen fuel cell has been widely proposed as a clean and efficient alternative to gasoline-powered internal combustion engines, liquid methanol,  $\text{CH}_3\text{OH}$ , is a far more attractive fuel to store and transport than hydrogen gas. Furthermore, methanol is a clean-burning liquid, and its use would require only minor modifications to existing engines and to fuel-delivery infrastructure.

One of the intriguing aspects of methanol as a fuel is that manufacturing it could make use of carbon dioxide, a source of global warming.  $\infty$  (Section 18.4) Methanol can be made by combining  $\text{CO}_2$  and  $\text{H}_2$ , although the process is presently costly. Imagine, though, that the synthesis can be improved and that the  $\text{CO}_2$  used in the synthesis is captured from exhaust gases from power plants or even directly from the atmosphere. In such cases, the  $\text{CO}_2$  released by subsequently burning the methanol would be cancelled by the carbon dioxide captured to make it. Thus, the process would be carbon neutral, meaning that it would not increase the concentration

of  $\text{CO}_2$  in the atmosphere. The prospect of a liquid fuel that could replace conventional fuels without contributing to the greenhouse effect has spurred considerable research to reduce the cost of methanol synthesis and to develop and improve methanol fuel cell technology.

A direct methanol fuel cell has been developed that is similar to the PEM hydrogen fuel cell. The reactions in the cell are

The direct methanol fuel cell is currently too expensive to be used in passenger cars because of the quantity of platinum catalyst it requires to operate. Nevertheless, small methanol fuel cells could appear in mobile devices such as computers or cell phones in the near future.

## 20.8 CORROSION

Batteries are examples of how spontaneous redox reactions can be used productively. In this section we will examine the undesirable redox reactions that lead to the **corrosion** of metals. Corrosion reactions are spontaneous redox reactions in which a metal is attacked by some substance in its environment and converted to an unwanted compound.

For nearly all metals, oxidation is a thermodynamically favorable process in air at room temperature. When the oxidation process is not inhibited in some way, it can be very destructive to whatever object is made from the metal. Oxidation can form an insulating protective oxide layer, however, that prevents further reaction of the underlying metal. Based on the standard reduction potential for  $\text{Al}^{3+}$ , for example, we would expect aluminum metal to be very readily oxidized. The many aluminum soft-drink and beer cans that litter the environment are ample evidence, however, that aluminum undergoes only very slow chemical corrosion. The exceptional stability of this active metal in air is due to the formation of a thin protective coat of oxide—a hydrated form of  $\text{Al}_2\text{O}_3$ —on the surface of the metal. The oxide coat is impermeable to  $\text{O}_2$  or  $\text{H}_2\text{O}$  and so protects the underlying metal from further corrosion. Magnesium metal is similarly protected. Some metal alloys, such as stainless steel, likewise form protective impervious oxide coats. The semiconductor silicon, as we saw in Chapter 12, also readily forms a protective  $\text{SiO}_2$  coating that is important to its use in electronic circuits.

### Corrosion of Iron

The rusting of iron (Figure 20.23  $\blacktriangleleft$ ) is a familiar corrosion process that carries a significant economic impact. Up to 20% of the iron produced annually in the United States is used to replace iron objects that have been discarded because of rust damage.

The rusting of iron requires both oxygen and water. Other factors—such as the pH of the solution, the presence of salts, contact with metals more difficult to oxidize than iron, and stress on the iron—can accelerate rusting.

The corrosion of iron is electrochemical in nature. The corrosion process involves oxidation and reduction, and the metal itself conducts electricity. Thus, electrons can move through the metal from a region where oxidation occurs to another region where reduction occurs, as in voltaic cells.

**▲ Figure 20.23 Corrosion.** The corrosion of iron is an electrochemical process of great economic importance. The annual cost of metallic corrosion in the United States is estimated to be \$70 billion.

Because the standard reduction potential for the reduction of  $\text{Fe}^{2+}(\text{aq})$  is less positive than that for the reduction of  $\text{O}_2$ ,  $\text{Fe}(\text{s})$  can be oxidized by  $\text{O}_2(\text{g})$ .

A portion of the iron can serve as an anode at which the oxidation of  $\text{Fe}$  to  $\text{Fe}^{2+}$  occurs. The electrons produced migrate through the metal to another portion of the surface that serves as the cathode, at which  $\text{O}_2$  is reduced. The reduction of  $\text{O}_2$  requires  $\text{H}^+$ , so lowering the concentration of  $\text{H}^+$  (increasing the pH) makes the reduction of  $\text{O}_2$  less favorable. Iron in contact with a solution whose pH is greater than 9 does not corrode.

The  $\text{Fe}^{2+}$  formed at the anode is eventually oxidized further to  $\text{Fe}^{3+}$ , which forms the hydrated iron(III) oxide known as rust\*:

Because the cathode is generally the area having the largest supply of  $\text{O}_2$ , rust often deposits there. If you look closely at a shovel after it has stood outside in the moist air with wet dirt adhered to its blade, you may notice that pitting has occurred under the dirt but that rust has formed elsewhere, where  $\text{O}_2$  is more readily available. The corrosion process is summarized in Figure 20.24.

The enhanced corrosion caused by the presence of salts is usually evident on autos in areas where roads are heavily salted during winter. Like a salt bridge in a voltaic cell, the ions of the salt provide the electrolyte necessary to complete the electrical circuit.

▲ Figure 20.24 Corrosion of iron in contact with water.

## Preventing the Corrosion of Iron

Iron is often covered with a coat of paint or another metal such as tin or zinc to protect its surface against corrosion. Covering the surface with paint or tin is simply a means of preventing oxygen and water from reaching the iron surface. If the coating is broken and the iron is exposed to oxygen and water, corrosion will begin.

*Galvanized iron*, which is iron coated with a thin layer of zinc, uses the principles of electrochemistry to protect the iron from corrosion even after the surface coat is broken. The standard reduction potentials for iron and zinc are

Because the  $E_{\text{red}}^\circ$  value for the reduction of  $\text{Fe}^{2+}$  is less negative (more positive) than that for the reduction of  $\text{Zn}^{2+}$ ,  $\text{Fe}^{2+}$  is easier to reduce than  $\text{Zn}^{2+}$ . Conversely,  $\text{Zn}(\text{s})$  is easier to oxidize than  $\text{Fe}(\text{s})$ . Thus, even if the zinc coating is broken and the galvanized iron is exposed to oxygen and water, the zinc, which is most easily oxidized, serves as the anode and is corroded instead of the iron. The iron serves as the cathode at which  $\text{O}_2$  is reduced, as shown in Figure 20.25.

Protecting a metal from corrosion by making it the cathode in an electrochemical cell is known as **cathodic protection**. The metal that is oxidized while protecting the cathode is called the *sacrificial anode*. Underground pipelines are often protected against corrosion by making the pipeline the

▲ Figure 20.25 Cathodic protection of iron in contact with zinc.

\*Frequently, metal compounds obtained from aqueous solution have water associated with them. For example, copper(II) sulfate crystallizes from water with five moles of water per mole of  $\text{CuSO}_4$ . We represent this formula as  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ . Such compounds are called hydrates.  $\rightleftharpoons$  (Section 13.1) Rust is a hydrate of iron(III) oxide with a variable amount of water of hydration. We represent this variable water content by writing the formula as  $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ .

▲ **Figure 20.26 Cathodic protection of an iron water pipe.** A mixture of gypsum, sodium sulfate, and clay surrounds the magnesium anode to promote conductivity of ions. The pipe, in effect, is the cathode of a voltaic cell.

cathode of a voltaic cell. Pieces of an active metal such as magnesium are buried along the pipeline and connected to it by wire, as shown in Figure 20.26. In moist soil, where corrosion can occur, the active metal serves as the anode, and the pipe experiences cathodic protection.

### GIVE IT SOME THOUGHT

Based on the standard reduction potentials in Table 20.1, which of the following metals could provide cathodic protection to iron: Al, Cu, Ni, Zn?

## 20.9 ELECTROLYSIS

Voltaic cells are based on spontaneous oxidation-reduction reactions. Conversely, it is possible to use electrical energy to cause nonspontaneous redox reactions to occur. For example, electricity can be used to decompose molten sodium chloride into its component elements:

Such processes, which are driven by an outside source of electrical energy, are called **electrolysis reactions** and take place in **electrolytic cells**.

An electrolytic cell consists of two electrodes in a molten salt or a solution. A battery or some other source of direct electrical current acts as an electron pump, pushing electrons into one electrode and pulling them from the other. Just as in voltaic cells, the electrode at which the reduction occurs is called the cathode, and the electrode at which oxidation occurs is called the anode.

In the electrolysis of molten NaCl, shown in Figure 20.27,  $\text{Na}^+$  ions pick up electrons and are reduced to Na at the cathode. As the  $\text{Na}^+$  ions near the cathode are depleted, additional  $\text{Na}^+$  ions migrate in. Similarly, there is net movement of  $\text{Cl}^-$  ions to the anode, where they are oxidized. The electrode reactions for the electrolysis of molten NaCl are summarized as follows:

► **Figure 20.27 Electrolysis of molten sodium chloride.**  $\text{Cl}^-$  ions are oxidized to  $\text{Cl}_2(g)$  at the anode, and  $\text{Na}^+$  ions are reduced to  $\text{Na}(l)$  at the cathode. Pure NaCl melts at 801 °C.

Notice the manner in which the voltage source is connected to the electrodes in Figure 20.27. In a voltaic cell (or any other source of direct current) the electrons move from the negative terminal (Figure 20.6). Thus, the electrode of the electrolytic cell that is connected to the negative terminal of the voltage source is the cathode of the cell; it receives electrons that are used to reduce a substance. The electrons that are removed during the oxidation process at the anode travel to the positive terminal of the voltage source, thus completing the circuit of the cell.

The electrolysis of molten salts is an important industrial process for the production of active metals such as magnesium, sodium, and aluminum. We will have more to say about it in Chapter 23, when we discuss how ores are refined into metals.

Because of the high melting points of ionic substances, the electrolysis of molten salts requires very high temperatures.  $\infty$  (Section 11.8) Do we obtain the same products if we electrolyze the aqueous solution of a salt instead of the molten salt? Frequently the answer is no; the electrolysis of an aqueous solution is complicated by the presence of water, because we must consider whether the water is oxidized to form  $O_2$  or reduced to form  $H_2$  rather than the ions of the salt. These reactions also depend on pH.

So far in our discussion of electrolysis, we have encountered only electrodes that were *inert*; they did not undergo reaction but merely served as the surface where oxidation and reduction occurred. Several practical applications of electrochemistry, however, are based on *active* electrodes—electrodes that participate in the electrolysis process. *Electroplating*, for example, uses electrolysis to deposit a thin layer of one metal on another metal to improve beauty or resistance to corrosion (Figure 20.28  $\blacktriangle$ ). We can illustrate the principles of electrolysis with active electrodes by describing how to electroplate nickel on a piece of steel.

Figure 20.29  $\blacktriangleright$  illustrates the electrolytic cell for our electroplating experiment. The anode of the cell is a strip of nickel metal, and the cathode is the piece of steel that will be electroplated. The electrodes are immersed in a solution of  $NiSO_4(aq)$ . What happens at the electrodes when the external voltage source is turned on? Reduction will occur at the cathode. The standard reduction potential of  $Ni^{2+}$  ( $E_{red}^\circ = -0.28\text{ V}$ ) is less negative than that of  $H_2O$  ( $E_{red}^\circ = -0.83\text{ V}$ ), so  $Ni^{2+}$  will be preferentially reduced at the cathode.

At the anode we need to consider which substances can be oxidized. For the  $NiSO_4(aq)$  solution, only the  $H_2O$  solvent is readily oxidized because neither  $Ni^{2+}$  nor the  $SO_4^{2-}$  can be oxidized (both already have their elements in their highest possible oxidation state). The Ni atoms in the anode, however, can undergo oxidation. Thus, the two possible oxidation processes are

where the potentials are the standard *reduction* potentials of these reactions. Because this is an oxidation, the half-reaction with the more negative value of  $E_{red}^\circ$  is favored. (Remember the behavior summarized in Figure 20.14: The strongest reducing agents, which are the substances oxidized most readily, have the most negative values of  $E_{red}^\circ$ .) We can summarize the electrode reactions as

If we look at the overall reaction, it appears as if nothing has been accomplished. During the electrolysis, however, we are transferring Ni atoms from the Ni anode to the steel cathode, plating the steel electrode with a thin layer of nickel atoms. The standard emf for the overall reaction is  $E_{cell}^\circ = E_{red}^\circ(\text{cathode}) - E_{red}^\circ(\text{anode}) = 0$ .

(a)

(b)

$\blacktriangle$  **Figure 20.28 Electroplating of silverware.** (a) The silverware is being withdrawn from the electroplating bath. (b) The polished final product.

$\blacktriangle$  **Figure 20.29 Electrolytic cell with an active metal electrode.** Nickel dissolves from the anode to form  $Ni^{2+}(aq)$ . At the cathode  $Ni^{2+}(aq)$  is reduced and forms a nickel “plate” on the cathode.

**▲ Figure 20.30 Relationship between charge and amount of reactant and product in electrolysis reactions.** This flowchart shows the steps relating the quantity of electrical charge used in electrolysis to the amounts of substances oxidized or reduced.

Only a small emf is needed to provide the “push” to transfer the nickel atoms from one electrode to the other. In Chapter 23 we will explore further the utility of electrolysis with active electrodes as a means of purifying crude metals.

### Quantitative Aspects of Electrolysis

The stoichiometry of a half-reaction shows how many electrons are needed to achieve an electrolytic process. For example, the reduction of  $\text{Na}^+$  to Na is a one-electron process:

Thus, one mole of electrons will plate out 1 mol of Na metal, two moles of electrons will plate out 2 mol of Na metal, and so forth. Similarly, two moles of electrons are required to produce 1 mol of copper from  $\text{Cu}^{2+}$ , and three moles of electrons are required to produce 1 mol of aluminum from  $\text{Al}^{3+}$ .

For any half-reaction, the amount of a substance that is reduced or oxidized in an electrolytic cell is directly proportional to the number of electrons passed into the cell.

The quantity of charge passing through an electrical circuit, such as that in an electrolytic cell, is generally measured in *coulombs*. As noted in Section 20.5, the charge on one mole of electrons is 96,485 C (1 faraday). A coulomb is the quantity of charge passing a point in a circuit in 1 s when the current is 1 ampere (A). Therefore, the number of coulombs passing through a cell can be obtained by multiplying the amperage and the elapsed time in seconds.

$$\text{Coulombs} = \text{amperes} \times \text{seconds} \quad [20.18]$$

Figure 20.30▲ shows how the quantities of substances produced or consumed in electrolysis are related to the quantity of electrical charge that is used. The same relationships can also be applied to voltaic cells. In other words, electrons can be thought of as reagents in electrolysis reactions.

#### ■ SAMPLE EXERCISE 20.14 | Relating Electrical Charge and Quantity of Electrolysis

Calculate the number of grams of aluminum produced in 1.00 h by the electrolysis of molten  $\text{AlCl}_3$  if the electrical current is 10.0 A.

#### SOLUTION

**Analyze:** We are told that  $\text{AlCl}_3$  is electrolyzed to form Al and asked to calculate the number of grams of Al produced in 1.00 h with 10.0 A.

**Plan:** Figure 20.30 provides a road map of the problem. First, the product of the amperage and the time in seconds gives the number of coulombs of electrical charge being used (Equation 20.18). Second, the coulombs can be converted with the Faraday constant ( $F = 96,485 \text{ C/mole electrons}$ ) to tell us the number of moles of electrons being supplied. Third, reduction of 1 mol of  $\text{Al}^{3+}$  to Al requires three moles of electrons. Hence we can use the number of moles of electrons to calculate the number of moles of Al metal it produces. Finally, we convert moles of Al into grams.

**Solve:** First, we calculate the coulombs of electrical charge that are passed into the electrolytic cell:

$$\text{Coulombs} = \text{amperes} \times \text{seconds} = (10.0 \text{ A})(1.00 \text{ h}) \frac{(3600 \text{ s})}{\text{h}} = 3.60 \times 10^4 \text{ C}$$

Second, we calculate the number of moles of electrons that pass into the cell:

$$\text{Moles e}^- = (3.60 \times 10^4 \text{ C}) \left( \frac{1 \text{ mole e}^-}{96,485 \text{ C}} \right) = 0.373 \text{ mol e}^-$$

Third, we relate the number of moles of electrons to the number of moles of aluminum being formed, using the half-reaction for the reduction of  $\text{Al}^{3+}$ :

Thus, three moles of electrons ( $3F$  of electrical charge) are required to form 1 mol of Al:

$$\text{Moles Al} = (0.373 \text{ mol e}^{-}) \left( \frac{1 \text{ mol Al}}{3 \text{ mol e}^{-}} \right) = 0.124 \text{ mol Al}$$

Finally, we convert moles to grams:

$$\text{Grams Al} = (0.124 \text{ mol Al}) \left( \frac{27.0 \text{ g Al}}{1 \text{ mol Al}} \right) = 3.36 \text{ g Al}$$

Because each step involves a multiplication by a new factor, the steps can be combined into a single sequence of factors:

$$\text{Grams Al} = (3.60 \times 10^4 \text{ C}) \left( \frac{1 \text{ mole e}^{-}}{96,485 \text{ C}} \right) \left( \frac{1 \text{ mol Al}}{3 \text{ mol e}^{-}} \right) \left( \frac{27.0 \text{ g Al}}{1 \text{ mol Al}} \right) = 3.36 \text{ g Al}$$

### ■ PRACTICE EXERCISE

(a) The half-reaction for formation of magnesium metal upon electrolysis of molten  $\text{MgCl}_2$  is  $\text{Mg}^{2+} + 2 \text{e}^{-} \longrightarrow \text{Mg}$ . Calculate the mass of magnesium formed upon passage of a current of 60.0 A for a period of  $4.00 \times 10^3$  s.

(b) How many seconds would be required to produce 50.0 g of Mg from  $\text{MgCl}_2$  if the current is 100.0 A?

**Answers:** (a) 30.2 g of Mg, (b)  $3.97 \times 10^3$  s

## Electrical Work

We have already seen that a positive value of  $E$  is associated with a negative value for the free-energy change and, thus, with a spontaneous process. We also know that for any spontaneous process,  $\Delta G$  is a measure of the maximum useful work,  $w_{\text{max}}$ , that can be extracted from the process:  $\Delta G = w_{\text{max}}$ . [∞ \(Section 5.2\)](#) Because  $\Delta G = -nFE$ , the maximum useful electrical work obtainable from a voltaic cell is

$$w_{\text{max}} = -nFE \quad [20.19]$$

The cell emf,  $E$ , is a positive number for a voltaic cell, so  $w_{\text{max}}$  will be a negative number for a voltaic cell. Work done by a system on its surroundings is indicated by a negative sign for  $w$ . [∞ \(Section 5.2\)](#) Thus, the negative value for  $w_{\text{max}}$  means that a voltaic cell does work on its surroundings.

In an electrolytic cell we use an external source of energy to bring about a nonspontaneous electrochemical process. In this case  $\Delta G$  is positive and  $E_{\text{cell}}$  is negative. To force the process to occur, we need to apply an external potential,  $E_{\text{ext}}$ , which must be larger in magnitude than  $E_{\text{cell}}$ :  $E_{\text{ext}} > -E_{\text{cell}}$ . For example, if a nonspontaneous process has  $E_{\text{cell}} = -0.9 \text{ V}$ , then the external potential  $E_{\text{ext}}$  must be greater than 0.9 V in order for the process to occur.

When an external potential  $E_{\text{ext}}$  is applied to a cell, the surroundings are doing work on the system. The amount of work performed is given by

$$w = nFE_{\text{ext}} \quad [20.20]$$

Unlike Equation 20.19, there is no minus sign in Equation 20.20. The work calculated in Equation 20.20 will be a positive number because the surroundings are doing work on the system. The quantity  $n$  in Equation 20.20 is the number of moles of electrons forced into the system by the external potential. The product  $n \times F$  is the total electrical charge supplied to the system by the external source of electricity.

Electrical work can be expressed in energy units of watts times time. The **watt** (W) is a unit of electrical power (that is, the rate of energy expenditure).

$$1 \text{ W} = 1 \text{ J/s}$$

Thus, a watt-second is a joule. The unit employed by electric utilities is the kilowatt-hour (kWh), which equals  $3.6 \times 10^6 \text{ J}$ .

$$1 \text{ kWh} = (1000 \text{ W})(1 \text{ hr}) \left( \frac{3600 \text{ s}}{1 \text{ hr}} \right) \left( \frac{1 \text{ J/s}}{1 \text{ W}} \right) = 3.6 \times 10^6 \text{ J} \quad [20.21]$$

Using these considerations, we can calculate the maximum work obtainable from the voltaic cells and the minimum work required to bring about desired electrolysis reactions.

### ■ SAMPLE EXERCISE 20.15 | Calculating Energy in Kilowatt-hours

Calculate the number of kilowatt-hours of electricity required to produce  $1.0 \times 10^3$  kg of aluminum by electrolysis of  $\text{Al}^{3+}$  if the applied voltage is 4.50 V.

#### SOLUTION

**Analyze:** We are given the mass of Al produced from  $\text{Al}^{3+}$  and the applied voltage and asked to calculate the energy, in kilowatt-hours, required for the reduction.

**Plan:** From the mass of Al, we can calculate first the number of moles of Al and then the number of coulombs required to obtain that mass. We can then use Equation 20.20,  $w = nFE_{\text{ext}}$ , where  $nF$  is the total charge in coulombs and  $E_{\text{ext}}$  is the applied potential, 4.50 V.

**Solve:** First, we need to calculate  $nF$ , the number of coulombs required:

$$\begin{aligned} \text{Coulombs} &= (1.00 \times 10^3 \text{ kg Al}) \left( \frac{1000 \text{ g Al}}{1 \text{ kg Al}} \right) \left( \frac{1 \text{ mol Al}}{27.0 \text{ g Al}} \right) \left( \frac{3 \text{ mol e}^-}{1 \text{ mol Al}} \right) \left( \frac{96,485 \text{ C}}{1 \text{ mole e}^-} \right) \\ &= 1.07 \times 10^{10} \text{ C} \end{aligned}$$

We can now calculate  $w$ . In doing so, we must apply several conversion factors, including Equation 20.21, which gives the conversion between kilowatt-hours and joules:

$$\begin{aligned} \text{Kilowatt-hours} &= (1.07 \times 10^{10} \text{ C})(4.50 \text{ V}) \left( \frac{1 \text{ J}}{1 \text{ C}\cdot\text{V}} \right) \left( \frac{1 \text{ kWh}}{3.6 \times 10^6 \text{ J}} \right) \\ &= 1.34 \times 10^4 \text{ kWh} \end{aligned}$$

**Comment:** This quantity of energy does not include the energy used to mine, transport, and process the aluminum ore, and to keep the electrolysis bath molten during electrolysis. A typical electrolytic cell used to reduce aluminum ore to aluminum metal is only 40% efficient, with 60% of the electrical energy being dissipated as heat. It therefore requires approximately 33 kWh of electricity to produce 1 kg of aluminum. The aluminum industry consumes about 2% of the electrical energy generated in the United States. Because this energy is used mainly to reduce aluminum, recycling this metal saves large quantities of energy.

### ■ PRACTICE EXERCISE

Calculate the number of kilowatt-hours of electricity required to produce 1.00 kg of Mg from electrolysis of molten  $\text{MgCl}_2$  if the applied emf is 5.00 V. Assume that the process is 100% efficient.

*Answer:* 11.0 kWh

### ■ SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

The  $K_{\text{sp}}$  at 298 K for iron(II) fluoride is  $2.4 \times 10^{-6}$ . (a) Write a half-reaction that gives the likely products of the two-electron reduction of  $\text{FeF}_2(\text{s})$  in water. (b) Use the  $K_{\text{sp}}$  value and the standard reduction potential of  $\text{Fe}^{2+}(\text{aq})$  to calculate the standard reduction potential for the half-reaction in part (a). (c) Rationalize the difference in the reduction potential for the half-reaction in part (a) with that for  $\text{Fe}^{2+}(\text{aq})$ .

#### SOLUTION

**Analyze:** We are going to have to combine what we know about equilibrium constants and electrochemistry to obtain reduction potentials.

**Plan:** For (a) we need to determine which ion,  $\text{Fe}^{2+}$  or  $\text{F}^-$ , is more likely to be reduced by 2 electrons and write the overall reaction for  $\text{FeF}_2 + 2 \text{e}^- \longrightarrow ?$  For (b) we need to write the  $K_{\text{sp}}$  reaction and manipulate it to get  $E^\circ$  for the reaction in (a). For (c) we need to see what we get for (a) and (b).

#### Solve:

(a) Iron(II) fluoride is an ionic substance that consists of  $\text{Fe}^{2+}$  and  $\text{F}^-$  ions. We are asked to predict where two electrons could be added to  $\text{FeF}_2$ . We can't envision adding the electrons to the  $\text{F}^-$  ions to form  $\text{F}^{2-}$ , so it seems likely that we could reduce the  $\text{Fe}^{2+}$  ions to  $\text{Fe}(\text{s})$ . We therefore predict the half-reaction

(b) The  $K_{\text{sp}}$  value refers to the following equilibrium  $\rightleftharpoons$  (Section 17.4):

We were also asked to use the standard reduction potential of  $\text{Fe}^{2+}$ , whose half-reaction and standard voltage are listed in Appendix E:

Recall that according to Hess's law, we can add reactions to get the one we want and we can add thermodynamic quantities like  $\Delta H$  and  $\Delta G$  to solve for the enthalpy or free energy of the reaction we want.  $\square$  (Section 5.6) In this case notice that if we add the  $K_{sp}$  reaction to the standard reduction half-reaction for  $\text{Fe}^{2+}$ , we get the half-reaction we want:

Reaction 3 is still a half-reaction, so we do see the free electrons.

If we knew  $\Delta G^\circ$  for reactions 1 and 2, we could add them to get  $\Delta G^\circ$  for reaction 3. Recall that we can relate  $\Delta G^\circ$  to  $E^\circ$  by  $\Delta G^\circ = -nFE^\circ$  and to  $K$  by  $\Delta G^\circ = -RT \ln K$ . We know  $K$  for reaction 1; it is  $K_{sp}$ . We know  $E^\circ$  for reaction 2. Therefore we can calculate  $\Delta G^\circ$  for reactions 1 and 2:

Reaction 1:

$$\Delta G^\circ = -RT \ln K = -(8.314 \text{ J/K mol})(298 \text{ K}) \ln(2.4 \times 10^{-6}) = 3.21 \times 10^4 \text{ J/mol}$$

Reaction 2:

$$\Delta G^\circ = -nFE^\circ = -(2 \text{ mol})(96,485 \text{ C/mol})(-0.440 \text{ J/C}) = 8.49 \times 10^4 \text{ J}$$

(Recall that 1 volt is 1 joule per coulomb.)

Then,  $\Delta G^\circ$  for reaction 3, the one we want, is  $3.21 \times 10^4 \text{ J}$  (for one mole of  $\text{FeF}_2$ ) +  $8.49 \times 10^4 \text{ J} = 1.17 \times 10^5 \text{ J}$ . We can convert this to  $E^\circ$  easily from the relationship  $\Delta G^\circ = -nFE^\circ$ :

$$1.17 \times 10^5 \text{ J} = -(2 \text{ mol})(96,485 \text{ C/mol}) E^\circ$$

$$E^\circ = -0.606 \text{ J/C} = -0.606 \text{ V.}$$

(c) The standard reduction potential for  $\text{FeF}_2$  ( $-0.606 \text{ V}$ ) is more negative than that for  $\text{Fe}^{2+}$  ( $-0.440 \text{ V}$ ), telling us that the reduction of  $\text{FeF}_2$  is the less favorable process. When  $\text{FeF}_2$  is reduced, we not only reduce the  $\text{Fe}^{2+}$  ions but also break up the ionic solid. Because this additional energy must be overcome, the reduction of  $\text{FeF}_2$  is less favorable than the reduction of  $\text{Fe}^{2+}$ .

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 20.1** In this chapter we have focused on **electrochemistry**, the branch of chemistry that relates electricity and chemical reactions. Electrochemistry involves oxidation-reduction reactions, also called redox reactions. These reactions involve a change in the oxidation state of one or more elements. In every oxidation-reduction reaction one substance is oxidized (its oxidation state, or number, increases) and one substance is reduced (its oxidation state, or number, decreases). The substance that is oxidized is referred to as a **reducing agent**, or **reductant**, because it causes the reduction of some other substance. Similarly, the substance that is reduced is referred to as an **oxidizing agent**, or **oxidant**, because it causes the oxidation of some other substance.

**Section 20.2** An oxidation-reduction reaction can be balanced by dividing the reaction into two **half-reactions**, one for oxidation and one for reduction. A half-reaction is a balanced chemical equation that includes electrons. In oxidation half-reactions the electrons are on the product

(right) side of the reaction; we can envision that these electrons are transferred from a substance when it is oxidized. In reduction half-reactions the electrons are on the reactant (left) side of the reaction. Each half-reaction is balanced separately, and the two are brought together with proper coefficients to balance the electrons on each side of the equation.

**Section 20.3** A **voltaic** (or **galvanic**) **cell** uses a spontaneous oxidation-reduction reaction to generate electricity. In a voltaic cell the oxidation and reduction half-reactions often occur in separate compartments. Each compartment has a solid surface called an electrode, where the half-reaction occurs. The electrode where oxidation occurs is called the **anode**; reduction occurs at the **cathode**. The electrons released at the anode flow through an external circuit (where they do electrical work) to the cathode. Electrical neutrality in the solution is maintained by the migration of ions between the two compartments through a device such as a salt bridge.

**Section 20.4** A voltaic cell generates an **electromotive force (emf)** that moves the electrons from the anode to the cathode through the external circuit. The origin of emf is a difference in the electrical potential energy of the two electrodes in the cell. The emf of a cell is called its **cell potential**,  $E_{\text{cell}}$ , and is measured in volts. The cell potential under standard conditions is called the **standard emf**, or the **standard cell potential**, and is denoted  $E_{\text{cell}}^{\circ}$ .

A **standard reduction potential**,  $E_{\text{red}}^{\circ}$ , can be assigned for an individual half-reaction. This is achieved by comparing the potential of the half-reaction to that of the **standard hydrogen electrode (SHE)**, which is defined to have  $E_{\text{red}}^{\circ} = 0 \text{ V}$  and is based on the following half-reaction:

The standard cell potential of a voltaic cell is the difference between the standard reduction potentials of the half-reactions that occur at the cathode and the anode:  $E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$ . The value of  $E_{\text{cell}}^{\circ}$  is positive for a voltaic cell.

For a reduction half-reaction,  $E_{\text{red}}^{\circ}$  is a measure of the tendency of the reduction to occur; the more positive the value for  $E_{\text{red}}^{\circ}$ , the greater the tendency of the substance to be reduced. Thus,  $E_{\text{red}}^{\circ}$  provides a measure of the oxidizing strength of a substance. Fluorine ( $\text{F}_2$ ) has the most positive value for  $E_{\text{red}}^{\circ}$  and is the strongest oxidizing agent. Substances that are strong oxidizing agents produce products that are weak reducing agents, and vice versa.

**Section 20.5** The emf,  $E$ , is related to the change in the Gibbs free energy,  $\Delta G$ :  $\Delta G = -nFE$ , where  $n$  is the number of electrons transferred during the redox process and  $F$  is *Faraday's constant*, defined as the quantity of electrical charge on one mole of electrons. This amount of charge is 1 **faraday (F)**:  $1 \text{ F} = 96,485 \text{ C/mol}$ . Because  $E$  is related to  $\Delta G$ , the sign of  $E$  indicates whether a redox process is spontaneous:  $E > 0$  indicates a spontaneous process, and  $E < 0$  indicates a nonspontaneous one. Because  $\Delta G$  is also related to the equilibrium constant for a reaction ( $\Delta G = -RT \ln K$ ), we can relate  $E$  to  $K$  as well.

**Section 20.6** The emf of a redox reaction varies with temperature and with the concentrations of reactants and products. The **Nernst equation** relates the emf under nonstandard conditions to the standard emf and the reaction quotient  $Q$ :

$$E = E^{\circ} - (RT/nF) \ln Q = E^{\circ} - (0.0592/n) \log Q$$

The factor 0.0592 is valid when  $T = 298 \text{ K}$ . A **concentration cell** is a voltaic cell in which the same half-reaction occurs at both the anode and cathode but with different concentrations of reactants in each compartment.

At equilibrium,  $Q = K$  and  $E = 0$ . The standard emf is therefore related to the equilibrium constant.

**Section 20.7** A **battery** is a self-contained electrochemical power source that contains one or more voltaic cells. Batteries are based on a variety of different redox reactions. Several common batteries were discussed. The lead-acid battery, the nickel-cadmium battery, the nickel-metal-hydride battery, and the lithium-ion battery are examples of rechargeable batteries. The common alkaline dry cell is not rechargeable. **Fuel cells** are voltaic cells that utilize redox reactions in which reactants such as  $\text{H}_2$  have to be continuously supplied to the cell to generate voltage.

**Section 20.8** Electrochemical principles help us understand **corrosion**, undesirable redox reactions in which a metal is attacked by some substance in its environment. The corrosion of iron into rust is caused by the presence of water and oxygen, and it is accelerated by the presence of electrolytes, such as road salt. The protection of a metal by putting it in contact with another metal that more readily undergoes oxidation is called **cathodic protection**. Galvanized iron, for example, is coated with a thin layer of zinc; because zinc is oxidized more readily than iron, the zinc serves as a sacrificial anode in the redox reaction.

**Section 20.9** An **electrolysis reaction**, which is carried out in an **electrolytic cell**, employs an external source of electricity to drive a nonspontaneous electrochemical reaction. The negative terminal of the external source is connected to the cathode of the cell, and the positive terminal to the anode. The current-carrying medium within an electrolytic cell may be either a molten salt or an electrolyte solution. The products of electrolysis can generally be predicted by comparing the reduction potentials associated with possible oxidation and reduction processes. The electrodes in an electrolytic cell can be active, meaning that the electrode can be involved in the electrolysis reaction. Active electrodes are important in electroplating and in metallurgical processes.

The quantity of substances formed during electrolysis can be calculated by considering the number of electrons involved in the redox reaction and the amount of electrical charge that passes into the cell. The maximum amount of electrical work produced by a voltaic cell is given by the product of the total charge delivered,  $nF$ , and the emf,  $E$ :  $w_{\text{max}} = -nFE$ . The work performed in an electrolysis is given by  $w = nFE_{\text{ext}}$ , where  $E_{\text{ext}}$  is the applied external potential. The **watt** is a unit of power:  $1 \text{ W} = 1 \text{ J/s}$ . Electrical work is often measured in kilowatt-hours.

## KEY SKILLS

- Identify oxidation, reduction, oxidizing agent, and reducing agent in a chemical equation.
- Complete and balance redox equations using the method of half-reactions.
- Sketch a voltaic cell and identify its cathode, anode, and the directions that electrons and ions move.
- Calculate standard emfs (cell potentials),  $E_{\text{cell}}^{\circ}$ , from standard reduction potentials.

- Use reduction potentials to predict whether a redox reaction is spontaneous.
- Relate  $E_{\text{cell}}^{\circ}$  to  $\Delta G^{\circ}$  and equilibrium constants.
- Calculate emf under nonstandard conditions.
- Describe the reactions in electrolytic cells.
- Relate amounts of products and reactants in redox reactions to electrical charge.

## KEY EQUATIONS

- $E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$  [20.8] Relating standard emf to standard reduction potentials of the reduction (cathode) and oxidation (anode) half reactions
- $\Delta G = -nFE$  [20.11] Relating free energy change and emf
- $E = E^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q$  (at 298 K) [20.16] The Nernst equation, expressing the effect of concentration on cell potential

## VISUALIZING CONCEPTS

- 20.1** In the Brønsted-Lowry concept of acids and bases, acid-base reactions are viewed as proton-transfer reactions. The stronger the acid, the weaker is its conjugate base. In what ways are redox reactions analogous? [Sections 20.1 and 20.2]
- 20.2** Consider the reaction in Figure 20.3. Describe what would happen if (a) the solution contained cadmium(II) sulfate and the metal was zinc, (b) the solution contained silver nitrate and the metal was copper. [Section 20.3]
- 20.3** The diagram below represents a molecular view of a process occurring at an electrode in a voltaic cell.

- (a) Does the process represent oxidation or reduction?  
 (b) Is the electrode the anode or cathode? (c) Why are the atoms in the electrode represented by larger spheres than the ions in the solution? [Section 20.3]
- 20.4** Assume that you want to construct a voltaic cell that uses the following half reactions:

You begin with the incomplete cell pictured below, in which the electrodes are immersed in water.

(a) What additions must you make to the cell for it to generate a standard emf? (b) Which electrode functions as the cathode? (c) Which direction do electrons move through the external circuit? (d) What voltage will the cell generate under standard conditions? [Sections 20.3 and 20.4]

- 20.5** Where on Figure 20.14 would you find (a) the chemical species that is the easiest to oxidize, and (b) the chemical species that is the easiest to reduce? [Section 20.4]
- 20.6** For the generic reaction  $\text{A}(\text{aq}) + \text{B}(\text{aq}) \longrightarrow \text{A}^{-}(\text{aq}) + \text{B}^{+}(\text{aq})$  for which  $E^{\circ}$  is a positive number, answer the following questions:  
 (a) What is being oxidized, and what is being reduced?  
 (b) If you made a voltaic cell out of this reaction, what half-reaction would be occurring at the cathode, and what half-reaction would be occurring at the anode?  
 (c) Which half-reaction from (b) is higher in potential energy?  
 (d) What is the sign of the free energy change for the reaction? [Sections 20.4 and 20.5]
- 20.7** Consider the half reaction  $\text{Ag}^{+}(\text{aq}) + \text{e}^{-} \longrightarrow \text{Ag}(\text{s})$ .  
 (a) Which of the lines in the following diagram indicates how the reduction potential varies with the concentration of  $\text{Ag}^{+}$ ? (b) What is the value of  $E_{\text{red}}$  when  $\log[\text{Ag}^{+}] = 0$ ? [Section 20.6]

- 20.8** Draw a generic picture of a fuel cell. What is the main difference between it and a battery, regardless of the redox reactions that occur inside? [Section 20.7]
- 20.9** How does a zinc coating on iron protect the iron from unwanted oxidation? [Section 20.8]
- 20.10** You may have heard that “antioxidants” are good for your health. Based on what you have learned in this chapter, what do you deduce an “antioxidant” is? [Sections 20.1 and 20.2]

## EXERCISES

## Oxidation-Reduction Reactions

- 20.11** (a) What is meant by the term *oxidation*? (b) On which side of an oxidation half-reaction do the electrons appear? (c) What is meant by the term *oxidant*? (d) What is meant by the term *oxidizing agent*?
- 20.12** (a) What is meant by the term *reduction*? (b) On which side of a reduction half-reaction do the electrons appear? (c) What is meant by the term *reductant*? (d) What is meant by the term *reducing agent*?
- 20.13** Indicate whether each of the following statements is true or false:
- (a) If something is oxidized, it is formally losing electrons.  
 (b) For the reaction  $\text{Fe}^{3+}(aq) + \text{Co}^{2+}(aq) \rightarrow \text{Fe}^{2+}(aq) + \text{Co}^{3+}(aq)$ ,  $\text{Fe}^{3+}(aq)$  is the reducing agent and  $\text{Co}^{2+}(aq)$  is the oxidizing agent.  
 (c) If there are no changes in the oxidation state of the reactants or products of a particular reaction, that reaction is not a redox reaction.
- 20.14** Indicate whether each of the following statements is true or false:
- (a) If something is reduced, it is formally losing electrons.  
 (b) A reducing agent gets oxidized as it reacts.  
 (c) Oxidizing agents can convert CO into  $\text{CO}_2$ .

**20.15** In each of the following balanced oxidation-reduction equations, identify those elements that undergo changes in oxidation number and indicate the magnitude of the change in each case.

- (a)  $\text{I}_2\text{O}_5(s) + 5 \text{CO}(g) \rightarrow \text{I}_2(s) + 5 \text{CO}_2(g)$   
 (b)  $2 \text{Hg}^{2+}(aq) + \text{N}_2\text{H}_4(aq) \rightarrow 2 \text{Hg}(l) + \text{N}_2(g) + 4 \text{H}^+(aq)$   
 (c)  $3 \text{H}_2\text{S}(aq) + 2 \text{H}^+(aq) + 2 \text{NO}_3^-(aq) \rightarrow 3 \text{S}(s) + 2 \text{NO}(g) + 4 \text{H}_2\text{O}(l)$   
 (d)  $\text{Ba}^{2+}(aq) + 2 \text{OH}^-(aq) + \text{H}_2\text{O}_2(aq) + 2 \text{ClO}_2(aq) \rightarrow \text{Ba}(\text{ClO}_2)_2(s) + 2 \text{H}_2\text{O}(l) + \text{O}_2(g)$
- 20.16** Indicate whether the following balanced equations involve oxidation-reduction. If they do, identify the elements that undergo changes in oxidation number.
- (a)  $\text{PBr}_3(l) + 3 \text{H}_2\text{O}(l) \rightarrow \text{H}_3\text{PO}_3(aq) + 3 \text{HBr}(aq)$   
 (b)  $\text{NaI}(aq) + 3 \text{HOCl}(aq) \rightarrow \text{NaIO}_3(aq) + 3 \text{HCl}(aq)$   
 (c)  $3 \text{SO}_2(g) + 2 \text{HNO}_3(aq) + 2 \text{H}_2\text{O}(l) \rightarrow 3 \text{H}_2\text{SO}_4(aq) + 2 \text{NO}(g)$   
 (d)  $2 \text{H}_2\text{SO}_4(aq) + 2 \text{NaBr}(s) \rightarrow \text{Br}_2(l) + \text{SO}_2(g) + \text{Na}_2\text{SO}_4(aq) + 2 \text{H}_2\text{O}(l)$

## Balancing Oxidation-Reduction Reactions

- 20.17** At  $900^\circ\text{C}$  titanium tetrachloride vapor reacts with molten magnesium metal to form solid titanium metal and molten magnesium chloride. (a) Write a balanced equation for this reaction. (b) What is being oxidized, and what is being reduced? (c) Which substance is the reductant, and which is the oxidant?
- 20.18** Hydrazine ( $\text{N}_2\text{H}_4$ ) and dinitrogen tetroxide ( $\text{N}_2\text{O}_4$ ) form a self-igniting mixture that has been used as a rocket propellant. The reaction products are  $\text{N}_2$  and  $\text{H}_2\text{O}$ . (a) Write a balanced chemical equation for this reaction. (b) What is being oxidized, and what is being reduced? (c) Which substance serves as the reducing agent, and which as the oxidizing agent?
- 20.19** Complete and balance the following half-reactions. In each case indicate whether the half-reaction is an oxidation or a reduction.
- (a)  $\text{Sn}^{2+}(aq) \rightarrow \text{Sn}^{4+}(aq)$  (acidic or basic solution)  
 (b)  $\text{TiO}_2(s) \rightarrow \text{Ti}^{2+}(aq)$  (acidic solution)  
 (c)  $\text{ClO}_3^-(aq) \rightarrow \text{Cl}^-(aq)$  (acidic solution)  
 (d)  $\text{N}_2(g) \rightarrow \text{NH}_4^+(aq)$  (acidic solution)  
 (e)  $\text{OH}^-(aq) \rightarrow \text{O}_2(g)$  (basic solution)  
 (f)  $\text{SO}_3^{2-}(aq) \rightarrow \text{SO}_4^{2-}(aq)$  (basic solution)  
 (g)  $\text{N}_2(g) \rightarrow \text{NH}_3(g)$  (basic solution)
- 20.20** Complete and balance the following half-reactions. In each case indicate whether the half-reaction is an oxidation or a reduction.
- (a)  $\text{Mo}^{3+}(aq) \rightarrow \text{Mo}(s)$  (acidic or basic solution)  
 (b)  $\text{H}_2\text{SO}_3(aq) \rightarrow \text{SO}_4^{2-}(aq)$  (acidic solution)

- (c)  $\text{NO}_3^-(aq) \rightarrow \text{NO}(g)$  (acidic solution)  
 (d)  $\text{O}_2(g) \rightarrow \text{H}_2\text{O}(l)$  (acidic solution)  
 (e)  $\text{Mn}^{2+}(aq) \rightarrow \text{MnO}_2(s)$  (basic solution)  
 (f)  $\text{Cr}(\text{OH})_3(s) \rightarrow \text{CrO}_4^{2-}(aq)$  (basic solution)  
 (g)  $\text{O}_2(g) \rightarrow \text{H}_2\text{O}(l)$  (basic solution)

**20.21** Complete and balance the following equations, and identify the oxidizing and reducing agents:

- (a)  $\text{Cr}_2\text{O}_7^{2-}(aq) + \text{I}^-(aq) \rightarrow \text{Cr}^{3+}(aq) + \text{IO}_3^-(aq)$  (acidic solution)  
 (b)  $\text{MnO}_4^-(aq) + \text{CH}_3\text{OH}(aq) \rightarrow \text{Mn}^{2+}(aq) + \text{HCO}_2\text{H}(aq)$  (acidic solution)  
 (c)  $\text{I}_2(s) + \text{OCl}^-(aq) \rightarrow \text{IO}_3^-(aq) + \text{Cl}^-(aq)$  (acidic solution)  
 (d)  $\text{As}_2\text{O}_3(s) + \text{NO}_3^-(aq) \rightarrow \text{H}_3\text{AsO}_4(aq) + \text{N}_2\text{O}_3(aq)$  (acidic solution)  
 (e)  $\text{MnO}_4^-(aq) + \text{Br}^-(aq) \rightarrow \text{MnO}_2(s) + \text{BrO}_3^-(aq)$  (basic solution)  
 (f)  $\text{Pb}(\text{OH})_4^{2-}(aq) + \text{ClO}^-(aq) \rightarrow \text{PbO}_2(s) + \text{Cl}^-(aq)$  (basic solution)

**20.22** Complete and balance the following equations, and identify the oxidizing and reducing agents. Recall that the O atoms in hydrogen peroxide,  $\text{H}_2\text{O}_2$ , have an atypical oxidation state.  $\infty$  (Table 2.5)

- (a)  $\text{NO}_2^-(aq) + \text{Cr}_2\text{O}_7^{2-}(aq) \rightarrow \text{Cr}^{3+}(aq) + \text{NO}_3^-(aq)$  (acidic solution)  
 (b)  $\text{S}(s) + \text{HNO}_3(aq) \rightarrow \text{H}_2\text{SO}_3(aq) + \text{N}_2\text{O}(g)$  (acidic solution)

## Voltaic Cells

**20.23** (a) What are the similarities and differences between Figure 20.3 and Figure 20.4? (b) Why are  $\text{Na}^{+}$  ions drawn into the cathode compartment as the voltaic cell shown in Figure 20.5 operates?

**20.24** (a) What is the role of the porous glass disc shown in Figure 20.4? (b) Why do  $\text{NO}_3^{-}$  ions migrate into the anode compartment as the voltaic cell shown in Figure 20.5 operates?

**20.25** A voltaic cell similar to that shown in Figure 20.5 is constructed. One electrode compartment consists of a silver strip placed in a solution of  $\text{AgNO}_3$ , and the other has an iron strip placed in a solution of  $\text{FeCl}_2$ . The overall cell reaction is

(a) What is being oxidized, and what is being reduced? (b) Write the half-reactions that occur in the two electrode compartments. (c) Which electrode is the anode, and which is the cathode? (d) Indicate the signs of the

electrodes. (e) Do electrons flow from the silver electrode to the iron electrode, or from the iron to the silver? (f) In which directions do the cations and anions migrate through the solution?

**20.26** A voltaic cell similar to that shown in Figure 20.5 is constructed. One electrode compartment consists of an aluminum strip placed in a solution of  $\text{Al}(\text{NO}_3)_3$ , and the other has a nickel strip placed in a solution of  $\text{NiSO}_4$ . The overall cell reaction is

(a) What is being oxidized, and what is being reduced? (b) Write the half-reactions that occur in the two electrode compartments. (c) Which electrode is the anode, and which is the cathode? (d) Indicate the signs of the electrodes. (e) Do electrons flow from the aluminum electrode to the nickel electrode, or from the nickel to the aluminum? (f) In which directions do the cations and anions migrate through the solution? Assume the Al is not coated with its oxide.

## Cell EMF under Standard Conditions

**20.27** (a) What does the term *electromotive force* mean? (b) What is the definition of the *volt*? (c) What does the term *cell potential* mean?

**20.28** (a) Which electrode of a voltaic cell, the cathode or the anode, corresponds to the higher potential energy for the electrons? (b) What are the units for electrical potential? How does this unit relate to energy expressed in joules? (c) What is special about a *standard* cell potential?

**20.29** (a) Write the half-reaction that occurs at a hydrogen electrode in acidic aqueous solution when it serves as the cathode of a voltaic cell. (b) What is *standard* about the standard hydrogen electrode? (c) What is the role of the platinum foil in a standard hydrogen electrode?

**20.30** (a) Write the half-reaction that occurs at a hydrogen electrode in acidic aqueous solution when it serves as the anode of a voltaic cell. (b) The platinum electrode in a standard hydrogen electrode is specially prepared to have a large surface area. Why is this important? (c) Sketch a standard hydrogen electrode.

**20.31** (a) What is a *standard reduction potential*? (b) What is the standard reduction potential of a standard hydrogen electrode?

**20.32** (a) Why is it impossible to measure the standard reduction potential of a single half-reaction? (b) Describe how the standard reduction potential of a half-reaction can be determined.

**20.33** A voltaic cell that uses the reaction

has a measured standard cell potential of +1.19 V.

(a) Write the two half-cell reactions. (b) By using data from Appendix E, determine  $E_{\text{red}}^{\circ}$  for the reduction of  $\text{Tl}^{3+}(\text{aq})$  to  $\text{Tl}^{+}(\text{aq})$ . (c) Sketch the voltaic cell, label the anode and cathode, and indicate the direction of electron flow.

**20.34** A voltaic cell that uses the reaction

has a measured standard cell potential of +1.03 V.

(a) Write the two half-cell reactions. (b) By using data from Appendix E, determine  $E_{\text{red}}^{\circ}$  for the reaction involving Pd. (c) Sketch the voltaic cell, label the anode and cathode, and indicate the direction of electron flow.

**20.35** Using standard reduction potentials (Appendix E), calculate the standard emf for each of the following reactions:

**20.36** Using data in Appendix E, calculate the standard emf for each of the following reactions:

**20.37** The standard reduction potentials of the following half-reactions are given in Appendix E:

- (a) Determine which combination of these half-cell reactions leads to the cell reaction with the largest positive cell emf, and calculate the value. (b) Determine which combination of these half-cell reactions leads to the cell reaction with the smallest positive cell emf, and calculate the value.
- 20.38 Given the following half-reactions and associated standard reduction potentials:

- (a) Write the cell reaction for the combination of these half-cell reactions that leads to the largest positive cell emf, and calculate the value. (b) Write the cell reaction for the combination of half-cell reactions that leads to the smallest positive cell emf, and calculate that value.

- 20.39 A 1 M solution of  $\text{Cu}(\text{NO}_3)_2$  is placed in a beaker with a strip of Cu metal. A 1 M solution of  $\text{SnSO}_4$  is placed in a second beaker with a strip of Sn metal. A salt bridge connects the two beakers, and wires to a voltmeter link the two metal electrodes. (a) Which electrode serves as the anode, and which as the cathode? (b) Which electrode gains mass and which loses mass as the cell reaction proceeds? (c) Write the equation for the overall cell reaction. (d) What is the emf generated by the cell under standard conditions?

- 20.40 A voltaic cell consists of a strip of cadmium metal in a solution of  $\text{Cd}(\text{NO}_3)_2$  in one beaker, and in the other beaker a platinum electrode is immersed in a NaCl solution, with  $\text{Cl}_2$  gas bubbled around the electrode. A salt bridge connects the two beakers. (a) Which electrode serves as the anode, and which as the cathode? (b) Does the Cd electrode gain or lose mass as the cell reaction proceeds? (c) Write the equation for the overall cell reaction. (d) What is the emf generated by the cell under standard conditions?

## Strengths of Oxidizing and Reducing Agents

- 20.41 From each of the following pairs of substances, use data in Appendix E to choose the one that is the stronger reducing agent:

- (a) Fe(s) or Mg(s)  
 (b) Ca(s) or Al(s)  
 (c)  $\text{H}_2$ (g, acidic solution) or  $\text{H}_2\text{S}$ (g)  
 (d)  $\text{H}_2\text{SO}_3$ (aq) or  $\text{H}_2\text{C}_2\text{O}_4$ (aq)

- 20.42 From each of the following pairs of substances, use data in Appendix E to choose the one that is the stronger oxidizing agent:

- (a)  $\text{Cl}_2$ (g) or  $\text{Br}_2$ (l)  
 (b)  $\text{Zn}^{2+}$ (aq) or  $\text{Cd}^{2+}$ (aq)  
 (c)  $\text{BrO}_3^-$ (aq) or  $\text{IO}_3^-$ (aq)  
 (d)  $\text{H}_2\text{O}_2$ (aq) or  $\text{O}_3$ (g)

- 20.43 By using the data in Appendix E, determine whether each of the following substances is likely to serve as an oxidant or a reductant: (a)  $\text{Cl}_2$ (g), (b)  $\text{MnO}_4^-$ (aq, acidic solution), (c) Ba(s), (d) Zn(s).

- 20.44 Is each of the following substances likely to serve as an oxidant or a reductant: (a)  $\text{Ce}^{3+}$ (aq), (b) Ca(s), (c)  $\text{ClO}_3^-$ (aq), (d)  $\text{N}_2\text{O}_5$ (g)?

- 20.45 (a) Assuming standard conditions, arrange the following in order of increasing strength as oxidizing agents in acidic solution:  $\text{Cr}_2\text{O}_7^{2-}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{Cu}^{2+}$ ,  $\text{Cl}_2$ ,  $\text{O}_2$ . (b) Arrange the following in order of increasing strength as reducing agents in acidic solution: Zn,  $\text{I}^-$ ,  $\text{Sn}^{2+}$ ,  $\text{H}_2\text{O}_2$ , Al.

- 20.46 Based on the data in Appendix E, (a) which of the following is the strongest oxidizing agent and which is the weakest in acidic solution:  $\text{Ce}^{4+}$ ,  $\text{Br}_2$ ,  $\text{H}_2\text{O}_2$ , Zn? (b) Which of the following is the strongest reducing agent, and which is the weakest in acidic solution:  $\text{F}^-$ , Zn,  $\text{N}_2\text{H}_5^+$ ,  $\text{I}_2$ , NO?

- 20.47 The standard reduction potential for the reduction of  $\text{Eu}^{3+}$ (aq) to  $\text{Eu}^{2+}$ (aq) is  $-0.43 \text{ V}$ . Using Appendix E, which of the following substances is capable of reducing  $\text{Eu}^{3+}$ (aq) to  $\text{Eu}^{2+}$ (aq) under standard conditions: Al, Co,  $\text{H}_2\text{O}_2$ ,  $\text{N}_2\text{H}_5^+$ ,  $\text{H}_2\text{C}_2\text{O}_4$ ?

- 20.48 The standard reduction potential for the reduction of  $\text{RuO}_4^-(aq)$  to  $\text{RuO}_4^{2-}(aq)$  is  $+0.59 \text{ V}$ . By using Appendix E, which of the following substances can oxidize  $\text{RuO}_4^{2-}(aq)$  to  $\text{RuO}_4^-(aq)$  under standard conditions:  $\text{Br}_2$ (l),  $\text{BrO}_3^-(aq)$ ,  $\text{Mn}^{2+}$ (aq),  $\text{O}_2$ (g),  $\text{Sn}^{2+}$ (aq)?

## Free Energy and Redox Reactions

- 20.49 Given the following reduction half-reactions:

- (a) Write balanced chemical equations for the oxidation of  $\text{Fe}^{2+}$ (aq) by  $\text{S}_2\text{O}_6^{2-}$ (aq), by  $\text{N}_2\text{O}(g)$ , and by  $\text{VO}_2^+(aq)$ . (b) Calculate  $\Delta G^\circ$  for each reaction at 298 K. (c) Calculate the equilibrium constant  $K$  for each reaction at 298 K.

- 20.50 For each of the following reactions, write a balanced equation, calculate the standard emf, calculate  $\Delta G^\circ$  at 298 K, and calculate the equilibrium constant  $K$  at 298 K. (a) Aqueous iodide ion is oxidized to  $\text{I}_2$ (s) by  $\text{Hg}_2^{2+}$ (aq). (b) In acidic solution, copper(I) ion is oxidized to copper(II) ion by nitrate ion. (c) In basic solution,  $\text{Cr}(\text{OH})_3$ (s) is oxidized to  $\text{CrO}_4^{2-}$ (aq) by  $\text{ClO}^-(aq)$ .

- 20.51** If the equilibrium constant for a two-electron redox reaction at 298 K is  $1.5 \times 10^{-4}$ , calculate the corresponding  $\Delta G^\circ$  and  $E_{\text{cell}}^\circ$ .
- 20.52** If the equilibrium constant for a one-electron redox reaction at 298 K is  $8.7 \times 10^4$ , calculate the corresponding  $\Delta G^\circ$  and  $E_{\text{cell}}^\circ$ .
- 20.53** Using the standard reduction potentials listed in Appendix E, calculate the equilibrium constant for each of the following reactions at 298 K:  
 (a)  $\text{Fe}(s) + \text{Ni}^{2+}(aq) \longrightarrow \text{Fe}^{2+}(aq) + \text{Ni}(s)$   
 (b)  $\text{Co}(s) + 2\text{H}^+(aq) \longrightarrow \text{Co}^{2+}(aq) + \text{H}_2(g)$   
 (c)  $10 \text{Br}^-(aq) + 2 \text{MnO}_4^-(aq) + 16 \text{H}^+(aq) \longrightarrow 2 \text{Mn}^{2+}(aq) + 8 \text{H}_2\text{O}(l) + 5 \text{Br}_2(l)$
- 20.54** Using the standard reduction potentials listed in Appendix E, calculate the equilibrium constant for each of the following reactions at 298 K:  
 (a)  $\text{Cu}(s) + 2 \text{Ag}^+(aq) \longrightarrow \text{Cu}^{2+}(aq) + 2 \text{Ag}(s)$   
 (b)  $3 \text{Ce}^{4+}(aq) + \text{Bi}(s) + \text{H}_2\text{O}(l) \longrightarrow 3 \text{Ce}^{3+}(aq) + \text{BiO}^+(aq) + 2 \text{H}^+(aq)$   
 (c)  $\text{N}_2\text{H}_5^+(aq) + 4 \text{Fe}(\text{CN})_6^{3-}(aq) \longrightarrow \text{N}_2(g) + 5 \text{H}^+(aq) + 4 \text{Fe}(\text{CN})_6^{4-}(aq)$
- 20.55** A cell has a standard emf of +0.177 V at 298 K. What is the value of the equilibrium constant for the cell reaction (a) if  $n = 1$ ? (b) if  $n = 2$ ? (c) if  $n = 3$ ?
- 20.56** At 298 K a cell reaction has a standard emf of +0.17 V. The equilibrium constant for the cell reaction is  $5.5 \times 10^5$ . What is the value of  $n$  for the cell reaction?

## Cell EMF under Nonstandard Conditions

- 20.57** (a) Under what circumstances is the Nernst equation applicable? (b) What is the numerical value of the reaction quotient,  $Q$ , under standard conditions? (c) What happens to the emf of a cell if the concentrations of the reactants are increased?
- 20.58** (a) A voltaic cell is constructed with all reactants and products in their standard states. Will this condition hold as the cell operates? Explain. (b) Can the Nernst equation be used at temperatures other than room temperature? Explain. (c) What happens to the emf of a cell if the concentrations of the products are increased?
- 20.59** What is the effect on the emf of the cell shown in Figure 20.11, which has the overall reaction  $\text{Zn}(s) + 2 \text{H}^+(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{H}_2(g)$ , for each of the following changes? (a) The pressure of the  $\text{H}_2$  gas is increased in the cathode compartment. (b) Zinc nitrate is added to the anode compartment. (c) Sodium hydroxide is added to the cathode compartment, decreasing  $[\text{H}^+]$ . (d) The surface area of the anode is doubled.
- 20.60** A voltaic cell utilizes the following reaction:  

$$\text{Al}(s) + 3 \text{Ag}^+(aq) \longrightarrow \text{Al}^{3+}(aq) + 3 \text{Ag}(s)$$
 What is the effect on the cell emf of each of the following changes? (a) Water is added to the anode compartment, diluting the solution. (b) The size of the aluminum electrode is increased. (c) A solution of  $\text{AgNO}_3$  is added to the cathode compartment, increasing the quantity of  $\text{Ag}^+$  but not changing its concentration. (d)  $\text{HCl}$  is added to the  $\text{AgNO}_3$  solution, precipitating some of the  $\text{Ag}^+$  as  $\text{AgCl}$ .
- 20.61** A voltaic cell is constructed that uses the following reaction and operates at 298 K:  

$$\text{Zn}(s) + \text{Ni}^{2+}(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{Ni}(s)$$
 (a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when  $[\text{Ni}^{2+}] = 3.00 \text{ M}$  and  $[\text{Zn}^{2+}] = 0.100 \text{ M}$ ? (c) What is the emf of the cell when  $[\text{Ni}^{2+}] = 0.200 \text{ M}$ , and  $[\text{Zn}^{2+}] = 0.900 \text{ M}$ ?
- 20.62** A voltaic cell utilizes the following reaction and operates at 298 K:  

$$3 \text{Ce}^{4+}(aq) + \text{Cr}(s) \longrightarrow 3 \text{Ce}^{3+}(aq) + \text{Cr}^{3+}(aq)$$
 (a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when  $[\text{Ce}^{4+}] = 3.0 \text{ M}$ ,  $[\text{Ce}^{3+}] = 0.10 \text{ M}$ , and  $[\text{Cr}^{3+}] = 0.010 \text{ M}$ ? (c) What is the emf of the cell when  $[\text{Ce}^{4+}] = 0.10 \text{ M}$ ,  $[\text{Ce}^{3+}] = 1.75 \text{ M}$ , and  $[\text{Cr}^{3+}] = 2.5 \text{ M}$ ?
- 20.63** A voltaic cell utilizes the following reaction:  

$$4 \text{Fe}^{2+}(aq) + \text{O}_2(g) + 4 \text{H}^+(aq) \longrightarrow 4 \text{Fe}^{3+}(aq) + 2 \text{H}_2\text{O}(l)$$
 (a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when  $[\text{Fe}^{2+}] = 1.3 \text{ M}$ ,  $[\text{Fe}^{3+}] = 0.010 \text{ M}$ ,  $P_{\text{O}_2} = 0.50 \text{ atm}$ , and the pH of the solution in the cathode compartment is 3.50?
- 20.64** A voltaic cell utilizes the following reaction:  

$$2 \text{Fe}^{3+}(aq) + \text{H}_2(g) \longrightarrow 2 \text{Fe}^{2+}(aq) + 2 \text{H}^+(aq)$$
 (a) What is the emf of this cell under standard conditions? (b) What is the emf for this cell when  $[\text{Fe}^{3+}] = 2.50 \text{ M}$ ,  $P_{\text{H}_2} = 0.85 \text{ atm}$ ,  $[\text{Fe}^{2+}] = 0.0010 \text{ M}$ , and the pH in both compartments is 5.00?
- 20.65** A voltaic cell is constructed with two  $\text{Zn}^{2+}$ -Zn electrodes. The two cell compartments have  $[\text{Zn}^{2+}] = 1.8 \text{ M}$  and  $[\text{Zn}^{2+}] = 1.00 \times 10^{-2} \text{ M}$ , respectively. (a) Which electrode is the anode of the cell? (b) What is the standard emf of the cell? (c) What is the cell emf for the concentrations given? (d) For each electrode, predict whether  $[\text{Zn}^{2+}]$  will increase, decrease, or stay the same as the cell operates.
- 20.66** A voltaic cell is constructed with two silver-silver chloride electrodes, each of which is based on the following half-reaction:  

$$\text{AgCl}(s) + e^- \longrightarrow \text{Ag}(s) + \text{Cl}^-(aq)$$
 The two cell compartments have  $[\text{Cl}^-] = 0.0150 \text{ M}$  and  $[\text{Cl}^-] = 2.55 \text{ M}$ , respectively. (a) Which electrode is the cathode of the cell? (b) What is the standard emf of the cell? (c) What is the cell emf for the concentrations given? (d) For each electrode, predict whether  $[\text{Cl}^-]$  will increase, decrease, or stay the same as the cell operates.
- 20.67** The cell in Figure 20.11 could be used to provide a measure of the pH in the cathode compartment. Calculate the pH of the cathode compartment solution if the cell emf at 298 K is measured to be +0.684 V when  $[\text{Zn}^{2+}] = 0.30 \text{ M}$  and  $P_{\text{H}_2} = 0.90 \text{ atm}$ .

- 20.68 A voltaic cell is constructed that is based on the following reaction:

## Batteries and Fuel Cells

- 20.69 (a) What happens to the emf of a battery as it is used? Why does this happen? (b) The AA-size and D-size alkaline batteries are both 1.5-V batteries that are based on the same electrode reactions. What is the major difference between the two batteries? What performance feature is most affected by this difference?
- 20.70 (a) Suggest an explanation for why liquid water is needed in an alkaline battery. (b) What is the advantage of using highly concentrated or solid reactants in a voltaic cell?
- 20.71 During a period of discharge of a lead-acid battery, 402 g of Pb from the anode is converted into  $\text{PbSO}_4(s)$ . What mass of  $\text{PbO}_2(s)$  is reduced at the cathode during this same period?
- 20.72 During the discharge of an alkaline battery, 4.50 g of Zn are consumed at the anode of the battery. What mass of  $\text{MnO}_2$  is reduced at the cathode during this discharge?
- 20.73 Heart pacemakers are often powered by lithium-silver chromate "button" batteries. The overall cell reaction is:
- $$2 \text{Li}(s) + \text{Ag}_2\text{CrO}_4(s) \longrightarrow \text{Li}_2\text{CrO}_4(s) + 2 \text{Ag}(s)$$
- (a) Lithium metal is the reactant at one of the electrodes of the battery. Is it the anode or the cathode? (b) Choose the two half-reactions from Appendix E that *most closely approximate* the reactions that occur in the battery. What standard emf would be generated by a voltaic cell based on these half-reactions? (c) The battery generates an emf of +3.5 V. How close is this value to the one calculated in part (b)? (d) Calculate the emf that would be generated at body temperature, 37 °C. How does this compare to the emf you calculated in part (b)?
- 20.74 Mercuric oxide dry-cell batteries are often used where a high energy density is required, such as in watches and cameras. The two half-cell reactions that occur in the battery are
- $$\text{HgO}(s) + \text{H}_2\text{O}(l) + 2 e^- \longrightarrow \text{Hg}(l) + 2 \text{OH}^-(aq)$$
- $$\text{Zn}(s) + 2 \text{OH}^-(aq) \longrightarrow \text{ZnO}(s) + \text{H}_2\text{O}(l) + 2 e^-$$
- (a) Write the overall cell reaction. (b) The value of  $E_{\text{red}}^{\circ}$  for the cathode reaction is +0.098 V. The overall cell potential is +1.35 V. Assuming that both half-cells operate under standard conditions, what is the standard reduction potential for the anode reaction? (c) Why is the potential of the anode reaction different than would be expected if the reaction occurred in an acidic medium?
- 20.75 (a) Suppose that an alkaline battery was manufactured using cadmium metal rather than zinc. What effect would this have on the cell emf? (b) What environmental advantage is provided by the use of nickel-metal-hydride batteries over the nickel-cadmium batteries?
- 20.76 (a) The nonrechargeable lithium batteries used for photography use lithium metal as the anode. What advantages might be realized by using lithium rather than zinc, cadmium, lead, or nickel? (b) The rechargeable lithium-ion battery does not use lithium metal as an electrode material. Nevertheless, it still has a substantial advantage over nickel-based batteries. Suggest an explanation.
- 20.77 The hydrogen-oxygen fuel cell has a standard emf of 1.23 V. What advantages and disadvantages are there to using this device as a source of power, compared to a 1.55-V alkaline battery?
- 20.78 (a) What is the difference between a battery and a fuel cell? (b) Can the "fuel" of a fuel cell be a solid? Explain.

## Corrosion

- 20.79 (a) Write the anode and cathode reactions that cause the corrosion of iron metal to aqueous iron(II). (b) Write the balanced half-reactions involved in the air oxidation of  $\text{Fe}^{2+}(aq)$  to  $\text{Fe}_2\text{O}_3 \cdot 3 \text{H}_2\text{O}$ .
- 20.80 (a) Based on standard reduction potentials, would you expect copper metal to oxidize under standard conditions in the presence of oxygen and hydrogen ions? (b) When the Statue of Liberty was refurbished, Teflon spacers were placed between the iron skeleton and the copper metal on the surface of the statue. What role do these spacers play?
- 20.81 (a) Magnesium metal is used as a sacrificial anode to protect underground pipes from corrosion. Why is the magnesium referred to as a "sacrificial anode"? (b) Looking in Appendix E, suggest what metal the underground pipes could be made from in order for magnesium to be successful as a sacrificial anode.
- 20.82 An iron object is plated with a coating of cobalt to protect against corrosion. Does the cobalt protect iron by cathodic protection? Explain.
- 20.83 A plumber's handbook states that you should not connect a brass pipe directly to a galvanized steel pipe because electrochemical reactions between the two metals will cause corrosion. The handbook recommends you use, instead, an insulating fitting to connect them. Brass is a mixture of copper and zinc. What spontaneous redox reaction(s) might cause the corrosion? Justify your answer with standard emf calculations.
- 20.84 A plumber's handbook states that you should not connect a copper pipe directly to a steel pipe because electrochemical reactions between the two metals will cause corrosion. The handbook recommends you use, instead, an insulating fitting to connect them. What spontaneous redox reaction(s) might cause the corrosion? Justify your answer with standard emf calculations.

## Electrolysis; Electrical Work

- 20.85** (a) What is *electrolysis*? (b) Are electrolysis reactions thermodynamically spontaneous? Explain. (c) What process occurs at the anode in the electrolysis of molten NaCl?
- 20.86** (a) What is an *electrolytic cell*? (b) The negative terminal of a voltage source is connected to an electrode of an electrolytic cell. Is the electrode the anode or the cathode of the cell? Explain. (c) The electrolysis of water is often done with a small amount of sulfuric acid added to the water. What is the role of the sulfuric acid?
- 20.87** (a) A  $\text{Cr}^{3+}(\text{aq})$  solution is electrolyzed, using a current of 7.60 A. What mass of Cr(s) is plated out after 2.00 days? (b) What amperage is required to plate out 0.250 mol Cr from a  $\text{Cr}^{3+}$  solution in a period of 8.00 h?
- 20.88** Metallic magnesium can be made by the electrolysis of molten  $\text{MgCl}_2$ . (a) What mass of Mg is formed by passing a current of 4.55 A through molten  $\text{MgCl}_2$ , for 3.50 days? (b) How many minutes are needed to plate out 10.00 g Mg from molten  $\text{MgCl}_2$ , using 3.50 A of current?

- 20.89** A voltaic cell is based on the reaction

Under standard conditions, what is the maximum electrical work, in joules, that the cell can accomplish if 75.0 g of Sn is consumed?

- 20.90** Consider the voltaic cell illustrated in Figure 20.5, which is based on the cell reaction

Under standard conditions, what is the maximum electrical work, in joules, that the cell can accomplish if 50.0 g of copper is plated out?

- 20.91** (a) Calculate the mass of Li formed by electrolysis of molten LiCl by a current of  $7.5 \times 10^4$  A flowing for a period of 24 h. Assume the electrolytic cell is 85% efficient. (b) What is the energy requirement for this electrolysis per mole of Li formed if the applied emf is +7.5 V?
- 20.92** Elemental calcium is produced by the electrolysis of molten  $\text{CaCl}_2$ . (a) What mass of calcium can be produced by this process if a current of  $7.5 \times 10^3$  A is applied for 48 h? Assume that the electrolytic cell is 68% efficient. (b) What is the total energy requirement for this electrolysis if the applied emf is +5.00 V?

## ADDITIONAL EXERCISES

- 20.93** A *disproportionation* reaction is an oxidation-reduction reaction in which the same substance is oxidized and reduced. Complete and balance the following disproportionation reactions:

- 20.94** This oxidation-reduction reaction in acidic solution is spontaneous:

A solution containing  $\text{KMnO}_4$  and  $\text{H}_2\text{SO}_4$  is poured into one beaker, and a solution of  $\text{FeSO}_4$  is poured into another. A salt bridge is used to join the beakers. A platinum foil is placed in each solution, and a wire that passes through a voltmeter connects the two solutions. (a) Sketch the cell, indicating the anode and the cathode, the direction of electron movement through the external circuit, and the direction of ion migrations through the solutions. (b) Sketch the process that occurs at the atomic level at the surface of the anode. (c) Calculate the emf of the cell under standard conditions. (d) Calculate the emf of the cell at 298 K when the concentrations are the following:  $\text{pH} = 0.0$ ,  $[\text{Fe}^{2+}] = 0.10 \text{ M}$ ,  $[\text{MnO}_4^{-}] = 1.50 \text{ M}$ ,  $[\text{Fe}^{3+}] = 2.5 \times 10^{-4} \text{ M}$ ,  $[\text{Mn}^{2+}] = 0.001 \text{ M}$ .

- 20.95** A common shorthand way to represent a voltaic cell is to list its components as follows:

A double vertical line represents a salt bridge or a porous barrier. A single vertical line represents a change in phase, such as from solid to solution. (a) Write the half-reactions and overall cell reaction represented by  $\text{Fe}|\text{Fe}^{2+}||\text{Ag}^{+}|\text{Ag}$ ; sketch the cell. (b) Write the half-reactions and overall cell reaction represented by  $\text{Zn}|\text{Zn}^{2+}||\text{H}^{+}|\text{H}_2$ ; sketch the cell. (c) Using the notation just described, represent a cell based on the following reaction:

Pt is used as an inert electrode in contact with the  $\text{ClO}_3^{-}$  and  $\text{Cl}^{-}$ . Sketch the cell.

- 20.96** Predict whether the following reactions will be spontaneous in acidic solution under standard conditions: (a) oxidation of Sn to  $\text{Sn}^{2+}$  by  $\text{I}_2$  (to form  $\text{I}^{-}$ ), (b) reduction of  $\text{Ni}^{2+}$  to Ni by  $\text{I}^{-}$  (to form  $\text{I}_2$ ), (c) reduction of  $\text{Ce}^{4+}$  to  $\text{Ce}^{3+}$  by  $\text{H}_2\text{O}_2$ , (d) reduction of  $\text{Cu}^{2+}$  to Cu by  $\text{Sn}^{2+}$  (to form  $\text{Sn}^{4+}$ ).
- [20.97]** Gold exists in two common positive oxidation states, +1 and +3. The standard reduction potentials for these oxidation states are

(a) Can you use these data to explain why gold does not tarnish in the air? (b) Suggest several substances that should be strong enough oxidizing agents to oxidize gold metal. (c) Miners obtain gold by soaking gold-containing ores in an aqueous solution of sodium cyanide. A very soluble complex ion of gold forms in the aqueous solution because of the redox reaction

What is being oxidized, and what is being reduced, in this reaction? (d) Gold miners then react the basic aqueous product solution from part (c) with Zn dust to get gold metal. Write a balanced redox reaction for this process. What is being oxidized, and what is being reduced?

- 20.98** Two important characteristics of voltaic cells are their cell potential and the total charge that they can deliver. Which of these characteristics depends on the amount of reactants in the cell, and which one depends on their concentration?
- 20.99** A voltaic cell is constructed from an  $\text{Ni}^{2+}(\text{aq})\text{-Ni}(\text{s})$  half-cell and an  $\text{Ag}^{+}(\text{aq})\text{-Ag}(\text{s})$  half-cell. The initial concentration of  $\text{Ni}^{2+}(\text{aq})$  in the  $\text{Ni}^{2+}\text{-Ni}$  half-cell is  $[\text{Ni}^{2+}] = 0.0100\text{ M}$ . The initial cell voltage is  $+1.12\text{ V}$ . (a) By using data in Table 20.1, calculate the standard emf of this voltaic cell. (b) Will the concentration of  $\text{Ni}^{2+}(\text{aq})$  increase or decrease as the cell operates? (c) What is the initial concentration of  $\text{Ag}^{+}(\text{aq})$  in the  $\text{Ag}^{+}\text{-Ag}$  half-cell?
- [20.100]** A voltaic cell is constructed that uses the following half-cell reactions:

The cell is operated at  $298\text{ K}$  with  $[\text{Cu}^{+}] = 0.25\text{ M}$  and  $[\text{I}^{-}] = 3.5\text{ M}$ . (a) Determine  $E$  for the cell at these concentrations. (b) Which electrode is the anode of the cell? (c) Is the answer to part (b) the same as it would be if the cell were operated under standard conditions? (d) If  $[\text{Cu}^{+}]$  was equal to  $0.15\text{ M}$ , at what concentration of  $\text{I}^{-}$  would the cell have zero potential?

- 20.101** Derive an equation that directly relates the standard emf of a redox reaction to its equilibrium constant.
- 20.102** Using data from Appendix E, calculate the equilibrium constant for the disproportionation of the copper(I) ion at room temperature:  $2\text{Cu}^{+}(\text{aq}) \longrightarrow \text{Cu}^{2+}(\text{aq}) + \text{Cu}(\text{s})$
- 20.103** (a) Write the reactions for the discharge and charge of a nickel-cadmium rechargeable battery. (b) Given the following reduction potentials, calculate the standard emf of the cell:

(c) A typical nicad voltaic cell generates an emf of  $+1.30\text{ V}$ . Why is there a difference between this value and the one you calculated in part (b)? (d) Calculate the equilibrium constant for the overall nicad reaction based on this typical emf value.

- 20.104** The capacity of batteries such as the typical AA alkaline battery is expressed in units of milliamp-hours (mAh).

An "AA" alkaline battery yields a nominal capacity of  $2850\text{ mAh}$ . (a) What quantity of interest to the consumer is being expressed by the units of mAh? (b) The starting voltage of a fresh alkaline battery is  $1.55\text{ V}$ . The voltage decreases during discharge and is  $0.80\text{ V}$  when the battery has delivered its rated capacity. If we assume that the voltage declines linearly as current is withdrawn, estimate the total maximum electrical work the battery could perform during discharge.

- 20.105** If you were going to apply a small potential to a steel ship resting in the water as a means of inhibiting corrosion, would you apply a negative or a positive charge? Explain.
- 20.106** The following quotation is taken from an article dealing with corrosion of electronic materials: "Sulfur dioxide, its acidic oxidation products, and moisture are well established as the principal causes of outdoor corrosion of many metals." Using Ni as an example, explain why the factors cited affect the rate of corrosion. Write chemical equations to illustrate your points. (Note:  $\text{NiO}(\text{s})$  is soluble in acidic solution.)

- [20.107]** (a) How many coulombs are required to plate a layer of chromium metal  $0.25\text{ mm}$  thick on an auto bumper with a total area of  $0.32\text{ m}^2$  from a solution containing  $\text{CrO}_4^{2-}$ ? The density of chromium metal is  $7.20\text{ g/cm}^3$ . (b) What current flow is required for this electroplating if the bumper is to be plated in  $10.0\text{ s}$ ? (c) If the external source has an emf of  $+6.0\text{ V}$  and the electrolytic cell is  $65\%$  efficient, how much electrical power is expended to electroplate the bumper?

- 20.108** (a) What is the maximum amount of work that a 6-V lead-acid battery of a golf cart can accomplish if it is rated at  $300\text{ A}\cdot\text{h}$ ? (b) List some of the reasons why this amount of work is never realized.

- [20.109]** Some years ago a unique proposal was made to raise the *Titanic*. The plan involved placing pontoons within the ship using a surface-controlled submarine-type vessel. The pontoons would contain cathodes and would be filled with hydrogen gas formed by the electrolysis of water. It has been estimated that it would require about  $7 \times 10^8\text{ mol}$  of  $\text{H}_2$  to provide the buoyancy to lift the ship (*J. Chem. Educ.*, Vol. 50, 1973, 61). (a) How many coulombs of electrical charge would be required? (b) What is the minimum voltage required to generate  $\text{H}_2$  and  $\text{O}_2$  if the pressure on the gases at the depth of the wreckage ( $2\text{ mi}$ ) is  $300\text{ atm}$ ? (c) What is the minimum electrical energy required to raise the *Titanic* by electrolysis? (d) What is the minimum cost of the electrical energy required to generate the necessary  $\text{H}_2$  if the electricity costs 85 cents per kilowatt-hour to generate at the site?

## INTEGRATIVE EXERCISES

- 20.110** Two wires from a battery are tested with a piece of filter paper moistened with NaCl solution containing phenolphthalein, an acid-base indicator that is colorless in acid and pink in base. When the wires touch the paper about an inch apart, the rightmost wire produces a pink coloration on the filter paper and the leftmost produces none. Which wire is connected to the positive terminal of the battery? Explain.

- 20.111** The Haber process is the principal industrial route for converting nitrogen into ammonia:

- (a) What is being oxidized, and what is being reduced? (b) Using the thermodynamic data in Appendix C, calculate the equilibrium constant for the process at room temperature. (c) Calculate the standard emf of the Haber process at room temperature.

[20.112] In a galvanic cell the cathode is an  $\text{Ag}^+$  (1.00 M)/Ag(s) half-cell. The anode is a standard hydrogen electrode immersed in a buffer solution containing 0.10 M benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) and 0.050 M sodium benzoate ( $\text{C}_6\text{H}_5\text{COO}^-\text{Na}^+$ ). The measured cell voltage is 1.030 V. What is the  $\text{pK}_a$  of benzoic acid?

20.113 Consider the general oxidation of a species A in solution:  $\text{A} \longrightarrow \text{A}^+ + \text{e}^-$ . The term "oxidation potential" is sometimes used to describe the ease with which species A is oxidized—the easier a species is to oxidize, the greater its oxidation potential. (a) What is the relationship between the standard oxidation potential of A and the standard reduction potential of  $\text{A}^+$ ? (b) Which of the metals listed in Table 4.5 has the highest standard oxidation potential? Which has the lowest? (c) For a series of substances, the trend in oxidation potential is often related to the trend in the first ionization energy. Explain why this relationship makes sense.

[20.114] Gold metal dissolves in aqua regia, a mixture of concentrated hydrochloric acid and concentrated nitric acid. The standard reduction potentials

are important in gold chemistry. (a) Use half-reactions to write a balanced equation for the reaction of Au and nitric acid to produce  $\text{Au}^{3+}$  and  $\text{NO}(\text{g})$ , and calculate the standard emf of this reaction. Is this reaction spontaneous? (b) Use half-reactions to write a balanced equation for the reaction of Au and hydrochloric acid to produce  $\text{AuCl}_4^-(\text{aq})$  and  $\text{H}_2(\text{g})$ , and calculate the standard emf of this reaction. Is this reaction spontaneous? (c) Use half-reactions to write a balanced equation for the reaction of Au and aqua regia to produce  $\text{AuCl}_4^-(\text{aq})$  and  $\text{NO}(\text{g})$ , and calculate the standard emf of this reaction. Is this reaction spontaneous under standard conditions? (d) Use the Nernst equation to explain why aqua regia made from concentrated hydrochloric and nitric acids is able to dissolve gold.

20.115 A voltaic cell is based on  $\text{Ag}^+(\text{aq})/\text{Ag}(\text{s})$  and  $\text{Fe}^{3+}(\text{aq})/\text{Fe}^{2+}(\text{aq})$  half-cells. (a) What is the standard emf of the cell? (b) Which reaction occurs at the cathode, and which at the anode of the cell? (c) Use  $S^\circ$  values in Appendix C and the relationship between cell potential and free-energy change to predict whether the standard cell potential increases or decreases when the temperature is raised above 25 °C.

20.116 Hydrogen gas has the potential as a clean fuel in reaction with oxygen. The relevant reaction is

Consider two possible ways of utilizing this reaction as an electrical energy source: (i) Hydrogen and oxygen gases are combusted and used to drive a generator, much as coal is currently used in the electric power industry; (ii) hydrogen and oxygen gases are used to generate electricity directly by using fuel cells that operate at 85 °C.

(a) Use data in Appendix C to calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  for the above reaction. We will assume that these values do not change appreciably with temperature. (b) Based on the values from part (a), what trend would you expect for the magnitude of  $\Delta G$  for the above reaction as the temperature increases? (c) What is the significance of the change in the magnitude of  $\Delta G$  with temperature with respect to the utility of hydrogen as a fuel (recall Equation 19.15)? (d) Based on the analysis here, would it be more efficient to use the combustion method or the fuel-cell method to generate electrical energy from hydrogen?

20.117 Cytochrome c, a complicated molecule that we will represent as  $\text{CyFe}^{2+}$ , reacts with the air we breathe to supply energy required to synthesize adenosine triphosphate (ATP). The body uses ATP as an energy source to drive other reactions. (Section 19.7) At pH 7.0 the following reduction potentials pertain to this oxidation of  $\text{CyFe}^{2+}$ :

(a) What is  $\Delta G$  for the oxidation of  $\text{CyFe}^{2+}$  by air? (b) If the synthesis of 1.00 mol of ATP from adenosine diphosphate (ADP) requires a  $\Delta G$  of 37.7 kJ, how many moles of ATP are synthesized per mole of  $\text{O}_2$ ?

[20.118] The standard potential for the reduction of  $\text{AgSCN}(\text{s})$  is +0.0895 V.

Using this value and the electrode potential for  $\text{Ag}^+(\text{aq})$ , calculate the  $K_{\text{sp}}$  for  $\text{AgSCN}$ .

[20.119] The  $K_{\text{sp}}$  value for  $\text{PbS}(\text{s})$  is  $8.0 \times 10^{-28}$ . By using this value together with an electrode potential from Appendix E, determine the value of the standard reduction potential for the reaction

[20.120] A pH meter (Figure 16.6) employs a voltaic cell for which the cell potential is very sensitive to pH. A simple (but impractical) pH meter can be constructed by using two hydrogen electrodes: one standard hydrogen electrode (Figure 20.10) and a hydrogen electrode (with 1 atm pressure of  $\text{H}_2$  gas) dipped into the solution of unknown pH. The two half-cells are connected by a salt bridge or porous glass disk. (a) Sketch the cell described above. (b) Write the half-cell reactions for the cell, and calculate the standard emf. (c) What is the pH of the solution in the half-cell that has the standard hydrogen electrode? (d) What is the cell emf when the pH of the unknown solution is 5.0? (e) How precise would a voltmeter have to be in order to detect a change in the pH of 0.01 pH units?

[20.121] A student designs an ammeter (a device that measures electrical current) that is based on the electrolysis of water into hydrogen and oxygen gases. When electrical current of unknown magnitude is run through the device for 2.00 min, 12.3 mL of water-saturated  $\text{H}_2(\text{g})$  is collected. The temperature of the system is 25.5 °C, and the atmospheric pressure is 768 torr. What is the magnitude of the current in amperes?

CHAPTER  
**21**

# NUCLEAR CHEMISTRY

THE SUN'S ENERGY COMES FROM NUCLEAR reactions of hydrogen atoms in its core.

## WHAT'S AHEAD

---

### 21.1 Radioactivity

In this chapter we will learn how to describe nuclear reactions by equations analogous to chemical equations, in which the nuclear charges and masses of reactants and products are in balance. Radioactive nuclei most commonly decay by emission of *alpha*, *beta*, or *gamma* radiations.

### 21.2 Patterns of Nuclear Stability

We recognize that nuclear stability is determined largely by the *neutron-to-proton ratio*. For stable nuclei, this ratio increases with increasing atomic number. All nuclei with 84 or more protons are radioactive. Heavy nuclei gain stability by a series of nuclear disintegrations leading to stable nuclei.

### 21.3 Nuclear Transmutations

We study *nuclear transmutations*, which are nuclear reactions induced by bombardment of a nucleus by a neutron or an accelerated charged particle, such as an alpha particle.

### 21.4 Rates of Radioactive Decay

We also learn that radioisotope decays are first-order kinetic processes that exhibit characteristic half-lives. The decays of radioisotopes can be used to determine the ages of ancient artifacts and geological formations.

### 21.5 Detection of Radioactivity

We see that the radiation emitted by a radioactive substance is detected with Geiger counters and scintillation counters.

### 21.6 Energy Changes in Nuclear Reactions

We recognize that energy changes in nuclear reactions are related to mass changes via Einstein's famous equation,  $E = mc^2$ . The *binding energies of nuclei* are reflected in the difference between the masses of nuclei and the sum of the masses of the nucleons of which they are composed.

### 21.7 Nuclear Power: Fission

We learn that in a *nuclear fission* reaction a heavy nucleus splits under nuclear bombardment to form two or more product nuclei, with release of energy. This type of nuclear reaction is the energy source for nuclear power plants.

### 21.8 Nuclear Power: Fusion

We observe that *nuclear fusion* results from the fusion of two light nuclei to form a more stable, heavier one.

### 21.9 Radiation in the Environment and Living Systems

We discover that naturally occurring radioisotopes bathe our planet, and us, with low levels of radiation. The radiation emitted in nuclear reactions has the potential to cause cell damage in animals that can, in turn, lead to cancer and other illnesses. Appropriate use of radiation, on the other hand, can be used medically to diagnose and treat cancer.

**THE SUN IS THE MAJOR ENERGY SOURCE FOR OUR PLANET AND IS ESSENTIAL TO LIFE ON EARTH.** Sunlight provides approximately 1000 watts (1 watt = 1 J/s) of power per square meter at Earth's surface. Sunlight is used by plants for photosynthesis, the process that produces food for plants and oxygen that

most life on Earth needs to survive. What makes the Sun shine? Hydrogen fuses in the Sun's core to make helium, releasing tremendous amounts of energy in the process. This hydrogen fusion reaction is an example of a *nuclear reaction*.

A nuclear reaction involves changes in the nucleus of an atom. *Nuclear chemistry* is the study of nuclear reactions, with an emphasis on their uses in chemistry and their effects on biological systems. Nuclear chemistry affects our lives in many ways, particularly in energy and medical applications. For example, radioactive elements can be used as therapeutic and diagnostic tools.

▲ **Figure 21.1 Radioisotope scanning.** A gamma ray detector scan of a normal human heart, obtained following intravenous injection of the radioisotope thallium-201, a gamma emitter. The donut-shaped pink and red area represents uptake of the radioisotope by healthy heart muscles.

Radiation therapy is a common form of cancer therapy in which gamma rays, emitted from a radioactive substance such as cobalt-60, are directed to cancerous tumors to destroy them. In the widely used thallium “stress test,” a compound containing thallium-201 (another radioactive substance that emits gamma rays) is injected intravenously into the patient. A scanner detects the gamma emissions from the thallium that has concentrated in the heart muscle and reveals the condition of the heart and surrounding arteries (Figure 21.1 ◀). Radioactivity is also used to help determine the mechanisms of chemical reactions, to trace the movement of atoms in biological systems and the environment, and to date important historical artifacts.

Nuclear reactions are also used to generate electricity. Roughly 10% of the total electricity generated in the world comes from nuclear power plants. The percentage of electricity generated from nuclear power varies widely among countries: 80% in France, 50% in Sweden, 20% in the United States, less than 5% each in India and China, and essentially zero in Italy (Figure 21.2 ▼). The use of nuclear energy for power generation and the disposal of nuclear wastes from power plants are controversial social and political issues. It is imperative, therefore, that as a citizen with a stake in these matters, you have some understanding of nuclear reactions and the uses of radioactive substances.

## 21.1 RADIOACTIVITY

To understand nuclear reactions, we must review and develop some ideas introduced in Section 2.3. First, recall that two types of subatomic particle reside in the nucleus: the *proton* and the *neutron*. We will refer to these particles as **nucleons**.

► **Figure 21.2 Nuclear energy usage for electricity, 2004.** This bar graph shows, for selected countries, the percentage of electricity supplied by nuclear power.

Recall also that all atoms of a given element have the same number of protons; this number is the element's *atomic number*. The atoms of a given element can have different numbers of neutrons, however, so they can have different *mass numbers*; the mass number is the total number of nucleons in the nucleus. Atoms with the same atomic number but different mass numbers are known as *isotopes*.

The different isotopes of an element are distinguished by their mass numbers. For example, the three naturally occurring isotopes of uranium are uranium-234, uranium-235, and uranium-238, where the numerical suffixes represent the mass numbers. These isotopes are also labeled, using chemical symbols, as  ${}^{234}_{92}\text{U}$ ,  ${}^{235}_{92}\text{U}$ , and  ${}^{238}_{92}\text{U}$ . The superscript is the mass number; the subscript is the atomic number.

Different isotopes have different natural abundances. For example, 99.3% of naturally occurring uranium is uranium-238, 0.7% is uranium-235, and only a trace is uranium-234. Different nuclei also have different stabilities. Indeed, the nuclear properties of an atom depend on the number of protons and neutrons in its nucleus. A *nuclide* is a nucleus with a specified number of protons and neutrons. Nuclei that are radioactive are called **radionuclides**, and atoms containing these nuclei are called **radioisotopes**.

## Nuclear Equations

Most nuclei found in nature are stable and remain intact indefinitely. Radionuclides, however, are unstable and spontaneously emit particles and electromagnetic radiation. Emission of radiation is one of the ways in which an unstable nucleus is transformed into a more stable one with less energy. The emitted radiation is the carrier of the excess energy. Uranium-238, for example, is radioactive, undergoing a nuclear reaction in which helium-4 nuclei are spontaneously emitted. The helium-4 particles are known as **alpha ( $\alpha$ ) particles**, and a stream of these particles is called *alpha radiation*. When a uranium-238 nucleus loses an alpha particle, the remaining fragment has an atomic number of 90 and a mass number of 234. If you look at the periodic table, you will find that the element with atomic number 90 is Th, thorium. Therefore, the products of uranium-238 decomposition are an alpha particle and a thorium-234 nucleus. We represent this reaction by the following *nuclear equation*:

When a nucleus spontaneously decomposes in this way, it is said to have decayed, or to have undergone *radioactive decay*. Because an alpha particle is involved in this reaction, scientists also describe the process as alpha decay.

### GIVE IT SOME THOUGHT

What change in the mass number of a nucleus occurs when the nucleus emits an alpha particle?

In Equation 21.1 the sum of the mass numbers is the same on both sides of the equation ( $238 = 234 + 4$ ). Likewise, the sum of the atomic numbers on both sides of the equation is equal ( $92 = 90 + 2$ ). Mass numbers and atomic numbers must be balanced in all nuclear equations.

The radioactive properties of the nucleus are independent of the chemical state of the atom. In writing nuclear equations, therefore, we are not concerned with the chemical form (element or compound) of the atom in which the nucleus resides.

**SAMPLE EXERCISE 21.1** | Predicting the Product of a Nuclear Reaction

What product is formed when radium-226 undergoes alpha decay?

**SOLUTION**

**Analyze:** We are asked to determine the nucleus that results when radium-226 loses an alpha particle.

**Plan:** We can best do this by writing a balanced nuclear reaction for the process.

**Solve:** The periodic table shows that radium has an atomic number of 88. The complete chemical symbol for radium-226 is therefore  ${}^{226}_{88}\text{Ra}$ . An alpha particle is a helium-4 nucleus, and so its symbol is  ${}^4_2\text{He}$  (sometimes written as  ${}^4_2\alpha$ ). The alpha particle is a product of the nuclear reaction, and so the equation is of the form

where  $A$  is the mass number of the product nucleus and  $Z$  is its atomic number. Mass numbers and atomic numbers must balance, so

$$226 = A + 4$$

and

$$88 = Z + 2$$

Hence,

$$A = 222 \quad \text{and} \quad Z = 86$$

Again, from the periodic table, the element with  $Z = 86$  is radon (Rn). The product, therefore, is  ${}^{222}_{86}\text{Rn}$ , and the nuclear equation is

**PRACTICE EXERCISE**

Which element undergoes alpha decay to form lead-208?

*Answer:*  ${}^{212}_{84}\text{Po}$

## Types of Radioactive Decay

The three most common kinds of radioactive decay are alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ) radiation. [Section 2.2](#) Table 21.1  $\blacktriangledown$  summarizes some of the important properties of these kinds of radiation. As we have just discussed, alpha radiation consists of a stream of helium-4 nuclei known as alpha particles, which we denote as  ${}^4_2\text{He}$  or  ${}^4_2\alpha$ .

Beta radiation consists of streams of **beta ( $\beta$ ) particles**, which are high-speed electrons emitted by an unstable nucleus. Beta particles are represented in nuclear equations by the symbol  ${}^0_{-1}\text{e}$  or sometimes  ${}^0_{-1}\beta$ . The superscript zero indicates that the mass of the electron is exceedingly small compared to the mass of a nucleon. The subscript  $-1$  represents the negative charge of the particle, which is opposite that of the proton. Iodine-131 is an isotope that undergoes decay by beta emission:

**TABLE 21.1** ■ Properties of Alpha, Beta, and Gamma Radiation

Property	Type of Radiation		
	$\alpha$	$\beta$	$\gamma$
Charge	2+	1-	0
Mass	$6.64 \times 10^{-24}$ g	$9.11 \times 10^{-28}$ g	0
Relative penetrating power	1	100	10,000
Nature of radiation	${}^4_2\text{He}$ nuclei	Electrons	High-energy photons

You can see from Equation 21.2 that beta decay causes the atomic number to increase from 53 to 54. Therefore, beta emission is equivalent to the conversion of a neutron ( ${}^1_0\text{n}$ ) to a proton ( ${}^1_1\text{p}$  or  ${}^1_1\text{H}$ ), thereby increasing the atomic number by 1:

Just because an electron is ejected from the nucleus, however, we should not think that the nucleus is composed of these particles, any more than we consider a match to be composed of sparks simply because it gives them off when struck. The electron comes into being only when the nucleus undergoes a nuclear reaction.

**Gamma radiation** (or gamma rays) consists of high-energy photons (that is, electromagnetic radiation of very short wavelength). It changes neither the atomic number nor the mass number of a nucleus and is represented as  ${}^0_0\gamma$ , or merely  $\gamma$ . Gamma radiation usually accompanies other radioactive emission because it represents the energy lost when the remaining nucleons reorganize into more stable arrangements. Generally, the gamma rays are not shown when writing nuclear equations.

Two other types of radioactive decay are positron emission and electron capture. A **positron** is a particle that has the same mass as an electron, but an opposite charge.\* The positron is represented as  ${}^0_1\text{e}$ . The isotope carbon-11 decays by positron emission:

Positron emission causes the atomic number to decrease from 6 to 5. The emission of a positron has the effect of converting a proton to a neutron, thereby decreasing the atomic number of the nucleus by 1:

**Electron capture** is the capture by the nucleus of an electron from the electron cloud surrounding the nucleus. Rubidium-81 undergoes decay in this fashion, as shown in Equation 21.6:

Because the electron is consumed rather than formed in the process, it is shown on the reactant side of the equation. Electron capture, like positron emission, has the effect of converting a proton to a neutron:

Table 21.2 summarizes the symbols used to represent the various elementary particles commonly encountered in nuclear reactions.

**TABLE 21.2** Common Particles in Radioactive Decay and Nuclear Transformations

Particle	Symbol
Neutron	${}^1_0\text{n}$
Proton	${}^1_1\text{H}$ or ${}^1_1\text{p}$
Electron	${}^0_{-1}\text{e}$
Alpha particle	${}^4_2\text{He}$ or ${}^4_2\alpha$
Beta particle	${}^0_{-1}\text{e}$ or ${}^0_{-1}\beta$
Positron	${}^0_1\text{e}$

### GIVE IT SOME THOUGHT

Which of the particles listed in Table 21.2 result in no change in nuclear charge when emitted in nuclear decay?

### SAMPLE EXERCISE 21.2 | Writing Nuclear Equations

Write nuclear equations for the following processes: (a) mercury-201 undergoes electron capture; (b) thorium-231 decays to form protactinium-231.

#### SOLUTION

**Analyze:** We must write balanced nuclear equations in which the masses and charges of reactants and products are equal.

**Plan:** We can begin by writing the complete chemical symbols for the nuclei and decay particles that are given in the problem.

\*The positron has a very short life because it is annihilated when it collides with an electron, producing gamma rays:  ${}^0_1\text{e} + {}^0_{-1}\text{e} \longrightarrow 2{}^0_0\gamma$ .

**Solve:**

(a) The information given in the question can be summarized as

The mass numbers must have the same sum on both sides of the equation:

$$201 + 0 = A$$

Thus, the product nucleus must have a mass number of 201. Similarly, balancing the atomic numbers gives

$$80 - 1 = Z$$

Thus, the atomic number of the product nucleus must be 79, which identifies it as gold (Au):

(b) In this case we must determine what type of particle is emitted in the course of the radioactive decay:

From  $231 = 231 + A$  and  $90 = 91 + Z$ , we deduce  $A = 0$  and  $Z = -1$ . According to Table 21.2, the particle with these characteristics is the beta particle (electron). We therefore write

**PRACTICE EXERCISE**

Write a balanced nuclear equation for the reaction in which oxygen-15 undergoes positron emission.

**Answer:**  ${}_{8}^{15}\text{O} \longrightarrow {}_{7}^{15}\text{N} + {}_0^{+1}\text{e}$

## 21.2 PATTERNS OF NUCLEAR STABILITY

The stability of a particular nucleus depends on a variety of factors. No single rule allows us to predict whether a particular nucleus is radioactive and how it might decay. However, several empirical observations will help you predict the stability of a nucleus.

### Neutron-to-Proton Ratio

Because like charges repel each other, it may seem surprising that a large number of protons can reside within the small volume of the nucleus. At close distances, however, a strong force of attraction, called the *nuclear force*, exists between nucleons. Neutrons are intimately involved in this attractive force. All nuclei other than  ${}^1_1\text{H}$  contain neutrons. As the number of protons in the nucleus increases, there is an ever-greater need for neutrons to counteract the effect of proton-proton repulsions. Stable nuclei with low atomic numbers (up to about 20) have approximately equal numbers of neutrons and protons. For nuclei with higher atomic numbers, the number of neutrons exceeds the number of protons. Indeed, the number of neutrons necessary to create a stable nucleus increases more rapidly than the number of protons, as shown in Figure 21.3. Thus, the neutron-to-proton ratios of stable nuclei increase with increasing atomic number.

The colored band in Figure 21.3 is the area within which all stable nuclei are found. This area is known as the *belt of stability*. The belt of stability ends at element 83 (bismuth). All nuclei with 84 or more protons (atomic number  $\geq 84$ ) are radioactive. For example, all isotopes of uranium, atomic number 92, are radioactive.

### GIVE IT SOME THOUGHT

Using Figure 21.3, estimate the optimal number of neutrons for a nucleus containing 70 protons.

▲ **Figure 21.3 The belt of stability.** The number of neutrons is graphed versus the number of protons for stable nuclei. As the atomic number increases, the neutron-to-proton ratio of the stable nuclei increases. The stable nuclei are located in the shaded area of the graph known as the belt of stability. The majority of radioactive nuclei occur outside this belt.

The type of radioactive decay that a particular radionuclide undergoes depends largely on how its neutron-to-proton ratio compares to those of nearby nuclei within the belt of stability. We can envision three general situations:

1. **Nuclei above the belt of stability (high neutron-to-proton ratios).** These neutron-rich nuclei can lower their ratio and move toward the belt of stability by emitting a beta particle. Beta emission decreases the number of neutrons and increases the number of protons in a nucleus, as shown in Equation 21.3.
2. **Nuclei below the belt of stability (low neutron-to-proton ratios).** These proton-rich nuclei can increase their ratio by either positron emission or electron capture. Both kinds of decay increase the number of neutrons and decrease the number of protons, as shown in Equations 21.5 and 21.7. Positron emission is more common than electron capture among the lighter nuclei. However, electron capture becomes increasingly common as nuclear charge increases.
3. **Nuclei with atomic numbers  $\geq 84$ .** These heavy nuclei, which lie beyond the upper right edge of the band of stability, tend to undergo alpha emission. Emission of an alpha particle decreases both the number of neutrons and the number of protons by 2, moving the nucleus diagonally toward the belt of stability.

These three situations are summarized in Figure 21.4 ►.

▲ **Figure 21.4 Proton and neutron changes in nuclear processes.**

The graph shows the results of alpha emission ( $\frac{4}{2}\text{He}$ ), beta emission ( ${}_{-1}^0\text{e}$ ), positron emission ( ${}_{+1}^0\text{e}$ ), and electron capture on the number of protons and neutrons in a nucleus. Moving from left to right or from bottom to top, each square represents an additional proton or neutron, respectively. Moving in the reverse direction indicates the loss of a proton or neutron.

## Further Observations

Two further observations can help you predict nuclear stability:

- Nuclei with 2, 8, 20, 28, 50, or 82 protons or 2, 8, 20, 28, 50, 82, or 126 neutrons are generally more stable than nuclei that do not contain these numbers of nucleons. These numbers of protons and neutrons are called **magic numbers**.
- Nuclei with even numbers of both protons and neutrons are generally more stable than those with odd numbers of nucleons, as shown in Table 21.3 ▶.

These observations can be understood in terms of the *shell model of the nucleus*, in which nucleons are described as residing in shells analogous to the shell structure for electrons in atoms. Just as certain numbers of electrons (2, 8, 18, 36, 54, and 86) correspond to stable closed-shell electron configurations, so also the magic numbers of nucleons represent closed shells in nuclei. As an example of the stability of nuclei with magic numbers of nucleons, note that the radioactive series depicted in Figure 21.5 ends with formation of the stable  $^{206}_{82}\text{Pb}$  nucleus, which has a magic number of protons (82).

Evidence also suggests that pairs of protons and pairs of neutrons have a special stability, analogous to the pairs of electrons in molecules. Thus, stable nuclei with an even number of protons and an even number of neutrons are far more numerous than those with odd numbers (Table 21.3).

**TABLE 21.3** ■ The Number of Stable Isotopes with Even and Odd Numbers of Protons and Neutrons

Number of Stable Isotopes	Protons	Neutrons
157	Even	Even
53	Even	Odd
50	Odd	Even
5	Odd	Odd

### ■ SAMPLE EXERCISE 21.4 | Predicting Nuclear Stability

Predict which of these nuclei are especially stable:  $^4_2\text{He}$ ,  $^{40}_{20}\text{Ca}$ ,  $^{98}_{43}\text{Tc}$ ?

#### SOLUTION

**Analyze:** We are asked to identify especially stable nuclei, given their mass numbers and atomic numbers.

**Plan:** We look to see whether the numbers of protons and neutrons correspond to magic numbers.

**Solve:** The  $^4_2\text{He}$  nucleus (the alpha particle) has a magic number of both protons (2) and neutrons (2) and is very stable. The  $^{40}_{20}\text{Ca}$  nucleus also has a magic number of both protons (20) and neutrons (20) and is especially stable.

The  $^{98}_{43}\text{Tc}$  nucleus does not have a magic number of either protons or neutrons. In fact, it has an odd number of both protons (43) and neutrons (55). There are very few stable nuclei with odd numbers of both protons and neutrons. Indeed, technetium-98 is radioactive.

#### ■ PRACTICE EXERCISE

Which of the following nuclei would you expect to exhibit a special stability:  $^{118}_{50}\text{Sn}$ ,  $^{210}_{85}\text{At}$ ,  $^{208}_{82}\text{Pb}$ ?

**Answer:**  $^{118}_{50}\text{Sn}$ ,  $^{208}_{82}\text{Pb}$

## 21.3 NUCLEAR TRANSMUTATIONS

Thus far we have examined nuclear reactions in which a nucleus spontaneously decays. A nucleus can also change identity if it is struck by a neutron or by another nucleus. Nuclear reactions that are induced in this way are known as **nuclear transmutations**.

In 1919, Ernest Rutherford performed the first conversion of one nucleus into another. He succeeded in converting nitrogen-14 into oxygen-17, plus a proton, using the high-velocity alpha particles emitted by radium. The reaction is

This reaction demonstrated that striking nuclei with particles such as alpha particles could induce nuclear reactions. Such reactions made it possible to synthesize hundreds of radioisotopes in the laboratory.

Nuclear transmutations are sometimes represented by listing, in order, the target nucleus, the bombarding particle, the ejected particle, and the product nucleus. Written in this fashion, Equation 21.8 is  $^{14}\text{N}(\alpha, \text{p})^{13}\text{O}$ . The alpha particle, proton, and neutron are abbreviated as  $\alpha$ ,  $\text{p}$ , and  $\text{n}$ , respectively.

▲ **Figure 21.6** Schematic drawing of a cyclotron. Charged particles are accelerated around the ring by applying alternating voltage to the dees.

### ■ SAMPLE EXERCISE 21.5 | Writing a Balanced Nuclear Equation

Write the balanced nuclear equation for the process summarized as  $^{27}_{13}\text{Al}(\text{n}, \alpha)^{24}_{11}\text{Na}$ .

#### SOLUTION

**Analyze:** We must go from the condensed descriptive form of the nuclear reaction to the balanced nuclear equation.

**Plan:** We arrive at the full nuclear equation by writing  $\text{n}$  and  $\alpha$ , each with its associated subscripts and superscripts.

**Solve:** The  $\text{n}$  is the abbreviation for a neutron ( $^1_0\text{n}$ ), and  $\alpha$  represents an alpha particle ( $^4_2\text{He}$ ). The neutron is the bombarding particle, and the alpha particle is a product. Therefore, the nuclear equation is

#### ■ PRACTICE EXERCISE

Using a shorthand notation, write the nuclear reaction

*Answer:*  $^{16}_8\text{O}(\text{p}, \alpha)^{13}_7\text{N}$

▲ **Figure 21.7** CERN (Conseil Européen pour la Recherche Nucléaire), Geneva, Switzerland. Particles are accelerated to very high energies by circulating them through magnets in the ring, which has a circumference of 27 km.

## Accelerating Charged Particles

Charged particles, such as alpha particles, must be moving very fast to overcome the electrostatic repulsion between them and the target nucleus. The higher the nuclear charge on either the projectile or the target, the faster the projectile must be moving to bring about a nuclear reaction. Many methods have been devised to accelerate charged particles, using strong magnetic and electrostatic fields. These **particle accelerators**, popularly called “atom smashers,” bear such names as *cyclotron* and *synchrotron*. The cyclotron is illustrated in Figure 21.6. The hollow D-shaped electrodes are called “dees.” The projectile particles are introduced into a vacuum chamber within the cyclotron. The particles are then accelerated by making the dees alternately positively and negatively charged. Magnets placed above and below the dees keep the particles moving in a spiral path until they are finally

deflected out of the cyclotron and emerge to strike a target substance. Particle accelerators are used to synthesize heavy elements, to investigate the fundamental structure of matter, and ultimately answer questions about the beginning of the universe. Figure 21.7 shows an aerial view of CERN (Conseil Européen pour la Recherche Nucléaire), the European Organization for Nuclear Research, near Geneva, Switzerland.

## Using Neutrons

Most synthetic isotopes used in medicine and scientific research are made using neutrons as projectiles. Because neutrons are neutral, they are not repelled by the nucleus. Consequently, they do not need to be accelerated, as do charged particles, to cause nuclear reactions. The necessary neutrons are produced by the reactions that occur in nuclear reactors. For example, cobalt-60, which is used in radiation therapy for cancer, is produced by neutron capture. Iron-58 is placed in a nuclear reactor, where neutrons bombard it. The following sequence of reactions takes place:

### GIVE IT SOME THOUGHT

Can neutrons be accelerated in a particle accelerator, using electrostatic or magnetic fields? Why or why not?

## Transuranium Elements

Artificial transmutations have been used to produce the elements with atomic number above 92. These elements are known as the **transuranium elements** because they occur immediately following uranium in the periodic table. Elements 93 (neptunium, Np) and 94 (plutonium, Pu) were discovered in 1940. They were produced by bombarding uranium-238 with neutrons:

Elements with still larger atomic numbers are normally formed in small quantities in particle accelerators. Curium-242, for example, is formed when a plutonium-239 target is struck with accelerated alpha particles:

In 1994 a team of European scientists synthesized element 111 by bombarding a bismuth target for several days with a beam of nickel atoms:

Amazingly, their discovery was based on the detection of only three atoms of the new element. The nuclei were very short lived, and they undergo alpha decay within milliseconds of their synthesis. In 2004 scientists reported the synthesis of elements 113 and 115. As of this writing, these results have yet to be confirmed, although the results look promising. Evidence for element 118 was reported in 2006. Names and symbols have not yet been chosen for these new elements.

## 21.4 RATES OF RADIOACTIVE DECAY

Some radioisotopes, such as uranium-238, are found in nature, although they are not stable. Other radioisotopes do not exist in nature, even though they can be synthesized in nuclear reactions. To understand this distinction, we must realize that different nuclei undergo radioactive decay at different rates. Many radioisotopes decay essentially completely in a matter of seconds or less, so we do not find them in nature. Uranium-238, on the other hand, decays very slowly. Therefore, despite its instability, we can still observe what remains from its formation in the early history of the universe.

TABLE 21.4 ■ The Half-lives and Type of Decay for Several Radioisotopes

	Isotope	Half-life (yr)	Type of Decay
Natural radioisotopes	$^{238}_{92}\text{U}$	$4.5 \times 10^9$	Alpha
	$^{235}_{92}\text{U}$	$7.0 \times 10^8$	Alpha
	$^{232}_{90}\text{Th}$	$1.4 \times 10^{10}$	Alpha
	$^{40}_{19}\text{K}$	$1.3 \times 10^9$	Beta
	$^{14}_6\text{C}$	5715	Beta
Synthetic radioisotopes	$^{239}_{94}\text{Pu}$	24,000	Alpha
	$^{137}_{55}\text{Cs}$	30	Beta
	$^{90}_{38}\text{Sr}$	28.8	Beta
	$^{131}_{53}\text{I}$	0.022	Beta

▲ Figure 21.8 Decay of a 10.0-g sample of  $^{90}_{38}\text{Sr}$  ( $t_{1/2} = 28.8$  yr).

Radioactive decay is a first-order kinetic process. Recall that a first-order process has a characteristic **half-life**, which is the time required for half of any given quantity of a substance to react. (Section 14.4) The rates of decay of nuclei are commonly expressed in terms of their half-lives. Each isotope has its own characteristic half-life. For example, the half-life of strontium-90 is 28.8 yr. If we started with 10.0 g of strontium-90, only 5.0 g of that isotope would remain after 28.8 yr, 2.5 g would remain after another 28.8 yr, and so on. Strontium-90 decays to yttrium-90:

The loss of strontium-90 as a function of time is shown in Figure 21.8 ◀.

Half-lives as short as millionths of a second and as long as billions of years are known. The half-lives of some radioisotopes are listed in Table 21.4 ▲. One important feature of half-lives for nuclear decay is that they are unaffected by external conditions such as temperature, pressure, or state of chemical combination. Unlike toxic chemicals, therefore, radioactive atoms cannot be rendered harmless by chemical reaction or by any other practical treatment. At this point we can do nothing but allow these nuclei to lose radioactivity at their characteristic rates. In the meantime, we must take precautions to prevent radioisotopes, such as those produced in nuclear power plants (Section 21.7), from entering the environment because of the damage radiation can cause.

### ■ SAMPLE EXERCISE 21.6 | Calculation Involving Half-Lives

The half-life of cobalt-60 is 5.3 yr. How much of a 1.000-mg sample of cobalt-60 is left after a 15.9-yr period?

#### SOLUTION

**Analyze:** We are given the half-life for cobalt-60 and asked to calculate the amount of cobalt-60 remaining from an initial 1.000-mg sample after a 15.9-yr period.

**Plan:** We will use the fact that the half-life of a first-order decay process is a constant.

**Solve:** We notice that  $5.3 \times 3 = 15.9$ . Therefore, a period of 15.9 yr is three half-lives for cobalt-60. At the end of one half-life, 0.500 mg of cobalt-60 remains, 0.250 mg at the end of two half-lives, and 0.125 mg at the end of three half-lives.

#### ■ PRACTICE EXERCISE

Carbon-11, used in medical imaging, has a half-life of 20.4 min. The carbon-11 nuclides are formed, and the carbon atoms are then incorporated into an appropriate compound. The resulting sample is injected into a patient, and the medical image is obtained. If the entire process takes five half-lives, what percentage of the original carbon-11 remains at this time?

**Answer:** 3.12%

## Radiometric Dating

Because the half-life of any particular nuclide is constant, the half-life can serve as a nuclear clock to determine the ages of different objects. The method of dating objects based on their isotopes and isotope abundances is called radiometric dating.

Carbon-14, for example, has been used to determine the age of organic materials (Figure 21.9 ►). This technique is known as radiocarbon dating. The procedure is based on the formation of carbon-14 by capture of solar neutrons in the upper atmosphere:

This reaction provides a small but reasonably constant source of carbon-14. The carbon-14 is radioactive, undergoing beta decay with a half-life of 5715 yr:

The carbon-14 is incorporated into carbon dioxide, which is in turn incorporated, through photosynthesis, into more complex carbon-containing molecules within plants. When animals eat the plants, the carbon-14 becomes incorporated within them. Because a living plant or animal has a constant intake of carbon compounds, it is able to maintain a ratio of carbon-14 to carbon-12 that is nearly identical with that of the atmosphere. Once the organism dies, however, it no longer ingests carbon compounds to replenish the carbon-14 that is lost through radioactive decay. The ratio of carbon-14 to carbon-12 therefore decreases. By measuring this ratio and comparing it to that of the atmosphere, we can estimate the age of an object. For example, if the ratio diminishes to half that of the atmosphere, we can conclude that the object is one half-life, or 5715 yr, old. This method cannot be used to date objects older than about 50,000 yr. After this length of time the radioactivity is too low to be measured accurately.

In radiocarbon dating, a reasonable assumption is that the ratio of carbon-14 to carbon-12 in the atmosphere has been relatively constant for the past 50,000 yr. However, because variations in solar activity control the amount of carbon-14 produced in the atmosphere, the carbon-14/carbon-12 ratio can fluctuate. We can correct for this effect by using other kinds of data. Recently scientists have compared carbon-14 data with data from tree rings, corals, lake sediments, ice cores, and other natural sources to correct variations in the carbon-14 “clock” back to 26,000 yr.

Other isotopes can be similarly used to date other types of objects. For example, it takes  $4.5 \times 10^9$  yr for half of a sample of uranium-238 to decay to lead-206. The age of rocks containing uranium can therefore be determined by measuring the ratio of lead-206 to uranium-238. If the lead-206 had somehow become incorporated into the rock by normal chemical processes instead of by radioactive decay, the rock would also contain large amounts of the more abundant isotope lead-208. In the absence of large amounts of this “geonormal” isotope of lead, it is assumed that all of the lead-206 was at one time uranium-238.

The oldest rocks found on Earth are approximately  $3 \times 10^9$  yr old. This age indicates that Earth’s crust has been solid for at least this length of time. Scientists estimate that it required  $1 \times 10^9$  to  $1.5 \times 10^9$  yr for Earth to cool and its surface to become solid, making the age of Earth  $4.0$  to  $4.5 \times 10^9$  (between four to four-and-a-half billion) yr.

## Calculations Based on Half-life

So far, our discussion has been mainly qualitative. We now consider the topic of half-lives from a more quantitative point of view. This approach enables us to answer questions of the following types: How do we determine the half-life of uranium-238? Similarly, how do we quantitatively determine the age of an object?

▲ **Figure 21.9 Radiocarbon dating.** This machine, a linear accelerator, analyzes the amount of carbon-14 in carbon dioxide, produced by combustion of a sample in oxygen. The ratio of carbon-14 to carbon-12 is related to the time since the death of the animal or plant being investigated.

Radioactive decay is a first-order kinetic process. Its rate, therefore, is proportional to the number of radioactive nuclei  $N$  in the sample:

$$\text{Rate} = kN \quad [21.18]$$

The first-order rate constant,  $k$ , is called the *decay constant*. The rate at which a sample decays is called its **activity**, and it is often expressed as the number of disintegrations observed per unit time. The **becquerel** (Bq) is the SI unit for expressing the activity of a particular radiation source (that is, the rate at which nuclear disintegrations are occurring). A becquerel is defined as one nuclear disintegration per second. An older, but still widely used, unit of activity is the **curie** (Ci), defined as  $3.7 \times 10^{10}$  disintegrations per second, which is the rate of decay of 1 g of radium. Thus, a 4.0-mCi sample of cobalt-60 undergoes  $(4.0 \times 10^{-3}) \times (3.7 \times 10^{10})$  disintegrations per second =  $1.5 \times 10^8$  disintegrations per second and has an activity of  $1.5 \times 10^8$  Bq. As a radioactive sample decays, the amount of radiation emanating from the sample decays as well. For example, the half-life of cobalt-60 is 5.26 yr. The 4.0-mCi sample of cobalt-60 would, after 5.26 yr, have a radiation activity of 2.0 mCi, or  $7.5 \times 10^7$  Bq.

### GIVE IT SOME THOUGHT

Why can't spontaneous radioactive decay be a zero-order or second-order kinetic process?

As we saw in Section 14.4, a first-order rate law can be transformed into the following equation:

$$\ln \frac{N_t}{N_0} = -kt \quad [21.19]$$

In this equation  $t$  is the time interval of decay,  $k$  is the decay constant,  $N_0$  is the initial number of nuclei (at time zero), and  $N_t$  is the number remaining after the time interval. Both the mass of a particular radioisotope and its activity are proportional to the number of radioactive nuclei. Thus, either the ratio of the mass at any time  $t$  to the mass at time  $t = 0$  or the ratio of the activities at time  $t$  and  $t = 0$  can be substituted for  $N_t/N_0$  in Equation 21.19.

From Equation 21.19 we can obtain the relationship between the decay constant,  $k$ , and half-life,  $t_{1/2}$ . [↔ \(Section 14.4\)](#)

$$k = \frac{0.693}{t_{1/2}} \quad [21.20]$$

Thus, if we know the value of either the decay constant or the half-life, we can calculate the value of the other.

### GIVE IT SOME THOUGHT

(a) Would doubling the mass of a radioactive sample change the amount of radioactivity the sample shows? (b) Would doubling the mass change the half-life for the radioactive decay?

#### **SAMPLE EXERCISE 21.7** | Calculating the Age of a Mineral

A rock contains 0.257 mg of lead-206 for every milligram of uranium-238. The half-life for the decay of uranium-238 to lead-206 is  $4.5 \times 10^9$  yr. How old is the rock?

#### **SOLUTION**

**Analyze:** We are told that a rock sample has a certain amount of lead-206 for every unit weight of uranium-238 and asked to estimate the age of the rock.

**Plan:** Lead-206 is the product of the radioactive decay of uranium-238. We will assume that the only source of lead-206 in the rock is from the decay of uranium-238, with a known half-life. To apply first-order kinetics expressions (Equations 21.19 and 21.20) to calculate the time elapsed since the rock was formed, we first need to calculate how much initial uranium-238 there was for every 1 milligram that remains today.

**Solve:** Let's assume that the rock currently contains 1.000 mg of uranium-238 and therefore 0.257 mg of lead-206. The amount of uranium-238 in the rock when it was first formed therefore equals 1.000 mg plus the quantity that has decayed to lead-206. Because the mass of lead atoms is not the same as uranium atoms, we cannot just add 1.000 mg and 0.257 mg. We have to multiply the present mass of lead-206 (0.257 mg) by the ratio of the mass number of uranium to that of lead, into which it has decayed. The total original  $^{238}_{92}\text{U}$  was thus

$$\begin{aligned}\text{Original } ^{238}_{92}\text{U} &= 1.000 \text{ mg} + \frac{238}{206} (0.257 \text{ mg}) \\ &= 1.297 \text{ mg}\end{aligned}$$

Using Equation 21.20, we can calculate the decay constant for the process from its half-life:

$$k = \frac{0.693}{4.5 \times 10^9 \text{ yr}} = 1.5 \times 10^{-10} \text{ yr}^{-1}$$

Rearranging Equation 21.19 to solve for time,  $t$ , and substituting known quantities gives

$$t = -\frac{1}{k} \ln \frac{N_t}{N_0} = -\frac{1}{1.5 \times 10^{-10} \text{ yr}^{-1}} \ln \frac{1.000}{1.297} = 1.7 \times 10^9 \text{ yr}$$

**Comment:** If you want to cross-check this result, you could also use the fact that uranium-237 decays to lead-207 with a half-life of  $7 \times 10^8$  yr, and measure the relative amounts of uranium-237 and lead-207 in the rock.

### PRACTICE EXERCISE

A wooden object from an archeological site is subjected to radiocarbon dating. The activity of the sample that is due to  $^{14}\text{C}$  is measured to be 11.6 disintegrations per second. The activity of a carbon sample of equal mass from fresh wood is 15.2 disintegrations per second. The half-life of  $^{14}\text{C}$  is 5715 yr. What is the age of the archeological sample?

**Answer:** 2230 yr

### SAMPLE EXERCISE 21.8 | Calculations Involving Radioactive Decay

If we start with 1.000 g of strontium-90, 0.953 g will remain after 2.00 yr. (a) What is the half-life of strontium-90? (b) How much strontium-90 will remain after 5.00 yr? (c) What is the initial activity of the sample in Bq and in Ci?

#### SOLUTION

**(a) Analyze:** We are asked to calculate a half-life,  $t_{1/2}$ , based on data that tell us how much of a radioactive nucleus has decayed in a given period of time and ( $N_0 = 1.000$  g,  $N_t = 0.953$  g, and  $t = 2.00$  yr).

**Plan:** We first calculate the rate constant for the decay,  $k$ , then use that to compute  $t_{1/2}$ .

**Solve:** Equation 21.19 is solved for the decay constant,  $k$ , and then Equation 21.20 is used to calculate half-life,  $t_{1/2}$ :

$$\begin{aligned}k &= -\frac{1}{t} \ln \frac{N_t}{N_0} = -\frac{1}{2.00 \text{ yr}} \ln \frac{0.953 \text{ g}}{1.000 \text{ g}} \\ &= -\frac{1}{2.00 \text{ yr}} (-0.0481) = 0.0241 \text{ yr}^{-1} \\ t_{1/2} &= \frac{0.693}{k} = \frac{0.693}{0.0241 \text{ yr}^{-1}} = 28.8 \text{ yr}\end{aligned}$$

**(b) Analyze:** We are asked to calculate the amount of a radionuclide remaining after a given period of time.

**Plan:** We need to calculate the amount of strontium at time  $t$ ,  $N_t$ , using the initial quantity,  $N_0$ , and the rate constant for decay,  $k$ , calculated in part (a).

**Solve:** Again using Equation 21.19, with  $k = 0.0241 \text{ yr}^{-1}$ , we have

$$\ln \frac{N_t}{N_0} = -kt = -(0.0241 \text{ yr}^{-1})(5.00 \text{ yr}) = -0.120$$

$N_t/N_0$  is calculated from  $\ln(N_t/N_0) = -0.120$  using the  $e^x$  or INV LN function of a calculator:

$$\frac{N_t}{N_0} = e^{-0.120} = 0.887$$

Because  $N_0 = 1.000 \text{ g}$ , we have

$$N_t = (0.887)N_0 = (0.887)(1.000 \text{ g}) = 0.887 \text{ g}$$

**(c) Analyze:** We are asked to calculate the activity of the sample in becquerels and curies.

**Plan:** We must calculate the number of disintegrations per second per atom, and then multiply by the number of atoms in the sample.

**Solve:** The number of disintegrations per atom per second is given by the rate constant,  $k$ .

$$k = \left(\frac{0.0241}{\text{yr}}\right)\left(\frac{1 \text{ yr}}{365 \text{ days}}\right)\left(\frac{1 \text{ day}}{24 \text{ h}}\right)\left(\frac{1 \text{ h}}{3600 \text{ s}}\right) = 7.64 \times 10^{-10} \text{ s}^{-1}$$

To obtain the total number of disintegrations per second, we calculate the number of atoms in the sample. We multiply this quantity by  $k$ , where we express  $k$  as the number of disintegrations per atom per second, to obtain the number of disintegrations per second:

$$\begin{aligned} (1.000 \text{ g } ^{90}\text{Sr})\left(\frac{1 \text{ mol } ^{90}\text{Sr}}{90 \text{ g } ^{90}\text{Sr}}\right)\left(\frac{6.022 \times 10^{23} \text{ atoms Sr}}{1 \text{ mol } ^{90}\text{Sr}}\right) &= 6.7 \times 10^{21} \text{ atoms } ^{90}\text{Sr} \\ \text{Total disintegrations/s} &= \left(\frac{7.64 \times 10^{-10} \text{ disintegrations}}{\text{atom} \cdot \text{s}}\right)(6.7 \times 10^{21} \text{ atoms}) \\ &= 5.1 \times 10^{12} \text{ disintegrations/s} \end{aligned}$$

Because a Bq is one disintegration per second, the activity is just  $5.1 \times 10^{12} \text{ Bq}$ . The activity in Ci is given by

$$(5.1 \times 10^{12} \text{ disintegrations/s})\left(\frac{1 \text{ Ci}}{3.7 \times 10^{10} \text{ disintegrations/s}}\right) = 1.4 \times 10^2 \text{ Ci}$$

We have used only two significant figures in products of these calculations because we do not know the atomic weight of  $^{90}\text{Sr}$  to more than two significant figures without looking it up in a special source.

### **PRACTICE EXERCISE**

A sample to be used for medical imaging is labeled with  $^{18}\text{F}$ , which has a half-life of 110 min. What percentage of the original activity in the sample remains after 300 min?

*Answer:* 15.1%

## 21.5 DETECTION OF RADIOACTIVITY

A variety of methods have been devised to detect emissions from radioactive substances. Henri Becquerel discovered radioactivity because radiation caused fogging of photographic plates. Photographic plates and film have long been used to detect radioactivity. The radiation affects photographic film in much the same way as X-rays do. With care, film can be used to give a quantitative

▲ **Figure 21.10** Badge dosimeter.

Badges such as the one on this worker's lapel are used to monitor the extent to which the individual has been exposed to high-energy radiation. The radiation dose is determined from the extent of fogging of the film in the dosimeter. Monitoring the radiation in this way helps prevent overexposure for people whose jobs require them to use radioactive materials or X-rays.

▲ **Figure 21.11** Schematic drawing of a Geiger counter.

measure of activity. The greater the extent of exposure to radiation, the darker is the area of the developed negative. People who work with radioactive substances carry film badges to record the extent of their exposure to radiation (Figure 21.10 ▲).

Radioactivity can also be detected and measured using a device known as a Geiger counter. The operation of a Geiger counter is based on the ionization of matter caused by radiation. The ions and electrons produced by the ionizing radiation permit conduction of an electrical current. The basic design of a Geiger counter is shown in Figure 21.11 ▲. It consists of a metal tube filled with gas. The cylinder has a "window" made of material that can be penetrated by alpha, beta, or gamma rays. In the center of the tube is a wire. The wire is connected to one terminal of a source of direct current, and the metal cylinder is attached to the other terminal. Current flows between the wire and metal cylinder whenever entering radiation produces ions. The current pulse created when radiation enters the tube is amplified; each pulse is counted as a measure of the amount of radiation.

### GIVE IT SOME THOUGHT

Will alpha, beta, and gamma rays pass through the window of a Geiger counter detection tube with equal efficiency?

Certain substances that are electronically excited by radiation can also be used to detect and measure radiation. For example, some substances excited by radiation give off light as electrons return to their lower-energy states. These substances are called *phosphors*. Different substances respond to different particles. Zinc sulfide, for example, responds to alpha particles. An instrument called a scintillation counter (Figure 21.12 ►) is used to detect and measure radiation, based on the tiny flashes of light produced when radiation strikes a suitable phosphor. The flashes are magnified electronically and counted to measure the amount of radiation.

▲ **Figure 21.12** A scintillation counter. Such counters are used to quantitatively measure the level of radiation.

## Radiotracers

Because radioisotopes can be detected so readily, they can be used to follow an element through its chemical reactions. The incorporation of carbon atoms from  $\text{CO}_2$  into glucose during photosynthesis, for example, has been studied using  $\text{CO}_2$  enriched in carbon-14:

The  $\text{CO}_2$  is said to be “labeled” with the carbon-14. The use of the carbon-14 label provides direct experimental evidence that carbon dioxide in the environment is chemically converted to glucose in plants. Analogous labeling experiments for oxygen, using oxygen-18, show that the  $\text{O}_2$  produced during photosynthesis comes from water, not carbon dioxide. When it is possible to isolate and purify intermediates and products from reactions, detection devices such as scintillation counters can be used to “follow” the radioisotope as it moves from the starting material through the various intermediate compounds to the final product. These types of experiments are useful for identifying elementary steps in a reaction mechanism. [↔ \(Section 14.6\)](#)

The use of radioisotopes is possible because all isotopes of an element have essentially identical chemical properties. When a small quantity of a radioisotope is mixed with the naturally occurring stable isotopes of the same element, all the isotopes go through the same reactions together. The element’s path is revealed by the radioactivity of the radioisotope. Because the radioisotope can be used to trace the path of the element, it is called a **radiotracer**.

### Chemistry and Life

#### MEDICAL APPLICATIONS OF RADIOTRACERS

**R**adiotracers have found wide use as diagnostic tools in medicine. Table 21.5  $\blacktriangledown$  lists some radiotracers and their uses. These radioisotopes are incorporated into a compound that is administered to the patient, usually intravenously. The diagnostic use of these isotopes is based upon the ability of the radioactive compound to localize and concentrate in the organ or tissue under investigation. Iodine-131, for example, has been used to test the activity of the thyroid gland. This gland is the only important user of iodine in the body. The patient drinks a solution of NaI containing iodine-131. Only a very small amount is used so that the patient does not receive a harmful dose of radioactivity. A Geiger counter placed close to the thyroid, in the neck region, determines the ability of the thyroid to take up the iodine. A normal thyroid will absorb about 12% of the iodine within a few hours.

TABLE 21.5  $\blacklozenge$  Some Radionuclides Used as Radiotracers

Nuclide	Half-life	Area of the Body Studied
Iodine-131	8.04 days	Thyroid
Iron-59	44.5 days	Red blood cells
Phosphorus-32	14.3 days	Eyes, liver, tumors
Technetium-99	6.0 hours	Heart, bones, liver, and lungs
Thallium-201	73 hours	Heart, arteries
Sodium-24	14.8 hours	Circulatory system

The medical applications of radiotracers are further illustrated by positron emission tomography (PET). PET is used for clinical diagnosis of many diseases. In this method compounds containing radionuclides that decay by positron emission are injected into a patient. These compounds are chosen to enable researchers to monitor blood flow, oxygen and glucose metabolic rates, and other biological functions. Some of the most interesting work involves the study of the brain, which depends on glucose for most of its energy. Changes in how this sugar is metabolized or used by the brain may signal a disease such as cancer, epilepsy, Parkinson’s disease, or schizophrenia.

The compound to be detected in the patient must be labeled with a radionuclide that is a positron emitter. The most widely used nuclides are carbon-11 (half-life 20.4 min), fluorine-18 (half-life 110 min), oxygen-15 (half-life 2 min), and nitrogen-13 (half-life 10 min). Glucose, for example, can be labeled with  $^{11}\text{C}$ . Because the half-lives of positron emitters are so short, the chemist must quickly incorporate the radionuclide into the sugar (or other appropriate) molecule and inject the compound immediately. The patient is placed in an elaborate instrument that measures the positron emission and constructs a computer-based image of the organ in which the emitting compound is localized. The nature of this image provides clues to the presence of disease or other abnormality and helps medical researchers understand how a particular disease affects the functioning of the brain.

## 21.6 ENERGY CHANGES IN NUCLEAR REACTIONS

The energies associated with nuclear reactions can be considered with the aid of Einstein's famous equation relating mass and energy:

$$E = mc^2 \quad [21.22]$$

In this equation  $E$  stands for energy,  $m$  for mass, and  $c$  for the speed of light,  $2.9979 \times 10^8$  m/s. This equation states that the mass and energy of an object are proportional. If a system loses mass, it loses energy (exothermic); if it gains mass, it gains energy (endothermic). Because the proportionality constant in the equation,  $c^2$ , is such a large number, even small changes in mass are accompanied by large changes in energy.

The mass changes in chemical reactions are too small to detect. For example, the mass change associated with the combustion of 1 mol of  $\text{CH}_4$  (an exothermic process) is  $-9.9 \times 10^{-9}$  g. Because the mass change is so small, it is possible to treat chemical reactions as though mass is conserved.

The mass changes and the associated energy changes in nuclear reactions are much greater than those in chemical reactions. The mass change accompanying the radioactive decay of a mole of uranium-238, for example, is 50,000 times greater than that for the combustion of 1 mol of  $\text{CH}_4$ . Let's examine the energy change for the nuclear reaction

The nuclei in this reaction have the following masses:  ${}_{92}^{238}\text{U}$ , 238.0003 amu;  ${}_{90}^{234}\text{Th}$ , 233.9942 amu; and  ${}_2^4\text{He}$ , 4.0015 amu. The mass change,  $\Delta m$ , is the total mass of the products minus the total mass of the reactants. The mass change for the decay of a mole of uranium-238 can then be expressed in grams:

$$233.9942 \text{ g} + 4.0015 \text{ g} - 238.0003 \text{ g} = -0.0046 \text{ g}$$

The fact that the system has lost mass indicates that the process is exothermic. All spontaneous nuclear reactions are exothermic.

The energy change per mole associated with this reaction can be calculated using Einstein's equations:

$$\begin{aligned} \Delta E &= \Delta(mc^2) = c^2 \Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2 (-0.0046 \text{ g}) \left( \frac{1 \text{ kg}}{1000 \text{ g}} \right) \\ &= -4.1 \times 10^{11} \frac{\text{kg} \cdot \text{m}^2}{\text{s}^2} = -4.1 \times 10^{11} \text{ J} \end{aligned}$$

Notice that  $\Delta m$  is converted to kilograms, the SI unit of mass, to obtain  $\Delta E$  in joules, the SI unit for energy. The negative sign for the energy change indicates that energy is released in the reaction—in this case, over 400 billion joules per mole of uranium!

### **SAMPLE EXERCISE 21.9** | Calculating Mass Change in a Nuclear Reaction

How much energy is lost or gained when a mole of cobalt-60 undergoes beta decay:  ${}_{27}^{60}\text{Co} \longrightarrow {}_{-1}^0\text{e} + {}_{28}^{60}\text{Ni}$ ? The mass of the  ${}_{27}^{60}\text{Co}$  atom is 59.933819 amu, and that of a  ${}_{28}^{60}\text{Ni}$  atom is 59.930788 amu.

#### **SOLUTION**

**Analyze:** We are asked to calculate the energy change in a nuclear reaction.

**Plan:** We must first calculate the mass change in the process. We are given atomic masses, but we need the masses of the nuclei in the reaction. We calculate these by taking account of the masses of the electrons that contribute to the atomic masses.

**Solve:** A  $^{60}_{27}\text{Co}$  atom has 27 electrons. The mass of an electron is  $5.4858 \times 10^{-4}$  amu. (See the list of fundamental constants in the back inside cover.) We subtract the mass of the 27 electrons from the mass of the  $^{60}_{27}\text{Co}$  atom to find the mass of the  $^{60}_{27}\text{Co}$  nucleus:

$$59.933819 \text{ amu} - (27)(5.4858 \times 10^{-4} \text{ amu}) = 59.919007 \text{ amu (or } 59.919007 \text{ g/mol)}$$

Likewise, for  $^{60}_{28}\text{Ni}$ , the mass of the nucleus is

$$59.930788 \text{ amu} - (28)(5.4858 \times 10^{-4} \text{ amu}) = 59.915428 \text{ amu (or } 59.915428 \text{ g/mol)}$$

The mass change in the nuclear reaction is the total mass of the products minus the mass of the reactant:

$$\begin{aligned} \Delta m &= \text{mass of electron} + \text{mass } ^{60}_{28}\text{Ni nucleus} - \text{mass of } ^{60}_{27}\text{Co nucleus} \\ &= 0.00054858 \text{ amu} + 59.915428 \text{ amu} - 59.919007 \text{ amu} \\ &= -0.003030 \text{ amu} \end{aligned}$$

Thus, when a mole of cobalt-60 decays,

$$\Delta m = -0.003030 \text{ g}$$

Because the mass decreases ( $\Delta m < 0$ ), energy is released ( $\Delta E < 0$ ). The quantity of energy released *per mole* of cobalt-60 is calculated using Equation 21.22:

$$\begin{aligned} \Delta E &= c^2 \Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2 (-0.003030 \text{ g}) \left( \frac{1 \text{ kg}}{1000 \text{ g}} \right) \\ &= -2.723 \times 10^{11} \frac{\text{kg} \cdot \text{m}^2}{\text{s}^2} = -2.723 \times 10^{11} \text{ J} \end{aligned}$$

### PRACTICE EXERCISE

Positron emission from  $^{11}\text{C}$ ,  $^{11}_6\text{C} \rightarrow ^{11}_5\text{B} + ^0_1\text{e}$ , occurs with release of  $2.87 \times 10^{11}$  J per mole of  $^{11}\text{C}$ . What is the mass change per mole of  $^{11}\text{C}$  in this nuclear reaction?

**Answer:**  $-3.19 \times 10^{-3}$  g

## Nuclear Binding Energies

Scientists discovered in the 1930s that the masses of nuclei are always less than the masses of the individual nucleons of which they are composed. For example, the helium-4 nucleus has a mass of 4.00150 amu. The mass of a proton is 1.00728 amu, and that of a neutron is 1.00866 amu. Consequently, two protons and two neutrons have a total mass of 4.03188 amu:

$$\text{Mass of two protons} = 2(1.00728 \text{ amu}) = 2.01456 \text{ amu}$$

$$\text{Mass of two neutrons} = 2(1.00866 \text{ amu}) = \underline{2.01732 \text{ amu}}$$

$$\text{Total mass} = 4.03188 \text{ amu}$$

The mass of the individual nucleons is 0.03038 amu greater than that of the helium-4 nucleus:

$$\text{Mass of two protons and two neutrons} = 4.03188 \text{ amu}$$

$$\text{Mass of } ^4_2\text{He nucleus} = \underline{4.00150 \text{ amu}}$$

$$\text{Mass difference} = 0.03038 \text{ amu}$$

The mass difference between a nucleus and its constituent nucleons is called the **mass defect**. The origin of the mass defect is readily understood if we consider that energy must be added to a nucleus to break it into separated protons and neutrons:

The addition of energy to a system must be accompanied by a proportional increase in mass. The mass change for the conversion of helium-4 into separated

TABLE 21.6 ■ Mass Defects and Binding Energies for Three Nuclei

Nucleus	Mass of Nucleus (amu)	Mass of Individual Nucleons (amu)	Mass Defect (amu)	Binding Energy (J)	Binding Energy per Nucleon (J)
${}^4_2\text{He}$	4.00150	4.03188	0.03038	$4.53 \times 10^{-12}$	$1.13 \times 10^{-12}$
${}^{56}_{26}\text{Fe}$	55.92068	56.44914	0.52846	$7.90 \times 10^{-11}$	$1.41 \times 10^{-12}$
${}^{238}_{92}\text{U}$	238.00031	239.93451	1.93420	$2.89 \times 10^{-10}$	$1.21 \times 10^{-12}$

nucleons is  $\Delta m = 0.03038$  amu, as shown in these calculations. The energy required for this process is

$$\begin{aligned}\Delta E &= c^2 \Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2 (0.03038 \text{ amu}) \left( \frac{1 \text{ g}}{6.022 \times 10^{23} \text{ amu}} \right) \left( \frac{1 \text{ kg}}{1000 \text{ g}} \right) \\ &= 4.534 \times 10^{-12} \text{ J}\end{aligned}$$

The energy required to separate a nucleus into its individual nucleons is called the **nuclear binding energy**. The larger the binding energy, the more stable is the nucleus toward decomposition. The nuclear binding energies of helium-4 and two other nuclei (iron-56 and uranium-238) are compared in Table 21.6▲. The binding energies per nucleon (that is, the binding energy of each nucleus divided by the total number of nucleons in that nucleus) are also compared in the table.

The binding energies per nucleon can be used to compare the stabilities of different combinations of nucleons (such as 2 protons and 2 neutrons arranged either as  ${}^4_2\text{He}$  or  $2\,{}^2_1\text{H}$ ). Figure 21.13► shows the average binding energy per nucleon plotted against mass number. The binding energy per nucleon at first increases in magnitude as the mass number increases, reaching about  $1.4 \times 10^{-12}$  J for nuclei whose mass numbers are in the vicinity of iron-56. It then decreases slowly to about  $1.2 \times 10^{-12}$  J for very heavy nuclei. This trend indicates that nuclei of intermediate mass numbers are more tightly bound (and therefore more stable) than those with either smaller or larger mass numbers. This trend has two significant consequences: First, heavy nuclei gain stability and therefore give off energy if they are fragmented into two mid-sized nuclei. This process, known as **fission**, is used to generate energy in nuclear power plants. Second, even greater amounts of energy are released if very light nuclei are combined or fused together to give more massive nuclei. This **fusion** process is the essential energy-producing process in the Sun.

▲ **Figure 21.13 Nuclear binding energies.** The average binding energy per nucleon increases to a maximum at a mass number of 50 to 60 and decreases slowly thereafter. Because of these trends, fusion of light nuclei and fission of heavy nuclei are exothermic processes.

### GIVE IT SOME THOUGHT

Could fusing two stable nuclei that have mass numbers in the vicinity of 100 cause an energy-releasing process?

## 21.7 NUCLEAR POWER: FISSION

According to our discussion of the energy changes in nuclear reactions, both the splitting of heavy nuclei (fission) and the union of light nuclei (fusion) are exothermic processes. Commercial nuclear power plants and the most common forms of nuclear weaponry depend on the process of nuclear fission for their operation. The first nuclear fission to be discovered was that of uranium-235.

► **Figure 21.14 Diagram of uranium-235 fission.** The diagram shows just one of many fission patterns. In the process shown,  $3.5 \times 10^{-11}$  J of energy is produced per  $^{235}\text{U}$  nucleus.

This nucleus, as well as those of uranium-233 and plutonium-239, undergoes fission when struck by a slow-moving neutron.\* The induced fission process is illustrated in Figure 21.14▲. A heavy nucleus can split in many different ways. Two ways that the uranium-235 nucleus splits are shown in Equations 21.24 and 21.25:

▲ **Figure 21.15 Chain fission reaction.** Assuming that each fission produces two neutrons, the process leads to an accelerating rate of fission, with the number of fissions potentially doubling at each stage.

More than 200 isotopes of 35 elements have been found among the fission products of uranium-235. Most of them are radioactive.

On average, 2.4 neutrons are produced by every fission of a uranium-235 nucleus. If one fission produces two neutrons, these two neutrons can cause two additional fissions. The four neutrons thereby released can produce four fissions, and so forth, as shown in Figure 21.15◀. The number of fissions and the energy released quickly escalate, and if the process is unchecked, the result is a violent explosion. Reactions that multiply in this fashion are called **chain reactions**.

For a fission chain reaction to occur, the sample of fissionable material must have a certain minimum mass. Otherwise, neutrons escape from the sample before they have the opportunity to strike other nuclei and cause additional fission. The chain stops if too many neutrons are lost. The amount of fissionable material large enough to maintain the chain reaction with a constant rate of fission is called the **critical mass**. When a critical mass of material is present, one neutron on average from each fission is subsequently effective in producing another fission. The critical mass of uranium-235 is about 1 kg. If more than a critical mass of fissionable material is present, very few neutrons escape. The chain reaction thus multiplies the number of fissions, which can lead to a nuclear explosion. A mass in excess of a critical mass is referred to as a **supercritical mass**. The effect of mass on a fission reaction is illustrated in Figure 21.16▼.

► **Figure 21.16 Subcritical and supercritical fission.** The chain reaction in a subcritical mass soon stops because neutrons are lost from the mass without causing fission. As the size of the mass increases, fewer neutrons are able to escape. In a supercritical mass, the chain reaction is able to accelerate.

\*Other heavy nuclei can be induced to undergo fission. However, these three are the only ones of practical importance.

Figure 21.17  shows a schematic diagram of the first atomic bomb used in warfare, the bomb that was dropped on Hiroshima, Japan, on August 6, 1945. To trigger a fission reaction, two subcritical masses of uranium-235 are slammed together using chemical explosives. The combined masses of the uranium form a supercritical mass, which leads to a rapid, uncontrolled chain reaction and, ultimately, a nuclear explosion. The energy released by the bomb dropped on Hiroshima was equivalent to that of 20,000 tons of TNT (it therefore is called a *20-kiloton* bomb). Unfortunately, the basic design of a fission-based atomic bomb is quite simple. The fissionable materials are potentially available to any nation with a nuclear reactor. This simplicity has resulted in the proliferation of atomic weapons.

## Nuclear Reactors

Nuclear fission produces the energy generated by nuclear power plants. The “fuel” of the nuclear reactor is a fissionable substance, such as uranium-235. Typically, uranium is enriched to about 3% uranium-235 and then used in the form of  $\text{UO}_2$  pellets. These enriched uranium pellets are encased in zirconium or stainless steel tubes. Rods composed of materials such as cadmium or boron control the fission process by absorbing neutrons. These *control rods* regulate

 **Figure 21.17** An atomic bomb design. A conventional explosive is used to bring two subcritical masses together to form a supercritical mass.

## A Closer Look

### THE DAWNING OF THE NUCLEAR AGE

The fission of uranium-235 was first achieved during the late 1930s by Enrico Fermi and his colleagues in Rome, and shortly thereafter by Otto Hahn and his coworkers in Berlin. Both groups were trying to produce transuranium elements. In 1938 Hahn identified barium among his reaction products. He was puzzled by this observation and questioned the identification because the presence of barium was so unexpected. He sent a detailed letter describing his experiments to Lise Meitner, a former coworker. Meitner had been forced to leave Germany because of the anti-Semitism of the Third Reich and had settled in Sweden. She surmised that Hahn’s experiment indicated a new nuclear process was occurring in which the uranium-235 split. She called this process *nuclear fission*.

Meitner passed word of this discovery to her nephew, Otto Frisch, a physicist working at Niels Bohr’s institute in Copenhagen. He repeated the experiment, verifying Hahn’s observations and finding that tremendous energies were involved. In January 1939, Meitner and Frisch published a short article describing this new reaction. In March 1939, Leo Szilard and Walter Zinn at Columbia University discovered that more neutrons are produced than are used in each fission. As we have seen, this result allows a chain reaction process to occur.

News of these discoveries and an awareness of their potential use in explosive devices spread rapidly within the scientific community. Several scientists finally persuaded Albert Einstein, the most famous physicist of the time, to write a letter to President Franklin D. Roosevelt explaining the implications of these discoveries. Einstein’s letter, written in August 1939, outlined the possible military applications of nuclear fission and emphasized the danger that weapons based on fission would pose if they were to be developed by the Nazis.

Roosevelt judged it imperative that the United States investigate the possibility of such weapons. Late in 1941 the decision was made to build a bomb based on the fission reaction. An enormous research project, known as the “Manhattan Project,” began.

On December 2, 1942, the first artificial self-sustaining nuclear fission chain reaction was achieved in an abandoned squash court at the University of Chicago (Figure 21.18 ). This accomplishment led to the development of the first atomic bomb, at Los Alamos National Laboratory in New Mexico in July 1945. In August 1945 the United States dropped atomic bombs on two Japanese cities, Hiroshima and Nagasaki. The nuclear age had arrived.

 **Figure 21.18** The first self-sustaining nuclear fission reactor. This photograph shows part of the original nuclear reactor at the University of Chicago.

▲ **Figure 21.19** Diagram of a reactor core. The diagram shows fuel elements, control rods, and cooling fluid. A moderator, used to slow the neutrons, is also present.

the flux of neutrons to keep the reaction chain self-sustaining, while preventing the reactor core from overheating.\*

The reactor is started by a neutron-emitting source; it is stopped by inserting the control rods more deeply into the reactor core at the site of the fission (Figure 21.19 ◀). The reactor core also contains a *moderator*, which acts to slow down neutrons so that they can be captured more readily by the fuel. Graphite is commonly used as a moderator. A *cooling liquid* circulates through the reactor core to carry away the heat generated by the nuclear fission. In some reactor designs, the cooling liquid also serves as the neutron moderator.

The design of a nuclear power plant is basically the same as that of a power plant that burns fossil fuel (except that the burner is replaced by a reactor core). In both instances steam is used to drive a turbine connected to an electrical generator. The steam must be condensed; therefore, additional cooling water, generally obtained from a large source such as a river or lake, is needed. The nuclear power plant design shown in Figure 21.20 ▼ is currently the most popular. The primary coolant, which passes through the core, is in a closed system, which lessens the chance that radioactive products could escape the core. Additionally, the reactor is surrounded by a reinforced concrete shell to shield personnel and nearby residents from radiation and to protect the reactor from external forces. After passing through the reactor core, the primary coolant is very hot. The heat content of the coolant is used to generate high-pressure steam in a heat exchanger. In the United States, more recent nuclear reactor designs use gas cooling instead of liquid cooling, which means fewer pipes and valves; but the basic operating principle is unchanged.

Newer designs for nuclear reactors are being developed. South Africa is building a nuclear power plant near Capetown, expected to be operational in 2010, that is based on the “pebble-bed” reactor design that was originally conceived in the United States just after World War II. In the pebble-bed design, small specks of low-enriched uranium are coated with ceramics and graphite

▼ **Figure 21.20** The basic design of a nuclear power plant. (a) A fluid such as water or liquid sodium carries heat produced by the reactor core to a heat exchanger in which steam is generated. The heat exchange liquid moves in a closed loop. The steam is used to drive an electrical generator. (b) A nuclear power plant in Salem, New Jersey. Notice the dome-shaped concrete containment shell.

(a)

(b)

\*The reactor core cannot reach supercritical levels and explode with the violence of an atomic bomb because the concentration of uranium-235 is too low. However, if the core overheats, sufficient damage can lead to release of radioactive materials into the environment.

and pressed into balls that are about the size of an orange. These balls are the “pebbles,” and contain only a few percent uranium. When ready to run, about half a million pebbles are placed in the reactor core along with the control rods. Helium gas is the coolant. As the nuclear reactions proceed, the pebbles heat the helium, and the helium drives a turbine connected to a generator. One advantage of the pebble-bed reactor is that helium is not subject to steam explosions, like water, and does not readily absorb neutrons to produce radioactive products. Another advantage is that the pebble-bed reactor does not need to be shut down to add more fuel; engineers can take some pebbles out of the bottom and weigh them, to see if there is still usable fuel inside, and add usable pebbles to the top of the pile.

Fission products accumulate as a reactor operates. These products decrease the efficiency of the reactor by capturing neutrons. Current commercial reactors must be stopped periodically to replace or reprocess the nuclear fuel. When the fuel rods are removed from the reactor, they are initially very radioactive. It was originally intended that they be stored for several months in pools at the reactor site to allow decay of short-lived radioactive nuclei. They were then to be transported in shielded containers to reprocessing plants where the fuel would be separated from the fission products. Reprocessing plants have been plagued with operational difficulties, however, and there is intense opposition in the United States to the transport of nuclear wastes on the nation’s roads. Even if the transportation difficulties could be overcome, the high level of radioactivity of the spent fuel makes reprocessing a hazardous operation. At present in the United States, the spent fuel rods are simply being kept in storage at reactor sites. However, in 2007, the U.S. federal government proposed initiatives that would allow for reprocessing of spent nuclear fuel, overturning a 30-year ban. Russia, the United Kingdom, France, China, and Japan have already developed reprocessing methods and sites.

Storage poses a major problem because the fission products are extremely radioactive. It is estimated that 20 half-lives are required for their radioactivity to reach levels acceptable for biological exposure. Based on the 28.8-yr half-life of strontium-90, one of the longer-lived and most dangerous of the products, the wastes must be stored for 600 years. Plutonium-239 is one of the by-products present in the expended fuel rods. It is formed by absorption of a neutron by uranium-238, followed by two successive beta emissions. (Remember that most of the uranium in the fuel rods is uranium-238.) If the fuel rods are processed, the plutonium-239 is largely recovered because it can be used as a nuclear fuel. However, if the plutonium is not removed, fuel rod storage must be for a very long time because plutonium-239 has a half-life of 24,000 yr.

A considerable amount of research is being devoted to disposal of radioactive wastes. At present, the most attractive possibilities appear to be formation of glass, ceramic, or synthetic rock from the wastes, as a means of immobilizing them. These solid materials would then be placed in containers of high corrosion resistance and durability and buried deep underground. The U.S. Department of Energy has designated Yucca Mountain in Nevada as a disposal site, and extensive construction has been done there. However, because the radioactivity will persist for a long time, there must be assurances that the solids and their containers will not crack from the heat generated by nuclear decay, allowing radioactivity to find its way into underground water supplies.

In spite of all these difficulties, nuclear power is making a modest comeback as an energy source. In 2005, there were 441 working nuclear power plants in the world, most of which are at least 20 years old. Another 26 nuclear power plants are under construction, mostly in Asia, and plans for many more are in progress. The threat of global warming has moved some organizations to propose nuclear power as a major energy source for the planet in the future. However, this goal would require the construction of at least a thousand new nuclear power plants over the next 50 years.

## 21.8 NUCLEAR POWER: FUSION

Energy is produced when light nuclei are fused into heavier ones. Reactions of this type are responsible for the energy produced by the Sun. Spectroscopic studies indicate that the Sun is composed of 73% H, 26% He, and only 1% of all other elements, by mass. Among the several fusion processes that are believed to occur are:

Fusion is appealing as an energy source because of the availability of light isotopes and because fusion products are generally not radioactive. Despite this fact, fusion is not presently used to generate energy. The problem is that high energies, achieved by high temperatures, are needed to overcome the repulsion between nuclei. Fusion reactions are therefore also known as **thermonuclear reactions**. The lowest temperature required for any fusion is that needed to fuse deuterium ( ${}^2_1\text{H}$ ) and tritium ( ${}^3_1\text{H}$ ), shown in Equation 21.30. This reaction requires a temperature of about 40,000,000 K:

Such high temperatures have been achieved by using an atomic bomb to initiate the fusion process. This is done in the thermonuclear, or hydrogen, bomb. This approach is unacceptable, however, for controlled power generation.

Numerous problems must be overcome before fusion becomes a practical energy source. In addition to the high temperatures necessary to initiate the reaction, there is the problem of confining the reaction. No known structural material is able to withstand the enormous temperatures necessary for fusion. Research has centered on the use of an apparatus called a *tokamak*, which uses strong magnetic fields to contain and to heat the reaction (Figure 21.21 ▼). Temperatures of over 100,000,000 K have been achieved in a tokamak. In the interior of the Sun, where hydrogen nuclei fuse to form helium nuclei, the temperature is estimated to be 13,600,000 K. This temperature is “low” enough that the reaction is slow—otherwise, the Sun would have consumed its hydrogen long ago.

► **Figure 21.21 A tokamak fusion test reactor.** A tokamak is essentially a magnetic “bottle” for confining and heating nuclei in an effort to cause them to fuse.

## 21.9 RADIATION IN THE ENVIRONMENT AND LIVING SYSTEMS

We are continually bombarded by radiation from both natural and artificial sources. We are exposed to infrared, ultraviolet, and visible radiation from the Sun, in addition to radio waves from radio and television stations, microwaves from microwave ovens, and X-rays from various medical procedures. We are also exposed to radioactivity from the soil and other natural materials (Table 21.7▼). Understanding the different energies of these various kinds of radiation is necessary to understand their different effects on matter.

When matter absorbs radiation, the energy of the radiation can cause either excitation or ionization of the matter. Excitation occurs when the absorbed radiation excites electrons to higher energy states or increases the motion of molecules, causing them to move, vibrate, or rotate. Ionization occurs when the radiation removes an electron from an atom or molecule. In general, radiation that causes ionization, called **ionizing radiation**, is far more harmful to biological systems than radiation that does not cause ionization. The latter, called **nonionizing radiation**, is generally of lower energy, such as radiofrequency electromagnetic radiation ∞(Section 6.2), or slow-moving neutrons. Most living tissue contains at least 70% water by mass. When living tissue is irradiated, water molecules absorb most of the energy of the radiation. Thus, it is common to define ionizing radiation as radiation that can ionize water, a process requiring a minimum energy of 1216 kJ/mol. Alpha, beta, and gamma rays (as well as X-rays and higher-energy ultraviolet radiation) possess energies in excess of this quantity and are therefore forms of ionizing radiation.

When ionizing radiation passes through living tissue, electrons are removed from water molecules, forming highly reactive  $\text{H}_2\text{O}^+$  ions. An  $\text{H}_2\text{O}^+$  ion can react with another water molecule to form an  $\text{H}_3\text{O}^+$  ion and a neutral OH molecule:

The unstable and highly reactive OH molecule is a **free radical**, a substance with one or more unpaired electrons, as seen in the Lewis structure:  $\cdot\ddot{\text{O}}-\text{H}$ . The OH molecule is also called the hydroxyl radical. The presence of the unpaired electron is often emphasized by writing the species with a single dot,  $\cdot\text{OH}$ . In cells and tissues such particles can attack a host of surrounding biomolecules to produce new free radicals, which, in turn, attack yet other compounds. Thus, the formation of a single free radical can initiate a large number of chemical reactions that are ultimately able to disrupt the normal operations of cells.

The damage produced by radiation depends on the activity and energy of the radiation, the length of exposure, and whether the source is inside or outside the body. Gamma rays are particularly harmful outside the body because they penetrate human tissue very effectively, just as X-rays do. Consequently, their damage is not limited to the skin. In contrast, most alpha rays are stopped by skin, and beta rays are able to penetrate only about 1 cm beyond the surface of the skin (Figure 21.22▶). Neither is as dangerous as gamma rays, therefore, *unless*

▲ Figure 21.22 The relative penetrating abilities of alpha, beta, and gamma radiation.

TABLE 21.7 ■ Average Abundances and Activities of Natural Radionuclides\*

	Potassium-40	Rubidium-87	Thorium-232	Uranium-238

\*\*Includes lead-210 and polonium-210, daughter nuclei of uranium-238.

the radiation source somehow enters the body. Within the body, alpha rays are particularly dangerous because they transfer their energy efficiently to the surrounding tissue, initiating considerable damage.

In general, the tissues that show the greatest damage from radiation are those that reproduce rapidly, such as bone marrow, blood-forming tissues, and lymph nodes. The principal effect of extended exposure to low doses of radiation is to cause cancer. Cancer is caused by damage to the growth-regulation mechanism of cells, inducing cells to reproduce in an uncontrolled manner. Leukemia, which is characterized by excessive growth of white blood cells, is probably the major type of cancer caused by radiation.

In light of the biological effects of radiation, it is important to determine whether any levels of exposure are safe. Unfortunately, we are hampered in our attempts to set realistic standards because we do not fully understand the effects of long-term exposure to radiation. Scientists concerned with setting health standards have used the hypothesis that the effects of radiation are proportional to exposure, even down to low doses. Any amount of radiation is assumed to cause some finite risk of injury, and the effects of high dosage rates are extrapolated to those of lower ones. Other scientists believe, however, that there is a threshold below which there are no radiation risks. Until scientific evidence enables us to settle the matter with some confidence, it is safer to assume that even low levels of radiation present some danger.

**TABLE 21.8** ■ Effects of Short-Term Exposures to Radiation

Dose (rem)	Effect
0–25	No detectable clinical effects
25–50	Slight, temporary decrease in white blood cell counts
100–200	Nausea; marked decrease in white blood cells
500	Death of half the exposed population within 30 days after exposure

### Radiation Doses

Two units commonly used to measure the amount of exposure to radiation are the *gray* and the *rad*. The **gray** (Gy), which is the SI unit of absorbed dose, corresponds to the absorption of 1 J of energy per kilogram of tissue. The **rad** (radiation absorbed dose) corresponds to the absorption of  $1 \times 10^{-2}$  J of energy per kilogram of tissue. Thus, 1 Gy = 100 rads. The rad is the unit most often used in medicine.

Not all forms of radiation harm biological materials with the same efficiency. A rad of alpha radiation, for example, can produce more damage than a rad of beta radiation. To correct for these differences, the radiation dose is multiplied by a factor that measures the relative biological damage caused by the radiation.

This multiplication factor is known as the *relative biological effectiveness* of the radiation, abbreviated *RBE*. The RBE is approximately 1 for gamma and beta radiation, and 10 for alpha radiation. The exact value of the RBE varies with dose rate, total dose, and the type of tissue affected. The product of the radiation dose in rads and the RBE of the radiation gives the effective dosage in units of **rem** (roentgen equivalent for man):

$$\text{Number of rems} = (\text{number of rads}) (\text{RBE})$$

[21.32]

The SI unit for effective dosage is the sievert (Sv), obtained by multiplying the RBE times the SI unit for radiation dose, the gray; hence, 1 Sv = 100 rem. The rem is the unit

▲ **Figure 21.23** Sources of the average annual exposure of the U.S. population to high-energy radiation.

The total average annual exposure is 360 mrem. Data from "Ionizing Radiation Exposure of the Population of the United States," Report 93, 1987, National Council on Radiation Protection.

of radiation damage that is usually used in medicine.

The effects of short-term exposures to radiation appear in Table 21.8. An exposure of 600 rem is fatal to most humans. To put this number in perspective, a typical dental X-ray entails an exposure of about 0.5 mrem. The average exposure for a person in 1 year due to all natural sources of ionizing radiation (called *background radiation*) is about 360 mrem (Figure 21.23).

## Chemistry Put to Work ENVIRONMENTAL APPLICATIONS OF RADIOISOTOPES

Naturally occurring radioisotopes are of great value to environmental chemists, geologists, oceanographers, and ecologists. We have already seen how the relative amounts of carbon-14 in organic materials leads to estimates of their age, up to tens of thousands of years old. Different radioisotopes in other systems—layers of ocean sediment, gas bubbles trapped in the deep ice in the Arctic—can be used in a similar manner to track changes in the environment over shorter or longer time scales, depending on the half-life of the radionuclide.

For example, phosphorus-32 and phosphorus-33 are radioisotopes formed in the atmosphere from cosmic ray bombardment of argon gas. These phosphorus isotopes have half-lives of 14 days and 25 days, respectively. They enter the ocean in the form of rain. Chemical oceanographers can learn how phosphorus is distributed in the marine environment (as dissolved inorganic phosphates, as taken up by sea creatures, and so forth) and how rapidly it is distributed over the course of two months by measuring the relative amounts of these two isotopes.

Radon-222 is a naturally occurring gas that is a disintegration product of uranium-238, and therefore is far more abundant on land than at sea (Table 21.7). Figure 21.24 shows a map of Biscayne Bay, Florida, and the relative concentrations of radon-222 in units of disintegrations per minute per liter measured along the coast. The “hot spot” in red is evidence of an underground river that is discharging freshwater into the ocean. Results like this help scientists take into account more

and more features of the natural world to predict rates of change of salinity, temperature, nutrients, and many other interrelated parameters across our planet.

▲ **Figure 21.24** Map of radon-222 concentrations measured in Biscayne Bay, Florida. The concentrations are measured in units of disintegrations per minute per liter. Higher levels of activity are associated with water that has recently flowed from geological formations.

### Radon

The radioactive noble gas radon has been much publicized in recent years as a potential risk to health. Radon-222 is a product of the nuclear disintegration series of uranium-238 (Figure 21.5) and is continually generated as uranium in rocks and soil decays. As Figure 21.23 indicates, radon exposure is estimated to account for more than half the 360-mrem average annual exposure to ionizing radiation.

The interplay between the chemical and nuclear properties of radon makes it a health hazard. Because radon is a noble gas, it is extremely unreactive and is therefore free to escape from the ground without chemically reacting along the way. It is readily inhaled and exhaled with no direct chemical effects. The half-life of  $^{222}\text{Rn}$ , however, is only 3.82 days. It decays, by losing an alpha particle, into a radioisotope of polonium:

Because radon has such a short half-life and alpha particles have a high RBE, inhaled radon is considered a probable cause of lung cancer. Even worse, however, is the decay product, polonium-218, which is an alpha-emitting chemically active element that has an even shorter half-life (3.11 min) than radon-222:

The atoms of polonium-218 can become trapped in the lungs, where they bathe the delicate tissue with harmful alpha radiation. The resulting damage is estimated to contribute to 10% of all lung cancer deaths in the United States.

The U.S. Environmental Protection Agency (EPA) has recommended that radon-222 levels not exceed 4 pCi per liter of air in homes. Homes located in areas where the natural uranium content of the soil is high often have levels much greater than that. Because of public awareness, radon-testing kits are readily available in many parts of the country (Figure 21.25).

▲ **Figure 21.25** Radon home-testing kit. Kits such as this are available for measuring radon levels in the home.

**Chemistry and Life** RADIATION THERAPY

High-energy radiation poses a health hazard because of the damage it does to cells. Healthy cells are either destroyed or damaged by radiation, leading to physiological disorders. Radiation can also destroy *unhealthy* cells, however, including cancerous cells. All cancers are characterized by the runaway growth of abnormal cells. This growth can produce masses of abnormal tissue, called *malignant tumors*. Malignant tumors can be caused by the exposure of healthy cells to high-energy radiation. Somewhat paradoxically, however, malignant tumors can be destroyed by exposing them to the same radiation that caused them, because rapidly reproducing cells are very susceptible to radiation damage. Thus, cancerous cells are more susceptible to destruction by radiation than healthy ones, allowing radiation to be used effectively in the treatment of cancer. As early as 1904, physicians attempted to use the radiation emitted by radioactive substances to treat tumors by destroying the mass of unhealthy tissue. The treatment of disease by high-energy radiation is called *radiation therapy*.

Many different radionuclides are currently used in radiation therapy. Some of the more commonly used ones are listed in Table 21.9, along with their half-lives. Most of the half-lives are quite short, meaning that these radioisotopes emit a great deal of radiation in a short period of time.

The radiation source used in radiation therapy may be inside or outside the body. In almost all cases radiation therapy is designed to use the high-energy gamma radiation emitted by radioisotopes. Alpha and beta radiation, which are not as penetrating as gamma radiation, can be blocked by appropriate packaging. For example,  $^{192}\text{Ir}$  is often administered as “seeds” consisting of a core of radioactive isotope

coated with 0.1 mm of platinum metal. The platinum coating stops the alpha and beta rays, but the gamma rays penetrate it readily. The radioactive seeds can be surgically implanted in a tumor. In other cases human physiology allows the radioisotope to be ingested. For example, most of the iodine in the human body ends up in the thyroid gland, so thyroid cancer can be treated by using large doses of  $^{131}\text{I}$ . Radiation therapy on deep organs, where a surgical implant is impractical, often uses a  $^{60}\text{Co}$  “gun” outside the body to shoot a beam of gamma rays at the tumor. Particle accelerators are also used as an external source of high-energy radiation for radiation therapy.

Because gamma radiation is so strongly penetrating, it is nearly impossible to avoid damaging healthy cells during radiation therapy. Many cancer patients undergoing radiation treatment experience unpleasant and dangerous side effects such as fatigue, nausea, hair loss, a weakened immune system, and occasionally even death; but if other treatments such as *chemotherapy* (the use of drugs to combat cancer) fail, radiation therapy is a good option.

**TABLE 21.9** ■ Some Radioisotopes Used in Radiation Therapy

Isotope	Half-life	Isotope	Half-life
$^{32}\text{P}$	14.3 days	$^{137}\text{Cs}$	30 yr
$^{60}\text{Co}$	5.27 yr	$^{192}\text{Ir}$	74.2 days
$^{90}\text{Sr}$	28.8 yr	$^{198}\text{Au}$	2.7 days
$^{125}\text{I}$	60.25 days	$^{222}\text{Rn}$	3.82 days
$^{131}\text{I}$	8.04 days	$^{226}\text{Ra}$	1600 yr

**SAMPLE INTEGRATIVE EXERCISE** | Putting Concepts Together

Potassium ion is present in foods and is an essential nutrient in the human body. One of the naturally occurring isotopes of potassium, potassium-40, is radioactive. Potassium-40 has a natural abundance of 0.0117% and a half-life of  $t_{1/2} = 1.28 \times 10^9$  yr. It undergoes radioactive decay in three ways: 98.2% is by electron capture, 1.35% is by beta emission, and 0.49% is by positron emission. (a) Why should we expect  $^{40}\text{K}$  to be radioactive? (b) Write the nuclear equations for the three modes by which  $^{40}\text{K}$  decays. (c) How many  $^{40}\text{K}^+$  ions are present in 1.00 g of KCl? (d) How long does it take for 1.00% of the  $^{40}\text{K}$  in a sample to undergo radioactive decay?

**SOLUTION**

(a) The  $^{40}\text{K}$  nucleus contains 19 protons and 21 neutrons. There are very few stable nuclei with odd numbers of both protons and neutrons.  $\infty$  (Section 21.2).

(b) Electron capture is capture of an inner-shell electron ( ${}_{-1}^0\text{e}$ ) by the nucleus:

Beta emission is loss of a beta particle ( ${}_{-1}^0\text{e}$ ) by the nucleus:

Positron emission is loss of  ${}_{+1}^0\text{e}$  by the nucleus:

(c) The total number of  $K^+$  ions in the sample is

$$(1.00 \text{ g KCl}) \left( \frac{1 \text{ mol KCl}}{74.55 \text{ g KCl}} \right) \left( \frac{1 \text{ mol } K^+}{1 \text{ mol KCl}} \right) \left( \frac{6.022 \times 10^{23} K^+}{1 \text{ mol } K^+} \right) = 8.08 \times 10^{21} K^+ \text{ ions}$$

Of these, 0.0117% are  $^{40}K^+$  ions:

$$(8.08 \times 10^{21} K^+ \text{ ions}) \left( \frac{0.0117 \text{ } ^{40}K^+ \text{ ions}}{100 K^+ \text{ ions}} \right) = 9.45 \times 10^{17} \text{ } ^{40}K^+ \text{ ions}$$

(d) The decay constant (the rate constant) for the radioactive decay can be calculated from the half-life, using Equation 21.20:

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{1.28 \times 10^9 \text{ yr}} = (5.41 \times 10^{-10})/\text{yr}$$

The rate equation, Equation 21.19, then allows us to calculate the time required:

$$\begin{aligned} \ln \frac{N_t}{N_0} &= -kt \\ \ln \frac{99}{100} &= -((5.41 \times 10^{-10})/\text{yr})t \\ -0.01005 &= -((5.41 \times 10^{-10})/\text{yr})t \\ t &= \frac{-0.01005}{(-5.41 \times 10^{-10})/\text{yr}} = 1.86 \times 10^7 \text{ yr} \end{aligned}$$

That is, it would take 18.6 million years for just 1.00% of the  $^{40}K$  in a sample to decay.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 21.1** The nucleus contains protons and neutrons, both of which are called **nucleons**. Nuclei that are **radioactive** spontaneously emit radiation. These radioactive nuclei are called **radionuclides**, and the atoms containing them are called **radioisotopes**. When a radionuclide decomposes, it is said to undergo radioactive decay. In nuclear equations, reactant and product nuclei are represented by giving their mass numbers and atomic numbers, as well as their chemical symbol. The totals of the mass numbers on both sides of the equation are equal; the totals of the atomic numbers on both sides are also equal. There are five common kinds of radioactive decay: emission of **alpha ( $\alpha$ ) particles** ( $^4_2\text{He}$ ), emission of **beta ( $\beta$ ) particles** ( $^0_{-1}\text{e}$ ), **positron emission** ( $^0_1\text{e}$ ), **electron capture**, and emission of **gamma ( $\gamma$ ) radiation** ( $^0_0\gamma$ ).

**Section 21.2** The neutron-to-proton ratio is an important factor determining nuclear stability. By comparing a nuclide's neutron-to-proton ratio with those in the band of stability, we can predict the mode of radioactive decay. In general, neutron-rich nuclei tend to emit beta particles; proton-rich nuclei tend to either emit positrons or undergo

electron capture; and heavy nuclei tend to emit alpha particles. The presence of **magic numbers** of nucleons and an even number of protons and neutrons also help determine the stability of a nucleus. A nuclide may undergo a series of decay steps before a stable nuclide forms. This series of steps is called a **radioactive series**, or a **nuclear disintegration series**.

**Section 21.3 Nuclear transmutations**, induced conversions of one nucleus into another, can be brought about by bombarding nuclei with either charged particles or neutrons. **Particle accelerators** increase the kinetic energies of positively charged particles, allowing these particles to overcome their electrostatic repulsion by the nucleus. Nuclear transmutations are used to produce the **transuranium elements**, those elements with atomic numbers greater than that of uranium.

**Sections 21.4 and 21.5** The SI unit for the activity of a radioactive source is the **becquerel (Bq)**, defined as one nuclear disintegration per second. A related unit, the **curie (Ci)**, corresponds to  $3.7 \times 10^{10}$  disintegrations per second.

Nuclear decay is a first-order process. The decay rate (**activity**) is therefore proportional to the number of radioactive nuclei, and radionuclides have constant **half-lives**. Some can therefore be used to date objects;  $^{14}\text{C}$ , for example, is used to date organic objects. Geiger counters and scintillation counters count the emissions from radioactive samples. The ease of detection of radioisotopes also permits their use as **radiotracers**, to follow elements through their reactions.

**Section 21.6** The energy produced in nuclear reactions is accompanied by measurable losses of mass in accordance with Einstein's relationship,  $\Delta E = c^2 \Delta m$ . The difference in mass between nuclei and the nucleons of which they are composed is known as the **mass defect**. The mass defect of a nuclide makes it possible to calculate its **nuclear binding energy**, the energy required to separate the nucleus into individual nucleons. Energy is produced when heavy nuclei split (**fission**) and when light nuclei fuse (**fusion**).

**Sections 21.7 and 21.8** Uranium-235, uranium-233, and plutonium-239 undergo fission when they capture a neutron. The resulting nuclear reaction is a **nuclear chain reaction**, a reaction in which the neutrons produced in one fission cause further fission reactions. A reaction that maintains a constant rate is said to be critical, and the mass necessary to maintain this constant rate is called a **critical mass**. A mass in excess of the critical mass is termed a **supercritical mass**. In nuclear reactors the fission rate is controlled to generate a constant power.

The reactor core consists of fissionable fuel, control rods, a moderator, and cooling fluid. The nuclear power plant resembles a conventional power plant except that the reactor core replaces the fuel burner. There is concern about the disposal of highly radioactive nuclear wastes that are generated in nuclear power plants.

Nuclear fusion requires high temperatures because nuclei must have large kinetic energies to overcome their mutual repulsions. Fusion reactions are therefore called **thermonuclear reactions**. It is not yet possible to generate a controlled fusion process.

**Section 21.9** **Ionizing radiation** is energetic enough to remove an electron from a water molecule; radiation with less energy is called **nonionizing radiation**. Ionizing radiation generates **free radicals**, reactive substances with one or more unpaired electrons. The effects of long-term exposure to low levels of radiation are not completely understood, but it is usually assumed that the extent of biological damage varies in direct proportion to the level of exposure.

The amount of energy deposited in biological tissue by radiation is called the radiation dose and is measured in units of grays or rads. One **gray** (Gy) corresponds to a dose of 1 J/kg of tissue. The **rad** is a smaller unit; 100 rads = 1 Gy. The effective dose, which measures the biological damage created by the deposited energy, is measured in units of rems or sieverts (Sv). The **rem** is obtained by multiplying the number of rads by the relative biological effectiveness (RBE); 100 rem = 1 Sv.

## KEY SKILLS

- Write balanced nuclear equations.
- Know the difference between fission and fusion.
- Predict nuclear stability in terms of neutron-to-proton ratio.
- Calculate ages of objects or amounts of material from data on nucleon abundances using the half-life of a radioactive material.
- Convert between nuclear activity units.
- Calculate mass and energy changes for nuclear reactions.
- Understand the meaning of radiation dosage terms.
- Understand the biological effects of different kinds of radiation.

## KEY EQUATIONS

- $\ln \frac{N_t}{N_0} = -kt$  [21.19] First-order rate law for nuclear decay
- $k = \frac{0.693}{t_{1/2}}$  [21.20] Relationship between nuclear decay constant and half-life; this is derived from the previous equation at  $N_t = (1/2)N_0$
- $E = mc^2$  [21.22] Einstein's equation that relates mass and energy

## VISUALIZING CONCEPTS

- 21.1** Indicate whether each of the following nuclides lies within the belt of stability in Figure 21.3: (a) neon-24, (b) chlorine-32, (c) tin-108, (d) polonium-216. For any that do not, describe a nuclear decay process that would alter the neutron-to-proton ratio in the direction of increased stability. [Section 21.2]
- 21.2** Write the balanced nuclear equation for the reaction represented by the diagram shown here. [Section 21.2]

- 21.3** Draw a diagram similar to that shown in Exercise 21.2 that illustrates the nuclear reaction  ${}_{83}^{211}\text{Bi} \rightarrow {}_2^4\text{He} + {}_{81}^{207}\text{Tl}$ . [Section 21.2]
- 21.4** The accompanying graph illustrates the decay of  ${}_{42}^{88}\text{Mo}$ , which decays via positron emission. (a) What is the half-life of the decay? (b) What is the rate constant for the decay? (c) What fraction of the original sample of  ${}_{42}^{88}\text{Mo}$  remains after 12 minutes? (d) What is the product of the decay process? [Section 21.4]

- 21.5** A  ${}_{44}^{100}\text{Ru}$  atom has a mass of 99.90422 amu. (a) Why is the mass of this nuclide not much closer to 100? (b) Explain the observed mass using Figure 21.13. (c) Calculate the binding energy per nucleon for  ${}_{44}^{100}\text{Ru}$ . [Section 21.6]
- 21.6** The diagram shown below illustrates a fission process. (a) What is the second nuclear product of the fission? (b) Use Figure 21.3 to predict whether the nuclear products of this fission reaction are stable. [Section 21.7]

## EXERCISES

## Radioactivity

- 21.7** Indicate the number of protons and neutrons in the following nuclei: (a)  ${}_{25}^{55}\text{Mn}$ , (b)  ${}^{201}\text{Hg}$ , (c) potassium-39.
- 21.8** Indicate the number of protons and neutrons in the following nuclei: (a)  ${}_{55}^{136}\text{Cs}$ , (b)  ${}^{119}\text{Sn}$ , (c) barium-141.
- 21.9** Give the symbol for (a) a neutron, (b) an alpha particle, (c) gamma radiation.
- 21.10** Give the symbol for (a) a proton, (b) a beta particle, (c) a positron.
- 21.11** Write balanced nuclear equations for the following processes: (a) rubidium-90 undergoes beta decay; (b) selenium-72 undergoes electron capture; (c) krypton-76 undergoes positron emission; (d) radium-226 emits alpha radiation.
- 21.12** Write balanced nuclear equations for the following transformations: (a) gold-191 undergoes electron capture; (b) gold-201 decays to a mercury isotope; (c) gold-198 undergoes beta decay; (d) gold-188 decays by positron emission.
- 21.13** Decay of which nucleus will lead to the following products: (a) bismuth-211 by beta decay; (b) chromium-50 by positron emission; (c) tantalum-179 by electron capture; (d) radium-226 by alpha decay?
- 21.14** What particle is produced during the following decay processes: (a) sodium-24 decays to magnesium-24; (b) mercury-188 decays to gold-188; (c) iodine-122 decays to xenon-122; (d) plutonium-242 decays to uranium-238?
- 21.15** The naturally occurring radioactive decay series that begins with  ${}^{235}\text{U}$  stops with formation of the stable  ${}_{82}^{207}\text{Pb}$  nucleus. The decays proceed through a series of alpha-particle and beta-particle emissions. How many of each type of emission are involved in this series?
- 21.16** A radioactive decay series that begins with  ${}^{235}_{90}\text{Th}$  ends with formation of the stable nuclide  ${}_{82}^{208}\text{Pb}$ . How many alpha-particle emissions and how many beta-particle emissions are involved in the sequence of radioactive decays?

## Nuclear Stability

- 21.17** Predict the type of radioactive decay process for the following radionuclides: (a)  ${}^8_5\text{B}$ , (b)  ${}^{66}_{29}\text{Cu}$ , (c) phosphorus-32, (d) chlorine-39.
- 21.18** Each of the following nuclei undergoes either beta or positron emission. Predict the type of emission for each: (a)  ${}^{66}_{32}\text{Ge}$ , (b)  ${}^{105}_{45}\text{Rh}$ , (c) iodine-137, (d) cerium-133.
- 21.19** One of the nuclides in each of the following pairs is radioactive. Predict which is radioactive and which is stable: (a)  ${}^{39}_{19}\text{K}$  and  ${}^{40}_{19}\text{K}$ , (b)  ${}^{209}_{83}\text{Bi}$  and  ${}^{208}_{83}\text{Bi}$ , (c) nickel-58 and nickel-65. Explain.
- 21.20** In each of the following pairs, which nuclide would you expect to be the more abundant in nature: (a)  ${}^{115}_{48}\text{Cd}$  or  ${}^{112}_{48}\text{Cd}$ , (b)  ${}^{30}_{13}\text{Al}$  or  ${}^{27}_{13}\text{Al}$ , (c) palladium-106 or palladium-113, (d) xenon-128 or cesium-128? Justify your choices.
- 21.21** Which of the following nuclides have magic numbers of both protons and neutrons: (a) helium-4, (b) oxygen-18, (c) calcium-40, (d) zinc-66, (e) lead-208?
- 21.22** Tin has 10 stable isotopes, but antimony only has two. How can we explain this difference?
- 21.23** Using the concept of magic numbers, explain why alpha emission is relatively common, but proton emission is nonexistent.
- 21.24** Which of the following nuclides would you expect to be radioactive:  ${}^{62}_{28}\text{Ni}$ ,  ${}^{58}_{29}\text{Cu}$ ,  ${}^{108}_{47}\text{Ag}$ , tungsten-184, polonium-206? Justify your choices.

## Nuclear Transmutations

- 21.25** Why are nuclear transmutations involving neutrons generally easier to accomplish than those involving protons or alpha particles?
- 21.26** Rutherford was able to carry out the first nuclear transmutation reactions by bombarding nitrogen-14 nuclei with alpha particles. In the famous experiment on scattering of alpha particles by gold foil (Section 2.2), however, a nuclear transmutation reaction did not occur. What is the difference between the two experiments? What would one need to do to carry out a successful nuclear transmutation reaction involving gold nuclei and alpha particles?
- 21.27** Complete and balance the following nuclear equations by supplying the missing particle:
- (a)  ${}^{252}_{98}\text{Cf} + {}^{10}_{0}\text{n} \longrightarrow 3 {}^1_0\text{n} + ?$   
 (b)  ${}^1_1\text{H} + {}^3_2\text{He} \longrightarrow {}^4_2\text{He} + ?$
- (c)  ${}^1_1\text{H} + {}^1_1\text{B} \longrightarrow 3 ?$   
 (d)  ${}^{122}_{53}\text{I} \longrightarrow {}^{122}_{54}\text{Xe} + ?$   
 (e)  ${}^{52}_{26}\text{Fe} \longrightarrow {}^0_{-1}\text{e} + ?$
- 21.28** Complete and balance the following nuclear equations by supplying the missing particle:
- (a)  ${}^{32}_{16}\text{S} + {}^1_0\text{n} \longrightarrow {}^1_1\text{p} + ?$   
 (b)  ${}^4_2\text{He} + {}^0_{-1}\text{e}$  (orbital electron)  $\longrightarrow ?$   
 (c)  $? \longrightarrow {}^{187}_{7}\text{Os} + {}^0_{-1}\text{e}$   
 (d)  ${}^{98}_{42}\text{Mo} + {}^1_1\text{H} \longrightarrow {}^1_0\text{n} + ?$   
 (e)  ${}^{235}_{92}\text{U} + {}^1_0\text{n} \longrightarrow {}^{135}_{54}\text{Xe} + 2 {}^1_0\text{n} + ?$
- 21.29** Write balanced equations for (a)  ${}^{238}_{92}\text{U}(\alpha, \text{n}){}^{241}_{94}\text{Pu}$ , (b)  ${}^{14}_7\text{N}(\alpha, \text{p}){}^{17}_8\text{O}$ , (c)  ${}^{56}_{26}\text{Fe}(\alpha, \beta){}^{60}_{29}\text{Cu}$ .
- 21.30** Write balanced equations for each of the following nuclear reactions: (a)  ${}^{238}_{92}\text{U}(\text{n}, \gamma){}^{239}_{92}\text{U}$ , (b)  ${}^{14}_7\text{N}(\text{p}, \alpha){}^{11}_6\text{C}$ , (c)  ${}^{18}_8\text{O}(\text{n}, \beta){}^{19}_8\text{F}$ .

## Rates of Radioactive Decay

- 21.31** Each statement below refers to a comparison between two radioisotopes, A and X. Indicate whether each of the following statements is true or false, and why.
- (a) If the half-life for A is shorter than the half-life for X, A has a larger decay rate constant.  
 (b) If X is "not radioactive," its half-life is essentially zero.  
 (c) If A has a half-life of 10 years, and X has a half-life of 10,000 years, A would be a more suitable radioisotope to measure processes occurring on the 40-year time scale.
- 21.32** It has been suggested that strontium-90 (generated by nuclear testing) deposited in the hot desert will undergo radioactive decay more rapidly because it will be exposed to much higher average temperatures. (a) Is this a reasonable suggestion? (b) Does the process of radioactive decay have an activation energy, like the Arrhenius behavior of many chemical reactions [∞∞](#)(Section 14.5)? Discuss.
- 21.33** The half-life of tritium (hydrogen-3) is 12.3 yr. If 56.2 mg of tritium is released from a nuclear power plant during the course of an accident, what mass of this nuclide will remain after 12.3 yr? After 100 yr?
- 21.34** It takes 5.2 minutes for a 1.000-g sample of  ${}^{210}\text{Fr}$  to decay to 0.250 g. What is the half-life of  ${}^{210}\text{Fr}$ ?
- 21.35** Cobalt-60 is a strong gamma emitter that has a half-life of 5.26 yr. The cobalt-60 in a radiotherapy unit must be replaced when its radioactivity falls to 75% of the original sample. (a) If an original sample was purchased in June 2006, when will it be necessary to replace the cobalt-60? (b) How can you store cobalt-60 so that it is safe to handle?
- 21.36** How much time is required for a 6.25-mg sample of  ${}^{51}\text{Cr}$  to decay to 0.75 mg if it has a half-life of 27.8 days?
- [21.37]** Radium-226, which undergoes alpha decay, has a half-life of 1600 yr. (a) How many alpha particles are emitted in 5.0 min by a 10.0-mg sample of  ${}^{226}\text{Ra}$ ? (b) What is the activity of the sample in mCi?

- [21.38] Cobalt-60, which undergoes beta decay, has a half-life of 5.26 yr. (a) How many beta particles are emitted in 180 s by a 3.75-mg sample of  $^{60}\text{Co}$ ? (b) What is the activity of the sample in Bq?
- 21.39 The cloth shroud from around a mummy is found to have a  $^{14}\text{C}$  activity of 9.7 disintegrations per minute per gram of carbon as compared with living organisms that undergo 16.3 disintegrations per minute per gram of carbon. From the half-life for  $^{14}\text{C}$  decay, 5715 yr, calculate the age of the shroud.
- 21.40 A wooden artifact from a Chinese temple has a  $^{14}\text{C}$  activity of 38.0 counts per minute as compared with an activity of 58.2 counts per minute for a standard of zero age. From the half-life for  $^{14}\text{C}$  decay, 5715 yr, determine the age of the artifact.
- 21.41 Potassium-40 decays to argon-40 with a half-life of  $1.27 \times 10^9$  yr. What is the age of a rock in which the mass ratio of  $^{40}\text{Ar}$  to  $^{40}\text{K}$  is 4.2?
- 21.42 The half-life for the process  $^{238}\text{U} \longrightarrow ^{206}\text{Pb}$  is  $4.5 \times 10^9$  yr. A mineral sample contains 75.0 mg of  $^{238}\text{U}$  and 18.0 mg of  $^{206}\text{Pb}$ . What is the age of the mineral?

## Energy Changes

- 21.43 The thermite reaction,  $\text{Fe}_2\text{O}_3(\text{s}) + 2 \text{Al}(\text{s}) \longrightarrow 2 \text{Fe}(\text{s}) + \text{Al}_2\text{O}_3(\text{s})$ , is one of the most exothermic reactions known. The heat released is sufficient to melt the iron product; consequently, the thermite reaction is used to weld metal under the ocean.  $\Delta H^\circ$  for the thermite reaction is  $-851.5$  kJ/mole. What is the mass change per mole of  $\text{Fe}_2\text{O}_3$  that accompanies this reaction?
- 21.44 An analytical laboratory balance typically measures mass to the nearest 0.1 mg. What energy change would accompany the loss of 0.1 mg in mass?
- 21.45 How much energy must be supplied to break a single aluminum-27 nucleus into separated protons and neutrons if an aluminum-27 atom has a mass of 26.9815386 amu? How much energy is required for 100.0 grams of aluminum-27? (The mass of an electron is given on the inside back cover.)
- 21.46 How much energy must be supplied to break a single  $^{21}\text{Ne}$  nucleus into separated protons and neutrons if the nucleus has a mass of 20.98846 amu? What is the nuclear binding energy for 1 mol of  $^{21}\text{Ne}$ ?
- 21.47 Calculate the binding energy per nucleon for the following nuclei: (a)  $^{12}_6\text{C}$  (nuclear mass, 11.996708 amu); (b)  $^{37}_{17}\text{Cl}$  (nuclear mass, 36.956576 amu); (c) rhodium-103 (atomic mass, 102.905504 amu).
- 21.48 Calculate the binding energy per nucleon for the following nuclei: (a)  $^{14}_7\text{N}$  (nuclear mass, 13.999234 amu); (b)  $^{48}_{22}\text{Ti}$  (nuclear mass, 47.935878 amu); (c) xenon-129 (atomic mass, 128.904779 amu).
- 21.49 The energy from solar radiation falling on Earth is  $1.07 \times 10^{16}$  kJ/min. (a) How much loss of mass from the Sun occurs in one day from just the energy falling on Earth? (b) If the energy released in the reaction
- $$^{235}\text{U} + \frac{1}{0}\text{n} \longrightarrow \frac{141}{54}\text{Ba} + \frac{92}{36}\text{Kr} + 3 \frac{1}{0}\text{n}$$
- ( $^{235}\text{U}$  nuclear mass, 234.9935 amu;  $^{141}\text{Ba}$  nuclear mass, 140.8833 amu;  $^{92}\text{Kr}$  nuclear mass, 91.9021 amu) is taken as typical of that occurring in a nuclear reactor, what mass of uranium-235 is required to equal 0.10% of the solar energy that falls on Earth in 1.0 day?
- 21.50 Based on the following atomic mass values— $^1\text{H}$ , 1.00782 amu;  $^2\text{H}$ , 2.01410 amu;  $^3\text{H}$ , 3.01605 amu;  $^3\text{He}$ , 3.01603 amu;  $^4\text{He}$ , 4.00260 amu—and the mass of the neutron given in the text, calculate the energy released per mole in each of the following nuclear reactions, all of which are possibilities for a controlled fusion process:
- (a)  $^2_1\text{H} + ^3_1\text{H} \longrightarrow ^4_2\text{He} + \frac{1}{0}\text{n}$   
 (b)  $^2_1\text{H} + ^2_1\text{H} \longrightarrow ^3_2\text{He} + \frac{1}{0}\text{n}$   
 (c)  $^2_1\text{H} + ^3_2\text{He} \longrightarrow ^4_2\text{He} + \frac{1}{1}\text{H}$
- 21.51 Which of the following nuclei is likely to have the largest mass defect per nucleon: (a)  $^{59}\text{Co}$ , (b)  $^{11}\text{B}$ , (c)  $^{118}\text{Sn}$ , (d)  $^{243}\text{Cm}$ ? Explain your answer.
- 21.52 Based on Figure 21.13, what is the most stable nucleus in the periodic table?

## Effects and Uses of Radioisotopes

- 21.53 Iodine-131 is a convenient radioisotope to monitor thyroid activity in humans. It is a beta emitter with a half-life of 8.02 days. The thyroid is the only gland in the body that uses iodine. A person undergoing a test of thyroid activity drinks a solution of NaI, in which only a small fraction of the iodide is radioactive. (a) Why is NaI a good choice for the source of iodine? (b) If a Geiger counter is placed near the person's thyroid (which is near the neck) right after the sodium iodide solution is taken, what will the data look like as a function of time? (c) A normal thyroid will take up about 12% of the ingested iodide in a few hours. How long will it take for the radioactive iodide taken up and held by the thyroid to decay to 0.01% of the original amount?
- 21.54 Chlorine-36 is a convenient radiotracer. It is a weak beta emitter, with  $t_{1/2} = 3 \times 10^5$  yr. Describe how you would use this radiotracer to carry out each of the following experiments. (a) Determine whether trichloroacetic acid,  $\text{CCl}_3\text{COOH}$ , undergoes any ionization of its chlorines as chloride ion in aqueous solution. (b) Demonstrate that the equilibrium between dissolved  $\text{BaCl}_2$  and solid  $\text{BaCl}_2$  in a saturated solution is a dynamic process. (c) Determine the effects of soil pH on the uptake of chloride ion from the soil by soybeans.
- 21.55 Explain the following terms that apply to fission reactions: (a) chain reaction, (b) critical mass.
- 21.56 Explain the function of the following components of a nuclear reactor: (a) control rods, (b) moderator.

- 21.57** Complete and balance the nuclear equations for the following fission or fusion reactions:  
 (a)  ${}^2_1\text{H} + {}^2_1\text{H} \longrightarrow {}^3_2\text{He} + \text{---}$   
 (b)  ${}^{235}_{92}\text{U} + {}^1_0\text{n} \longrightarrow {}^{133}_{51}\text{Sb} + {}^{98}_{41}\text{Nb} + \text{--- } {}^1_0\text{n}$
- 21.58** Complete and balance the nuclear equations for the following fission reactions:  
 (a)  ${}^{235}_{92}\text{U} + {}^1_0\text{n} \longrightarrow {}^{160}_{62}\text{Sm} + {}^{72}_{30}\text{Zn} + \text{--- } {}^1_0\text{n}$   
 (b)  ${}^{239}_{94}\text{Pu} + {}^1_0\text{n} \longrightarrow {}^{144}_{58}\text{Ce} + \text{---} + 2 {}^1_0\text{n}$
- 21.59** A portion of the Sun's energy comes from the reaction  

$$4 {}^1_1\text{H} \longrightarrow {}^4_2\text{He} + 2 {}^0_1\text{e}$$
 This reaction requires a temperature of about  $10^6$  to  $10^7\text{K}$ .  
 (a) Why is such a high temperature required? (b) Is the Sun solid?
- [21.60]** The spent fuel rods from a fission reactor are much more intensely radioactive than the original fuel rods.  
 (a) What does this tell you about the products of the fission process in relationship to the belt of stability, Figure 21.3? (b) Given that only two or three neutrons are released per fission event and knowing that the nucleus undergoing fission has a neutron-to-proton ratio characteristic of a heavy nucleus, what sorts of decay would you expect to be dominant among the fission products?
- 21.61** Hydroxyl radicals can pluck hydrogen atoms from molecules ("hydrogen abstraction"), and hydroxide ions can pluck protons from molecules ("deprotonation"). Write the reaction equations and Lewis dot structures

for the hydrogen abstraction and deprotonation reactions for the generic carboxylic acid  $\text{R-COOH}$  with hydroxyl radical and hydroxide ion, respectively. Why is hydroxyl radical more toxic to living systems than hydroxide ion?

- 21.62** Use Lewis structures to represent the reactants and products in Equation 21.31. Why is the  $\text{H}_2\text{O}^+$  ion a free radical species?
- 21.63** A laboratory rat is exposed to an alpha-radiation source whose activity is 14.3 mCi. (a) What is the activity of the radiation in disintegrations per second? In becquerels? (b) The rat has a mass of 385 g and is exposed to the radiation for 14.0 s, absorbing 35% of the emitted alpha particles, each having an energy of  $9.12 \times 10^{-13}\text{J}$ . Calculate the absorbed dose in millirads and grays. (c) If the RBE of the radiation is 9.5, calculate the effective absorbed dose in mrem and Sv.
- 21.64** A 65-kg person is accidentally exposed for 240 s to a 15-mCi source of beta radiation coming from a sample of  ${}^{90}\text{Sr}$ . (a) What is the activity of the radiation source in disintegrations per second? In becquerels? (b) Each beta particle has an energy of  $8.75 \times 10^{-14}\text{J}$ , and 7.5% of the radiation is absorbed by the person. Assuming that the absorbed radiation is spread over the person's entire body, calculate the absorbed dose in rads and in grays. (c) If the RBE of the beta particles is 1.0, what is the effective dose in mrem and in sieverts? (d) How does the magnitude of this dose of radiation compare with that of a mammogram (300 mrem)?

## ADDITIONAL EXERCISES

- 21.65** Radon-222 decays to a stable nucleus by a series of three alpha emissions and two beta emissions. What is the stable nucleus that is formed?
- 21.66** A free neutron is unstable and decays into a proton with a half-life of 10.4 min. (a) What other particle forms? (b) Why don't neutrons in atomic nuclei decay at the same rate?
- 21.67** Americium-241 is an alpha emitter used in smoke detectors. The alpha radiation ionizes molecules in an air-filled gap between two electrodes in the smoke detector, leading to current. When smoke is present, the ionized molecules bind to smoke particles and the current decreases; when the current is reduced sufficiently, an alarm sounds.  
 (a) Write the nuclear equation corresponding to the alpha decay of americium-241. (b) Why is an alpha emitter a better choice than a gamma emitter for a smoke detector? (c) In a commercial smoke detector, only 0.2 micrograms of americium are present. Calculate the energy that is equivalent to the mass loss of this amount of americium due to alpha radiation. The atomic mass of americium-241 is 241.056829 amu. (d) The half-life of americium-241 is 432 years; the half life of americium-240 is 2.12 days. Why is the 241 isotope a better choice for a smoke detector?
- 21.68** Chlorine has two stable nuclides,  ${}^{35}\text{Cl}$  and  ${}^{37}\text{Cl}$ . In contrast,  ${}^{36}\text{Cl}$  is a radioactive nuclide that decays by beta emission. (a) What is the product of decay of  ${}^{36}\text{Cl}$ ? (b) Based on the empirical rules about nuclear stability, explain why the nucleus of  ${}^{36}\text{Cl}$  is less stable than either  ${}^{35}\text{Cl}$  or  ${}^{37}\text{Cl}$ .
- 21.69** Nuclear scientists have synthesized approximately 1600 nuclei not known in nature. More might be discovered with heavy-ion bombardment using high-energy particle accelerators. Complete and balance the following reactions, which involve heavy-ion bombardments:  
 (a)  ${}^6_3\text{Li} + {}^{56}_{28}\text{Ni} \longrightarrow ?$   
 (b)  ${}^{40}_{20}\text{Ca} + {}^{248}_{96}\text{Cm} \longrightarrow {}^{142}_{62}\text{Sm} + ?$   
 (c)  ${}^{88}_{38}\text{Sr} + {}^{84}_{36}\text{Kr} \longrightarrow {}^{116}_{46}\text{Pd} + ?$   
 (d)  ${}^{40}_{20}\text{Ca} + {}^{238}_{92}\text{U} \longrightarrow {}^{70}_{30}\text{Zn} + 4 {}^1_0\text{n} + 2?$
- [21.70]** The synthetic radioisotope technetium-99, which decays by beta emission, is the most widely used isotope in nuclear medicine. The following data were collected on a sample of  ${}^{99}\text{Tc}$ :

Disintegrations per Minute	Time (h)
180	0
130	2.5
104	5.0
77	7.5
59	10.0
46	12.5
24	17.5

Using these data, make an appropriate graph and curve fit to determine the half-life.

- [21.71] According to current regulations, the maximum permissible dose of strontium-90 in the body of an adult is  $1 \mu\text{Ci}$  ( $1 \times 10^{-6} \text{Ci}$ ). Using the relationship  $\text{rate} = kN$ , calculate the number of atoms of strontium-90 to which this dose corresponds. To what mass of strontium-90 does this correspond? The half-life for strontium-90 is 28.8 yr.
- [21.72] Suppose you had a detection device that could count every decay event from a radioactive sample of plutonium-239 ( $t_{1/2}$  is 24,000 yr). How many counts per second would you obtain from a sample containing 0.385 g of plutonium-239?
- 21.73 Methyl acetate ( $\text{CH}_3\text{COOCH}_3$ ) is formed by the reaction of acetic acid with methyl alcohol. If the methyl alcohol is labeled with oxygen-18, the oxygen-18 ends up in the methyl acetate:
- $$\text{CH}_3\overset{\text{O}}{\parallel}\text{COH} + \text{H}^{18}\text{OCH}_3 \longrightarrow \text{CH}_3\overset{\text{O}}{\parallel}\text{C}^{18}\text{OCH}_3 + \text{H}_2\text{O}$$
- Do the C—OH bond of the acid and the O—H bond of the alcohol break in the reaction, or do the O—H bond of the acid and the C—OH bond of the alcohol break? Explain.
- 21.74 An experiment was designed to determine whether an aquatic plant absorbed iodide ion from water. Iodine-131 ( $t_{1/2} = 8.02$  days) was added as a tracer, in the form of iodide ion, to a tank containing the plants. The initial activity of a  $1.00\text{-}\mu\text{L}$  sample of the water was 214 counts per minute. After 30 days the level of activity in a  $1.00\text{-}\mu\text{L}$  sample was 15.7 counts per minute. Did the plants absorb iodide from the water? Explain.
- 21.75 The nuclear masses of  ${}^7\text{Be}$ ,  ${}^9\text{Be}$ , and  ${}^{10}\text{Be}$  are 7.0147, 9.0100, and 10.0113 amu, respectively. Which of these nuclei has the largest binding energy per nucleon?
- [21.76] A 26.00-g sample of water containing tritium,  ${}^3\text{H}$ , emits  $1.50 \times 10^3$  beta particles per second. Tritium is a weak beta emitter, with a half-life of 12.3 yr. What fraction of all the hydrogen in the water sample is tritium?
- 21.77 The Sun radiates energy into space at the rate of  $3.9 \times 10^{26} \text{J/s}$ . (a) Calculate the rate of mass loss from the Sun in kg/s. (b) How does this mass loss arise? (c) It is estimated that the Sun contains  $9 \times 10^{56}$  free protons. How many protons per second are consumed in nuclear reactions in the Sun?
- [21.78] The average energy released in the fission of a single uranium-235 nucleus is about  $3 \times 10^{-11} \text{J}$ . If the conversion of this energy to electricity in a nuclear power plant is 40% efficient, what mass of uranium-235 undergoes fission in a year in a plant that produces 1000 MW (megawatts)? Recall that a watt is 1 J/s.
- [21.79] Tests on human subjects in Boston in 1965 and 1966, following the era of atomic bomb testing, revealed average quantities of about 2 pCi of plutonium radioactivity in the average person. How many disintegrations per second does this level of activity imply? If each alpha particle deposits  $8 \times 10^{-13} \text{J}$  of energy and if the average person weighs 75 kg, calculate the number of rads and rems of radiation in 1 yr from such a level of plutonium.

## INTEGRATIVE EXERCISES

- 21.80 A 53.8-mg sample of sodium perchlorate contains radioactive chlorine-36 (whose atomic mass is 36.0 amu). If 29.6% of the chlorine atoms in the sample are chlorine-36 and the remainder is naturally occurring nonradioactive chlorine atoms, how many disintegrations per second are produced by this sample? The half-life of chlorine-36 is  $3.0 \times 10^5$  yr.
- 21.81 Calculate the mass of octane,  $\text{C}_8\text{H}_{18}(\ell)$ , that must be burned in air to evolve the same quantity of energy as produced by the fusion of 1.0 g of hydrogen in the following fusion reaction:
- $$4 {}^1_1\text{H} \longrightarrow {}^4_2\text{He} + 2 {}^0_{-1}\text{e}$$
- Assume that all the products of the combustion of octane are in their gas phases. Use data from Exercise 21.50, Appendix C, and the inside covers of the text. The standard enthalpy of formation of octane is  $-250.1 \text{kJ/mol}$ .
- 21.82 A sample of an alpha emitter having an activity of 0.18 Ci is stored in a 25.0-mL sealed container at  $22^\circ\text{C}$  for 245 days. (a) How many alpha particles are formed during this time? (b) Assuming that each alpha particle is converted to a helium atom, what is the partial pressure of helium gas in the container after this 245-day period?
- [21.83] Charcoal samples from Stonehenge in England were burned in  $\text{O}_2$  and the resultant  $\text{CO}_2$  gas bubbled into a solution of  $\text{Ca}(\text{OH})_2$  (limewater), resulting in the precipitation of  $\text{CaCO}_3$ . The  $\text{CaCO}_3$  was removed by filtration and dried. A 788-mg sample of the  $\text{CaCO}_3$  had a radioactivity of  $1.5 \times 10^{-2} \text{Bq}$  due to carbon-14. By comparison, living organisms undergo 153 disintegrations per minute per gram of carbon. Using the half-life of carbon-14, 5715 yr, calculate the age of the charcoal sample.
- 21.84 When a positron is annihilated by combination with an electron, two photons of equal energy result. What is the wavelength of these photons? Are they gamma ray photons?
- 21.85 A 25.0-mL sample of 0.050 M barium nitrate solution was mixed with 25.0 mL of 0.050 M sodium sulfate solution labeled with radioactive sulfur-35. The activity of the initial sodium sulfate solution was  $1.22 \times 10^6 \text{Bq/mL}$ . After the resultant precipitate was removed by filtration, the remaining filtrate was found to have an activity of 250 Bq/mL. (a) Write a balanced chemical equation for the reaction that occurred. (b) Calculate the  $K_{sp}$  for the precipitate under the conditions of the experiment.

CHAPTER  
22

CHEMISTRY  
OF THE NONMETALS

A MODERN LIVING SPACE

## WHAT'S AHEAD

---

### 22.1 General Concepts: Periodic Trends and Chemical Reactions

We begin with a review of general periodic trends and types of chemical reactions, which will help us to focus on general patterns of behavior as we examine each family in the periodic table.

### 22.2 Hydrogen

The first nonmetal we consider is hydrogen, an element that forms compounds with most other nonmetals and many metals.

### 22.3 Group 8A: The Noble Gases

Next, we consider the noble gases, the elements of group 8A, which exhibit very limited chemical reactivity (the fluorides and oxides of Xe are the most numerous).

### 22.4 Group 7A: The Halogens

We then explore the most electronegative group of elements: the halogens, group 7A. They have a rich and important chemistry, with F and Cl being commercially very important.

### 22.5 Oxygen

We next consider oxygen, the most abundant element by mass in both Earth's crust and the human body. The chemistry of oxygen includes oxide and peroxide compounds.

### 22.6 The Other Group 6A Elements: S, Se, Te, and Po

We study the other members of group 6A (S, Se, Te, and Po), of which sulfur is the most important.

### 22.7 Nitrogen

We next consider nitrogen, a key component of our atmosphere. It forms compounds in which its oxidation number ranges from  $-3$  to  $+5$  including such important compounds as  $\text{NH}_3$  and  $\text{HNO}_3$ .

### 22.8 The Other Group 5A Elements: P, As, Sb, and Bi

Of the other members of group 5A (P, As, Sb, and Bi), we take a closer look at phosphorus—the only one that plays an important and beneficial role in biological systems. Phosphorus is also the most important commercially.

### 22.9 Carbon

We next focus on the inorganic compounds of carbon.

### 22.10 The Other Group 4A Elements: Si, Ge, Sn, and Pb

We then consider silicon, the most abundant and significant element of the other members of group 4A. Silicon oxides are the framework substances in Earth's crust.

### 22.11 Boron

Finally, we examine boron—the sole nonmetallic element of group 3A.

**THE CHAPTER-OPENING PHOTOGRAPH** shows an attractive modern living space. A great number of chemical elements have gone into making up the space and all its decorations. Chemical innovation has resulted in a host of materials that form the stuff of modern life.

In earlier chapters we have learned about a variety of chemical reaction types that allow chemists to prepare and purify materials. We have also learned how the properties of pure substances and mixtures depend on underlying molecular properties. ∞ (Chapter 11) But what are the chemical and physical properties of the elements that make up all these materials? In this and the next chapter, we will be looking at the properties of many elements and at how these properties determine the possibilities for useful applications.

As we look at the chapter-opening photograph, it is striking that so much of what we see is formed from nonmetallic elements. The pottery objects on the table are formed from clay, which is largely silicon dioxide. The seat

cushions are almost certainly woven from a polymeric fiber that is essentially all non-metallic.  $\infty$ (Section 12.6) The paint on the walls, the chair coverings, the glass of the windows, the lamp shades, and most of the furniture are mainly nonmetallic. Metals are certainly important, as they are necessary to manufacture the electrical wiring in the walls, perhaps steel girders in the building's frame, perhaps plumbing fixtures. Overall, however, the stuff of which this scene is constructed is largely nonmetallic in origin.

In this chapter we will take a panoramic view of the descriptive chemistry of the nonmetallic elements, starting with hydrogen and then progressing, group by group, from right to left in the periodic table. We will consider how the elements occur in nature, how they are isolated from their sources, and how they are used. We will emphasize hydrogen, oxygen, nitrogen, and carbon. These four nonmetals form many commercially important compounds and account for 99% of the atoms required by living cells.

As you study this so-called *descriptive chemistry*, it is important to look for trends rather than trying to memorize all the facts presented. The periodic table is your most valuable tool in this task.

▼ **Figure 22.1 Trends in elemental properties.** Key properties of the elements are a function of position in the periodic table.

## 22.1 GENERAL CONCEPTS: PERIODIC TRENDS AND CHEMICAL REACTIONS

Recall that we can classify elements as metals, metalloids, and nonmetals.  $\infty$ (Section 7.6) Except for hydrogen, which is a special case, the nonmetals occupy the upper right portion of the periodic table. This division of elements relates nicely to trends in the properties of the elements as summarized in Figure 22.1 ◀. Electronegativity, for example, increases as we move left to right across a row of the table, and it decreases as we move down a particular group. The nonmetals thus have higher electronegativities than the metals. This difference leads to the formation of ionic solids in reactions between metals and nonmetals.  $\infty$ (Sections 7.6, 8.2, and 8.4)

In contrast, compounds formed between nonmetals are molecular substances and are often gases, liquids, or volatile solids at room temperature.  $\infty$ (Sections 7.8 and 8.4)

Among the nonmetals, the chemistry exhibited by the first member of a group can differ in several important ways from that of subsequent members. For example, nonmetals in the third period and below can accommodate a larger number of bonded neighbors.  $\infty$ (Section 8.7) Another important difference is that the first element in any group can more readily form  $\pi$  bonds than members lower in the group. This trend is due, in part, to atomic size. Small atoms are able to approach each other more closely. As a result, the sideways overlap of  $p$  orbitals, which results in the formation of  $\pi$  bonds, is more effective for the first element in each group (Figure 22.2 ◀). More effective overlap means stronger  $\pi$  bonds, as is reflected in the bond enthalpies of their multiple bonds.  $\infty$ (Section 8.8) For example, the difference in the bond enthalpies of C—C and C=C bonds is about 270 kJ/mol (Table 8.4); this value reflects the “strength” of a carbon–carbon  $\pi$  bond. By comparison, the strength of a silicon–silicon  $\pi$  bond is only about 100 kJ/mol, significantly lower than that for carbon. As we shall see,  $\pi$  bonds are particularly important in the chemistry of carbon, nitrogen, and oxygen, which frequently form multiple bonds. The elements in periods 3, 4, 5, and 6 of the periodic table, on the other hand, have a tendency to form only single bonds.

The ready ability of second-period elements to form  $\pi$  bonds is an important factor in determining the structures of these elements and their compounds.

▲ **Figure 22.2  $\pi$  Bonds in second- and third-row elements.** Comparison of  $\pi$ -bond formation by sideways overlap of  $p$  orbitals between two carbon atoms and between two silicon atoms. The distance between nuclei increases as we move from carbon to silicon. The  $p$  orbitals do not overlap as effectively between two silicon atoms because of this greater separation.

Compare, for example, the elemental forms of carbon and silicon. Carbon has four major crystalline allotropes: diamond, graphite, buckminsterfullerene, and carbon nanotubes.  $\infty$  (Section 11.8) Diamond is a covalent-network solid that has C—C  $\sigma$  bonds but no  $\pi$  bonds. Graphite, buckminsterfullerene, and carbon nanotubes have  $\pi$  bonds that result from the sideways overlap of  $p$  orbitals. Elemental silicon exists only as a diamondlike covalent-network solid with  $\sigma$  bonds; silicon exhibits no form that is analogous to graphite, buckminsterfullerene or carbon nanotubes, apparently because Si—Si  $\pi$  bonds are weak.

We likewise see significant differences in the dioxides of carbon and silicon (Figure 22.3  $\blacktriangleright$ ).  $\text{CO}_2$  is a molecular substance with C—O double bonds, whereas  $\text{SiO}_2$  contains no double bonds.  $\text{SiO}_2$  is a covalent-network solid in which four oxygen atoms are bonded to each silicon atom by single bonds, forming an extended structure that has the empirical formula  $\text{SiO}_2$ .

### GIVE IT SOME THOUGHT

The element nitrogen is found in nature as  $\text{N}_2(\text{g})$ . Would you expect phosphorus to be found in nature as  $\text{P}_2(\text{g})$ ? Explain.

#### SAMPLE EXERCISE 22.1 | Identifying Elemental Properties

Consider the elements Li, K, N, P, and Ne. From this list select the element that (a) is the most electronegative, (b) has the greatest metallic character, (c) can bond to more than four surrounding atoms in a molecule, (d) forms  $\pi$  bonds most readily.

#### SOLUTION

**Analyze:** We are given a list of elements and asked to predict several properties that can be related to periodic trends.

**Plan:** We can use the preceding discussion, particularly the summary in Figure 22.1, to guide us to the answers. Thus, we need first to locate each element in the periodic table.

#### Solve:

(a) Electronegativity increases as we proceed toward the upper right portion of the periodic table, excluding the noble gases. Thus, nitrogen (N) is the most electronegative element among those listed.

(b) Metallic character correlates inversely with electronegativity—the less electronegative an element, the greater its metallic character. The element with the greatest metallic character is therefore potassium (K), which is closest to the lower left corner of the periodic table.

(c) Nonmetals tend to form molecular compounds, so we can narrow our choice to the three nonmetals on the list: N, P, and Ne. To form more than four bonds, an element must be able to expand its valence shell to allow more than an octet of electrons around it. Valence-shell expansion occurs for elements in the third period of the periodic table and below; nitrogen and neon are both in the second period and will not undergo valence-shell expansion. Thus, the answer is phosphorus (P).

(d) Nonmetals in the second period form  $\pi$  bonds more readily than elements in the third period and below. There are no compounds known that contain covalent bonds to the noble gas Ne. Thus, the other second-row element, N, is the element from the list that forms  $\pi$  bonds most readily.

#### PRACTICE EXERCISE

Consider the elements Be, C, Cl, Sb, and Cs. Select the element that (a) has the lowest electronegativity, (b) has the greatest nonmetallic character, (c) is most likely to participate in extensive  $\pi$  bonding, (d) is most likely to be a metalloid.

**Answers:** (a) Cs, (b) Cl, (c) C, (d) Sb

$\blacktriangle$  **Figure 22.3 Comparison of  $\text{SiO}_2$  and  $\text{CO}_2$ .**  $\text{SiO}_2$  has only single bonds, whereas  $\text{CO}_2$  has double bonds.

## Chemical Reactions

We will present a large number of chemical reactions in this and later chapters. You will find it helpful to observe general trends in the patterns of reactivity. We have already encountered several general categories of reactions: combustion reactions (Section 3.2), metathesis reactions (Section 4.2), Brønsted–Lowry acid–base (proton-transfer) reactions (Section 16.2), Lewis acid–base reactions

(Section 16.11), and redox reactions (Section 20.1). Because  $O_2$  and  $H_2O$  are abundant in our environment, it is particularly important to consider the possible reactions of these substances with other compounds. About one-third of the reactions discussed in this chapter involve either  $O_2$  (oxidation or combustion reactions) or  $H_2O$  (especially proton-transfer reactions).

In combustion reactions with  $O_2$ , hydrogen-containing compounds produce  $H_2O$ . Carbon-containing ones produce  $CO_2$  (unless the amount of  $O_2$  is insufficient, in which case  $CO$  or even  $C$  can form). Nitrogen-containing compounds tend to form  $N_2$ , although  $NO$  can form in special cases or in small amounts. The following reaction illustrates these generalizations:

The formation of  $H_2O$ ,  $CO_2$ , and  $N_2$  reflects the high thermodynamic stabilities of these substances, which are indicated by the large bond energies for the  $O-H$ ,  $C=O$ , and  $N\equiv N$  bonds that they contain (463, 799, and 941 kJ/mol, respectively). [↔ \(Section 8.8\)](#)

When dealing with proton-transfer reactions, remember that the weaker a Brønsted–Lowry acid, the stronger its conjugate base. [↔ \(Section 16.2\)](#) For example,  $H_2$ ,  $OH^-$ ,  $NH_3$ , and  $CH_4$  are exceedingly weak proton donors that have *no* tendency to act as acids in water. Thus, species formed from them by removing one or more protons (such as  $H^-$ ,  $O^{2-}$ , and  $NH_2^-$ ) are extremely strong bases. All react readily with water, removing protons from  $H_2O$  to form  $OH^-$ . The following reactions are illustrative:

### SAMPLE EXERCISE 22.2 | Predicting the Products of Chemical Reactions

Predict the products formed in each of the following reactions, and write a balanced equation:

- (a)  $\text{CH}_3\text{NHNH}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow$   
 (b)  $\text{Mg}_3\text{P}_2(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$

#### SOLUTION

**Analyze:** We are given the reactants for two chemical equations and asked to predict the products and then balance the equations.

**Plan:** We need to examine the reactants to see if we might recognize a reaction type. In (a) the carbon compound is reacting with  $O_2$ , which suggests a combustion reaction. In (b) water reacts with an ionic compound. The anion,  $P^{3-}$ , is a strong base and  $H_2O$  is able to act as an acid, so the reactants suggest an acid–base (proton-transfer) reaction.

**Solve:** (a) Based on the elemental composition of the carbon compound, this combustion reaction should produce  $CO_2$ ,  $H_2O$ , and  $N_2$ :

(b)  $Mg_3P_2$  is ionic, consisting of  $Mg^{2+}$  and  $P^{3-}$  ions. The  $P^{3-}$  ion, like  $N^{3-}$ , has a strong affinity for protons and reacts with  $H_2O$  to form  $OH^-$  and  $PH_3$  ( $PH_2^-$ ,  $PH^2-$ , and  $PH_3$  are all exceedingly weak proton donors).

$Mg(\text{OH})_2$  has low solubility in water and will precipitate.

### PRACTICE EXERCISE

Write a balanced equation for the reaction of solid sodium hydride with water.

**Answer:**  $\text{NaH}(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{NaOH}(\text{aq}) + \text{H}_2(\text{g})$

## 22.2 HYDROGEN

The English chemist Henry Cavendish (1731–1810) was the first to isolate pure hydrogen. Because the element produces water when burned in air, the French chemist Lavoisier gave it the name *hydrogen*, which means “water producer” (Greek: *hydro*, water; *gennao*, to produce).

Hydrogen is the most abundant element in the universe. It is the nuclear fuel consumed by our Sun and other stars to produce energy. [↔ \(Section 21.8\)](#) Although about 75% of the known mass of the universe is composed of hydrogen, it constitutes only 0.87% of Earth’s mass. Most of the hydrogen on our planet is found associated with oxygen. Water, which is 11% hydrogen by mass, is the most abundant hydrogen compound.

### Isotopes of Hydrogen

The most common isotope of hydrogen,  ${}^1_1\text{H}$ , has a nucleus consisting of a single proton. This isotope, sometimes referred to as **protium**,\* comprises 99.9844% of naturally occurring hydrogen.

Two other isotopes are known:  ${}^2_1\text{H}$ , whose nucleus contains a proton and a neutron, and  ${}^3_1\text{H}$ , whose nucleus contains a proton and two neutrons (Figure 22.4▶). The  ${}^2_1\text{H}$  isotope, called **deuterium**, comprises 0.0156% of naturally occurring hydrogen. It is not radioactive. Deuterium is often given the symbol D in chemical formulas, as in  $\text{D}_2\text{O}$  (deuterium oxide), which is known as *heavy water*.

Because an atom of deuterium is about twice as massive as an atom of protium, the properties of deuterium-containing substances vary somewhat from those of the “normal” protium-containing analogs. For example, the normal melting and boiling points of  $\text{D}_2\text{O}$  are 3.81 °C and 101.42 °C, respectively, whereas they are 0.00 °C and 100.00 °C for  $\text{H}_2\text{O}$ . Not surprisingly, the density of  $\text{D}_2\text{O}$  at 25 °C (1.104 g/mL) is greater than that of  $\text{H}_2\text{O}$  (0.997 g/mL). Replacing protium with deuterium (a process called *deuteration*) can also have a profound effect on the rates of reactions, a phenomenon called a *kinetic-isotope effect*. In fact, heavy water can be obtained by the electrolysis of ordinary water, because  $\text{D}_2\text{O}$  undergoes electrolysis at a slower rate and therefore becomes concentrated during the electrolysis.

The third isotope,  ${}^3_1\text{H}$ , is known as **tritium**. It is radioactive, with a half-life of 12.3 yr.

Because of its short half-life, only trace quantities of tritium exist naturally. The isotope can be synthesized in nuclear reactors by neutron bombardment of lithium-6.

Deuterium and tritium have proved valuable in studying the reactions of compounds containing hydrogen. A compound can be “labeled” by replacing one or more ordinary hydrogen atoms at specific locations within a molecule with deuterium or tritium. By comparing the location of the label in the reactants with that in the products, the mechanism of the reaction can often be inferred. When methyl alcohol ( $\text{CH}_3\text{OH}$ ) is placed in  $\text{D}_2\text{O}$ , for example, the H atom of the O—H bond exchanges rapidly with the D atoms in  $\text{D}_2\text{O}$ , forming  $\text{CH}_3\text{OD}$ . The H atoms of the  $\text{CH}_3$  group do not exchange. This experiment demonstrates the kinetic stability of C—H bonds and reveals the speed at which the O—H bond in the molecule breaks and re-forms.

▲ **Figure 22.4 Nuclei of the three isotopes of hydrogen.** (a) Protium,  ${}^1_1\text{H}$ , has a single proton (depicted as a red sphere) in its nucleus. (b) Deuterium,  ${}^2_1\text{H}$ , has a proton and a neutron (depicted as a gray sphere). (c) Tritium,  ${}^3_1\text{H}$ , has a proton and two neutrons. Remember that the nuclei are very small! [↔ \(Section 2.3\)](#)

\*Giving unique names to isotopes is limited to hydrogen. Because of the proportionally large differences in their masses, the isotopes of H show appreciably more differences in their properties than isotopes of heavier elements.

## Properties of Hydrogen

Hydrogen is the only element that is not a member of any family in the periodic table. Because of its  $1s^1$  electron configuration, it is generally placed above lithium in the periodic table. However, it is definitely *not* an alkali metal. It forms a positive ion much less readily than any alkali metal. The ionization energy of the hydrogen atom is 1312 kJ/mol, whereas that of lithium is 520 kJ/mol.

Hydrogen is sometimes placed above the halogens in the periodic table because the hydrogen atom can pick up one electron to form the *hydride ion*,  $H^-$ , which has the same electron configuration as helium. The electron affinity of hydrogen ( $E = -73$  kJ/mol), however, is not as large as that of any halogen; the electron affinity of fluorine is  $-328$  kJ/mol, and that of iodine is  $-295$  kJ/mol.  $\rightleftharpoons$  (Section 7.5) In general, hydrogen shows no closer resemblance to the halogens than it does to the alkali metals.

Elemental hydrogen exists at room temperature as a colorless, odorless, tasteless gas composed of diatomic molecules. We can call  $H_2$  dihydrogen, but it is more commonly referred to as molecular hydrogen or simply hydrogen. Because  $H_2$  is nonpolar and has only two electrons, attractive forces between molecules are extremely weak. As a result, the melting point ( $-259$  °C) and boiling point ( $-253$  °C) of  $H_2$  are very low.

The H—H bond enthalpy (436 kJ/mol) is high for a single bond (Table 8.4). By comparison, the Cl—Cl bond enthalpy is only 242 kJ/mol. Because  $H_2$  has a strong bond, most reactions of  $H_2$  are slow at room temperature. However, the molecule is readily activated by heat, irradiation, or catalysis. The activation process generally produces hydrogen atoms, which are very reactive. Once  $H_2$  is activated, it reacts rapidly and exothermically with a wide variety of substances.

Hydrogen forms strong covalent bonds with many elements, including oxygen; the O—H bond enthalpy is 463 kJ/mol. The formation of the strong O—H bond makes hydrogen an effective reducing agent for many metal oxides. When  $H_2$  is passed over heated CuO, for example, copper is produced.

When  $H_2$  is ignited in air, a vigorous reaction occurs, forming  $H_2O$ . Air containing as little as 4%  $H_2$  (by volume) is potentially explosive. Combustion of hydrogen-oxygen mixtures is commonly used in liquid-fuel rocket engines such as those of the Space Shuttles. The hydrogen and oxygen are stored at low temperatures in liquid form.

## Preparation of Hydrogen

When a small quantity of  $H_2$  is needed in the laboratory, it is usually obtained by the reaction between an active metal such as zinc and a dilute strong acid such as HCl or  $H_2SO_4$ .

Large quantities of  $H_2$  are produced by reacting methane ( $CH_4$ , the principal component of natural gas) with steam at 1100 °C. We can view this process as involving the following reactions:

When heated to about 1000 °C, carbon also reacts with steam to produce a mixture of  $H_2$  and CO gases.

This mixture, known as *water gas*, is used as an industrial fuel.

## A Closer Look

## THE HYDROGEN ECONOMY

The reaction of hydrogen with oxygen is highly exothermic:

Because the only product of the reaction is water vapor, the prospect of using hydrogen as a fuel in an automotive fuel cell is attractive. [↔ \(Section 20.7\)](#) Alternatively, hydrogen could be combusted directly with oxygen from the atmosphere in an internal combustion engine. In either case, it would be necessary to generate elemental hydrogen on a large scale and arrange for its transport and storage. The advantages of the so-called hydrogen economy must be viewed, therefore, in light of the potential difficulties and costs. The generation of hydrogen from fossil fuels is feasible, but that strategy may create difficulties in transport and handling of hydrogen gas, a dangerously combustible substance.

The generation of  $\text{H}_2$  through electrolysis of water is in principle the cleanest route, because this process produces only hydrogen and oxygen. [↔ \(Figure 1.7 and Section 20.9\)](#) However, the energy required to electrolyze water must come from somewhere. If we burn fossil fuels to generate the electricity used for the production of hydrogen, we have not advanced very far toward a true hydrogen economy. If the energy for electrolysis came instead from a hydroelectric or nuclear power

plant, from solar cells or via wind generators (Figure 22.5 [▼](#)), consumption of nonrenewable energy sources and undesired production of  $\text{CO}_2$  could be avoided.

*Related Exercises:* 22.29, 22.30, 22.99

**▲ Figure 22.5 Wind power.** Windmills represent one pathway toward electrical energy that can drive a hydrogen economy.

Simple electrolysis of water consumes too much energy and is consequently too costly to be used commercially to produce  $\text{H}_2$ . However,  $\text{H}_2$  is produced as a by-product in the electrolysis of brine ( $\text{NaCl}$ ) solutions in the course of  $\text{Cl}_2$  and  $\text{NaOH}$  manufacture:

### Uses of Hydrogen

Hydrogen is a commercially important substance: About  $2 \times 10^8$  kg (200,000 tons) is produced annually in the United States. Over two-thirds of the  $\text{H}_2$  produced is used to synthesize ammonia by the Haber process. [↔ \(Section 15.2\)](#) Hydrogen is also used to manufacture methanol ( $\text{CH}_3\text{OH}$ ) via the catalytic reaction of  $\text{CO}$  and  $\text{H}_2$  at high pressure and temperature.

### Binary Hydrogen Compounds

Hydrogen reacts with other elements to form compounds of three general types: (1) ionic hydrides, (2) metallic hydrides, and (3) molecular hydrides.

The **ionic hydrides** are formed by the alkali metals and by the heavier alkaline earths ( $\text{Ca}$ ,  $\text{Sr}$ , and  $\text{Ba}$ ). These active metals are much less electronegative than hydrogen. Consequently, hydrogen acquires electrons from them to form hydride ions ( $\text{H}^-$ ):

The hydride ion is very basic and reacts readily with compounds having even weakly acidic protons to form  $\text{H}_2$ . For example,  $\text{H}^-$  reacts readily with  $\text{H}_2\text{O}$ .

Ionic hydrides can therefore be used as convenient (although expensive) sources of  $\text{H}_2$ . Calcium hydride ( $\text{CaH}_2$ ) is sold commercially and is used to inflate life

▲ **Figure 22.6** The reaction of  $\text{CaH}_2$  with water. (a) Powdered  $\text{CaH}_2$  about to be added to water. (b) The reaction is vigorous and exothermic. The reddish purple color is due to phenolphthalein added to the water, which indicates the formation of  $\text{OH}^-$  ions. The bubbling is due to the formation of  $\text{H}_2$  gas.

rafts, weather balloons, and the like, where a simple, compact means of generating  $\text{H}_2$  is desired. The reaction of  $\text{CaH}_2$  with  $\text{H}_2\text{O}$  is shown in Figure 22.6 ◀.

The reaction between  $\text{H}^-$  and  $\text{H}_2\text{O}$  (Equation 22.15) is an acid–base reaction and a redox reaction. The  $\text{H}^-$  ion, therefore, is a good base *and* a good reducing agent. In fact, hydrides are able to reduce  $\text{O}_2$  to  $\text{OH}^-$ .

Thus, hydrides are normally stored in an environment that is free of both moisture and air.

**Metallic hydrides** are formed when hydrogen reacts with transition metals. These compounds are so named because they retain their metallic conductivity and other metallic properties. In many metallic hydrides, the ratio of metal atoms to hydrogen atoms is not fixed or in small whole numbers. The composition can vary within a range, depending on the conditions of synthesis.  $\text{TiH}_2$  can be produced, for example, but preparations usually yield  $\text{TiH}_{1.8}$ , which has about 10% less hydrogen than  $\text{TiH}_2$ . These nonstoichiometric metallic hydrides are sometimes called *interstitial hydrides*.

The **molecular hydrides**, formed by nonmetals and semimetals, are either gases or liquids under standard conditions. The simple molecular hydrides are listed in Figure 22.7 ◀, together with their standard free energies of formation,  $\Delta G_f^\circ$ . In each family the thermal stability (measured by  $\Delta G_f^\circ$ ) decreases as we move down the family. (Recall that the more stable a compound is with respect to its elements under standard conditions, the more negative  $\Delta G_f^\circ$  is.) We will discuss the molecular hydrides further in the course of examining the other nonmetallic elements.

### GIVE IT SOME THOUGHT

If the reaction  $\text{H}_2(\text{g}) + \text{Se}(\text{s}) \rightleftharpoons \text{H}_2\text{Se}(\text{g})$  were at equilibrium with an  $\text{H}_2(\text{g})$  pressure of 1 atm, would there be much  $\text{H}_2\text{Se}(\text{g})$  present?

## 22.3 GROUP 8A: THE NOBLE GASES

The elements of group 8A are chemically unreactive. Indeed, most of our references to these elements have been in relation to their physical properties, as when we discussed intermolecular forces. ◀ (Section 11.2) The relative inertness of these elements is due to the presence of a completed octet of valence-shell electrons (except He, which has a filled 1s shell). The stability of such an arrangement is reflected in the high ionization energies of the group 8A elements. ◀ (Section 7.4)

The group 8A elements are all gases at room temperature. They are components of Earth's atmosphere, except for radon, which exists only as a short-lived radioisotope. ◀ (Section 21.9) Only argon is relatively abundant (Table 18.1). Neon, argon, krypton, and xenon are recovered from liquid air by distillation. Argon is used as a blanketing atmosphere in electric lightbulbs. The gas conducts heat away from the filament but does not react with it. It is also used as a protective atmosphere to prevent oxidation in welding and certain high-temperature metallurgical processes.

Helium is, in many ways, the most important of the noble gases. Liquid helium is used as a coolant to conduct experiments at very low temperatures. Helium boils at 4.2 K under 1 atm pressure, the lowest boiling point of any substance. Fortunately, helium is found in relatively high concentrations in many natural-gas wells. Some of this helium is separated to meet current demands, and some is kept for later use.

TABLE 22.1 ■ Properties of Xenon Compounds

<sup>c</sup>A solid; decomposes at -40 °C.

## Noble-Gas Compounds

Because the noble gases are exceedingly stable, they will undergo reaction only under rigorous conditions. Furthermore, we might expect that the heavier noble gases would be most likely to form compounds because their ionization energies are lower (Figure 7.11). A lower ionization energy suggests the possibility of sharing an electron with another atom, leading to a chemical bond. In addition, because the group 8A elements (except helium) already contain eight electrons in their valence shell, formation of covalent bonds will require an expanded valence shell. Valence-shell expansion occurs most readily with larger atoms. ∞ (Section 8.7)

The first noble-gas compound was reported in 1962. This discovery caused a sensation because it undercut the belief that the noble-gas elements were truly chemically inert. The initial study involved xenon in combination with fluorine, the element we would expect to be most reactive. Since that time chemists have prepared several xenon compounds of fluorine and oxygen. Some properties of these substances are listed in Table 22.1 ▲. The three fluorides (XeF<sub>2</sub>, XeF<sub>4</sub>, and XeF<sub>6</sub>) are made by direct reaction of the elements. By varying the ratio of reactants and altering reaction conditions, one of the three compounds can be obtained. The oxygen-containing compounds are formed when the fluorides are reacted with water, as in Equation 22.17:

### SAMPLE EXERCISE 22.3 | Predicting a Molecular Structure

Use the VSEPR model to predict the structure of XeF<sub>4</sub>.

#### SOLUTION

**Analyze:** We must predict the geometrical structure, given only the molecular formula.

**Plan:** To predict the structure, we must first write the Lewis structure for the molecule. We then count the number of electron pairs (domains) around the central Xe atom and use that number and the number of bonds to predict the geometry, as discussed in Section 9.2.

**Solve:** The total number of valence-shell electrons involved is 36 (8 from xenon and 7 from each of the four fluorines). This leads to the Lewis structure shown in Figure 22.8(a) ▶. Xe has 12 electrons in its valence shell, so we expect an octahedral disposition of 6 electron pairs. Two of these are nonbonded pairs. Because nonbonded pairs have a larger volume requirement than bonded pairs (Section 9.2), it is reasonable to expect these nonbonded pairs to be opposite one another. The expected structure is square planar, as shown in Figure 22.8(b).

**Comment:** The experimentally determined structure agrees with this prediction.

#### PRACTICE EXERCISE

Describe the electron-domain geometry and the molecular geometry of XeF<sub>2</sub>.

**Answer:** trigonal bipyramidal, linear

▲ Figure 22.8 Xenon tetrafluoride. (a) Lewis structure. (b) Molecular geometry.

The other noble-gas elements form compounds much less readily than xenon. For many years, only one binary krypton compound,  $\text{KrF}_2$ , was known with certainty, and it decomposes to its elements at  $-10^\circ\text{C}$ . Other compounds of krypton have been isolated at very low temperatures (40 K).

## 22.4 GROUP 7A: THE HALOGENS

7A
9 F
17 Cl
35 Br
53 I
85 At

The elements of group 7A, the halogens, have outer electron configurations of  $ns^2np^5$ , where  $n$  ranges from 2 through 6. The halogens have large negative electron affinities (Section 7.5), and they most often achieve a noble-gas configuration by gaining an electron, which results in a  $-1$  oxidation state. Fluorine, being the most electronegative element, exists in compounds only in the  $-1$  state. The other halogens also exhibit positive oxidation states up to  $+7$  in combination with more electronegative atoms such as O. In the positive oxidation states the halogens tend to be good oxidizing agents, readily accepting electrons.

Chlorine, bromine, and iodine are found as the halides in seawater and in salt deposits. Fluorine occurs in the minerals fluorspar ( $\text{CaF}_2$ ), cryolite ( $\text{Na}_3\text{AlF}_6$ ), and fluorapatite [ $\text{Ca}_5(\text{PO}_4)_3\text{F}$ ].\* Only fluorspar is an important commercial source of fluorine.

All isotopes of astatine are radioactive. The longest lived isotope is astatine-210, which has a half-life of 8.1 hr and decays mainly by electron capture. Because astatine is so unstable to nuclear decay, very little is known about its chemistry.

### Properties and Preparation of the Halogens

Some of the properties of the halogens are summarized in Table 22.2. Most of the properties vary in a regular fashion as we go from fluorine to iodine. The electronegativity steadily decreases, for example, from 4.0 for fluorine to 2.5 for iodine.

Under ordinary conditions the halogens exist as diatomic molecules. The molecules are held together in the solid and liquid states by London dispersion forces.  $\rightleftharpoons$  (Section 11.2) Because  $\text{I}_2$  is the largest and most polarizable of the halogen molecules, the intermolecular forces between  $\text{I}_2$  molecules are the strongest. Thus,  $\text{I}_2$  has the highest melting point and boiling point. At room temperature and 1 atm pressure,  $\text{I}_2$  is a solid,  $\text{Br}_2$  is a liquid, and  $\text{Cl}_2$  and  $\text{F}_2$  are gases. Chlorine readily liquefies upon compression at room temperature and is normally stored and handled in liquid form under pressure in steel containers.

The comparatively low bond enthalpy in  $\text{F}_2$  (155 kJ/mol) accounts in part for the extreme reactivity of elemental fluorine. Because of its high reactivity,  $\text{F}_2$  is very difficult to work with. Certain metals, such as copper and nickel, can be used to contain  $\text{F}_2$  because their surfaces form a protective coating of metal fluoride. Chlorine and the heavier halogens are also reactive, although less so than fluorine.

TABLE 22.2 ■ Some Properties of the Halogens

Property	F	Cl	Br	I
Atomic radius (Å)	0.71	0.99	1.14	1.33
Ionic radius, $\text{X}^-$ (Å)	1.33	1.81	1.96	2.20
First ionization energy (kJ/mol)	1681	1251	1140	1008
Electron affinity (kJ/mol)	-328	-349	-325	-295
Electronegativity	4.0	3.0	2.8	2.5
X—X single-bond enthalpy (kJ/mol)	155	242	193	151
Reduction potential (V):				
$\frac{1}{2}\text{X}_2(\text{aq}) + \text{e}^- \longrightarrow \text{X}^-(\text{aq})$	2.87	1.36	1.07	0.54

\*Minerals are solid substances that occur in nature. They are usually known by their common names rather than by their chemical names. What we know as rock is merely an aggregate of different kinds of minerals.

Because of their high electronegativities, the halogens tend to gain electrons from other substances and thereby serve as oxidizing agents. The oxidizing ability of the halogens, which is indicated by their standard reduction potentials, decreases going down the group. As a result, a given halogen is able to oxidize the anions of the halogens below it in the group. For example,  $\text{Cl}_2$  will oxidize  $\text{Br}^-$  and  $\text{I}^-$ , but not  $\text{F}^-$ , as seen in Figure 22.9 ▶.

### SAMPLE EXERCISE 22.4 Predicting Chemical Reactions among the Halogens

Write the balanced equation for the reaction, if any, that occurs between (a)  $\text{I}^-(aq)$  and  $\text{Br}_2(l)$ , (b)  $\text{Cl}^-(aq)$  and  $\text{I}_2(s)$ .

#### SOLUTION

**Analyze:** We are asked to determine whether a reaction occurs when a particular halide and halogen are combined.

**Plan:** A given halogen is able to reduce anions of the halogens below it in the periodic table. Thus, the smaller (lower atomic number) halogen will end up as the halide ion. If the halogen with smaller atomic number is already the halide, there will be no reaction. Thus, the key to determining whether a reaction will occur is locating the elements in the periodic table.

#### Solve:

(a)  $\text{Br}_2$  is able to oxidize (remove electrons from) the anions of the halogens below it in the periodic table. Thus, it will oxidize  $\text{I}^-$

(b)  $\text{Cl}^-$  is the anion of a halogen above iodine in the periodic table. Thus,  $\text{I}_2$  cannot oxidize  $\text{Cl}^-$ ; there is no reaction.

### PRACTICE EXERCISE

Write the balanced chemical equation for the reaction that occurs between  $\text{Br}^-(aq)$  and  $\text{Cl}_2(aq)$ .

**Answer:**  $2 \text{Br}^-(aq) + \text{Cl}_2(aq) \longrightarrow \text{Br}_2(aq) + 2 \text{Cl}^-(aq)$

Notice in Table 22.2 that the standard reduction potential of  $\text{F}_2$  is exceptionally high. Fluorine gas readily oxidizes water:

Fluorine cannot be prepared by electrolytic oxidation of aqueous solutions of fluoride salts because water itself is oxidized more readily than  $\text{F}^-$ . ∞ (Section 20.9) In practice, the element is formed by electrolytic oxidation of a solution of  $\text{KF}$  in anhydrous  $\text{HF}$ .

Chlorine is produced mainly by electrolysis of either molten or aqueous sodium chloride, as described in Sections 20.9 and 23.4. Both bromine and iodine are obtained commercially from brines containing the halide ions by oxidation with  $\text{Cl}_2$ .

## Uses of the Halogens

Fluorine is an important industrial chemical. It is used, for example, to prepare fluorocarbons—very stable carbon–fluorine compounds used as refrigerants, lubricants, and plastics. Teflon<sup>®</sup> (Figure 22.10 ▶) is a polymeric fluorocarbon noted for its high thermal stability and lack of chemical reactivity.

Chlorine is by far the most commercially important halogen. About  $1 \times 10^{10}$  kg (10 million tons) of  $\text{Cl}_2$  is produced annually in the United States. In addition, hydrogen chloride production is about  $4.0 \times 10^9$  kg (4.4 million tons) annually. About half of this chlorine finds its way eventually into the manufacture of chlorine-containing organic compounds such as vinyl chloride ( $\text{C}_2\text{H}_3\text{Cl}$ ), used in making polyvinyl chloride (PVC) plastics. ∞ (Section 12.6)

▲ **Figure 22.9** Reaction of  $\text{Cl}_2$  with aqueous solutions of  $\text{NaF}$ ,  $\text{NaBr}$ , and  $\text{NaI}$ . Each solution is in contact with carbon tetrachloride ( $\text{CCl}_4$ ), which forms the lower layer in each container. The halogens are more soluble in  $\text{CCl}_4$  than in  $\text{H}_2\text{O}$ . Because the  $\text{F}^-$  ion in the  $\text{NaF}$  solution (left) does not react with  $\text{Cl}_2$ , both the aqueous layer and the  $\text{CCl}_4$  layer remain colorless. The  $\text{Br}^-$  ion in the  $\text{NaBr}$  solution (center) is oxidized by  $\text{Cl}_2$  to form  $\text{Br}_2$ , producing a yellow aqueous layer and an orange  $\text{CCl}_4$  layer. The  $\text{I}^-$  ion in the  $\text{NaI}$  solution (right) is oxidized to  $\text{I}_2$ , producing an amber aqueous layer and a violet  $\text{CCl}_4$  layer.

▲ **Figure 22.10** Structure of Teflon<sup>®</sup>, a fluorocarbon polymer. This polymer is an analog of polyethylene (Section 12.6) in which the H atoms of polyethylene have been replaced with F atoms.

**▲ Figure 22.11 Iodized salt.** Common table salt that has been iodized contains 0.02% KI by mass.

(a)

(b)

**▲ Figure 22.12 Reaction of  $\text{H}_2\text{SO}_4$  with NaI and NaBr.** (a) Sodium iodide is in the left test tube, and sodium bromide is in the tube on the right. Sulfuric acid is in the pipet. (b) Addition of sulfuric acid to the test tubes oxidizes sodium iodide to the dark-colored iodine seen in the tube on the left. Sodium bromide is oxidized to the yellow-brown bromine in the right tube. When more concentrated, bromine has a reddish brown color.

Much of the remainder is used as a bleaching agent in the paper and textile industries. When  $\text{Cl}_2$  dissolves in cold dilute base, it disproportionates into  $\text{Cl}^-$  and hypochlorite,  $\text{ClO}^-$ .

Sodium hypochlorite ( $\text{NaClO}$ ) is the active ingredient in many liquid bleaches. Chlorine is also used in water treatment to oxidize and thereby destroy bacteria. [☞ \(Section 18.6\)](#)

A common use of iodine is as KI in table salt. Iodized salt (Figure 22.11 [◀](#)) provides the small amount of iodine necessary in our diets; it is essential for the formation of thyroxin, a hormone secreted by the thyroid gland. Lack of iodine in the diet results in an enlarged thyroid gland, a condition called *goiter*.

## The Hydrogen Halides

All of the halogens form stable diatomic molecules with hydrogen. Aqueous solutions of  $\text{HCl}$ ,  $\text{HBr}$ , and  $\text{HI}$  are strong acids. The hydrogen halides can be formed by direct reaction of the elements. The most important means of preparing them, however, is by reacting a salt of the halide with a strong nonvolatile acid. Both  $\text{HF}$  and  $\text{HCl}$  are prepared in this manner by reaction of an inexpensive, readily available salt with concentrated sulfuric acid as illustrated in the following equation:

Neither  $\text{HBr}$  nor  $\text{HI}$  can be prepared by analogous reactions of salts with  $\text{H}_2\text{SO}_4$  because  $\text{H}_2\text{SO}_4$  oxidizes  $\text{Br}^-$  and  $\text{I}^-$  (Figure 22.12 [◀](#)). This difference in reactivity reflects the greater ease of oxidation of  $\text{Br}^-$  and  $\text{I}^-$  relative to  $\text{F}^-$  and  $\text{Cl}^-$ . These undesirable oxidations are avoided by using a nonvolatile acid, such as  $\text{H}_3\text{PO}_4$ , that is a weaker oxidizing agent than  $\text{H}_2\text{SO}_4$ .

### **■ SAMPLE EXERCISE 22.5** Writing a Balanced Chemical Equation

Write a balanced equation for the formation of hydrogen bromide gas from the reaction of solid sodium bromide with phosphoric acid.

#### **SOLUTION**

**Analyze:** We are asked to write a balanced equation for the reaction between  $\text{NaBr}$  and  $\text{H}_3\text{PO}_4$  to form  $\text{HBr}$  and another product.

**Plan:** As in Equation 22.20, a metathesis reaction takes place. [☞ \(Section 4.2\)](#) Let's assume that only one of the hydrogens of  $\text{H}_3\text{PO}_4$  undergoes reaction. (The actual number depends on the reaction conditions.) Thus, the remaining  $\text{H}_2\text{PO}_4^-$  ion will be associated with the  $\text{Na}^+$  ion as  $\text{NaH}_2\text{PO}_4$  among the products of the equation.

**Solve:** The balanced equation is

### **■ PRACTICE EXERCISE**

Write the balanced equation for the preparation of  $\text{HI}$  from  $\text{NaI}$  and  $\text{H}_3\text{PO}_4$ .  
*Answer:*  $\text{NaI}(\text{s}) + \text{H}_3\text{PO}_4(\text{l}) \longrightarrow \text{NaH}_2\text{PO}_4(\text{s}) + \text{HI}(\text{g})$

The hydrogen halides form hydrohalic acid solutions when dissolved in water. These solutions exhibit the characteristic properties of acids, such as reactions with active metals to produce hydrogen gas. [☞ \(Section 4.4\)](#) Hydrofluoric acid also reacts readily with silica ( $\text{SiO}_2$ ) and with silicates to form hexafluorosilicic acid ( $\text{H}_2\text{SiF}_6$ ):

Glass consists mostly of silicate structures (Section 22.10), and these reactions allow  $\text{HF}$  to etch, or frost, glass (Figure 22.13 [▶](#)).

## Interhalogen Compounds

Because the halogens exist as diatomic molecules, diatomic molecules of two different halogen atoms exist. These compounds are the simplest examples of **interhalogens**, compounds, such as  $\text{ClF}$  and  $\text{IF}_5$ , formed between two different halogen elements.

With one exception, the higher interhalogen compounds have a central Cl, Br, or I atom surrounded by 3, 5, or 7 fluorine atoms. The large size of the iodine atom allows the formation of  $\text{IF}_3$ ,  $\text{IF}_5$ ,  $\text{I}_7$ , in which the oxidation state of I is +3, +5, and +7, respectively. With the smaller bromine atom and chlorine atom, only compounds with 3 or 5 fluorines form. The only higher interhalogen compounds that do not have outer F atoms are  $\text{ICl}_3$  and  $\text{ICl}_5$ ; the large size of the I atom can accommodate five Cl atoms, whereas Br is not large enough to allow even  $\text{BrCl}_3$  to form. All of the interhalogen compounds are powerful oxidizing agents.

## Oxyacids and Oxyanions

Table 22.3 summarizes the formulas of the known oxyacids of the halogens and the way they are named.\*  $\infty$  (Section 2.8) The acid strengths of the oxyacids increase with increasing oxidation state of the central halogen atom.  $\infty$  (Section 16.10) All the oxyacids are strong oxidizing agents. The oxyanions, formed on removal of  $\text{H}^+$  from the oxyacids, are generally more stable than the oxyacids. Hypochlorite salts are used as bleaches and disinfectants because of the powerful oxidizing capabilities of the  $\text{ClO}^-$  ion. Sodium chlorite is used as a bleaching agent. Chlorate salts are similarly very reactive. For example, potassium chlorate is used to make matches and fireworks.

### GIVE IT SOME THOUGHT

Which would you expect to be the stronger oxidizing agent,  $\text{NaBrO}_3$  or  $\text{NaClO}_3$ ?

Perchloric acid and its salts are the most stable of the oxyacids and oxyanions. Dilute solutions of perchloric acid are quite safe, and many perchlorate salts are stable except when heated with organic materials. When heated, perchlorates can become vigorous, even violent, oxidizers. Considerable caution should be exercised, therefore, when handling these substances, and it is crucial to avoid contact between perchlorates and readily oxidized material such as active metals and combustible organic compounds. The use of ammonium perchlorate ( $\text{NH}_4\text{ClO}_4$ ) as the oxidizer in the solid booster rockets for the Space Shuttle demonstrates the oxidizing power of perchlorates. The solid propellant contains a mixture of  $\text{NH}_4\text{ClO}_4$  and powdered aluminum, the reducing agent. Each shuttle launch requires about  $6 \times 10^5$  kg (700 tons) of  $\text{NH}_4\text{ClO}_4$  (Figure 22.14 ▶).

TABLE 22.3 ■ The Stable Oxyacids of the Halogens

Oxidation State of Halogen	Formula of Acid			Acid Name
	Cl	Br	I	
+1	$\text{HClO}$	$\text{HBrO}$	$\text{HIO}$	<i>Hypohalous acid</i>
+3	$\text{HClO}_2$	—	—	<i>Halous acid</i>
+5	$\text{HClO}_3$	$\text{HBrO}_3$	$\text{HIO}_3$	<i>Hallic acid</i>
+7	$\text{HClO}_4$	$\text{HBrO}_4$	$\text{HIO}_4$ , $\text{H}_5\text{IO}_6$	<i>Perhalic acid</i>

\*Fluorine forms one oxyacid,  $\text{HOF}$ . Because the electronegativity of fluorine is greater than that of oxygen, we must consider fluorine to be in a  $-1$  oxidation state and oxygen to be in the  $0$  oxidation state in this compound.

▲ **Figure 22.13** Etched, or frosted, glass. Designs such as this are produced by first coating the glass with wax and then removing the wax only in the areas to be etched. When treated with hydrofluoric acid, the exposed areas of the glass are attacked, producing the etching effect.

▲ **Figure 22.14** Launch of the Space Shuttle Columbia from the Kennedy Space Center.

Since the 1950s both NASA and the Pentagon have used ammonium perchlorate,  $\text{NH}_4\text{ClO}_4$ , as a rocket fuel. The result is that traces of perchlorate ion are found in groundwater in many regions of the United States, with levels ranging from about 4 to 100 ppb.

Perchlorate is known to suppress hormone levels in humans by acting in the thyroid gland. However, it is disputed whether the amounts found in drinking water are sufficiently high to cause health problems. The Environmental Protection Agency currently states that a dose of 0.007 mg per kg of body weight per day is not expected to cause adverse health effects

in humans. For a 70 kg (154 lb.) person drinking 2 L of water per day, that amounts to a concentration of 25 ppb. California has proposed setting a standard of 6 ppb.

Removal of perchlorate ion from water supplies is not an easy matter. Although perchlorate is an oxidizing agent, the  $\text{ClO}_4^-$  ion is quite stable in aqueous solution. One promising avenue is to employ biological reduction, using microorganisms. While research continues on the best means of reducing perchlorate levels in drinking water, agencies of the federal government continue to explore the level that is safe.

*Related Exercises:* 22.39, 22.40, 22.101

▲ **Figure 22.15 Joseph Priestley (1733–1804).** Priestley became interested in chemistry at the age of 39. Priestley lived next door to a brewery from which he could obtain carbon dioxide, so his studies focused on this gas first and were later extended to other gases. Because he was suspected of sympathizing with the American and French revolutions, his church, home, and laboratory in Birmingham, England, were burned by a mob in 1791. Priestley had to flee in disguise. He eventually emigrated to the United States in 1794, where he lived his remaining years in relative seclusion in Pennsylvania.

## 22.5 OXYGEN

By the middle of the seventeenth century, scientists recognized that air contained a component associated with burning and breathing. That component was not isolated until 1774, however, when Joseph Priestley (Figure 22.15 ◀) discovered oxygen. Lavoisier subsequently named the element *oxygen*, meaning “acid former.”

Oxygen is found in combination with other elements in a great variety of compounds. Indeed, oxygen is the most abundant element by mass both in Earth’s crust and in the human body. It is the oxidizing agent for the metabolism of our foods and is crucial to human life.

### Properties of Oxygen

Oxygen has two allotropes,  $\text{O}_2$  and  $\text{O}_3$ . When we speak of molecular oxygen or simply oxygen, it is usually understood that we are speaking of *dioxygen* ( $\text{O}_2$ ), the normal form of the element;  $\text{O}_3$  is called *ozone*.

At room temperature dioxygen is a colorless and odorless gas. It condenses to a liquid at  $-183^\circ\text{C}$  and freezes at  $-218^\circ\text{C}$ . It is only slightly soluble in water (0.04 g/L, or 0.001 M at  $25^\circ\text{C}$ ), but its presence in water is essential to marine life.

The electron configuration of the oxygen atom is  $[\text{He}]2s^22p^4$ . Thus, oxygen can complete its octet of electrons either by picking up two electrons to form the oxide ion ( $\text{O}^{2-}$ ) or by sharing two electrons. In its covalent compounds it tends to form two bonds: either as two single bonds, as in  $\text{H}_2\text{O}$ , or as a double bond, as in formaldehyde ( $\text{H}_2\text{C}=\text{O}$ ). The  $\text{O}_2$  molecule itself contains a double bond.  $\text{O}=\text{O}$  (Section 9.8)

The bond in  $\text{O}_2$  is very strong (the bond enthalpy is 495 kJ/mol). Oxygen also forms strong bonds with many other elements. Consequently, many oxygen-containing compounds are thermodynamically more stable than  $\text{O}_2$ . In the absence of a catalyst, however, most reactions of  $\text{O}_2$  have high activation energies and thus require high temperatures to proceed at a suitable rate. Once a sufficiently exothermic reaction begins, however, it may accelerate rapidly, producing a reaction of explosive violence.

### Preparation of Oxygen

Nearly all commercial oxygen is obtained from air. The normal boiling point of  $\text{O}_2$  is  $-183^\circ\text{C}$ , whereas that of  $\text{N}_2$ , the other principal component of air, is  $-196^\circ\text{C}$ . Thus, when air is liquefied and then allowed to warm, the  $\text{N}_2$  boils off, leaving liquid  $\text{O}_2$  contaminated mainly by small amounts of  $\text{N}_2$  and Ar.

In the laboratory, O<sub>2</sub> can be obtained by heating either aqueous hydrogen peroxide or solid potassium chlorate (KClO<sub>3</sub>):

Manganese dioxide (MnO<sub>2</sub>) catalyzes both reactions.

Much of the O<sub>2</sub> in the atmosphere is replenished through the process of photosynthesis, in which green plants use the energy of sunlight to generate O<sub>2</sub> from atmospheric CO<sub>2</sub>. Photosynthesis, therefore, regenerates O<sub>2</sub> and uses up CO<sub>2</sub>.

## Uses of Oxygen

Oxygen is one of the most widely used industrial chemicals, ranking behind only sulfuric acid (H<sub>2</sub>SO<sub>4</sub>) and nitrogen (N<sub>2</sub>). About 3 × 10<sup>10</sup> kg (30 million tons) of O<sub>2</sub> is used annually in the United States. Oxygen can be shipped and stored either as a liquid or in steel containers as a compressed gas. About 70% of the O<sub>2</sub> output, however, is generated where it is needed.

Oxygen is by far the most widely used oxidizing agent. Over half of the O<sub>2</sub> produced is used in the steel industry, mainly to remove impurities from steel. It is also used to bleach pulp and paper. (Oxidation of colored compounds often gives colorless products.) In medicine, oxygen eases breathing difficulties. It is also used together with acetylene (C<sub>2</sub>H<sub>2</sub>) in oxyacetylene welding (Figure 22.16 ▶). The reaction between C<sub>2</sub>H<sub>2</sub> and O<sub>2</sub> is highly exothermic, producing temperatures in excess of 3000 °C:

## Ozone

Ozone is a pale blue poisonous gas with a sharp, irritating odor. Most people can detect about 0.01 ppm in air. Exposure to 0.1 to 1 ppm produces headaches, burning eyes, and irritation to the respiratory passages.

The structure of the O<sub>3</sub> molecule is shown in Figure 22.17 ▶. The molecule possesses a π bond that is delocalized over the three oxygen atoms. ∞ (Section 8.6) The molecule dissociates readily, forming reactive oxygen atoms:

Ozone is a stronger oxidizing agent than dioxygen. Ozone forms oxides with many elements under conditions where O<sub>2</sub> will not react; indeed, it oxidizes all the common metals except gold and platinum.

Ozone can be prepared by passing electricity through dry O<sub>2</sub> in a flow-through apparatus. The electrical discharge causes rupture of the O<sub>2</sub> bond, resulting in reactions like those described in Section 18.3.

Ozone cannot be stored for long, except at low temperature, because it readily decomposes to O<sub>2</sub>. The decomposition is catalyzed by certain metals, such as Ag, Pt, and Pd, and by many transition-metal oxides.

▲ **Figure 22.16** Welding with an oxyacetylene torch. The heat of combustion of acetylene is exceptionally high, thus giving rise to a very high flame temperature.

▲ **Figure 22.17** Structure of the ozone molecule.

### ■ SAMPLE EXERCISE 22.6 | Calculating an Equilibrium Constant

Using  $\Delta G_f^\circ$  for ozone from Appendix C, calculate the equilibrium constant,  $K$ , for Equation 22.25 at 298.0 K, assuming no electrical input.

#### SOLUTION

**Analyze:** We are asked to calculate the equilibrium constant for the formation of O<sub>3</sub> from O<sub>2</sub> (Equation 22.25), given the temperature and  $\Delta G_f^\circ$ .

**Plan:** The relationship between the standard free-energy change,  $\Delta G_f^\circ$ , for a reaction and the equilibrium constant for the reaction was given in Section 19.7, Equation 19.17.

**Solve:** From Appendix C we have

$$\Delta G_f^\circ(\text{O}_3) = 163.4 \text{ kJ/mol}$$

Thus, for Equation 22.25,

$$\Delta G^\circ = (2 \text{ mol O}_3)(163.4 \text{ kJ/mol O}_3) = 326.8 \text{ kJ}$$

From Equation 19.17 we have

$$\Delta G^\circ = -RT \ln K$$

Thus,

$$\ln K = \frac{-\Delta G^\circ}{RT} = \frac{-326.8 \times 10^3 \text{ J}}{(8.314 \text{ J/K}\cdot\text{mol})(298.0 \text{ K})} = -131.9$$

$$K = e^{-131.9} = 5 \times 10^{-58}$$

**Comment:** In spite of the unfavorable equilibrium constant, ozone can be prepared from  $\text{O}_2$  as described in the preceding text. The unfavorable free energy of formation is overcome by energy from the electrical discharge, and  $\text{O}_3$  is removed before the reverse reaction can occur, so a nonequilibrium mixture results.

### ■ PRACTICE EXERCISE

Using the data in Appendix C, calculate  $\Delta G^\circ$  and the equilibrium constant ( $K$ ) for Equation 22.24 at 298.0 K.

**Answer:**  $\Delta G^\circ = 66.7 \text{ kJ}$ ,  $K = 2 \times 10^{-12}$

Ozone is sometimes used to treat domestic water in place of chlorine. Like  $\text{Cl}_2$ , it kills bacteria and oxidizes organic compounds. The largest use of ozone, however, is in the preparation of pharmaceuticals, synthetic lubricants, and other commercially useful organic compounds, where  $\text{O}_3$  is used to sever carbon-carbon double bonds.

Ozone is an important component of the upper atmosphere, where it screens out ultraviolet radiation. In this way ozone protects Earth from the effects of these high-energy rays. For this reason, depletion of stratospheric ozone is a major scientific concern. [☞ \(Section 18.3\)](#) In the lower atmosphere, however, ozone is considered an air pollutant. It is a major constituent of smog. [☞ \(Section 18.4\)](#) Because of its oxidizing power, ozone damages living systems and structural materials, especially rubber.

## Oxides

The electronegativity of oxygen is second only to that of fluorine. As a result, oxygen exhibits negative oxidation states in all compounds except those with fluorine,  $\text{OF}_2$  and  $\text{O}_2\text{F}_2$ . The  $-2$  oxidation state is by far the most common. Compounds in this oxidation state are called *oxides*.

Nonmetals form covalent oxides. Most of these oxides are simple molecules with low melting and boiling points.  $\text{SiO}_2$  and  $\text{B}_2\text{O}_3$ , however, have polymeric structures. [☞ \(Sections 22.10 and 22.11\)](#) Most nonmetal oxides combine with water to give oxyacids. Sulfur dioxide ( $\text{SO}_2$ ), for example, dissolves in water to give sulfurous acid ( $\text{H}_2\text{SO}_3$ ):

This reaction and that of  $\text{SO}_3$  with  $\text{H}_2\text{O}$  to form  $\text{H}_2\text{SO}_4$  are largely responsible for acid rain. [☞ \(Section 18.4\)](#) The analogous reaction of  $\text{CO}_2$  with  $\text{H}_2\text{O}$  to form carbonic acid ( $\text{H}_2\text{CO}_3$ ) causes the acidity of carbonated water.

Oxides that react with water to form acids are called **acidic anhydrides** (anhydride means “without water”) or **acidic oxides**. A few nonmetal oxides, especially ones with the nonmetal in a low oxidation state—such as  $\text{N}_2\text{O}$ ,  $\text{NO}$ , and  $\text{CO}$ —do not react with water and are not acidic anhydrides.

### GIVE IT SOME THOUGHT

What acid is produced by the reaction of  $\text{I}_2\text{O}_5$  with water?

▲ **Figure 22.19** A self-contained breathing apparatus. The source of oxygen in this apparatus, used by firefighters and rescue workers, is the reaction between potassium superoxide ( $\text{KO}_2$ ) and water in the breath.

▲ **Figure 22.20** The molecular structure of hydrogen peroxide. Note that the atoms of  $\text{H}_2\text{O}_2$  do not lie in a single plane.

**TABLE 22.4** ■ Acid–Base Character of Chromium Oxides

Oxide	Oxidation State of Cr	Nature of Oxide
$\text{CrO}$	+2	Basic
$\text{Cr}_2\text{O}_3$	+3	Amphoteric
$\text{CrO}_3$	+6	Acidic

Oxides that can exhibit both acidic and basic characters are said to be *amphoteric*. ∞ (Section 17.5) If a metal forms more than one oxide, the basic character of the oxide decreases as the oxidation state of the metal increases, as illustrated in Table 22.4 ▲.

## Peroxides and Superoxides

Compounds containing O—O bonds and oxygen in an oxidation state of  $-1$  are called *peroxides*. Oxygen has an oxidation state of  $-\frac{1}{2}$  in  $\text{O}_2^-$ , which is called the *superoxide ion*. The most active metals (K, Rb, and Cs) react with  $\text{O}_2$  to give superoxides ( $\text{KO}_2$ ,  $\text{RbO}_2$ , and  $\text{CsO}_2$ ). Their active neighbors in the periodic table (Na, Ca, Sr, and Ba) react with  $\text{O}_2$ , producing peroxides ( $\text{Na}_2\text{O}_2$ ,  $\text{CaO}_2$ ,  $\text{SrO}_2$ , and  $\text{BaO}_2$ ). Less active metals and nonmetals produce normal oxides. ∞ (Section 7.6)

When superoxides dissolve in water,  $\text{O}_2$  is produced:

Because of this reaction, potassium superoxide ( $\text{KO}_2$ ) is used as an oxygen source in masks worn by rescue workers (Figure 22.19 ◀). Moisture in the breath causes the compound to decompose to form  $\text{O}_2$  and  $\text{KOH}$ . The  $\text{KOH}$  so formed removes  $\text{CO}_2$  from the exhaled breath:

Hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) is the most familiar and commercially important peroxide. The structure of  $\text{H}_2\text{O}_2$  is shown in Figure 22.20 ◀. Pure hydrogen peroxide is a clear, syrupy liquid that has a melting point of  $-0.4^\circ\text{C}$ . Concentrated hydrogen peroxide is a dangerously reactive substance because the decomposition to form water and oxygen gas is very exothermic.

This is a **disproportionation reaction**, one in which an element is simultaneously oxidized and reduced. The oxidation number of oxygen goes from  $-1$  to  $-2$  and  $0$ .

Hydrogen peroxide is marketed as a chemical reagent in aqueous solutions of up to about 30% by mass. A solution containing about 3%  $\text{H}_2\text{O}_2$  by mass is sold in drugstores and used as a mild antiseptic. Somewhat more concentrated solutions are employed to bleach fabrics.

The peroxide ion is also a by-product of metabolism that results from the reduction of molecular oxygen ( $\text{O}_2$ ). The body disposes of this reactive species with enzymes such as peroxidase and catalase.

## 22.6 THE OTHER GROUP 6A ELEMENTS: S, Se, Te, AND Po

In addition to oxygen, the other group 6A elements are sulfur, selenium, tellurium, and polonium. In this section we will survey the properties of the group as a whole and then examine the chemistry of sulfur, selenium, and tellurium. We will not say much about polonium, which has no stable isotopes and is found only in minute quantities in radium-containing minerals.

TABLE 22.5 ■ Some Properties of the Group 6A Elements

Property	O	S	Se	Te
Atomic radius (Å)	0.73	1.04	1.17	1.43
X <sup>2-</sup> ionic radius (Å)	1.40	1.84	1.98	2.21
First ionization energy (kJ/mol)	1314	1000	941	869
Electron affinity (kJ/mol)	-141	-200	-195	-190
Electronegativity	3.5	2.5	2.4	2.1
X—X single-bond enthalpy (kJ/mol)	146*	266	172	126
Reduction potential to H <sub>2</sub> X in acidic solution (V)	1.23	0.14	-0.40	-0.72

\*Based on O—O bond energy in H<sub>2</sub>O<sub>2</sub>.

## General Characteristics of the Group 6A Elements

The group 6A elements possess the general outer-electron configuration  $ns^2np^4$ , where  $n$  has values ranging from 2 through 6. Thus, these elements may attain a noble-gas electron configuration by the addition of two electrons, which results in a  $-2$  oxidation state. Except for oxygen, however, the group 6A elements are also commonly found in positive oxidation states up to  $+6$ , and they can have expanded valence shells. Thus, compounds such as SF<sub>6</sub>, SeF<sub>6</sub>, and TeF<sub>6</sub> occur in which the central atom is in the  $+6$  oxidation state with more than an octet of valence electrons.

Table 22.5 summarizes some of the more important properties of the atoms of the group 6A elements. In most of the properties listed in Table 22.5, we see a regular variation as a function of increasing atomic number. For example, atomic and ionic radii increase and ionization energies decrease, as expected, as we move down the family.

## Occurrence and Preparation of S, Se, and Te

Large underground deposits are the principal source of elemental sulfur. Sulfur also occurs widely as sulfide and sulfate minerals. Its presence as a minor component of coal and petroleum poses a major problem. Combustion of these “unclean” fuels leads to serious pollution by sulfur oxides. [↔ \(Section 18.4\)](#) Much effort has been directed at removing this sulfur, and these efforts have increased the availability of sulfur. The sale of this sulfur helps to partially offset the costs of the desulfurizing processes and equipment.

Selenium and tellurium occur in rare minerals such as Cu<sub>2</sub>Se, PbSe, Cu<sub>2</sub>Te, and PbTe. They also occur as minor constituents in sulfide ores of copper, iron, nickel, and lead.

## Properties and Uses of Sulfur, Selenium, and Tellurium

As we normally encounter it, sulfur is yellow, tasteless, and nearly odorless. It is insoluble in water and exists in several allotropic forms. The thermodynamically stable form at room temperature is rhombic sulfur, which consists of puckered S<sub>8</sub> rings, as shown in Figure 22.21. When heated above its melting point (113 °C), sulfur undergoes a variety of changes.

(a)

(b)

▼ **Figure 22.21 Elemental sulfur.** The common yellow crystalline form of rhombic sulfur, S<sub>8</sub>, consists of eight-membered puckered rings of S atoms.

▲ **Figure 22.22 Heating sulfur.** When sulfur is heated above its melting point (113 °C), it becomes dark and viscous. Here the liquid is shown falling into cold water, where it again solidifies.

▲ **Figure 22.23 Portion of the structure of crystalline selenium.** The dashed lines represent weak bonding interactions between atoms in adjacent chains. Tellurium has the same structure.

▲ **Figure 22.24 Iron pyrite (FeS<sub>2</sub>).** This substance is also known as fool's gold because its color has fooled people into thinking it was gold. Gold is much denser and softer than iron pyrite.

The molten sulfur first contains S<sub>8</sub> molecules and is fluid because the rings readily slip over one another. Further heating of this straw-colored liquid causes the rings to break; the fragments then join to form very long molecules that can become entangled. The sulfur consequently becomes highly viscous. This change is marked by a color change to dark reddish brown (Figure 22.22 ◀). Further heating breaks the chains, and the viscosity again decreases.

Most of the approximately  $1 \times 10^{10}$  kg (10 million tons) of sulfur produced in the United States each year is used to manufacture sulfuric acid. Sulfur is also used to vulcanize rubber, a process that toughens rubber by introducing cross-linking between polymer chains. ⇐ (Section 12.6)

The most stable allotropes of both selenium and tellurium are crystalline substances containing helical chains of atoms, as illustrated in Figure 22.23 ◀. Each atom of the chain is close to atoms in adjacent chains, and it appears that some sharing of electron pairs between these atoms occurs.

The electrical conductivity of selenium is very low in the dark, but increases greatly upon exposure to light. This property of the element is utilized in photoelectric cells and light meters. Photocopiers also depend on the photoconductivity of selenium. Photocopy machines contain a belt or drum coated with a film of selenium. This drum is electrostatically charged and then exposed to light reflected from the image being photocopied. The electric charge drains from the selenium where it has been made conductive by exposure to light. A black powder (the toner) sticks only to the areas that remain charged. The photocopy is made when the toner is transferred to a sheet of plain paper, which is heated to fuse the toner to the paper.

### Sulfides

Sulfur forms compounds by direct combination with many elements. When the element is less electronegative than sulfur, *sulfides*, which contain S<sup>2-</sup>, form. Iron(II) sulfide (FeS) forms, for example, by direct combination of iron and sulfur. Many metallic elements are found in the form of sulfide ores, such as PbS (galena) and HgS (cinnabar). A series of related ores containing the disulfide ion, S<sub>2</sub><sup>2-</sup> (analogous to the peroxide ion), are known as *pyrites*. Iron pyrite, FeS<sub>2</sub>, occurs as golden yellow cubic crystals (Figure 22.24 ◀). Because it has been occasionally mistaken for gold by miners, iron pyrite is often called fool's gold.

One of the most important sulfides is hydrogen sulfide (H<sub>2</sub>S). This substance is not normally produced by direct union of the elements because it is unstable at elevated temperatures and decomposes into the elements. It is normally prepared by action of dilute acid on iron(II) sulfide.

One of hydrogen sulfide's most readily recognized properties is its odor; H<sub>2</sub>S is largely responsible for the offensive odor of rotten eggs. Hydrogen sulfide is actually quite toxic. Fortunately, our noses are able to detect H<sub>2</sub>S at extremely low, nontoxic concentrations. A sulfur-containing organic molecule, such as dimethyl sulfide, (CH<sub>3</sub>)<sub>2</sub>S, which is similarly odoriferous and can be detected by smell at a level of one part per trillion, is added to natural gas as a safety factor to give it a detectable odor.

### Oxides, Oxyacids, and Oxyanions of Sulfur

Sulfur dioxide is formed when sulfur is combusted in air; it has a choking odor and is poisonous. The gas is particularly toxic to lower organisms, such as fungi, so it is used to sterilize dried fruit and wine. At 1 atm pressure and room temperature, SO<sub>2</sub> dissolves in water to produce a solution of about 1.6 M concentration. The SO<sub>2</sub> solution is acidic, and we describe it as sulfurous acid (H<sub>2</sub>SO<sub>3</sub>).

Salts of SO<sub>3</sub><sup>2-</sup> (sulfites) and HSO<sub>3</sub><sup>-</sup> (hydrogen sulfites or bisulfites) are well known. Small quantities of Na<sub>2</sub>SO<sub>3</sub> or NaHSO<sub>3</sub> are used as food additives to

prevent bacterial spoilage. Because some people are extremely allergic to sulfites, all food products with sulfites must now carry a warning label disclosing their presence.

Although combustion of sulfur in air produces mainly  $\text{SO}_2$ , small amounts of  $\text{SO}_3$  are also formed. The reaction produces chiefly  $\text{SO}_2$  because the activation-energy barrier for further oxidation to  $\text{SO}_3$  is very high unless the reaction is catalyzed. Sulfur trioxide is of great commercial importance because it is the anhydride of sulfuric acid. In the manufacture of sulfuric acid,  $\text{SO}_2$  is first obtained by burning sulfur. The  $\text{SO}_2$  is then oxidized to  $\text{SO}_3$ , using a catalyst such as  $\text{V}_2\text{O}_5$  or platinum. The  $\text{SO}_3$  is dissolved in  $\text{H}_2\text{SO}_4$  because it does not dissolve quickly in water, and then the  $\text{H}_2\text{S}_2\text{O}_7$  formed in this reaction, called pyrosulfuric acid, is added to water to form  $\text{H}_2\text{SO}_4$ :

### GIVE IT SOME THOUGHT

Is Equation 22.34 an example of an oxidation-reduction reaction?

Commercial sulfuric acid is 98%  $\text{H}_2\text{SO}_4$ . It is a dense, colorless, oily liquid that boils at  $340^\circ\text{C}$ . Sulfuric acid has many useful properties: It is a strong acid, a good dehydrating agent, and a moderately good oxidizing agent. Its dehydrating ability is demonstrated in Figure 22.25.

Year after year, the production of sulfuric acid is the largest of any chemical produced in the United States. About  $4 \times 10^{10}$  kg (40 million tons) is produced annually in this country. Sulfuric acid is employed in some way in almost all manufacturing. Consequently, its consumption is considered a measure of industrial activity.

Sulfuric acid is a strong acid, but only the first hydrogen is completely ionized in aqueous solution:

**▲ Figure 22.25 A dehydration reaction.** Sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) is a carbohydrate, containing two H atoms for each O atom. (a) The beaker contains solid sucrose (table sugar), initially white. Adding concentrated sulfuric acid, which is an excellent dehydrating agent, removes  $\text{H}_2\text{O}$  from the sucrose. (b, c) The product of the dehydration is carbon, the black mass remaining at the end of the reaction.

(a)

(b)

▲ **Figure 22.26 Structures of sulfate ions.** (a) The sulfate ion ( $\text{SO}_4^{2-}$ ), and (b) the thiosulfate ion ( $\text{S}_2\text{O}_3^{2-}$ ).

Consequently, sulfuric acid forms two series of compounds: sulfates and bisulfates (or hydrogen sulfates). Bisulfate salts are common components of the “dry acids” used for adjusting the pH of swimming pools and hot tubs; they are also components of many toilet bowl cleaners.

The thiosulfate ion ( $\text{S}_2\text{O}_3^{2-}$ ) is related to the sulfate ion and is formed by boiling an alkaline solution of  $\text{SO}_3^{2-}$  with elemental sulfur.

The term *thio* indicates substitution of sulfur for oxygen. The structures of the sulfate and thiosulfate ions are compared in Figure 22.26 ◀.

## 22.7 NITROGEN

Nitrogen was discovered in 1772 by the Scottish botanist Daniel Rutherford. He found that when a mouse was enclosed in a sealed jar, the animal quickly consumed the life-sustaining component of air (oxygen) and died. When the “fixed air” ( $\text{CO}_2$ ) in the container was removed, a “noxious air” remained that would not sustain combustion or life. We now know that gas as nitrogen.

Nitrogen constitutes 78% by volume of Earth’s atmosphere, where it occurs as  $\text{N}_2$  molecules. Although nitrogen is a key element in living organisms, compounds of nitrogen are not abundant in Earth’s crust. The major natural deposits of nitrogen compounds are those of  $\text{KNO}_3$  (saltpeter) in India and  $\text{NaNO}_3$  (Chile saltpeter) in Chile and other desert regions of South America.

### Properties of Nitrogen

Nitrogen is a colorless, odorless, and tasteless gas composed of  $\text{N}_2$  molecules. Its melting point is  $-210^\circ\text{C}$ , and its normal boiling point is  $-196^\circ\text{C}$ .

The  $\text{N}_2$  molecule is very unreactive because of the strong triple bond between nitrogen atoms (the  $\text{N}\equiv\text{N}$  bond enthalpy is  $941 \text{ kJ/mol}$ , nearly twice that for the bond in  $\text{O}_2$ ; see Table 8.4). When substances burn in air, they normally react with  $\text{O}_2$  but not with  $\text{N}_2$ . When magnesium burns in air, however, it also reacts with  $\text{N}_2$  to form magnesium nitride ( $\text{Mg}_3\text{N}_2$ ). A similar reaction occurs with lithium, forming  $\text{Li}_3\text{N}$ .

The nitride ion is a strong Brønsted–Lowry base. It reacts with water to form ammonia ( $\text{NH}_3$ ), as in the following reaction:

The electron configuration of the nitrogen atom is  $[\text{He}]2s^22p^3$ . The element exhibits all formal oxidation states from +5 to  $-3$ , as shown in Table 22.6 ◀. The +5, 0, and  $-3$  oxidation states are the most common and generally the most stable of these. Because nitrogen is more electronegative than all elements except fluorine, oxygen, and chlorine, it exhibits positive oxidation states only in combination with these three elements.

### Preparation and Uses of Nitrogen

Elemental nitrogen is obtained in commercial quantities by fractional distillation of liquid air. About  $4 \times 10^{10} \text{ kg}$  (40 million tons) of  $\text{N}_2$  is produced annually in the United States.

Because of its low reactivity, large quantities of  $\text{N}_2$  are used as an inert gaseous blanket to exclude  $\text{O}_2$  during the processing and packaging of foods, the manufacture of chemicals, the fabrication of metals, and the production of electronic devices. Liquid  $\text{N}_2$  is employed as a coolant to freeze foods rapidly.

**TABLE 22.6** ■ Oxidation States of Nitrogen

Oxidation State	Examples
+5	$\text{N}_2\text{O}_5$ , $\text{HNO}_3$ , $\text{NO}_3^-$

+2	$\text{NO}$
+1	$\text{N}_2\text{O}$ , $\text{H}_2\text{N}_2\text{O}_2$ , $\text{N}_2\text{O}_2^{2-}$ , $\text{HNF}_2$
0	$\text{N}_2$
$-1$	$\text{NH}_2\text{OH}$ , $\text{NH}_2\text{F}$
$-2$	$\text{N}_2\text{H}_4$
$-3$	$\text{NH}_3$ , $\text{NH}_4^+$ , $\text{NH}_2^-$

▲ **Figure 22.27 Nitrogen conversions.** Sequence of conversion of  $\text{N}_2$  into common nitrogen compounds.

The largest use of  $\text{N}_2$  is in the manufacture of nitrogen-containing fertilizers, which provide a source of *fixed* nitrogen. We have previously discussed nitrogen fixation in the “Chemistry and Life” box in Section 14.7 and in the “Chemistry Put to Work” box in Section 15.2. Our starting point in fixing nitrogen is the manufacture of ammonia via the Haber process. ∞ (Section 15.2) The ammonia can then be converted into a variety of useful, simple nitrogen-containing species, as shown in Figure 22.27 ▲. Many of the reactions along this chain of conversion are discussed in more detail later in this section.

## Hydrogen Compounds of Nitrogen

*Ammonia* is one of the most important compounds of nitrogen. It is a colorless toxic gas that has a characteristic irritating odor. As we have noted in previous discussions, the  $\text{NH}_3$  molecule is basic ( $K_b = 1.8 \times 10^{-5}$ ). ∞ (Section 16.7)

In the laboratory  $\text{NH}_3$  can be prepared by the action of  $\text{NaOH}$  on an ammonium salt. The  $\text{NH}_4^+$  ion, which is the conjugate acid of  $\text{NH}_3$ , transfers a proton to  $\text{OH}^-$ . The resultant  $\text{NH}_3$  is volatile and is driven from the solution by mild heating.

Commercial production of  $\text{NH}_3$  is achieved by the Haber process.

About  $1 \times 10^{10}$  kg (10 million tons) of ammonia is produced annually in the United States. About 75% is used for fertilizer.

*Hydrazine* ( $\text{N}_2\text{H}_4$ ) is another important hydride of nitrogen. As shown in Figure 22.28 ►, the hydrazine molecule contains an N—N single bond. Hydrazine is quite poisonous. It can be prepared by the reaction of ammonia with hypochlorite ion ( $\text{OCl}^-$ ) in aqueous solution.

The reaction is complex, involving several intermediates, including chloramine ( $\text{NH}_2\text{Cl}$ ). The poisonous  $\text{NH}_2\text{Cl}$  bubbles out of solution when household ammonia and chlorine bleach (which contains  $\text{OCl}^-$ ) are mixed. This reaction is one reason for the frequently cited warning not to mix bleach and household ammonia.

Pure hydrazine is a strong and versatile reducing agent. The major use of hydrazine and compounds related to it, such as methylhydrazine (Figure 22.28), is as rocket fuels.

▲ **Figure 22.28 Structures of hydrazine ( $\text{N}_2\text{H}_4$ ) and methylhydrazine ( $\text{CH}_3\text{NHNH}_2$ ).**

**SAMPLE EXERCISE 22.7** | Writing a Balanced Equation

Hydroxylamine ( $\text{NH}_2\text{OH}$ ) reduces copper(II) to the free metal in acid solutions. Write a balanced equation for the reaction, assuming that  $\text{N}_2$  is the oxidation product.

**SOLUTION**

**Analyze:** We are asked to write a balanced oxidation-reduction equation in which  $\text{NH}_2\text{OH}$  is converted to  $\text{N}_2$  and  $\text{Cu}^{2+}$  is converted to  $\text{Cu}$ .

**Plan:** Because this is a redox reaction, the equation can be balanced by the method of half-reactions discussed in Section 20.2. Thus, we begin with two half-reactions, one involving the  $\text{NH}_2\text{OH}$  and  $\text{N}_2$  and the other involving  $\text{Cu}^{2+}$  and  $\text{Cu}$ .

**Solve:** The unbalanced and incomplete half-reactions are

Balancing these equations as described in Section 20.2 gives

Adding these half-reactions gives the balanced equation:

**PRACTICE EXERCISE**

(a) In power plants, hydrazine is used to prevent corrosion of the metal parts of steam boilers by the  $\text{O}_2$  dissolved in the water. The hydrazine reacts with  $\text{O}_2$  in water to give  $\text{N}_2$  and  $\text{H}_2\text{O}$ . Write a balanced equation for this reaction. (b) Methylhydrazine,  $\text{N}_2\text{H}_3\text{CH}_3(\text{l})$ , is used with the oxidizer dinitrogen tetroxide,  $\text{N}_2\text{O}_4(\text{l})$ , to power the steering rockets of the Space Shuttle orbiter. The reaction of these two substances produces  $\text{N}_2$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$ . Write a balanced equation for this reaction.

**Answers:** (a)  $\text{N}_2\text{H}_4(\text{aq}) + \text{O}_2(\text{aq}) \longrightarrow \text{N}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l})$ ; (b)  $5 \text{N}_2\text{O}_4(\text{l}) + 4 \text{N}_2\text{H}_3\text{CH}_3(\text{l}) \longrightarrow 9 \text{N}_2(\text{g}) + 4 \text{CO}_2(\text{g}) + 12 \text{H}_2\text{O}(\text{g})$

**Oxides and Oxyacids of Nitrogen**

Nitrogen forms three common oxides:  $\text{N}_2\text{O}$  (nitrous oxide),  $\text{NO}$  (nitric oxide), and  $\text{NO}_2$  (nitrogen dioxide). It also forms two unstable oxides that we will not discuss,  $\text{N}_2\text{O}_3$  (dinitrogen trioxide) and  $\text{N}_2\text{O}_5$  (dinitrogen pentoxide).

*Nitrous oxide* ( $\text{N}_2\text{O}$ ) is also known as laughing gas because a person becomes somewhat giddy after inhaling only a small amount of it. This colorless gas was the first substance used as a general anesthetic. It is used as the compressed gas propellant in several aerosols and foams, such as in whipped cream. It can be prepared in the laboratory by carefully heating ammonium nitrate to about  $200^\circ\text{C}$ .

*Nitric oxide* ( $\text{NO}$ ) is also a colorless gas, but, unlike  $\text{N}_2\text{O}$ , it is slightly toxic. It can be prepared in the laboratory by reduction of dilute nitric acid, using copper or iron as a reducing agent, as shown in Figure 22.29 ▼.

**► Figure 22.29 Nitric oxide**

**formation.** (a) Nitric oxide ( $\text{NO}$ ) can be prepared by the reaction of copper with  $6 \text{ M}$  nitric acid. In this photograph a jar containing  $6 \text{ M}$   $\text{HNO}_3$  has been inverted over some pieces of copper. Colorless  $\text{NO}$ , which is only slightly soluble in water, is collected in the jar. The blue color of the solution is due to the presence of  $\text{Cu}^{2+}$  ions. (b) Colorless  $\text{NO}$  gas, collected as shown in (a). (c) When the stopper is removed from the jar of  $\text{NO}$ , the  $\text{NO}$  reacts with oxygen in the air to form yellow-brown  $\text{NO}_2$ .

(a)

(b)

(c)

Nitric oxide is also produced by direct reaction of  $N_2$  and  $O_2$  at high temperatures. This reaction is a significant source of nitrogen oxide air pollutants.  $\infty$  (Section 18.4) The direct combination of  $N_2$  and  $O_2$  is not used for commercial production of NO, however, because the yield is low; the equilibrium constant  $K_p$  at 2400 K is only 0.05.  $\infty$  (Section 15.7, "Chemistry Put to Work: Controlling Nitric Oxide Emissions")

The commercial route to NO (and hence to other oxygen-containing compounds of nitrogen) is via the catalytic oxidation of  $NH_3$ .

The catalytic conversion of  $NH_3$  to NO is the first step in a three-step process known as the **Ostwald process**, by which  $NH_3$  is converted commercially into nitric acid ( $HNO_3$ ). Nitric oxide reacts readily with  $O_2$ , forming  $NO_2$  when exposed to air (Figure 22.29).

When dissolved in water,  $NO_2$  forms nitric acid.

Nitrogen is both oxidized and reduced in this reaction, so it disproportionates. The reduction product NO can be converted back into  $NO_2$  by exposure to air and thereafter dissolved in water to prepare more  $HNO_3$ .

Recently NO has been found to be an important neurotransmitter in the human body. It causes the muscles that line blood vessels to relax, thus allowing an increased passage of blood (see the "Chemistry and Life" box on page 956).

*Nitrogen dioxide* ( $NO_2$ ) is a yellow-brown gas (Figure 22.29). Like NO, it is a major constituent of smog.  $\infty$  (Section 18.4) It is poisonous and has a choking odor. As discussed in the introduction of Chapter 15,  $NO_2$  and  $N_2O_4$  exist in equilibrium (Figures 15.1 and 15.2):

The two common oxyacids of nitrogen are nitric acid ( $HNO_3$ ) and nitrous acid ( $HNO_2$ ) (Figure 22.30). *Nitric acid* is a strong acid. It is also a powerful oxidizing agent, as the following standard reduction potential indicates:

Concentrated nitric acid will attack and oxidize most metals except Au, Pt, Rh, and Ir.

About  $7 \times 10^9$  kg (8 million tons) of nitric acid is produced annually in the United States. Its largest use is in the manufacture of  $NH_4NO_3$  for fertilizers, which accounts for about 80% of that produced.  $HNO_3$  is also used in the production of plastics, drugs, and explosives. Among the explosives made from nitric acid are nitroglycerin, trinitrotoluene (TNT), and nitrocellulose. The following reaction occurs when nitroglycerin explodes:

All the products of this reaction contain very strong bonds. As a result, the reaction is very exothermic. Furthermore, a tremendous amount of gaseous products forms from the liquid. The sudden formation of these gases, together with their expansion resulting from the heat generated by the reaction, produces the explosion.  $\infty$  (Section 8.8: "Chemistry Put to Work: Explosives and Alfred Nobel")

*Nitrous acid* ( $HNO_2$ ) (Figure 22.30) is considerably less stable than  $HNO_3$  and tends to disproportionate into NO and  $HNO_3$ . It is normally made by action of a strong acid, such as  $H_2SO_4$ , on a cold solution of a nitrite salt, such as  $NaNO_2$ . Nitrous acid is a weak acid ( $K_a = 4.5 \times 10^{-4}$ ).

▲ Figure 22.30 Structures of nitric acid and nitrous acid.

During the 1870s an interesting observation was made in Alfred Nobel's dynamite factories. Workers who suffered from heart disease that caused chest pains when they exerted themselves found relief from the pains during the workweek. It quickly became apparent that nitroglycerin, present in the air of the factory, acted to enlarge blood vessels. Thus, this powerfully explosive chemical became a standard treatment for angina pectoris, the chest pains accompanying heart failure (Figure 22.31). It took more than 100 years to discover that nitroglycerin was converted in the vascular smooth muscle into NO, which is the chemical agent actually causing dilation of the blood vessels. In 1998 the Nobel Prize in medicine and physiology was awarded to Robert F. Furchgott, Louis J. Ignarro, and Ferid Murad for their discoveries of the detailed pathways by which NO acts in the cardiovascular system. It was a sensation that this

simple, common air pollutant could exert important functions in the organism.

As useful as nitroglycerin is to this day in treating angina pectoris, it has a limitation in that prolonged administration results in development of tolerance, or desensitization, of the vascular muscle to further vasorelaxation by nitroglycerin. The bioactivation of nitroglycerin is the subject of active research in the hope that a means of circumventing desensitization can be found.

▲ Figure 22.31 Nitroglycerin tablets.

### GIVE IT SOME THOUGHT

What are the oxidation numbers of the nitrogen atoms in (a) nitric acid; (b) nitrous acid?

## 22.8 THE OTHER GROUP 5A ELEMENTS: P, As, Sb, AND Bi

5A
7 N
15 P
33 As
51 Sb
83 Bi

Of the other group 5A elements—phosphorus, arsenic, antimony, and bismuth—phosphorus has a central role in several aspects of biochemistry and environmental chemistry. In this section we will explore the chemistry of these other group 5A elements, with an emphasis on the chemistry of phosphorus.

### General Characteristics of the Group 5A Elements

The group 5A elements possess the outer-shell electron configuration  $ns^2np^3$ , where  $n$  has values ranging from 2 to 6. A noble-gas configuration results from the addition of three electrons to form the  $-3$  oxidation state. Ionic compounds containing  $X^{3-}$  ions are not common, however. More commonly, the group 5A element acquires an octet of electrons via covalent bonding. The oxidation number may range from  $-3$  to  $+5$ , depending on the nature and number of the atoms to which the group 5A element is bonded.

Because of its lower electronegativity, phosphorus is found more frequently in positive oxidation states than is nitrogen. Furthermore, compounds in which phosphorus has the  $+5$  oxidation state are not as strongly oxidizing as the corresponding compounds of nitrogen. Conversely, compounds in which phosphorus has a  $-3$  oxidation state are much stronger reducing agents than are the corresponding compounds of nitrogen.

Some of the important properties of the group 5A elements are listed in Table 22.7. The general pattern that emerges from these data is similar to what we have seen before with other groups: Size and metallic character increase as atomic number increases within the group.

The variation in properties among the elements of group 5A is more striking than that seen in groups 6A and 7A. Nitrogen at the one extreme exists as a gaseous diatomic molecule; it is clearly nonmetallic in character. At the other extreme, bismuth is a reddish white, metallic-looking substance that has most of the characteristics of a metal.

TABLE 22.7 ■ Properties of the Group 5A Elements

Property	N	P	As	Sb	Bi
Atomic radius (Å)	0.75	1.10	1.21	1.41	1.55
First ionization energy (kJ/mol)	1402	1012	947	834	703
Electron affinity (kJ/mol)	>0	-72	-78	-103	-91
Electronegativity	3.0	2.1	2.0	1.9	1.9
X—X single-bond enthalpy (kJ/mol)*	163	200	150	120	—
X≡X triple-bond enthalpy (kJ/mol)	941	490	380	295	192

\*Approximate values only.

The values listed for X—X single-bond enthalpies are not very reliable because it is difficult to obtain such data from thermochemical experiments. However, there is no doubt about the general trend: a low value for the N—N single bond, an increase at phosphorus, and then a gradual decline to arsenic and antimony. From observations of the elements in the gas phase, it is possible to estimate the X≡X triple-bond enthalpies, as listed in Table 22.7. Here we see a trend that is different from that for the X—X single bond. Nitrogen forms a much stronger triple bond than the other elements, and there is a steady decline in the triple-bond enthalpy down through the group. These data help us to appreciate why nitrogen alone of the group 5A elements exists as a diatomic molecule in its stable state at 25 °C. All the other elements exist in structural forms with single bonds between the atoms.

### Occurrence, Isolation, and Properties of Phosphorus

Phosphorus occurs mainly in the form of phosphate minerals. The principal source of phosphorus is phosphate rock, which contains phosphate principally as  $\text{Ca}_3(\text{PO}_4)_2$ . The element is produced commercially by reduction of calcium phosphate with carbon in the presence of  $\text{SiO}_2$ :

The phosphorus produced in this fashion is the allotrope known as white phosphorus. This form distills from the reaction mixture as the reaction proceeds.

White phosphorus consists of  $\text{P}_4$  tetrahedra (Figure 22.32▶). The  $60^\circ$  bond angles in  $\text{P}_4$  are unusually small for molecules, so there is much strain in the bonding, which is consistent with the high reactivity of white phosphorus. This allotrope bursts spontaneously into flames if exposed to air. When heated in the absence of air to about  $400 \text{ }^\circ\text{C}$ , white phosphorus is converted to a more stable allotrope known as red phosphorus, which does not ignite on contact with air. Red phosphorus is also considerably less poisonous than the white form. Both allotropes are shown in Figure 22.33▶. We will denote elemental phosphorus as simply P(s).

### Phosphorus Halides

Phosphorus forms a wide range of compounds with the halogens, the most important of which are the trihalides and pentahalides. Phosphorus trichloride ( $\text{PCl}_3$ ) is commercially the most significant of these compounds and is used to prepare a wide variety of products, including soaps, detergents, plastics, and insecticides.

Phosphorus chlorides, bromides, and iodides can be made by the direct oxidation of elemental phosphorus with the elemental halogen.  $\text{PCl}_3$ , for example, which is a liquid at room temperature, is made by passing a stream of dry chlorine gas over white or red phosphorus.

If excess chlorine gas is present, an equilibrium is established between  $\text{PCl}_3$  and  $\text{PCl}_5$ .

▲ Figure 22.32 Structure of white phosphorus. Tetrahedral structure of the  $\text{P}_4$  molecule.

▲ Figure 22.33 Phosphorus allotropes. White phosphorus is very reactive and is normally stored under water to protect it from oxygen. Red phosphorus is much less reactive than white phosphorus, and it is not necessary to store it under water.

▲ Figure 22.34 Structures of  $P_4O_6$  and  $P_4O_{10}$ .

▲ Figure 22.35 Structures of  $H_3PO_4$  and  $H_3PO_3$ .

The phosphorus halides hydrolyze on contact with water. The reactions occur readily, and most of the phosphorus halides fume in air because of reaction with water vapor. In the presence of excess water the products are the corresponding phosphorus oxyacid and hydrogen halide.

### Oxy Compounds of Phosphorus

Probably the most significant compounds of phosphorus are those in which the element is combined in some way with oxygen. Phosphorus(III) oxide ( $P_4O_6$ ) is obtained by allowing white phosphorus to oxidize in a limited supply of oxygen. When oxidation takes place in the presence of excess oxygen, phosphorus(V) oxide ( $P_4O_{10}$ ) forms. This compound is also readily formed by oxidation of  $P_4O_6$ . These two oxides represent the two most common oxidation states for phosphorus, +3 and +5. The structural relationship between  $P_4O_6$  and  $P_4O_{10}$  is shown in Figure 22.34. Notice the resemblance these molecules have to the  $P_4$  molecule, shown in Figure 22.32; all three substances have a  $P_4$  core.

#### ■ SAMPLE EXERCISE 22.8 Calculating a Standard Enthalpy Change

The reactive chemicals on the tip of a “strike anywhere” match are usually  $P_4S_3$  and an oxidizing agent such as  $KClO_3$ . When the match is struck on a rough surface, the heat generated by the friction ignites the  $P_4S_3$ , and the oxidizing agent brings about rapid combustion. The products of the combustion of  $P_4S_3$  are  $P_4O_{10}$  and  $SO_2$ . Calculate the standard enthalpy change for the combustion of  $P_4S_3$  in air, given the following standard enthalpies of formation:  $P_4S_3$  ( $-154.4$  kJ/mol),  $P_4O_{10}$  ( $-2940.1$  kJ/mol),  $SO_2$  ( $-296.9$  kJ/mol).

#### SOLUTION

**Analyze:** We are given the reactants ( $P_4S_3$  and  $O_2$  from air) and the products ( $P_4O_{10}$  and  $SO_2$ ) for a reaction, together with their standard enthalpies of formation, and asked to calculate the standard enthalpy change for the reaction.

**Plan:** We first need a balanced chemical equation for the reaction. The enthalpy change for the reaction is then equal to the enthalpies of formation of products minus those of reactants (Equation 5.31, Section 5.7). We also need to recall that the standard enthalpy of formation of any element in its standard state is zero. Thus,  $\Delta H_f^\circ(O_2) = 0$ .

**Solve:** The balanced chemical equation for the combustion is

Thus, we can write

$$\begin{aligned} \Delta H^\circ &= \Delta H_f^\circ(P_4O_{10}) + 3 \Delta H_f^\circ(SO_2) - \Delta H_f^\circ(P_4S_3) - 8 \Delta H_f^\circ(O_2) \\ &= -2940.1 \text{ kJ} + 3(-296.9) \text{ kJ} - (-154.4 \text{ kJ}) - 8(0) \\ &= -3676.4 \text{ kJ} \end{aligned}$$

**Comment:** The reaction is strongly exothermic, making it evident why  $P_4S_3$  is used on match tips.

#### ■ PRACTICE EXERCISE

Write the balanced equation for the reaction of  $P_4O_{10}$  with water, and calculate  $\Delta H^\circ$  for this reaction using data from Appendix C.

**Answer:**  $P_4O_{10}(s) + 6 H_2O(l) \longrightarrow 4 H_3PO_4(aq)$ ;  $-498.1$  kJ

Phosphorus(V) oxide is the anhydride of phosphoric acid ( $H_3PO_4$ ), a weak triprotic acid. In fact,  $P_4O_{10}$  has a very high affinity for water and is consequently used as a drying agent. Phosphorus(III) oxide is the anhydride of phosphorous acid ( $H_3PO_3$ ), a weak diprotic acid.\* The structures of  $H_3PO_4$  and  $H_3PO_3$  are shown in Figure 22.35. The hydrogen atom that is attached directly to phosphorus in  $H_3PO_3$  is not acidic because the P—H bond is essentially nonpolar.

\*Note that the element phosphorus (FOS·for·us) has a -us suffix, whereas phosphorous (fos·FOR·us) acid has an -ous suffix.

One characteristic of phosphoric and phosphorous acids is their tendency to undergo condensation reactions when heated. A **condensation reaction** is one in which two or more molecules combine to form a larger molecule by eliminating a small molecule, such as  $\text{H}_2\text{O}$ .  $\rightleftharpoons$  (Section 12.6) For example, two  $\text{H}_3\text{PO}_4$  molecules are joined by the elimination of one  $\text{H}_2\text{O}$  molecule to form  $\text{H}_4\text{P}_2\text{O}_7$ :

Phosphoric acid and its salts find their most important uses in detergents and fertilizers. The phosphates in detergents are often in the form of sodium tripolyphosphate ( $\text{Na}_5\text{P}_3\text{O}_{10}$ ). A typical detergent formulation contains 47% phosphate; 16% bleaches, perfumes, and abrasives; and 37% linear alkylsulfonate (LAS) surfactant, whose structural formula is

(We have used the notation for the benzene ring described in Section 8.6.) The phosphate ions form bonds with metal ions that contribute to the hardness of water. This keeps the metal ions from interfering with the action of the surfactant. The phosphates also keep the pH above 7 and thus prevent the surfactant molecules from becoming protonated (gaining an  $\text{H}^+$  ion).

Most mined phosphate rock is converted to fertilizers. The  $\text{Ca}_3(\text{PO}_4)_2$  in phosphate rock is insoluble ( $K_{sp} = 2.0 \times 10^{-29}$ ). It is converted to a soluble form for use in fertilizers by treating the phosphate rock with sulfuric or phosphoric acid. The reaction with phosphoric acid yields  $\text{Ca}(\text{H}_2\text{PO}_4)_2$ :

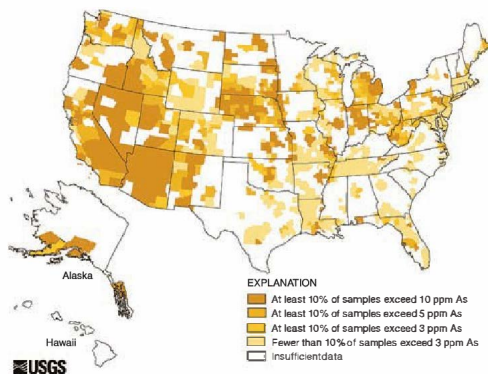

Although the solubility of  $\text{Ca}(\text{H}_2\text{PO}_4)_2$  allows it to be assimilated by plants, it also allows it to be washed from the soil and into bodies of water, thereby contributing to water pollution.  $\rightleftharpoons$  (Section 18.6)

Phosphorus compounds are important in biological systems. The element occurs in phosphate groups in RNA and DNA, the molecules responsible for the control of protein biosynthesis and transmission of genetic information.  $\rightleftharpoons$  (Section 25.10) It also occurs in adenosine triphosphate (ATP), which stores energy in biological cells and has the structure:

The present Environmental Protection Agency (EPA) standard for arsenic in public water supplies is 10 ppb (equivalent to 10  $\mu\text{g/L}$ ). Most regions of the United States tend to have low to moderate (2–10 ppb) groundwater arsenic levels (Figure 22.36 ▶). The western region tends to have higher levels, coming mainly from natural geological sources in the area. Estimates, for example, indicate that 35% of water-supply wells in Arizona have arsenic concentrations above 10 ppb.

The problem of arsenic in drinking water in the United States is dwarfed by the problem in other parts of the world—especially in Bangladesh, where the problem is tragic. Historically, surface water sources in that country have been contaminated with microorganisms, causing significant health problems, including one of the highest infant mortality rates in the world. During the 1970s, international agencies, headed by the United Nations Children’s Fund (UNICEF), began investing millions of dollars of aid money in Bangladesh for wells to provide “clean” drinking water. Unfortunately, no one tested the well water for the presence of arsenic; the problem was not discovered until the 1980s. The result has been the biggest outbreak of mass poisoning in history. Up to half of the country’s estimated 10 million wells have arsenic concentrations above 50 ppb.

▲ **Figure 22.36 Geographic distribution of arsenic.** Counties in which at least 10% of the groundwater samples exceeded 10 ppm As are indicated by the darkest color. As the color becomes lighter, the scale moves from 10 ppm to 5 ppm to 3 ppm, and then to cases where fewer than 10% of samples exceed 3 ppm. The white areas are those for which there were insufficient data.

The P—O—P bond of the end phosphate group is broken by hydrolysis with water, forming adenosine diphosphate (ADP). This reaction releases 33 kJ of energy.

This energy is used to perform the mechanical work in muscle contraction and in many other biochemical reactions (Figure 19.20).

## 22.9 CARBON

Carbon constitutes only 0.027% of Earth’s crust, so it is not an abundant element. Although some carbon occurs in elemental form as graphite and diamond, most is found in combined form. Over half occurs in carbonate compounds, such as  $\text{CaCO}_3$ . Carbon is also found in coal, petroleum, and natural gas. The importance of the element stems in large part from its occurrence in all living organisms: Life as we know it is based on carbon compounds. In this section we will take a brief look at carbon and its most common inorganic compounds. We will discuss organic chemistry in Chapter 25.

In water the most common forms of arsenic are the arsenate ion and its protonated hydrogen anions ( $\text{AsO}_4^{3-}$ ,  $\text{HAsO}_4^{2-}$ , and  $\text{H}_2\text{AsO}_4^-$ ) and the arsenite ion and its protonated forms ( $\text{AsO}_3^{3-}$ ,  $\text{HAsO}_3^{2-}$ ,  $\text{H}_2\text{AsO}_3^-$ , and  $\text{H}_3\text{AsO}_3$ ). These species are collectively referred to by the oxidation number of the arsenic as arsenic(V) and arsenic(III), respectively. Arsenic(V) is more prevalent in oxygen-rich (aerobic) surface waters, whereas arsenic(III) is more likely to occur in oxygen-poor (anaerobic) groundwaters. In the pH range from 4 to 10, the arsenic(V) is present primarily as  $\text{HAsO}_4^{2-}$  and  $\text{H}_2\text{AsO}_4^-$ , and the arsenic(III) is present primarily as the neutral acid  $\text{H}_3\text{AsO}_3$ .

One of the challenges in determining the health effects of arsenic in drinking waters is the different chemistry of arsenic(V) and arsenic(III), as well as the different concentrations required for physiological responses in different individuals. In Bangladesh, skin lesions (Figure 22.37) were the first sign of the arsenic problem. Statistical studies correlating arsenic levels with the occurrence of disease indicate a lung and bladder cancer risk arising from even low levels of arsenic.

The current technologies for removing arsenic perform most effectively when treating arsenic in the form of arsenic(V),

so water treatment strategies require preoxidation of the drinking water. Once in the form of arsenic(V), there are a number of possible removal strategies. For example,  $\text{Fe}_2(\text{SO}_4)_3$  could be added to precipitate  $\text{FeAsO}_4$ , which is then removed by filtration.

▲ Figure 22.37 Lesions and pigmentation changes resulting from arsenic poisoning.

## Elemental Forms of Carbon

Carbon exists in four allotropic crystalline forms: graphite, diamond, fullerenes, and carbon nanotubes. ∞ (Section 11.8) *Graphite* is a soft, black, slippery solid that has a metallic luster and conducts electricity. It consists of parallel sheets of carbon atoms that are held together by London forces [Figure 11.41(b)].

*Diamond* is a clear, hard solid in which the carbon atoms form a covalent network [Figure 11.41(a)]. Diamond is denser than graphite ( $d = 2.25 \text{ g/cm}^3$  for graphite;  $d = 3.51 \text{ g/cm}^3$  for diamond). At very high pressures and temperatures (approximately 100,000 atm at 3000 °C) graphite converts to diamond (Figure 22.38). About  $3 \times 10^4 \text{ kg}$  of industrial-grade diamonds are synthesized each year, mainly for use in cutting, grinding, and polishing tools.

Fullerenes are molecular forms of carbon that were discovered in the mid-1980s. ∞ (Section 11.8, "A Closer Look: The Third Form of Carbon") Fullerenes consist of individual molecules like  $\text{C}_{60}$  and  $\text{C}_{70}$ . The  $\text{C}_{60}$  molecules resemble soccer balls (Figure 11.43). Numerous research groups are currently exploring the chemical properties of these substances. Closely related to these molecular forms of carbon are carbon nanotubes, which consist of single or multiple layers of carbon rolled into cylindrical form, as shown in Figure 22.39. ∞ (Section 12.9)

Graphite also exists in two common amorphous forms. **Carbon black** is formed when hydrocarbons such as methane are heated in a very limited supply of oxygen.

It is used as a pigment in black inks; large amounts are also used in making automobile tires. **Charcoal** is formed when wood is heated strongly in the absence of air. Charcoal has a very open structure, giving it an enormous surface area per unit mass. Activated charcoal, a pulverized form whose surface is cleaned by heating with steam, is widely used to adsorb molecules. It is used in filters to remove offensive odors from air and colored or bad-tasting impurities from water.

▲ Figure 22.38 Synthetic diamonds. Graphite and synthetic diamonds prepared from graphite. Most synthetic diamonds lack the size, color, and clarity of natural diamonds and are therefore not used in jewelry.

▲ Figure 22.39 A section of a carbon nanotube. Each intersection in the network represents a carbon atom bonded to three others.

## Oxides of Carbon

Carbon forms two principal oxides: carbon monoxide (CO) and carbon dioxide (CO<sub>2</sub>). *Carbon monoxide* is formed when carbon or hydrocarbons are burned in a limited supply of oxygen.

It is a colorless, odorless, and tasteless gas. It is toxic because it can bind to hemoglobin in the blood and thus interfere with oxygen transport. [⇐ \(Section 18.4\)](#) Low-level poisoning results in headaches and drowsiness; high-level poisoning can cause death. Automobile engines produce carbon monoxide, which is a major air pollutant.

Carbon monoxide is unusual in that it has a lone pair of electrons on carbon: :C≡O:. It is also isoelectronic with N<sub>2</sub>, so you might imagine that CO would be equally unreactive. Moreover, both substances have high bond energies (1072 kJ/mol for C≡O and 941 kJ/mol for N≡N). Because of the lower nuclear charge on carbon (compared with either N or O), however, the lone pair on carbon is not held as strongly as that on N or O. Consequently, CO is better able to function as an electron-pair donor (Lewis base) than is N<sub>2</sub>. It forms a wide variety of covalent compounds, known as metal carbonyls, with transition metals. Ni(CO)<sub>4</sub>, for example, is a volatile, toxic compound that is formed by simply warming metallic nickel in the presence of CO. The formation of metal carbonyls is the first step in the transition-metal catalysis of a variety of reactions of CO.

Carbon monoxide has several commercial uses. Because it burns readily, forming CO<sub>2</sub>, it is employed as a fuel.

### Chemistry Put to Work

#### CARBON FIBERS AND COMPOSITES

The properties of graphite are anisotropic; that is, they differ in different directions through the solid. Along the carbon planes, graphite possesses great strength because of the number and strength of the carbon-carbon bonds in this direction. The bonds between planes are relatively weak, however, making graphite weak in that direction.

Fibers of graphite can be prepared in which the carbon planes are aligned to varying extents parallel to the fiber axis. These fibers are lightweight (density of about 2 g/cm<sup>3</sup>) and chemically quite unreactive. The oriented fibers are made by first slowly pyrolyzing (decomposing by action of heat) organic fibers at about 150 °C to 300 °C. These fibers are then heated to about 2500 °C to graphitize them (convert amorphous carbon to graphite). Stretching the fiber during pyrolysis helps orient the graphite planes parallel to the fiber axis. More amorphous carbon fibers are formed by pyrolysis of organic fibers at lower temperatures (1200 °C to 400 °C). These amorphous materials, commonly called *carbon fibers*, are the type most commonly used in commercial materials.

Composite materials that take advantage of the strength, stability, and low density of carbon fibers are widely used. Composites are combinations of two or more materials. These materials are present as separate phases and are combined to form structures that take advantage of certain desirable properties of each component. In carbon composites the graphite fibers are often woven into a fabric that is embedded in a matrix that binds them into a solid structure. The fibers transmit loads evenly throughout the matrix. The finished composite is thus stronger than any one of its components.

Epoxy systems are useful matrices because of their excellent adherence. They are used widely in a number of applications, including high-performance graphite sports equipment such as tennis racquets, golf clubs, and, more recently, bicycle wheels and frames (Figure 22.40 ▼). Epoxy systems can be used only when the temperature remains below 150 °C. More heat-resistant resins are required for many aerospace applications, where carbon composites now find wide use.

▲ **Figure 22.40 Carbon composites.** Carbon composites are used extensively in aerospace and automotive applications and in sporting goods. These high-performance (and high-priced!) bike wheels have a carbon-fiber-composite frame, which makes them very lightweight and helps them absorb road shocks.

It is also an important reducing agent, widely used in metallurgical operations to reduce metal oxides, such as the iron oxides.

This reaction is discussed in greater detail in Section 23.2. Carbon monoxide is also used in the preparation of several organic compounds such as methanol ( $\text{CH}_3\text{OH}$ ) (Equation 22.13).

Carbon dioxide is produced when carbon-containing substances are burned in excess oxygen.

It is also produced when many carbonates are heated.

Large quantities are also obtained as a by-product of the fermentation of sugar during the production of ethanol.

In the laboratory,  $\text{CO}_2$  can be produced by the action of acids on carbonates, as shown in Figure 22.41:

Carbon dioxide is a colorless and odorless gas. It is a minor component of Earth's atmosphere but a major contributor to the so-called greenhouse effect.  $\infty$  (Section 18.4) Although it is not toxic, high concentrations of  $\text{CO}_2$  increase respiration rate and can cause suffocation. It is readily liquefied by compression. When cooled at atmospheric pressure, however,  $\text{CO}_2$  condenses as a solid rather than as a liquid. The solid sublimates at atmospheric pressure at  $-78^\circ\text{C}$ . This property makes solid  $\text{CO}_2$  valuable as a refrigerant that is always free of the liquid form. Solid  $\text{CO}_2$  is known as dry ice. About half of the  $\text{CO}_2$  consumed annually is used for refrigeration. The other major use of  $\text{CO}_2$  is in the production of carbonated beverages. Large quantities are also used to manufacture washing soda ( $\text{Na}_2\text{CO}_3 \cdot 10 \text{H}_2\text{O}$ ) and baking soda ( $\text{NaHCO}_3$ ). Baking soda is so named because the following reaction occurs during baking:

The  $\text{H}^+(\text{aq})$  is provided by vinegar, sour milk, or the hydrolysis of certain salts. The bubbles of  $\text{CO}_2$  that form are trapped in the dough, causing it to rise. Washing soda is used to precipitate metal ions that interfere with the cleansing action of soap.

### GIVE IT SOME THOUGHT

What solid would precipitate if you treated a solution containing  $\text{Mg}^{2+}$  ions with washing soda?

## Carbonic Acid and Carbonates

Carbon dioxide is moderately soluble in  $\text{H}_2\text{O}$  at atmospheric pressure. The resultant solutions are moderately acidic because of the formation of carbonic acid ( $\text{H}_2\text{CO}_3$ ).

Carbonic acid is a weak diprotic acid. Its acidic character causes carbonated beverages to have a sharp, slightly acidic taste.

Although carbonic acid cannot be isolated as a pure compound, hydrogen carbonates (bicarbonates) and carbonates can be obtained by neutralizing carbonic acid solutions. Partial neutralization produces  $\text{HCO}_3^-$ , and complete

▲ **Figure 22.41**  $\text{CO}_2$  formation. Solid  $\text{CaCO}_3$  reacts with a solution of hydrochloric acid to produce  $\text{CO}_2$  gas, seen here as the bubbles.

▲ **Figure 22.42** Carlsbad Caverns, New Mexico.

neutralization gives  $\text{CO}_3^{2-}$ . The  $\text{HCO}_3^-$  ion is a stronger base than acid ( $K_b = 2.3 \times 10^{-8}$ ;  $K_a = 5.6 \times 10^{-11}$ ). The carbonate ion is much more strongly basic ( $K_b = 1.8 \times 10^{-4}$ ).

Minerals containing the carbonate ion are plentiful. The principal carbonate minerals are calcite ( $\text{CaCO}_3$ ), magnesite ( $\text{MgCO}_3$ ), dolomite [ $\text{MgCa}(\text{CO}_3)_2$ ], and siderite ( $\text{FeCO}_3$ ). Calcite is the principal mineral in limestone rock, large deposits of which occur in many parts of the world. It is also the main constituent of marble, chalk, pearls, coral reefs, and the shells of marine animals such as clams and oysters. Although  $\text{CaCO}_3$  has low solubility in pure water, it dissolves readily in acidic solutions with evolution of  $\text{CO}_2$ .

Because water containing  $\text{CO}_2$  is slightly acidic (Equation 22.68),  $\text{CaCO}_3$  dissolves slowly in this medium:

This reaction occurs when surface waters move underground through limestone deposits. It is the principal way that  $\text{Ca}^{2+}$  enters groundwater, producing “hard water.” ⇌ (Section 18.6) If the limestone deposit is deep enough underground, the dissolution of the limestone produces a cave. Two well-known limestone caves are Mammoth Cave in Kentucky and Carlsbad Caverns in New Mexico (Figure 22.42 ◀).

One of the most important reactions of  $\text{CaCO}_3$  is its decomposition into  $\text{CaO}$  and  $\text{CO}_2$  at elevated temperatures, given earlier in Equation 22.64. About  $2 \times 10^{10}$  kg (20 million tons) of calcium oxide, known as lime or quicklime, is produced in the United States annually. Because calcium oxide reacts with water to form  $\text{Ca}(\text{OH})_2$ , it is an important commercial base. It is also important in making mortar, which is a mixture of sand, water, and  $\text{CaO}$  used in construction to bind bricks, blocks, and rocks together. Calcium oxide reacts with water and  $\text{CO}_2$  to form  $\text{CaCO}_3$ , which binds the sand in the mortar.

## Carbides

The binary compounds of carbon with metals, metalloids, and certain nonmetals are called **carbides**. There are three types: ionic, interstitial, and covalent. The more active metals form the ionic carbides. The most common ionic carbides contain the *acetylide* ion ( $\text{C}_2^{2-}$ ). This ion is isoelectronic with  $\text{N}_2$ , and its Lewis structure,  $[\text{:C}\equiv\text{C:}]^{2-}$ , has a carbon–carbon triple bond. The most important ionic carbide is calcium carbide ( $\text{CaC}_2$ ), which is produced by the reduction of  $\text{CaO}$  with carbon at high temperature:

The carbide ion is a very strong base that reacts with water to form acetylene ( $\text{H}-\text{C}\equiv\text{C}-\text{H}$ ), as in the following reaction:

Calcium carbide is therefore a convenient solid source of acetylene, which is used in welding (Figure 22.16).

Interstitial carbides are formed by many transition metals. The carbon atoms occupy open spaces (interstices) between metal atoms in a manner analogous to the interstitial hydrides. ∞ (Section 22.2) Tungsten carbide, for example, is very hard and very heat-resistant, and is thus used to make cutting tools.

Covalent carbides are formed by boron and silicon. Silicon carbide (SiC), known as Carborundum<sup>®</sup>, is used as an abrasive and in cutting tools. Almost as hard as diamond, SiC has a diamondlike structure with alternating Si and C atoms.

### Other Inorganic Compounds of Carbon

Hydrogen cyanide, HCN, is an extremely toxic gas that has the odor of bitter almonds. It is produced by the reaction of a cyanide salt, such as NaCN, with an acid. Aqueous solutions of HCN are known as hydrocyanic acid. Neutralization with a base, such as NaOH, produces cyanide salts, such as NaCN. Cyanides find use in the manufacture of several well-known plastics, including nylon and Orlon<sup>®</sup>. The CN<sup>-</sup> ion forms very stable complexes with most transition metals. ∞ (Section 17.5)

Carbon disulfide, CS<sub>2</sub>, is an important industrial solvent for waxes, greases, celluloses, and other nonpolar substances. It is a colorless volatile liquid (bp 46.3 °C). The vapor is very poisonous and highly flammable.

## 22.10 THE OTHER GROUP 4A ELEMENTS: Si, Ge, Sn, AND Pb

The other elements of group 4A, in addition to carbon, are silicon, germanium, tin, and lead. The general trend from nonmetallic to metallic character as we go down a family is strikingly evident in group 4A. Carbon is a nonmetal; silicon and germanium are metalloids; tin and lead are metals. In this section we will consider a few general characteristics of group 4A and then look more thoroughly at silicon.

### General Characteristics of the Group 4A Elements

Some properties of the group 4A elements are given in Table 22.8 ▼. The elements possess the outer-shell electron configuration  $ns^2np^2$ . The electronegativities of the elements are generally low; carbides that formally contain C<sup>4-</sup> ions are observed only in the case of a few compounds of carbon with very active metals. Formation of 4+ ions by electron loss is not observed for any of these elements; the ionization energies are too high. The +2 oxidation state is found in the chemistry of germanium, tin, and lead, however, and it is the principal oxidation state for lead. The vast majority of the compounds of the group 4A elements are covalently bonded. Carbon forms a maximum of four bonds. The other members of the family are able to form higher coordination numbers through valence-shell expansion.

Carbon differs from the other group 4A elements in its pronounced ability to form multiple bonds both with itself and with other nonmetals, especially N, O, and S. The origin of this behavior was considered earlier. ∞ (Section 22.1)

4A	
6	C
14	Si
32	Ge
50	Sn
82	Pb

TABLE 22.8 ■ Some Properties of the Group 4A Elements

Property	C	Si	Ge	Sn	Pb
Atomic radius (Å)	0.77	1.17	1.22	1.40	1.46
First ionization energy (kJ/mol)	1086	786	762	709	716
Electronegativity	2.5	1.8	1.8	1.8	1.9
X—X single-bond enthalpy (kJ/mol)	348	226	188	151	—

Table 22.8 shows that the strength of a bond between two atoms of a given element decreases as we go down group 4A. Carbon–carbon bonds are quite strong. Carbon, therefore, has a striking ability to form compounds in which carbon atoms are bonded to one another in extended chains and rings, which accounts for the large number of organic compounds that exist. Other elements, especially those near carbon in the periodic table, can also form chains and rings, but these bonds are far less important in the chemistries of these other elements. The Si—Si bond strength (226 kJ/mol), for example, is much smaller than the Si—O bond strength (386 kJ/mol). As a result, the chemistry of silicon is dominated by the formation of Si—O bonds, and Si—Si bonds play a rather minor role.

▲ **Figure 22.43 Elemental silicon.** To prepare electronic devices, silicon powder is melted and drawn into a single crystal by zone refining (top). Wafers of silicon (bottom) cut from the crystal are subsequently treated by a series of elegant techniques to produce various electronic devices.

### Occurrence and Preparation of Silicon

Silicon is the second most abundant element, after oxygen, in Earth's crust. It occurs in  $\text{SiO}_2$  and in an enormous variety of silicate minerals. The element is obtained by the reduction of molten silicon dioxide with carbon at high temperature.

Elemental silicon has a diamond-type structure [see Figure 11.41(a)]. Crystalline silicon is a gray metallic-looking solid that melts at  $1410^\circ\text{C}$  (Figure 22.43 ◀). The element is a semiconductor and is thus used in making transistors and solar cells. ⇨ (Section 12.3) To be used as a semiconductor, it must be extremely pure, possessing less than  $10^{-7}\%$  (1 ppb) impurities. One method of purification is to treat the element with  $\text{Cl}_2$  to form  $\text{SiCl}_4$ . The  $\text{SiCl}_4$  is a volatile liquid that is purified by fractional distillation and then converted back to elemental silicon by reduction with  $\text{H}_2$ :

The process of zone refining can further purify the element. In the zone-refining process, a heated coil is passed slowly along a silicon rod, as shown in Figure 22.44 ◀. A narrow band of the element is thereby melted. As the molten area is swept slowly along the length of the rod, the impurities concentrate in the molten region, following it to the end of the rod. The purified portion of the rod is retained for manufacture of electronic devices.

### Silicates

Silicon dioxide and other compounds that contain silicon and oxygen comprise over 90% of Earth's crust. **Silicates** are compounds in which a silicon atom is surrounded in a tetrahedral fashion by four oxygens, as shown in Figure 22.45(a) ▶. In silicates, silicon is found in its most common oxidation state, +4. The simple  $\text{SiO}_4^{4-}$  ion, which is known as the orthosilicate ion, is found in very few silicate minerals. We can view the silicate tetrahedra, however, as "building blocks" that are used to build mineral structures. The individual tetrahedra are linked together by a common oxygen atom that serves as a vertex of both tetrahedra.

We can link two silicate tetrahedra together, for example, by sharing one oxygen atom, as shown in Figure 22.45(b). The resultant structure, called the *disilicate* ion, has two Si atoms and seven O atoms. Si and O are in the +4 and -2 oxidation states, respectively, in all silicates, so the overall charge of the ion must be consistent with these oxidation states. Thus, the charge on  $\text{Si}_2\text{O}_7$  is  $(2)(+4) + (7)(-2) = -6$ ; it is the  $\text{Si}_2\text{O}_7^{6-}$  ion. The mineral *thortveitite* ( $\text{Sc}_2\text{Si}_2\text{O}_7$ ) contains  $\text{Si}_2\text{O}_7^{6-}$  ions.

In most silicate minerals a large number of silicate tetrahedra are linked together to form chains, sheets, or three-dimensional structures. We can connect two vertices of each tetrahedron to two other tetrahedra, for example, leading to an infinite chain with an  $\cdots\text{O}-\text{Si}-\text{O}-\text{Si}\cdots$  backbone. This structure,

▲ **Figure 22.44 Zone-refining apparatus.**

► **Figure 22.45 Silicate structures.** (a) Structure of the  $\text{SiO}_4$  tetrahedron of the  $\text{SiO}_4^{4-}$  ion. This ion is found in several minerals, including zircon ( $\text{ZrSiO}_4$ ). (b) Geometrical structure of the  $\text{Si}_2\text{O}_7^{6-}$  ion, which is formed when two  $\text{SiO}_4$  tetrahedra share a corner oxygen atom. This ion occurs in several minerals, including hardystonite,  $\text{Ca}_2\text{Zn}(\text{Si}_2\text{O}_7)$ .

called a single-strand silicate chain, is represented in Figure 22.46(a)▼. As shown, this chain can be viewed as repeating units of the  $\text{Si}_2\text{O}_6^{4-}$  ion or, in terms of its simplest formula,  $\text{SiO}_3^{2-}$ . The mineral *enstatite* ( $\text{MgSiO}_3$ ) consists of rows of single-strand silicate chains with  $\text{Mg}^{2+}$  ions between the strands to balance charge.

In Figure 22.46(b) each silicate tetrahedron is linked to three others, forming an infinite two-dimensional sheet structure. The simplest formula of this infinite sheet is  $\text{Si}_2\text{O}_5^{2-}$ . The mineral *talc*, also known as talcum powder, has the formula  $\text{Mg}_3(\text{Si}_2\text{O}_5)_2(\text{OH})_2$  and is based on this sheet structure. The  $\text{Mg}^{2+}$  and  $\text{OH}^-$  ions lie between the silicate sheets. The slippery feel of talcum powder is due to the silicate sheets sliding relative to one another, much like the sheets of carbon atoms slide in graphite, giving graphite its lubricating properties. ∞ (Section 11.8)

*Asbestos* is a general term applied to a group of fibrous silicate minerals. These minerals possess chainlike arrangements of the silicate tetrahedra or sheet structures in which the sheets are formed into rolls. The result is that the minerals have a fibrous character, as shown in Figure 22.47▼. Asbestos minerals have been widely used as thermal insulation, especially in high-temperature applications, because of the great chemical stability of the silicate structure. In addition, the fibers can be woven into asbestos cloth, which can be used for fireproof curtains and other applications. However, the fibrous structure of asbestos minerals poses a health risk. Tiny asbestos fibers readily penetrate soft tissues, such as the lungs, where they can cause diseases, including cancer. The use of asbestos as a common building material has therefore been discontinued.

▲ **Figure 22.46 Silicate chains and sheets.** Silicate structures consist of tetrahedra linked together through their vertices by a shared oxygen atom. (a) Representation of an infinite single-strand silicate chain. Each tetrahedron is linked to two others. The box shows the repeating unit of the chain, which is similar to the unit cell of solids (Section 11.7); the chain can be viewed as an infinite number of repeating units, laid side by side. The repeating unit has a formula of  $\text{Si}_2\text{O}_6^{4-}$  or has the simplest formula,  $\text{SiO}_3^{2-}$ . (b) Representation of a two-dimensional sheet structure. Each tetrahedron is linked to three others. The repeating unit of the sheet has the formula  $\text{Si}_2\text{O}_5^{2-}$ .

▲ **Figure 22.47** Serpentine asbestos. Note the fibrous character of this silicate mineral.

When all four vertices of each  $\text{SiO}_4$  tetrahedron are linked to other tetrahedra, the structure extends in three dimensions. This linking of the tetrahedra forms quartz ( $\text{SiO}_2$ ), which was depicted two-dimensionally in Figure 11.30(a). Because the structure is locked together in a three-dimensional array much like diamond [Figure 11.41(a)], quartz is harder than strand- or sheet-type silicates.

### ■ SAMPLE EXERCISE 22.10 | Determining an Empirical Formula

The mineral *chrysotile* is a noncarcinogenic asbestos mineral that is based on the sheet structure shown in Figure 22.46(b). In addition to silicate tetrahedra, the mineral contains  $\text{Mg}^{2+}$  and  $\text{OH}^-$  ions. Analysis of the mineral shows that there are 1.5 Mg atoms per Si atom. What is the empirical formula for chrysotile?

#### SOLUTION

**Analyze:** A mineral is described that has a sheet silicate structure with  $\text{Mg}^{2+}$  and  $\text{OH}^-$  ions to balance charge and 1.5 Mg for each 1 Si. We are asked to write the empirical formula for the mineral.

**Plan:** As shown in Figure 22.46(b), the silicate sheet structure is based on the  $\text{Si}_2\text{O}_5^{2-}$  ion. We first add  $\text{Mg}^{2+}$  to give the proper Mg/Si ratio. We then add  $\text{OH}^-$  ions to obtain a neutral compound.

**Solve:** The observation that the Mg:Si ratio equals 1.5 is consistent with three  $\text{Mg}^{2+}$  ions per  $\text{Si}_2\text{O}_5^{2-}$  ion. The addition of three  $\text{Mg}^{2+}$  ions would make  $\text{Mg}_3(\text{Si}_2\text{O}_5)^{4+}$ . In order to achieve charge balance in the mineral, there must be four  $\text{OH}^-$  ions per  $\text{Si}_2\text{O}_5^{2-}$  ion. Thus, the formula of chrysotile is  $\text{Mg}_3(\text{Si}_2\text{O}_5)(\text{OH})_4$ . Since this is not reducible to a simpler formula, this is the empirical formula.

### ■ PRACTICE EXERCISE

The cyclosilicate ion consists of three silicate tetrahedra linked together in a ring. The ion contains three Si atoms and nine O atoms. What is the overall charge on the ion?  
*Answer:* 6-

## Glass

Quartz melts at approximately  $1600^\circ\text{C}$ , forming a tacky liquid. In the course of melting, many silicon-oxygen bonds are broken. When the liquid is rapidly cooled, silicon-oxygen bonds are re-formed before the atoms are able to arrange themselves in a regular fashion. An amorphous solid, known as quartz glass or silica glass, results (see Figure 11.30). Many different substances can be added to  $\text{SiO}_2$  to cause it to melt at a lower temperature. The common glass used in windows and bottles is known as soda-lime glass. It contains  $\text{CaO}$  and  $\text{Na}_2\text{O}$  in addition to  $\text{SiO}_2$  from sand. The  $\text{CaO}$  and  $\text{Na}_2\text{O}$  are produced by heating two inexpensive chemicals, limestone ( $\text{CaCO}_3$ ) and soda ash ( $\text{Na}_2\text{CO}_3$ ). These carbonates decompose at elevated temperatures:

Other substances can be added to soda-lime glass to produce color or to change the properties of the glass in various ways. The addition of  $\text{CoO}$ , for example, produces the deep blue color of “cobalt glass.” Replacing  $\text{Na}_2\text{O}$  with  $\text{K}_2\text{O}$  results in a harder glass that has a higher melting point. Replacing  $\text{CaO}$  with  $\text{PbO}$  results in a denser “lead crystal” glass with a higher refractive index. Lead crystal is used for decorative glassware; the higher refractive index gives this glass a particularly sparkling appearance. Addition of nonmetal oxides, such as  $\text{B}_2\text{O}_3$  and  $\text{P}_4\text{O}_{10}$ , which form network structures related to the silicates, also changes the properties of the glass. Adding  $\text{B}_2\text{O}_3$  creates a glass with a higher melting point and a greater ability to withstand temperature changes. Such glasses, sold commercially under trade names such as Pyrex<sup>®</sup> and Kimax<sup>®</sup>, are used where resistance to thermal shock is important, such as in laboratory glassware or coffeemakers.

## Silicones

Silicones consist of O—Si—O chains in which the remaining bonding positions on each silicon are occupied by organic groups such as CH<sub>3</sub>. The chains are terminated by —Si(CH<sub>3</sub>)<sub>3</sub> groups:

Depending on the length of the chain and the degree of cross-linking between chains, silicones can be either oils or rubber-like materials. Silicones are nontoxic and have good stability toward heat, light, oxygen, and water. They are used commercially in a wide variety of products, including lubricants, car polishes, sealants, and gaskets. They are also used for waterproofing fabrics. When applied to a fabric, the oxygen atoms form hydrogen bonds with the molecules on the surface of the fabric. The hydrophobic (water-repelling) organic groups of the silicone are then left pointing away from the surface as a barrier.

## 22.11 BORON

Boron is the only element of group 3A that can be considered nonmetallic. The element has an extended network structure. Its melting point (2300 °C) is intermediate between that of carbon (3550 °C) and that of silicon (1410 °C). The electron configuration of boron is [He]2s<sup>2</sup>2p<sup>1</sup>.

In a family of compounds called **boranes**, the molecules contain only boron and hydrogen. The simplest borane is BH<sub>3</sub>. This molecule contains only six valence electrons and is therefore an exception to the octet rule. (Section 8.7) As a result, BH<sub>3</sub> reacts with itself to form *diborane* (B<sub>2</sub>H<sub>6</sub>). This reaction can be viewed as a Lewis acid–base reaction (Section 16.11), in which one B—H bonding pair of electrons in each BH<sub>3</sub> molecule is donated to the other. As a result, diborane is an unusual molecule in which hydrogen atoms appear to form two bonds (Figure 22.48 ▶).

Sharing hydrogen atoms between the two boron atoms compensates somewhat for the deficiency in valence electrons around each boron. Nevertheless, diborane is an extremely reactive molecule, spontaneously flammable in air. The reaction of B<sub>2</sub>H<sub>6</sub> with O<sub>2</sub> is highly exothermic.

Other boranes, such as pentaborane (B<sub>5</sub>H<sub>9</sub>), are also very reactive. Boranes were at one time explored as solid fuels for rockets.

Boron and hydrogen also form a series of anions, called *borane anions*. Salts of the borohydride ion (BH<sub>4</sub><sup>−</sup>) are widely used as reducing agents. For example, sodium borohydride (NaBH<sub>4</sub>) is a commonly used reducing agent for certain organic compounds, and you will encounter it again should you take a course in organic chemistry.

The only important oxide of boron is boric oxide (B<sub>2</sub>O<sub>3</sub>). This substance is the anhydride of boric acid, which we may write as H<sub>3</sub>BO<sub>3</sub> or B(OH)<sub>3</sub>. Boric acid is so weak an acid ( $K_a = 5.8 \times 10^{-10}$ ) that solutions of H<sub>3</sub>BO<sub>3</sub> are used as an eyewash. Upon heating, boric acid loses water by a condensation reaction similar to that described for phosphorus in Section 22.8:

	3A
	5 B
	13 Al
	31 Ga
	49 In
	81 Tl

▲ **Figure 22.48** The structure of **diborane (B<sub>2</sub>H<sub>6</sub>)**. Two of the H atoms bridge the two B atoms, giving a planar B<sub>2</sub>H<sub>2</sub> core to the molecule. Two of the remaining H atoms lie on either side of the B<sub>2</sub>H<sub>2</sub> core, giving a nearly tetrahedral bonding environment about the B atoms.

The diprotic acid  $\text{H}_2\text{B}_4\text{O}_7$  is called tetraboric acid. The hydrated sodium salt  $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10 \text{H}_2\text{O}$ , called borax, occurs in dry lake deposits in California and can also be readily prepared from other borate minerals. Solutions of borax are alkaline, and the substance is used in various laundry and cleaning products.

### SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

The interhalogen compound  $\text{BrF}_3$  is a volatile, straw-colored liquid. The compound exhibits appreciable electrical conductivity because of autoionization.

(a) What are the molecular structures of the  $\text{BrF}_2^+$  and  $\text{BrF}_4^-$  ions? (b) The electrical conductivity of  $\text{BrF}_3$  decreases with increasing temperature. Is the autoionization process exothermic or endothermic? (c) One chemical characteristic of  $\text{BrF}_3$  is that it acts as a Lewis acid toward fluoride ions. What do we expect will happen when  $\text{KBr}$  is dissolved in  $\text{BrF}_3$ ?

### SOLUTION

(a) The  $\text{BrF}_2^+$  ion has a total of  $7 + 2(7) - 1 = 20$  valence-shell electrons. The Lewis structure for the ion is

Because there are four electron-pair domains around the central Br atom, the resulting electron-pair geometry is tetrahedral.  $\infty$  (Section 9.2) Because bonding pairs of electrons occupy two of these domains, the molecular geometry is nonlinear.

The  $\text{BrF}_4^-$  ion has a total of  $7 + 4(7) + 1 = 36$  electrons, leading to the following Lewis structure.

Because there are six electron-pair domains around the central Br atom in this ion, the electron-pair geometry is octahedral. The two nonbonding pairs of electrons are located opposite each other on the octahedron, leading to a square-planar molecular geometry.

(b) The observation that conductivity decreases as temperature increases indicates that there are fewer ions present in the solution at the higher temperature. Thus, increasing the temperature causes the equilibrium to shift to the left. According to Le Châtelier's principle, this shift indicates that the reaction is exothermic as it proceeds from left to right.  $\infty$  (Section 15.7)

(c) A Lewis acid is an electron-pair acceptor. (Section 16.11) The fluoride ion has four valence-shell electron pairs and can act as a Lewis base (an electron-pair donor). Thus, we can envision the following reaction occurring:

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Introduction and Section 22.1** The periodic table is useful for organizing and remembering the descriptive chemistry of the elements. Among elements of a given group, size increases with increasing atomic number, and electronegativity and ionization energy decrease. Nonmetallic character parallels electronegativity, so the most nonmetallic elements are found in the upper right portion of the periodic table.

Among the nonmetallic elements, the first member of each group differs dramatically from the other members; it forms a maximum of four bonds to other atoms and exhibits a much greater tendency to form  $\pi$  bonds than the heavier elements in its group.

Because  $\text{O}_2$  and  $\text{H}_2\text{O}$  are abundant in our world, we focus on two important and general reaction types as we discuss the nonmetals: oxidation by  $\text{O}_2$  and proton-transfer reactions involving  $\text{H}_2\text{O}$  or aqueous solutions.

**Section 22.2** Hydrogen has three isotopes: **protium** ( $^1_1\text{H}$ ), **deuterium** ( $^2_1\text{H}$ ), and **tritium** ( $^3_1\text{H}$ ). Hydrogen is not a member of any particular periodic group, although it is usually placed above lithium. The hydrogen atom can either lose an electron, forming  $\text{H}^+$ , or gain one, forming  $\text{H}^-$  (the hydride ion). Because the  $\text{H}-\text{H}$  bond is relatively strong,  $\text{H}_2$  is fairly unreactive unless activated by heat or a catalyst. Hydrogen forms a very strong bond to oxygen, so the reactions of  $\text{H}_2$  with oxygen-containing compounds usually lead to the formation of  $\text{H}_2\text{O}$ . Because the bonds in  $\text{CO}$  and  $\text{CO}_2$  are even stronger than the  $\text{O}-\text{H}$  bond, the reaction of  $\text{H}_2\text{O}$  with carbon or certain organic compounds leads to the formation of  $\text{H}_2$ . The  $\text{H}^+(\text{aq})$  ion is able to oxidize many metals, forming  $\text{H}_2(\text{g})$ . The electrolysis of water also forms  $\text{H}_2(\text{g})$ .

The binary compounds of hydrogen are of three general types: **ionic hydrides** (formed by active metals), **metallic hydrides** (formed by transition metals), and **molecular hydrides** (formed by nonmetals). The ionic hydrides contain the  $\text{H}^-$  ion; because this ion is extremely basic, ionic hydrides react with  $\text{H}_2\text{O}$  to form  $\text{H}_2$  and  $\text{OH}^-$ .

**Sections 22.3 and 22.4** The noble gases (group 8A) exhibit a very limited chemical reactivity because of the exceptional stability of their electron configurations. The xenon fluorides and oxides and  $\text{KrF}_2$  are the best-established compounds of the noble gases.

The halogens (group 7A) occur as diatomic molecules. All except fluorine exhibit oxidation states varying from  $-1$  to  $+7$ . Fluorine is the most electronegative element, so it is restricted to the oxidation states  $0$  and  $-1$ . The oxidizing power of the element (the tendency to form the  $-1$  oxidation state) decreases as we proceed down the group. The hydrogen halides are among the most useful compounds of these elements; these gases dissolve in water to form the hydrohalic acids, such as  $\text{HCl}(\text{aq})$ . Hydrofluoric acid reacts with silica. The **interhalogens** are compounds formed between two different halogen elements. Chlorine, bromine, and iodine form a series of oxyacids, in which the halogen atom is in a positive oxidation state. These compounds and their associated oxyanions are strong oxidizing agents.

**Sections 22.5 and 22.6** Oxygen has two allotropes,  $\text{O}_2$  and  $\text{O}_3$  (ozone). Ozone is unstable compared to  $\text{O}_2$ , and it is a stronger oxidizing agent than  $\text{O}_2$ . Most reactions of  $\text{O}_2$  lead to oxides, compounds in which oxygen is in the

-2 oxidation state. The soluble oxides of nonmetals generally produce acidic aqueous solutions; they are called **acidic anhydrides** or **acidic oxides**. In contrast, soluble metal oxides produce basic solutions and are called **basic anhydrides** or **basic oxides**. Many metal oxides that are insoluble in water dissolve in acid, accompanied by the formation of  $\text{H}_2\text{O}$ . Peroxides contain O—O bonds and oxygen in the -1 oxidation state. Peroxides are unstable, decomposing to  $\text{O}_2$  and oxides. In such reactions peroxides are simultaneously oxidized and reduced, a process called **disproportionation**. Superoxides contain the  $\text{O}_2^-$  ion in which oxygen is in the  $-\frac{1}{2}$  oxidation state.

Sulfur is the most important of the other group 6A elements. It has several allotropic forms; the most stable one at room temperature consists of  $\text{S}_8$  rings. Sulfur forms two oxides,  $\text{SO}_2$  and  $\text{SO}_3$ , and both are important atmospheric pollutants. Sulfur trioxide is the anhydride of sulfuric acid, the most important sulfur compound and the most-produced industrial chemical. Sulfuric acid is a strong acid and a good dehydrating agent. Sulfur forms several oxyanions as well, including the  $\text{SO}_3^{2-}$  (sulfite),  $\text{SO}_4^{2-}$  (sulfate), and  $\text{S}_2\text{O}_3^{2-}$  (thiosulfate) ions. Sulfur is found combined with many metals as a sulfide, in which sulfur is in the -2 oxidation state. These compounds often react with acids to form hydrogen sulfide ( $\text{H}_2\text{S}$ ), which smells like rotten eggs.

**Sections 22.7 and 22.8** Nitrogen is found in the atmosphere as  $\text{N}_2$  molecules. Molecular nitrogen is chemically very stable because of the strong  $\text{N}\equiv\text{N}$  bond. Molecular nitrogen can be converted into ammonia via the Haber process. Once the ammonia is made, it can be converted into a variety of different compounds that exhibit nitrogen oxidation states ranging from -3 to +5. The most important industrial conversion of ammonia is the **Ostwald process**, in which ammonia is oxidized to nitric acid ( $\text{HNO}_3$ ). Nitrogen has three important oxides: nitrous oxide ( $\text{N}_2\text{O}$ ), nitric oxide ( $\text{NO}$ ), and nitrogen dioxide ( $\text{NO}_2$ ). Nitrous acid ( $\text{HNO}_2$ ) is a weak acid; its conjugate base is the nitrite ion ( $\text{NO}_2^-$ ). Another important nitrogen compound is hydrazine ( $\text{N}_2\text{H}_4$ ).

Phosphorus is the most important of the remaining group 5A elements. It occurs in nature in phosphate minerals. Phosphorus has several allotropes, including white phosphorus, which consists of  $\text{P}_4$  tetrahedra. In reaction with the halogens, phosphorus forms trihalides ( $\text{PX}_3$ )

and pentahalides ( $\text{PX}_5$ ). These compounds undergo hydrolysis to produce an oxyacid of phosphorus and  $\text{HX}$ . Phosphorus forms two oxides,  $\text{P}_4\text{O}_6$  and  $\text{P}_4\text{O}_{10}$ . Their corresponding acids, phosphorous acid and phosphoric acid, undergo **condensation reactions** when heated. Phosphorus compounds are important in biochemistry and as fertilizers.

**Sections 22.9 and 22.10** The allotropes of carbon include diamond, graphite, and the fullerene family of compounds, notably buckminsterfullerene. Carbon nanotubes are a less well-defined form of carbon related to the fullerenes. Amorphous forms of carbon include **charcoal** and **carbon black**. Carbon forms two common oxides,  $\text{CO}$  and  $\text{CO}_2$ . Aqueous solutions of  $\text{CO}_2$  produce the weak diprotic acid carbonic acid ( $\text{H}_2\text{CO}_3$ ), which is the parent acid of hydrogen carbonate and carbonate salts. Binary compounds of carbon are called **carbides**. Carbides may be ionic, interstitial, or covalent. Calcium carbide ( $\text{CaC}_2$ ) contains the strongly basic acetylide ion ( $\text{C}_2^{2-}$ ), which reacts with water to form acetylene. Other important inorganic carbon compounds include hydrogen cyanide ( $\text{HCN}$ ) and carbon disulfide ( $\text{CS}_2$ ).

The other group 4A elements show great diversity in physical and chemical properties. Silicon, the second most abundant element, is a semiconductor. It reacts with  $\text{Cl}_2$  to form  $\text{SiCl}_4$ , a liquid at room temperature. Silicon forms strong Si—O bonds and therefore occurs in a variety of silicate minerals. **Silicates** consist of  $\text{SiO}_4$  tetrahedra, linked together at their vertices to form chains, sheets, or three-dimensional structures. The most common three-dimensional silicate is quartz ( $\text{SiO}_2$ ). **Glass** is an amorphous (noncrystalline) form of  $\text{SiO}_2$ . Silicones contain O—Si—O chains with organic groups bonded to the Si atoms. Like silicon, germanium is a metalloid; tin and lead are metallic.

**Section 22.11** Boron is the only group 3A element that is a nonmetal. It forms a variety of compounds with hydrogen called boron hydrides, or **boranes**. Diborane ( $\text{B}_2\text{H}_6$ ) has an unusual structure with two hydrogen atoms that bridge between the two boron atoms. Boranes react with oxygen to form boric oxide ( $\text{B}_2\text{O}_3$ ), in which boron is in the +3 oxidation state. Boric oxide is the anhydride of boric acid ( $\text{H}_3\text{BO}_3$ ). Boric acid readily undergoes condensation reactions.

## KEY SKILLS

- Be able to use periodic trends to explain the basic differences between the elements of a group or period.
- Explain the ways in which the first element in a group differs from subsequent elements in the group.
- Be able to determine electron configurations, oxidation numbers, and molecular shapes.
- Know the sources of the common nonmetals, how they are obtained, and how they are used.
- Understand how phosphoric and phosphorous acids undergo condensation reactions.
- Explain how the bonding and structures of silicates relate to their chemical formulas and properties.

## VISUALIZING CONCEPTS

- 22.1 One of these structures is a stable compound; the other is not. Identify the stable compound, and explain why it is stable. Explain why the other compound is not stable. [Section 22.1]

- 22.2 (a) Identify the *type* of chemical reaction represented by the diagram below. (b) Place appropriate charges on the species on both sides of the equation. (c) Write the chemical equation for the reaction. [Section 22.1]

- 22.3 Which of the following species (there may be more than one) is/are likely to have the structure shown below: (a)  $\text{XeF}_4$ , (b)  $\text{BrF}_4^+$ , (c)  $\text{SiF}_4$ , (d)  $\text{TeCl}_4$ , (e)  $\text{HClO}_4$ ? (The colors shown do not reflect the identity of any element.) [Sections 22.3, 22.4, 22.6, and 22.10]

- 22.4 Draw an energy profile for the reaction shown in Equation 22.24, assuming that the barrier to dissociation of  $\text{O}_3(\text{g})$  is 115 kJ. [Section 22.5]
- 22.5 Write the molecular formula and Lewis structure for each of the following oxides of nitrogen: [Section 22.7]

- 22.6 Which property of the group 6A elements might be the one depicted in the following graph: (a) electronegativity, (b) first ionization energy, (c) density, (d)  $X-X$  single-bond enthalpy, (e) electron affinity? Explain your answer. [Sections 22.5 and 22.6]

- 22.7 The atomic and ionic radii of the first three group 6A elements are

Element	Atomic radius (pm)	Ionic radius (pm)
O	0.73	1.40
S	1.03	1.84
Se	1.17	1.98

- (a) Explain why the atomic radius increases in moving downward in the group. (b) Explain why the ionic radii are larger than the atomic radii. (c) Which of the three anions would you expect to be the strongest base in water? Explain. [Sections 22.5 and 22.6]

- 22.8 Which property of the third-row nonmetallic elements might be the one depicted in the graph below: (a) first ionization energy, (b) atomic radius, (c) electronegativity, (d) melting point, (e)  $X-X$  single-bond enthalpy? Explain both your choice and why the other choices would not be correct. [Sections 22.3, 22.4, 22.6, 22.8, and 22.10]

- 22.9 The structures of white and red phosphorus are shown here. Explain, using these structural models, why white phosphorus is much more reactive than red phosphorus. [Section 22.8]

White phosphorus

Red phosphorus

- 22.10 (a) Draw the Lewis structures for at least four species that have the general formula

where X and Y may be the same or different, and  $n$  may have a value from +1 to -2. (b) Which of the compounds is likely to be the strongest Brønsted base? Explain. [Sections 22.1, 22.7, and 22.9]

## EXERCISES

### Periodic Trends and Chemical Reactions

- 22.11 Identify each of the following elements as a metal, nonmetal, or metalloid: (a) phosphorus, (b) strontium, (c) manganese, (d) selenium, (e) rhodium, (f) krypton.
- 22.12 Identify each of the following elements as a metal, nonmetal, or metalloid: (a) gallium, (b) molybdenum, (c) tellurium, (d) arsenic, (e) xenon, (f) cadmium.
- 22.13 Consider the elements O, Ba, Co, Be, Br, and Se. From this list select the element that (a) is most electronegative, (b) exhibits a maximum oxidation state of +7, (c) loses an electron most readily, (d) forms  $\pi$  bonds most readily, (e) is a transition metal.
- 22.14 Consider the elements Li, K, Cl, C, Ne, and Ar. From this list select the element that (a) is most electronegative, (b) has the greatest metallic character, (c) most readily forms a positive ion, (d) has the smallest atomic radius, (e) forms  $\pi$  bonds most readily.
- 22.15 Explain the following observations: (a) The highest fluoride compound formed by nitrogen is  $\text{NF}_3$ , whereas phosphorus readily forms  $\text{PF}_5$ . (b) Although CO is a well-known compound, SiO does not exist under ordinary conditions. (c)  $\text{AsH}_3$  is a stronger reducing agent than  $\text{NH}_3$ .
- 22.16 Explain the following observations: (a)  $\text{HNO}_3$  is a stronger oxidizing agent than  $\text{H}_3\text{PO}_4$ . (b) Silicon can form an ion with six fluorine atoms,  $\text{SiF}_6^{2-}$ , whereas carbon is able to bond to a maximum of four,  $\text{CF}_4$ . (c) There are three compounds formed by carbon and hydrogen that contain two carbon atoms each ( $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{H}_4$ , and  $\text{C}_2\text{H}_6$ ), whereas silicon forms only one analogous compound ( $\text{Si}_2\text{H}_6$ ).
- 22.17 Complete and balance the following equations:
- (a)  $\text{Mg}_3\text{N}_2(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$   
 (b)  $\text{C}_3\text{H}_7\text{OH}(\text{l}) + \text{O}_2(\text{g}) \longrightarrow$   
 (c)  $\text{MnO}_2(\text{s}) + \text{C}(\text{s}) \xrightarrow{\Delta}$   
 (d)  $\text{AlP}(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$   
 (e)  $\text{Na}_2\text{S}(\text{s}) + \text{HCl}(\text{aq}) \longrightarrow$
- 22.18 Complete and balance the following equations:
- (a)  $\text{NaOCH}_3(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$   
 (b)  $\text{CuO}(\text{s}) + \text{HNO}_3(\text{aq}) \longrightarrow$   
 (c)  $\text{WO}_3(\text{s}) + \text{H}_2(\text{g}) \xrightarrow{\Delta}$   
 (d)  $\text{NH}_2\text{OH}(\text{l}) + \text{O}_2(\text{g}) \longrightarrow$   
 (e)  $\text{Al}_4\text{C}_3(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$

### Hydrogen, the Noble Gases, and the Halogens

- 22.19 (a) Give the names and chemical symbols for the three isotopes of hydrogen. (b) List the isotopes in order of decreasing natural abundance.
- 22.20 Which isotope of hydrogen is radioactive? Write the nuclear equation for the radioactive decay of this isotope.
- 22.21 Give a reason why hydrogen might be placed along with the group 1A elements of the periodic table.
- 22.22 Why are the properties of hydrogen different from those of either the group 1A or 7A elements?
- 22.23 Write a balanced equation for the preparation of  $\text{H}_2$  using (a) Mg and an acid, (b) carbon and steam, (c) methane and steam.
- 22.24 List (a) three commercial means of producing  $\text{H}_2$ , (b) three industrial uses of  $\text{H}_2$ .

22.25 Complete and balance the following equations:

- (a)  $\text{NaH}(s) + \text{H}_2\text{O}(l) \longrightarrow$   
 (b)  $\text{Fe}(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow$   
 (c)  $\text{H}_2(g) + \text{Br}_2(g) \longrightarrow$   
 (d)  $\text{Na}(l) + \text{H}_2(g) \longrightarrow$   
 (e)  $\text{PbO}(s) + \text{H}_2(g) \longrightarrow$

22.26 Write balanced equations for each of the following reactions (some of these are analogous to reactions shown in the chapter). (a) Aluminum metal reacts with acids to form hydrogen gas. (b) Steam reacts with magnesium metal to give magnesium oxide and hydrogen. (c) Manganese(IV) oxide is reduced to manganese(II) oxide by hydrogen gas. (d) Calcium hydride reacts with water to generate hydrogen gas.

22.27 Identify the following hydrides as ionic, metallic, or molecular: (a)  $\text{BaH}_2$ , (b)  $\text{H}_2\text{Te}$ , (c)  $\text{TiH}_{1.7}$ .

22.28 Identify the following hydrides as ionic, metallic, or molecular: (a)  $\text{B}_2\text{H}_6$ , (b)  $\text{RbH}$ , (c)  $\text{Th}_4\text{H}_{1.5}$ .

22.29 Describe two characteristics of hydrogen that are favorable for its use as a general energy source in vehicles.

22.30 Would hydrogen be a satisfactory basis for a fuel economy if the only available sources were cracking of natural gas and conversion of grain-based ethanol? Explain.

22.31 Why does xenon form stable compounds with fluorine, whereas argon does not?

22.32 Why are there so few compounds of the noble gases?

22.33 Write the chemical formula for each of the following compounds, and indicate the oxidation state of the halogen or noble-gas atom in each: (a) chlorate ion, (b) hydroiodic acid, (c) iodine trichloride, (d) sodium hypochlorite, (e) perchloric acid, (f) xenon tetrafluoride.

22.34 Write the chemical formula for each of the following, and indicate the oxidation state of the halogen or noble-gas

atom in each, (a) calcium hypobromite, (b) bromic acid, (c) xenon trioxide, (d) perchlorate ion, (e) iodous acid, (f) iodine pentafluoride.

22.35 Name the following compounds: (a)  $\text{Fe}(\text{ClO}_3)_3$ , (b)  $\text{HClO}_2$ , (c)  $\text{XeF}_6$ , (d)  $\text{BrF}_5$ , (e)  $\text{XeOF}_4$ , (f)  $\text{HIO}_3$  (named as an acid).

22.36 Name the following compounds: (a)  $\text{KClO}_3$ , (b)  $\text{Ca}(\text{IO}_3)_2$ , (c)  $\text{AlCl}_3$ , (d)  $\text{HBrO}_3$ , (e)  $\text{H}_5\text{IO}_6$ , (f)  $\text{XeF}_4$ .

22.37 Explain each of the following observations: (a) At room temperature  $\text{I}_2$  is a solid,  $\text{Br}_2$  is a liquid, and  $\text{Cl}_2$  and  $\text{F}_2$  are both gases. (b)  $\text{F}_2$  cannot be prepared by electrolytic oxidation of aqueous  $\text{F}^-$  solutions. (c) The boiling point of  $\text{HF}$  is much higher than those of the other hydrogen halides. (d) The halogens decrease in oxidizing power in the order  $\text{F}_2 > \text{Cl}_2 > \text{Br}_2 > \text{I}_2$ .

22.38 Explain the following observations: (a) for a given oxidation state, the acid strength of the oxyacid in aqueous solution decreases in the order chlorine > bromine > iodine. (b) Hydrofluoric acid cannot be stored in glass bottles. (c)  $\text{HI}$  cannot be prepared by treating  $\text{NaI}$  with sulfuric acid. (d) The interhalogen  $\text{ICl}_3$  is known, but  $\text{BrCl}_3$  is not.

[22.39] Ammonium perchlorate remains a significant pollutant in soils and water supplies even decades after it is placed into the environment. What can you conclude from this about the stability of the perchlorate anion? What feature of the anion's structure might promote this high stability, even though perchlorate is a strong oxidizing agent?

[22.40] Removal of perchlorate from water supplies is difficult. Naturally occurring microorganisms are, however, capable of destroying perchlorate in solution in minutes. What do you think might be the type of reaction occurring in the microorganisms, and what do you predict might be the fate of the perchlorate ion in the reaction?

## Oxygen and the Group 6A Elements

22.41 (a) List three industrial uses of  $\text{O}_2$ . (b) List two industrial uses of  $\text{O}_3$ .

22.42 Draw the Lewis structure of ozone. Explain why the  $\text{O}-\text{O}$  bond (1.28 Å) is longer in ozone than in  $\text{O}_2$  (1.21 Å).

22.43 Write balanced equations for each of the following reactions. (a) When mercury(II) oxide is heated, it decomposes to form  $\text{O}_2$  and mercury metal. (b) When copper(II) nitrate is heated strongly, it decomposes to form copper(II) oxide, nitrogen dioxide, and oxygen. (c) Lead(II) sulfide,  $\text{PbS}(s)$ , reacts with ozone to form  $\text{PbSO}_4(s)$  and  $\text{O}_2(g)$ . (d) When heated in air,  $\text{ZnS}(s)$  is converted to  $\text{ZnO}$ . (e) Potassium peroxide reacts with  $\text{CO}_2(g)$  to give potassium carbonate and  $\text{O}_2$ .

22.44 Complete and balance the following equations:

- (a)  $\text{CaO}(s) + \text{H}_2\text{O}(l) \longrightarrow$   
 (b)  $\text{Al}_2\text{O}_3(s) + \text{H}^+(aq) \longrightarrow$   
 (c)  $\text{Na}_2\text{O}_2(s) + \text{H}_2\text{O}(l) \longrightarrow$   
 (d)  $\text{N}_2\text{O}_3(g) + \text{H}_2\text{O}(l) \longrightarrow$

- (e)  $\text{KO}_2(s) + \text{H}_2\text{O}(l) \longrightarrow$   
 (f)  $\text{NO}(g) + \text{O}_3(g) \longrightarrow$

22.45 Predict whether each of the following oxides is acidic, basic, amphoteric, or neutral: (a)  $\text{NO}_2$ , (b)  $\text{CO}_2$ , (c)  $\text{Al}_2\text{O}_3$ , (d)  $\text{CaO}$ .

22.46 Select the more acidic member of each of the following pairs: (a)  $\text{Mn}_2\text{O}_7$  and  $\text{MnO}_2$ , (b)  $\text{SnO}$  and  $\text{SnO}_2$ , (c)  $\text{SO}_2$  and  $\text{SO}_3$ , (d)  $\text{SiO}_2$  and  $\text{SO}_2$ , (e)  $\text{Ga}_2\text{O}_3$  and  $\text{In}_2\text{O}_3$ , (f)  $\text{SO}_2$  and  $\text{SeO}_2$ .

22.47 Write the chemical formula for each of the following compounds, and indicate the oxidation state of the group 6A element in each: (a) selenous acid, (b) potassium hydrogen sulfite, (c) hydrogen telluride, (d) carbon disulfide, (e) calcium sulfate.

22.48 Write the chemical formula for each of the following compounds, and indicate the oxidation state of the group 6A element in each: (a) sulfur tetrachloride, (b) selenium trioxide, (c) sodium thiosulfate, (d) hydrogen sulfide, (e) sulfuric acid.

- 22.49** In aqueous solution, hydrogen sulfide reduces (a)  $\text{Fe}^{3+}$  to  $\text{Fe}^{2+}$ , (b)  $\text{Br}_2$  to  $\text{Br}^-$ , (c)  $\text{MnO}_4^-$  to  $\text{Mn}^{2+}$ , (d)  $\text{HNO}_3$  to  $\text{NO}_2$ . In all cases, under appropriate conditions, the product is elemental sulfur. Write a balanced net ionic equation for each reaction.
- 22.50** An aqueous solution of  $\text{SO}_2$  reduces (a) aqueous  $\text{KMnO}_4$  to  $\text{MnSO}_4(\text{aq})$ , (b) acidic aqueous  $\text{K}_2\text{Cr}_2\text{O}_7$  to aqueous  $\text{Cr}^{3+}$ , (c) aqueous  $\text{Hg}_2(\text{NO}_3)_2$  to mercury metal. Write balanced equations for these reactions.
- 22.51** Write the Lewis structure for each of the following species, and indicate the structure of each: (a)  $\text{SeO}_3^{2-}$ ; (b)  $\text{S}_2\text{Cl}_2$ ; (c) chlorosulfonic acid,  $\text{HSO}_3\text{Cl}$  (chlorine is bonded to sulfur).
- 22.52** The  $\text{SF}_5^-$  ion is formed when  $\text{SF}_4(\text{g})$  reacts with fluoride salts containing large cations, such as  $\text{CsF}(\text{s})$ . Draw the Lewis structures for  $\text{SF}_4$  and  $\text{SF}_5^-$ , and predict the molecular structure of each.

## Nitrogen and the Group 5A Elements

- 22.55** Write the chemical formula for each of the following compounds, and indicate the oxidation state of nitrogen in each: (a) sodium nitrite, (b) ammonia, (c) nitrous oxide, (d) sodium cyanide, (e) nitric acid, (f) nitrogen dioxide.
- 22.56** Write the chemical formula for each of the following compounds, and indicate the oxidation state of nitrogen in each: (a) nitric oxide, (b) hydrazine, (c) potassium cyanide, (d) sodium nitrite, (e) ammonium chloride, (f) lithium nitride.
- 22.57** Write the Lewis structure for each of the following species, and describe its geometry: (a)  $\text{HNO}_2$ , (b)  $\text{N}_3^-$ , (c)  $\text{N}_2\text{H}_5^+$ , (d)  $\text{NO}_3^-$ .
- 22.58** Write the Lewis structure for each of the following species, and describe its geometry: (a)  $\text{NH}_4^+$ , (b)  $\text{NO}_2^-$ , (c)  $\text{N}_2\text{O}$ , (d)  $\text{NO}_2$ .
- 22.59** Complete and balance the following equations:  
 (a)  $\text{Mg}_3\text{N}_2(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$   
 (b)  $\text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow$   
 (c)  $\text{N}_2\text{O}_5(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$   
 (d)  $\text{NH}_3(\text{aq}) + \text{H}^+(\text{aq}) \longrightarrow$   
 (e)  $\text{N}_2\text{H}_4(\text{l}) + \text{O}_2(\text{g}) \longrightarrow$
- 22.60** Write a balanced net ionic equation for each of the following reactions: (a) Dilute nitric acid reacts with zinc metal with formation of nitrous oxide. (b) Concentrated nitric acid reacts with sulfur with formation of nitrogen dioxide. (c) Concentrated nitric acid oxidizes sulfur dioxide with formation of nitric oxide. (d) Hydrazine is burned in excess fluorine gas, forming  $\text{NF}_3$ . (e) Hydrazine reduces  $\text{CrO}_4^{2-}$  to  $\text{Cr}(\text{OH})_4^-$  in base (hydrazine is oxidized to  $\text{N}_2$ ).
- 22.61** Write complete balanced half-reactions for (a) oxidation of nitrous acid to nitrate ion in acidic solution, (b) oxidation of  $\text{N}_2$  to  $\text{N}_2\text{O}$  in acidic solution.
- 22.53** Write a balanced equation for each of the following reactions: (a) Sulfur dioxide reacts with water. (b) Solid zinc sulfide reacts with hydrochloric acid. (c) Elemental sulfur reacts with sulfite ion to form thiosulfate. (d) Sulfur trioxide is dissolved in sulfuric acid.
- 22.54** Write a balanced equation for each of the following reactions. (You may have to guess at one or more of the reaction products, but you should be able to make a reasonable guess, based on your study of this chapter.) (a) Hydrogen selenide can be prepared by reaction of an aqueous acid solution on aluminum selenide. (b) Sodium thiosulfate is used to remove excess  $\text{Cl}_2$  from chlorine-bleached fabrics. The thiosulfate ion forms  $\text{SO}_4^{2-}$  and elemental sulfur, while  $\text{Cl}_2$  is reduced to  $\text{Cl}^-$ .
- 22.62** Write complete balanced half-reactions for (a) reduction of nitrate ion to  $\text{NO}$  in acidic solution, (b) oxidation of  $\text{HNO}_2$  to  $\text{NO}_2$  in acidic solution.
- 22.63** Write a molecular formula for each compound, and indicate the oxidation state of the group 5A element in each formula: (a) phosphorous acid, (b) pyrophosphoric acid, (c) antimony trichloride, (d) magnesium arsenide, (e) diphosphorus pentoxide.
- 22.64** Write a chemical formula for each compound or ion, and indicate the oxidation state of the group 5A element in each formula: (a) phosphate ion, (b) arsenous acid, (c) antimony(III) sulfide, (d) calcium dihydrogen phosphate, (e) potassium phosphide.
- 22.65** Account for the following observations: (a) Phosphorus forms a pentachloride, but nitrogen does not. (b)  $\text{H}_3\text{PO}_2$  is a monoprotic acid. (c) Phosphonium salts, such as  $\text{PH}_4\text{Cl}$ , can be formed under anhydrous conditions, but they can't be made in aqueous solution. (d) White phosphorus is extremely reactive.
- 22.66** Account for the following observations: (a)  $\text{H}_3\text{PO}_3$  is a diprotic acid. (b) Nitric acid is a strong acid, whereas phosphoric acid is weak. (c) Phosphate rock is ineffective as a phosphate fertilizer. (d) Phosphorus does not exist at room temperature as diatomic molecules, but nitrogen does. (e) Solutions of  $\text{Na}_3\text{PO}_4$  are quite basic.
- 22.67** Write a balanced equation for each of the following reactions: (a) preparation of white phosphorus from calcium phosphate, (b) hydrolysis of  $\text{PBr}_3$ , (c) reduction of  $\text{PBr}_3$  to  $\text{P}_4$  in the gas phase, using  $\text{H}_2$ .
- 22.68** Write a balanced equation for each of the following reactions: (a) hydrolysis of  $\text{PCl}_5$ , (b) dehydration of phosphoric acid (also called orthophosphoric acid) to form pyrophosphoric acid, (c) reaction of  $\text{P}_4\text{O}_{10}$  with water.

## Carbon, the Other Group 4A Elements, and Boron

22.69 Give the chemical formula for (a) hydrocyanic acid, (b) nickel tetracarbonyl, (c) barium bicarbonate, (d) calcium acetylide.

22.70 Give the chemical formula for (a) carbonic acid, (b) sodium cyanide, (c) potassium hydrogen carbonate, (d) acetylene.

22.71 Complete and balance the following equations:

22.72 Complete and balance the following equations:

22.73 Write a balanced equation for each of the following reactions: (a) Hydrogen cyanide is formed commercially by passing a mixture of methane, ammonia, and air over a catalyst at 800 °C. Water is a by-product of the reaction. (b) Baking soda reacts with acids to produce carbon dioxide gas. (c) When barium carbonate reacts in air with sulfur dioxide, barium sulfate and carbon dioxide form.

22.74 Write a balanced equation for each of the following reactions: (a) Burning magnesium metal in a carbon dioxide atmosphere reduces the CO<sub>2</sub> to carbon. (b) In photosynthesis, solar energy is used to produce glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>) and O<sub>2</sub> out of carbon dioxide and water. (c) When carbonate salts dissolve in water, they produce basic solutions.

22.75 Write the formulas for the following compounds, and indicate the oxidation state of the group 4A element or

of boron in each: (a) boric acid, (b) silicon tetrabromide, (c) lead(II) chloride, (d) sodium tetraborate decahydrate (borax), (e) boric oxide.

22.76 Write the formulas for the following compounds, and indicate the oxidation state of the group 4A element or of boron in each: (a) silicon dioxide, (b) germanium tetrachloride, (c) sodium borohydride, (d) stannous chloride, (e) diborane.

22.77 Select the member of group 4A that best fits each description: (a) has the lowest first ionization energy, (b) is found in oxidation states ranging from -4 to +4, (c) is most abundant in Earth's crust.

22.78 Select the member of group 4A that best fits each description: (a) forms chains to the greatest extent, (b) forms the most basic oxide, (c) is a metalloid that can form 2+ ions.

22.79 (a) What is the characteristic geometry about silicon in all silicate minerals? (b) Metasilicic acid has the empirical formula H<sub>2</sub>SiO<sub>3</sub>. Which of the structures shown in Figure 22.46 would you expect metasilicic acid to have?

22.80 Two silicate anions are known in which the linking of the tetrahedra forms a closed ring. One of these cyclic silicate anions contains three silicate tetrahedra, linked into a ring. The other contains six silicate tetrahedra. (a) Sketch these cyclic silicate anions. (b) Determine the formula and charge of each of the anions.

22.81 (a) How does the structure of diborane (B<sub>2</sub>H<sub>6</sub>) differ from that of ethane (C<sub>2</sub>H<sub>6</sub>)? (b) By using concepts discussed in Chapter 8, explain why diborane adopts the geometry that it does. (c) What is the significance of the statement that the hydrogen atoms in diborane are described as hydridic?

22.82 Write a balanced equation for each of the following reactions: (a) Diborane reacts with water to form boric acid and molecular hydrogen. (b) Upon heating, boric acid undergoes a condensation reaction to form tetraboric acid. (c) Boron oxide dissolves in water to give a solution of boric acid.

## ADDITIONAL EXERCISES

22.83 In your own words, define the following terms: (a) allotrope, (b) disproportionation, (c) interhalogen, (d) acidic anhydride, (e) condensation reaction.

22.84 Starting with D<sub>2</sub>O, suggest preparations of (a) ND<sub>3</sub>, (b) D<sub>2</sub>SO<sub>4</sub>, (c) NaOD, (d) DNO<sub>3</sub>, (e) C<sub>2</sub>D<sub>2</sub>, (f) DCN.

22.85 Although the ClO<sub>4</sub><sup>-</sup> and IO<sub>4</sub><sup>-</sup> ions have been known for a long time, BrO<sub>4</sub><sup>-</sup> was not synthesized until 1965. The ion was synthesized by oxidizing the bromate ion with xenon difluoride, producing xenon, hydrofluoric acid, and the perbromate ion. Write the balanced equation for this reaction.

22.86 Write a balanced equation for the reaction of each of the following compounds with water: (a) SO<sub>2</sub>(g), (b) Cl<sub>2</sub>O<sub>7</sub>(g), (c) Na<sub>2</sub>O<sub>2</sub>(s), (d) BaC<sub>2</sub>(s), (e) RbO<sub>2</sub>(s), (f) Mg<sub>3</sub>N<sub>2</sub>(s), (g) NaH(s).

22.87 What is the anhydride for each of the following acids: (a) H<sub>2</sub>SO<sub>4</sub>, (b) HClO<sub>3</sub>, (c) HNO<sub>2</sub>, (d) H<sub>2</sub>CO<sub>3</sub>, (e) H<sub>3</sub>PO<sub>4</sub>?

22.88 Explain why SO<sub>2</sub> can be used as a reducing agent but SO<sub>3</sub> cannot.

22.89 A sulfuric acid plant produces a considerable amount of heat. This heat is used to generate electricity, which helps reduce operating costs. The synthesis of H<sub>2</sub>SO<sub>4</sub>

consists of three main chemical processes: (1) oxidation of S to  $\text{SO}_2$ , (2) oxidation of  $\text{SO}_2$  to  $\text{SO}_3$ , (3) the dissolving of  $\text{SO}_3$  in  $\text{H}_2\text{SO}_4$  and its reaction with water to form  $\text{H}_2\text{SO}_4$ . If the third process produces 130 kJ/mol, how much heat is produced in preparing a mole of  $\text{H}_2\text{SO}_4$  from a mole of S? How much heat is produced in preparing a ton of  $\text{H}_2\text{SO}_4$ ?

- 22.90** (a) What is the oxidation state of P in  $\text{PO}_4^{3-}$  and of N in  $\text{NO}_3^-$ ? (b) Why doesn't N form a stable  $\text{NO}_4^{3-}$  ion analogous to P?
- 22.91** (a) The  $\text{P}_4$ ,  $\text{P}_4\text{O}_6$ , and  $\text{P}_4\text{O}_{10}$  molecules have a common structural feature of four P atoms arranged in a tetrahedron (Figures 22.32 and 22.34). Does this mean that the bonding between the P atoms is the same in all these cases? Explain. (b) Sodium trimetaphosphate ( $\text{Na}_3\text{P}_3\text{O}_9$ ) and sodium tetrametaphosphate ( $\text{Na}_4\text{P}_4\text{O}_{12}$ ) are used as water-softening agents. They contain cyclic  $\text{P}_3\text{O}_9^{3-}$  and  $\text{P}_4\text{O}_{12}^{4-}$  ions, respectively. Propose reasonable structures for these ions.
- 22.92** Silicon has a limited capacity to form linear, Si—Si bonded structures similar to those formed by carbon. (a) Predict the molecular formula of a hydride of silicon that contains a chain of three silicon atoms. (b) Write a balanced equation for the reaction between oxygen and the compound you predicted in part (a).
- 22.93** Ultrapure germanium, like silicon, is used in semiconductors. Germanium of "ordinary" purity is prepared by the high-temperature reduction of  $\text{GeO}_2$  with carbon. The Ge is converted to  $\text{GeCl}_4$  by treatment with  $\text{Cl}_2$  and then purified by distillation;  $\text{GeCl}_4$  is then hydrolyzed in

water to  $\text{GeO}_2$  and reduced to the elemental form with  $\text{H}_2$ . The element is then zone refined. Write a balanced chemical equation for each of the chemical transformations in the course of forming ultrapure Ge from  $\text{GeO}_2$ .

- 22.94** Complete and balance the following equations:
- (a)  $\text{MnO}_4^-(aq) + \text{H}_2\text{O}_2(aq) + \text{H}^+(aq) \longrightarrow$   
 (b)  $\text{Fe}^{2+}(aq) + \text{H}_2\text{O}_2(aq) \longrightarrow$   
 (c)  $\text{I}^-(aq) + \text{H}_2\text{O}_2(aq) + \text{H}^+(aq) \longrightarrow$   
 (d)  $\text{Cu}(s) + \text{H}_2\text{O}_2(aq) + \text{H}^+(aq) \longrightarrow$   
 (e)  $\text{I}^-(aq) + \text{O}_3(g) \longrightarrow \text{I}_2(s) + \text{O}_2(g) + \text{OH}^-(aq)$
- 22.95** Hydrogen peroxide is capable of oxidizing (a) hydrazine to  $\text{N}_2$  and  $\text{H}_2\text{O}$ , (b)  $\text{SO}_2$  to  $\text{SO}_4^{2-}$ , (c)  $\text{NO}_2^-$  to  $\text{NO}_3^-$ , (d)  $\text{H}_2\text{S}(g)$  to  $\text{S}(s)$ , (e)  $\text{Fe}^{2+}$  to  $\text{Fe}^{3+}$ . Write a balanced net ionic equation for each of these redox reactions.
- 22.96** Complete and balance the following equations:
- (a)  $\text{Li}_3\text{N}(s) + \text{H}_2\text{O}(l) \longrightarrow$   
 (b)  $\text{NH}_3(aq) + \text{H}_2\text{O}(l) \longrightarrow$   
 (c)  $\text{NO}_2(g) + \text{H}_2\text{O}(l) \longrightarrow$   
 (d)  $\text{NH}_3(g) + \text{O}_2(g) \xrightarrow{\text{catalyst}}$   
 (e)  $\text{H}_2\text{CO}_3(aq) \xrightarrow{\Delta}$   
 (f)  $\text{Ni}(s) + \text{CO}(g) \longrightarrow$   
 (g)  $\text{CS}_2(g) + \text{O}_2(g) \longrightarrow$   
 (h)  $\text{CaO}(s) + \text{SO}_2(g) \longrightarrow$   
 (i)  $\text{CH}_4(g) + \text{H}_2\text{O}(g) \xrightarrow{\Delta}$   
 (j)  $\text{LiH}(s) + \text{H}_2\text{O}(l) \longrightarrow$   
 (k)  $\text{Fe}_2\text{O}_3(s) + 3\text{H}_2(g) \longrightarrow$

## INTEGRATIVE EXERCISES

- 22.97** (a) How many grams of  $\text{H}_2$  can be stored in 10.0 lb of the alloy FeTi if the hydride  $\text{FeTiH}_2$  is formed? (b) What volume does this quantity of  $\text{H}_2$  occupy at STP?
- [22.98]** Using the thermochemical data in Table 22.1 and Appendix C, calculate the average Xe—F bond enthalpies in  $\text{XeF}_2$ ,  $\text{XeF}_4$ , and  $\text{XeF}_6$ , respectively. What is the significance of the trend in these quantities?
- 22.99** Hydrogen gas has a higher fuel value than natural gas on a mass basis but not on a volume basis. Thus, hydrogen is not competitive with natural gas as a fuel transported long distances through pipelines. Calculate the heats of combustion of  $\text{H}_2$  and  $\text{CH}_4$  (the principal component of natural gas) (a) per mole of each, (b) per gram of each, (c) per cubic meter of each at STP. Assume  $\text{H}_2\text{O}(l)$  as a product.
- 22.100** The solubility of  $\text{Cl}_2$  in 100 g of water at STP is  $310\text{ cm}^3$ . Assume that this quantity of  $\text{Cl}_2$  is dissolved and equilibrated as follows:
- $$\text{Cl}_2(aq) + \text{H}_2\text{O} \rightleftharpoons \text{Cl}^-(aq) + \text{HClO}(aq) + \text{H}^+(aq)$$
- If the equilibrium constant for this reaction is  $4.7 \times 10^{-4}$ , calculate the equilibrium concentration of  $\text{HClO}$  formed.
- [22.101]** When ammonium perchlorate decomposes thermally, the products of the reaction are  $\text{N}_2(g)$ ,  $\text{O}_2(g)$ ,  $\text{H}_2\text{O}(g)$ , and  $\text{HCl}(g)$ . (a) Write a balanced equation for the reaction. [Hint: You might find it easier to use fractional coefficients for the products.] (b) Calculate the enthalpy change in the reaction per mole of  $\text{NH}_4\text{ClO}_4$ . The standard enthalpy of formation of  $\text{NH}_4\text{ClO}_4(s)$  is  $-295.8\text{ kJ}$ . (c) When  $\text{NH}_4\text{ClO}_4(s)$  is employed in solid-fuel booster rockets, it is packed with powdered aluminum. Given the high temperature needed for  $\text{NH}_4\text{ClO}_4(s)$  decomposition and what the products of the reaction are, what role does the aluminum play?
- 22.102** The dissolved oxygen present in any highly pressurized, high-temperature steam boiler can be extremely corrosive to its metal parts. Hydrazine, which is completely miscible with water, can be added to remove oxygen by reacting with it to form nitrogen and water. (a) Write the balanced equation for the reaction between gaseous hydrazine and oxygen. (b) Calculate the enthalpy change accompanying this reaction. (c) Oxygen in air dissolves in water to the extent of 9.1 ppm at  $20^\circ\text{C}$  at sea level. How many grams of hydrazine are required to react with all the oxygen in  $3.0 \times 10^4\text{ L}$  (the volume of a small swimming pool) under these conditions?

- 22.103** One method proposed for removing  $\text{SO}_2$  from the flue gases of power plants involves reaction with aqueous  $\text{H}_2\text{S}$ . Elemental sulfur is the product. (a) Write a balanced chemical equation for the reaction. (b) What volume of  $\text{H}_2\text{S}$  at  $27^\circ\text{C}$  and 740 torr would be required to remove the  $\text{SO}_2$  formed by burning 1.0 ton of coal containing 3.5% S by mass? (c) What mass of elemental sulfur is produced? Assume that all reactions are 100% efficient.
- 22.104** The maximum allowable concentration of  $\text{H}_2\text{S}(g)$  in air is 20 mg per kilogram of air (20 ppm by mass). How many grams of FeS would be required to react with hydrochloric acid to produce this concentration at 1.00 atm and  $25^\circ\text{C}$  in an average room measuring  $2.7 \times 4.3 \times 4.3$  m? (Under these conditions, the average molar mass of air is 29.0 g/mol.)
- 22.105** The standard heats of formation of  $\text{H}_2\text{O}(g)$ ,  $\text{H}_2\text{S}(g)$ ,  $\text{H}_2\text{Se}(g)$ , and  $\text{H}_2\text{Te}(g)$  are  $-241.8$ ,  $-20.17$ ,  $+29.7$ , and  $+99.6$  kJ/mol, respectively. The enthalpies necessary to convert the elements in their standard states to one mole of gaseous atoms are 248, 277, 227, and 197 kJ/mol of atoms for O, S, Se, and Te, respectively. The enthalpy for dissociation of  $\text{H}_2$  is 436 kJ/mol. Calculate the average  $\text{H}-\text{O}$ ,  $\text{H}-\text{S}$ ,  $\text{H}-\text{Se}$ , and  $\text{H}-\text{Te}$  bond enthalpies, and comment on their trend.
- 22.106** Manganese silicide has the empirical formula  $\text{MnSi}$  and melts at  $1280^\circ\text{C}$ . It is insoluble in water but does dissolve in aqueous HF. (a) What type of compound do you expect  $\text{MnSi}$  to be, in terms of Table 11.7? (b) Write a likely balanced chemical equation for the reaction of  $\text{MnSi}$  with concentrated aqueous HF.
- 22.107** Hydrazine has been employed as a reducing agent for metals. Using standard reduction potentials, predict whether the following metals can be reduced to the metallic state by hydrazine under standard conditions in acidic solution: (a)  $\text{Fe}^{2+}$ , (b)  $\text{Sn}^{2+}$ , (c)  $\text{Cu}^{2+}$ , (d)  $\text{Ag}^+$ , (e)  $\text{Cr}^{3+}$ .
- 22.108** Both dimethylhydrazine,  $(\text{CH}_3)_2\text{NNH}_2$ , and methylhydrazine,  $\text{CH}_3\text{NHNH}_2$ , have been used as rocket fuels. When dinitrogen tetroxide ( $\text{N}_2\text{O}_4$ ) is used as the oxidizer, the products are  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ , and  $\text{N}_2$ . If the thrust of the rocket depends on the volume of the products produced, which of the substituted hydrazines produces a greater thrust per gram total mass of oxidizer plus fuel? (Assume that both fuels generate the same temperature and that  $\text{H}_2\text{O}(g)$  is formed.)
- 22.109** Carbon forms an unusual, unstable oxide of formula  $\text{C}_3\text{O}_2$ , called carbon suboxide. Carbon suboxide is made by using  $\text{P}_2\text{O}_5$  to dehydrate the dicarboxylic acid called malonic acid, which has the formula  $\text{HOOC}-\text{CH}_2-\text{COOH}$ . (a) Write a balanced reaction for the production of carbon suboxide from malonic acid. (b) Suggest a Lewis structure for  $\text{C}_3\text{O}_2$ . (Hint: The Lewis structure of malonic acid suggests which atoms are connected to which.) (c) By using the information in Table 8.5, predict the  $\text{C}-\text{C}$  and  $\text{C}-\text{O}$  bond lengths in  $\text{C}_3\text{O}_2$ . (d) Sketch the Lewis structure of a product that could result by the addition of 2 mol of  $\text{H}_2$  to 1 mol of  $\text{C}_3\text{O}_2$ .
- 22.110** Boron nitride has a graphite-like structure with  $\text{B}-\text{N}$  bond distances of  $1.45 \text{ \AA}$  within sheets and a separation of  $3.30 \text{ \AA}$  between sheets. At high temperatures the BN assumes a diamondlike form that is almost as hard as diamond. Rationalize the similarity between BN and elemental carbon.

## WHAT'S AHEAD

---

### 23.1 Occurrence and Distribution of Metals

We begin by examining the occurrence of metals in the *lithosphere* along with an introduction to *metallurgy*, which is the technology associated with extracting metals from their natural mineral sources and preparing them for use.

### 23.2 Pyrometallurgy

We see how high temperatures can be used to extract metals from minerals. Such processes play a particularly important role in the production of iron and steel.

### 23.3 Hydrometallurgy

We see how chemical processes that occur in aqueous solutions can be used to separate metals, with an emphasis on gold and aluminum.

### 23.4 Electrometallurgy

We investigate the use of electricity to reduce and refine metals via electrolysis. We also learn the importance of this approach for the production of sodium, aluminum, and copper.

### 23.5 Metallic Bonding

We review the physical properties of metals and then account for them in terms of two models for *metallic bonding*—the electron-sea model and the molecular-orbital model.

### 23.6 Alloys

We examine three different types of alloys, or metals that contain more than one element: solution alloys, heterogeneous alloys, and intermetallic compounds.

### 23.7 Transition Metals

We examine the physical properties, electron configurations, oxidation states, and magnetic properties of transition metals and their compounds.

### 23.8 Chemistry of Selected Transition Metals

To finish, we take a closer look at the chemistry of three key transition metals: chromium, iron, and copper.

**METALS HAVE PLAYED A MAJOR ROLE IN THE DEVELOPMENT OF CIVILIZATION**, and they continue to do so. For example, without the contributions of metallurgy, rock music as we know it would not exist. The strings of the guitar being played in the chapter-opening photograph are the product of complex

technology. The core of the strings is made of mild steel, varying in hardness and ductility, depending on the type of guitar on which it will be used. The core string is wound with fine *wrap wire*, composed typically of an alloy of copper and zinc for acoustic guitar use, or stainless steel for electric guitars. Artists can be very passionate about the particular makes and models of strings they use.

When we think of metals in everyday applications, we tend to think of iron and aluminum, perhaps also chromium or nickel. But even metals of very low natural abundance play vital roles in modern technology. To illustrate this point, Figure 23.1 ▼ shows the approximate composition of a high-performance jet engine. Notice that iron, long the dominant metal of technology, is not present to any significant extent.

In this chapter we will consider the chemical forms in which metallic elements occur in nature and the means by which we obtain metals from these sources. We will also examine how metals bond in solids and see how metals and mixtures of metals, called *alloys*, are employed in modern technology. Finally, we will look specifically at the properties of transition metals. As we will see, metals have a varied and interesting chemistry.

▲ **Figure 23.1 Composition of a jet engine.** The chart on the left shows the metallic elements employed in manufacturing a modern jet engine.

## 23.1 OCCURRENCE AND DISTRIBUTION OF METALS

The portion of our environment that constitutes the solid earth beneath our feet is called the **lithosphere**. The lithosphere provides most of the materials we use to feed, clothe, shelter, and entertain ourselves. Although the bulk of Earth is solid, we have access to only a small region near the surface. Whereas Earth's radius is 6370 km, the deepest mine extends only about 4 km into Earth.

Many of the metals that are most useful to us are not especially abundant in that portion of the lithosphere to which we have ready access. Deposits that contain metals in economically exploitable quantities are known as **ores**. Usually, the desired compounds or elements must be separated from a large quantity of unwanted material and then chemically processed to make them useful. The costs, in terms of money, energy, and environmental impact, associated with extraction of metals from their ores is an important issue for society. The occurrence and distribution of *concentrated* deposits of metals often play a role in international politics as nations compete for access to these materials. Advances in technology also drive demand for metals that are either rare or difficult to extract. As an illustration, consider the fact that over one-half of the world's supply of cobalt comes from a politically unstable region of Africa (Congo and Zambia). The supply and price of cobalt are increasingly important because cobalt is an important component of superalloys used in aircraft engines (Figure 23.1), as well as the cathodes of Li-ion batteries that power most portable electronic devices. Hence the price of your cell phone may depend in part on the policies of the government in Kinshasa.

### Minerals

With the exception of gold and the platinum-group metals (Ru, Rh, Pd, Os, Ir, and Pt), most metallic elements are found in nature in solid inorganic compounds called **minerals**. Table 23.1 ► lists the principal mineral sources of several common metals, three of which are shown in Figure 23.2 ►. Notice that minerals are identified by common names rather than by chemical names. Names of minerals are usually based on the locations where they were discovered, the person who discovered them, or some characteristic such as color.

Commercially, the most important sources of metals are oxide, sulfide, and carbonate minerals. Silicate minerals are very abundant, but they are generally difficult to concentrate and reduce. ⇄ (Section 22.10) Therefore, most silicates are not economical sources of metals.

(a) Malachite

(b) Magnetite

(c) Cinnabar

▲ Figure 23.2 Three common minerals.

TABLE 23.1 ■ Principal Mineral Sources of Some Common Metals

Metal	Mineral	Composition
Aluminum	Corundum	$\text{Al}_2\text{O}_3$
	Gibbsite	$\text{Al}(\text{OH})_3$
Chromium	Chromite	$\text{FeCr}_2\text{O}_4$
Copper	Chalcocite	$\text{Cu}_2\text{S}$
	Chalcopyrite	$\text{CuFeS}_2$
	Malachite	$\text{Cu}_2\text{CO}_3(\text{OH})_2$
Iron	Hematite	$\text{Fe}_2\text{O}_3$
	Magnetite	$\text{Fe}_3\text{O}_4$
Lead	Galena	$\text{PbS}$
Manganese	Pyrolusite	$\text{MnO}_2$
Mercury	Cinnabar	$\text{HgS}$
Molybdenum	Molybdenite	$\text{MoS}_2$
Tin	Cassiterite	$\text{SnO}_2$
Titanium	Rutile	$\text{TiO}_2$
	Ilmenite	$\text{FeTiO}_3$
Zinc	Sphalerite	$\text{ZnS}$

## Metallurgy

**Metallurgy** is the science and technology of extracting metals from their natural sources and preparing them for practical use. It usually involves several steps: (1) mining, (2) concentrating the ore or otherwise preparing it for further treatment, (3) reducing the ore to obtain the free metal, (4) refining or purifying the metal, and (5) mixing the metal with other elements to modify its properties. This last process produces an *alloy*, a metallic material that is composed of two or more elements (Section 23.6).

After being mined, an ore is usually crushed and ground and then treated to concentrate the desired metal. The concentration stage relies on differences in the properties of the mineral and the undesired material that accompanies it, which is called *gangue* (pronounced “gang”). After an ore is concentrated, a variety of chemical processes are used to obtain the metal in suitable purity. In Sections 23.2–23.4 we will examine some of the most common metallurgical processes. You will see that these techniques depend in large part on basic chemical concepts discussed earlier in the text.

## 23.2 PYROMETALLURGY

A large number of metallurgical processes utilize high temperatures to alter the mineral chemically and to ultimately reduce it to the free metal. The use of heat to alter or reduce the mineral is called **pyrometallurgy**. (*Pyro* means “at high temperature.”)

**Calcination** is the heating of an ore to bring about its decomposition and the elimination of a volatile product. The volatile product could be, for example,  $\text{CO}_2$  or  $\text{H}_2\text{O}$ . Carbonates are often calcined to drive off  $\text{CO}_2$ , forming the metal oxide. For example,

Most carbonates decompose reasonably rapidly at temperatures in the range of  $400^\circ\text{C}$  to  $500^\circ\text{C}$ , although  $\text{CaCO}_3$  requires a temperature of about  $1000^\circ\text{C}$ . Most hydrated minerals lose  $\text{H}_2\text{O}$  at temperatures on the order of  $100^\circ\text{C}$  to  $300^\circ\text{C}$ .

**Roasting** is a thermal treatment that causes chemical reactions between the ore and the furnace atmosphere. Roasting may lead to oxidation or reduction and may be accompanied by calcination. An important roasting process is the oxidation of sulfide ores, in which the metal sulfide is converted to the metal oxide, as in the following examples:

The sulfide ore of a less active metal, such as mercury, can be roasted to the free metal:

In many instances the free metal can be obtained by using a reducing atmosphere during roasting. Carbon monoxide provides such an atmosphere and is frequently used to reduce metal oxides:

This method of reduction is not always feasible, however, especially with active metals, which are difficult to reduce.

### GIVE IT SOME THOUGHT

Would you expect  $\text{CaO}$  to reduce to the free metal if heated in the presence of  $\text{CO}$ ? What about  $\text{Ag}_2\text{O}$ ?

**Smelting** is a melting process in which the materials formed in the course of chemical reactions separate into two or more layers. Smelting often involves a roasting stage in the same furnace. Two of the important types of layers formed in smelters are molten metal and slag. The molten metal may consist almost entirely of a single metal, or it may be a solution of two or more metals.

**Slag** consists mainly of molten silicate minerals, with aluminates, phosphates, and other ionic compounds as constituents. A slag is formed when a basic metal oxide such as  $\text{CaO}$  reacts at high temperatures with molten silica ( $\text{SiO}_2$ ):

Pyrometallurgical operations may involve the concentration and reduction of a mineral and the refining of the metal. **Refining** is the treatment of a crude, relatively impure metal product from a metallurgical process to improve its

purity and to define its composition better. Sometimes the goal of the refining process is to obtain the metal itself in pure form. The goal may also be to produce a mixture with a well-defined composition, as in the production of steels from crude iron.

### The Pyrometallurgy of Iron

The most important pyrometallurgical operation is the reduction of iron. Iron occurs in many different minerals, but the most important sources are two iron oxide minerals—hematite ( $\text{Fe}_2\text{O}_3$ ) and magnetite ( $\text{Fe}_3\text{O}_4$ ). Figure 23.3 shows the world production of iron ore as a function of country. China, Brazil, and Australia account for nearly two-thirds of the world's iron ore. As the higher-grade deposits of iron ore have become depleted, lower-grade ores have been tapped. *Taconite*, which consists of fine-grained silica with variable ratios of iron, present mainly as magnetite, has increased in importance as a source of iron from the great Mesabi Range west of Lake Superior. These deposits account for almost all of the iron ore production in the United States.

The reduction of iron oxides can be accomplished in a *blast furnace*, such as the one illustrated in Figure 23.4. A blast furnace is essentially a huge chemical reactor capable of continuous operation. The furnace is charged at the top with a mixture of iron ore, coke, and limestone. Coke is coal that has been heated in the absence of air to drive off volatile components. It is about 85% to 90% carbon. Coke serves as the fuel, producing heat as it is burned in the lower part of the furnace. Through reactions with oxygen and water, coke also serves as the source of the reducing gases CO and  $\text{H}_2$ . Limestone ( $\text{CaCO}_3$ ) serves as the source of the basic oxide CaO, which reacts with silicates and other components of the ore to form slag. Air, which enters the blast furnace at the bottom after preheating, is also an important raw material; it is required for combustion of the coke. Production of 1 kg of crude iron, called *pig iron*, requires about 2 kg of ore, 1 kg of coke, 0.3 kg of limestone, and 1.5 kg of air.

In the furnace, oxygen reacts with the carbon in the coke to form carbon monoxide:<sup>\*</sup>

Water vapor present in the air also reacts with carbon, forming both carbon monoxide and hydrogen:

The reaction of coke with oxygen is exothermic and provides heat for furnace operation, whereas its reaction with water vapor is endothermic. Addition of water vapor to the air thus provides a means of controlling furnace temperature.

In the upper part of the furnace, limestone decomposes to form CaO and  $\text{CO}_2$ . Here, also, the iron oxides are reduced by CO and  $\text{H}_2$ . For example, the important reactions for  $\text{Fe}_3\text{O}_4$  are

<sup>\*</sup>In the reactions shown the enthalpy changes are given as  $\Delta H^\circ$  values. Note, however, that the conditions in the furnace are far from standard.

Usable ore (in metric tons × 10<sup>6</sup>)

▲ **Figure 23.3 Worldwide mine production of iron ores.** The total worldwide production of iron ore was estimated to be  $1.69 \times 10^{12}$  kg in 2006.

▲ **Figure 23.4 A blast furnace.** The furnace is used for reducing iron ore. Notice the increasing temperatures as the materials pass downward through the furnace.

▲ **Figure 23.5 Molten iron from a blast furnace.** The iron is poured for transport to a basic oxygen converter. Steelmakers convert iron to steel by adding scrap steel and other metals as alloying agents.

▲ **Figure 23.6 Refining iron.** In this converter for refining iron, a mixture of oxygen and argon is blown through the molten iron and slag. The heat generated by the oxidation of impurities maintains the mixture in a molten state. When the desired composition is attained, the converter is tilted to pour out its contents.

Reduction of other elements present in the ore also occurs in the hottest parts of the furnace, where carbon is the major reducing agent.

Molten iron collects at the base of the furnace, as shown in Figure 23.4. It is overlaid with a layer of molten slag formed by the reaction of CaO with the silica present in the ore (Equation 23.6). The layer of slag over the molten iron helps to protect it from reacting with the incoming air. Periodically the furnace is tapped to drain off slag and molten iron. The iron produced in the furnace may be cast into solid ingots. Most of the iron, however, is used directly in the manufacture of steel. For this purpose, it is transported, while still liquid, to the steelmaking shop (Figure 23.5 ◀). The production of pig iron using blast furnaces has decreased in recent years because of alternative reduction processes and the increased use of iron scrap in steelmaking. Blast furnaces nevertheless remain a significant means of reducing iron oxides.

### Formation of Steel

As we will see in Section 23.6, steel is an alloy of iron. To produce steel with favorable properties, it is necessary to remove undesired impurities from the crude iron. Iron from a blast furnace typically contains 0.6–1.2% silicon, 0.4–2.0% manganese, and lesser amounts of phosphorus and sulfur. In addition, there is considerable dissolved carbon. In the production of steel these impurities are removed by oxidation in a vessel called a *converter*. In modern steelmaking the oxidizing agent is either pure O<sub>2</sub> or O<sub>2</sub> diluted with argon. Air cannot be used directly as the source of O<sub>2</sub> because N<sub>2</sub> reacts with the molten iron to form iron nitride, which causes the steel to become brittle.

A cross-sectional view of one converter design appears in Figure 23.6 ◀. In this converter O<sub>2</sub>, diluted with argon, is blown directly into the molten metal. The oxygen reacts exothermically with carbon, silicon, and many metal impurities, reducing the concentrations of these elements in the iron. Carbon and sulfur are expelled as CO and SO<sub>2</sub> gases, respectively. Silicon is oxidized to SiO<sub>2</sub> and adds to whatever slag may have been present initially in the melt. Metal oxides react with the SiO<sub>2</sub> to form silicates. The presence of a basic slag is also important for removal of phosphorus:

Nearly all of the O<sub>2</sub> blown into the converter is consumed in the oxidation reactions. By monitoring the O<sub>2</sub> concentration in the gas coming from the converter, it is possible to tell when the oxidation is essentially complete. Oxidation of the impurities present in the iron normally requires about 20 min. When the desired composition is attained, the contents of the converter are dumped into a large ladle. To produce steels with various kinds of properties, alloying elements are added as the ladle is being filled. The still-molten mixture is then poured into molds, where it solidifies.

#### ■ SAMPLE EXERCISE 23.1 | Enthalpy Changes in a Converter

Which produces more heat in a converter, oxidation of 1 mol of C or oxidation of 1 mol of Si?

#### SOLUTION

**Analyze:** We must compare the enthalpy change for 1 mol of C oxidized to form CO<sub>2</sub> with the enthalpy change for 1 mol of Si oxidized to form SiO<sub>2</sub>.

**Plan:** The reactions occur under conditions far different from the standard-state conditions for the substances. Nevertheless, we can estimate the enthalpy changes by using the thermodynamic values of Appendix C.

**Solve:** The oxidation reactions and enthalpy changes under standard conditions are

The actual numbers will differ substantially from these because the temperature is far from 298 K, because both C and Si are dissolved in the molten iron, and because  $\text{SiO}_2$  will be incorporated in the slag. Nevertheless, the differences in the enthalpies of reaction are so great that it seems certain that the enthalpy change will be larger for Si.

#### ■ PRACTICE EXERCISE

(a) What would you expect as the product when any dissolved manganese in the molten mixture is oxidized? (b) Would the manganese oxidation be exothermic or endothermic?

Answers: (a)  $\text{MnO}_2$ , (b) exothermic

## 23.3 HYDROMETALLURGY

Pyrometallurgical operations require large quantities of energy and are often a source of atmospheric pollution, especially by sulfur dioxide. For some metals, other techniques have been developed in which the metal is extracted from its ore by use of aqueous reactions. These processes are called **hydrometallurgy** (*hydro* means “water”).

The most important hydrometallurgical process is **leaching**, in which the desired metal-containing compound is selectively dissolved. If the compound is water soluble, water by itself is a suitable leaching agent. More commonly, the agent is an aqueous solution of an acid, a base, or a salt. Often the dissolving process involves formation of a complex ion.  $\rightleftharpoons$  (Section 17.5) As an example, we can consider the leaching of gold.

### Hydrometallurgy of Gold

As noted in the “A Closer Look” box in Section 4.5, gold metal is often found relatively pure in nature. As concentrated deposits of elemental gold have been depleted, lower-grade sources have become more important. Gold from low-grade ores can be concentrated by placing the crushed ore on large concrete slabs and spraying a solution of  $\text{NaCN}$  over it. In the presence of  $\text{CN}^-$  and air, the gold is oxidized, forming the stable  $\text{Au}(\text{CN})_2^-$  ion, which is soluble in water:

After a metal ion is selectively leached from an ore, it is precipitated from solution as the free metal or as an insoluble ionic compound. Gold, for example, is obtained from its cyanide complex by reduction with zinc powder:

The cyanide process for gold recovery has been widely criticized because of the potential for pollution of groundwater, rivers, and streams. For example, leakage from containment ponds into nearby streams in Romania several years ago resulted in poisoning of all aquatic life in small rivers that flow into the Danube. Alternatives to cyanide are being investigated. Thiosulfate ion,  $\text{S}_2\text{O}_3^{2-}$ ,  $\rightleftharpoons$  (Section 22.6) has been studied as an alternative, but the costs are higher than for the cyanide process.

### GIVE IT SOME THOUGHT

Gold dissolves in the presence of thiosulfate as follows:

What is the oxidizing agent in this reaction, what is the reducing agent, and what oxidation states of the reducing and oxidizing agents are involved?

## Hydrometallurgy of Aluminum

Among metals, aluminum is second only to iron in commercial use. Worldwide production of aluminum is about  $2.4 \times 10^{10}$  kg per year. The most useful ore of aluminum is *bauxite*, in which Al is present as hydrated oxides,  $\text{Al}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ . The value of  $x$  varies, depending on the particular mineral present. Because bauxite deposits in the United States are limited, most of the ore used in the production of aluminum must be imported.

The major impurities found in bauxite are  $\text{SiO}_2$  and  $\text{Fe}_2\text{O}_3$ . It is essential to separate  $\text{Al}_2\text{O}_3$  from these impurities before the metal is recovered by electrochemical reduction, as described in Section 23.4. The process used to purify bauxite, called the **Bayer process**, is a hydrometallurgical procedure. The ore is first crushed and ground, then digested in a concentrated aqueous NaOH solution, about 30% NaOH by mass, at a temperature in the range of 150 °C to 230 °C. Sufficient pressure, up to 30 atm, is maintained to prevent boiling. The  $\text{Al}_2\text{O}_3$  dissolves in this solution, forming the complex aluminate ion,  $\text{Al}(\text{OH})_4^-$ :

The iron(III) oxides do not dissolve in the strongly basic solution. This difference in the behavior of the aluminum and iron compounds arises because  $\text{Al}^{3+}$  is amphoteric, whereas  $\text{Fe}^{3+}$  is not.  $\infty$  (Section 17.5) Thus, the aluminate solution can be separated from the iron-containing solids by filtration. The pH of the solution is then lowered, causing the aluminum hydroxide to precipitate.

After the aluminum hydroxide precipitate has been filtered, it is calcined in preparation for electroreduction to the metal. The solution recovered from the filtration is reconcentrated so that it can be used again. This task is accomplished by heating to evaporate water from the solution, a procedure that requires much energy and is the most costly part of the Bayer process.

### GIVE IT SOME THOUGHT

What do you expect to be the product of the calcination of  $\text{Al}(\text{OH})_3$ ?

## 23.4 ELECTROMETALLURGY

Many processes that are used to reduce metal ores or to refine metals are based on electrolysis.  $\infty$  (Section 20.9) Collectively these processes are referred to as **electrometallurgy**. Electrometallurgical procedures can be broadly differentiated according to whether they involve electrolysis of a molten salt or of an aqueous solution.

Electrolytic methods are important for obtaining the more active metals, such as sodium, magnesium, and aluminum. These metals cannot be obtained from aqueous solution because water is more easily reduced than the metal ions. The standard reduction potentials of water under both acidic and basic conditions are more positive than those of  $\text{Na}^+$  ( $E_{\text{red}}^\circ = -2.71$  V),  $\text{Mg}^{2+}$  ( $E_{\text{red}}^\circ = -2.37$  V), and  $\text{Al}^{3+}$  ( $E_{\text{red}}^\circ = -1.66$  V):

To form such metals by electrochemical reduction, therefore, we must employ a nonaqueous, molten-salt medium in which the metal ion of interest is the most readily reduced species.

### Electrometallurgy of Sodium

In the commercial preparation of sodium, molten NaCl is electrolyzed in a specially designed cell called the **Downs cell**, illustrated in Figure 23.7. Calcium chloride ( $\text{CaCl}_2$ ) is added to lower the melting point of the molten NaCl from the

◀ **Figure 23.7 Production of sodium.** The Downs cell is used in the commercial production of sodium.

normal melting point of 804 °C to around 600 °C. The Na(l) and Cl<sub>2</sub>(g) produced in the electrolysis are kept from coming in contact and re-forming NaCl. In addition, the Na must be prevented from contact with oxygen because the metal would quickly oxidize under the high-temperature conditions of the cell reaction.

### GIVE IT SOME THOUGHT

Which ions carry the current in a Downs cell?

## Electrometallurgy of Aluminum

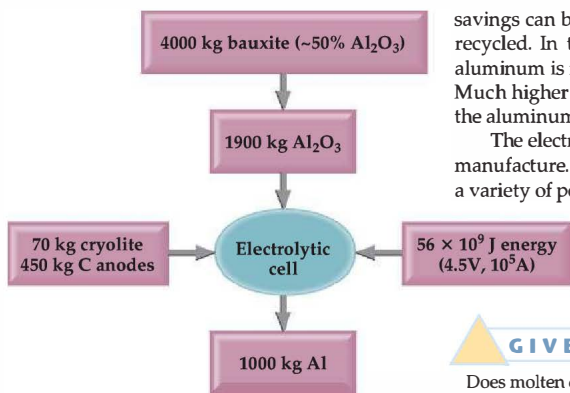

In Section 23.3 we discussed the Bayer process, in which bauxite is concentrated to produce aluminum hydroxide. When this concentrate is calcined at temperatures in excess of 1000 °C, anhydrous aluminum oxide (Al<sub>2</sub>O<sub>3</sub>) is formed. Anhydrous aluminum oxide melts at over 2000 °C. This is too high to permit its use as a molten medium for electrolytic formation of free aluminum. The electrolytic process commercially used to produce aluminum is known as the **Hall-Héroult process**, named after its inventors, Charles M. Hall and Paul Héroult (see the “A Closer Look” box in this section). The purified Al<sub>2</sub>O<sub>3</sub> is dissolved in molten cryolite (Na<sub>3</sub>AlF<sub>6</sub>), which has a melting point of 1012 °C and is an effective conductor of electric current. A schematic diagram of the electrolysis cell is shown in Figure 23.8▶. Graphite rods are employed as anodes and are consumed in the electrolysis process. The electrode reactions are as follows:

The amounts of raw materials and energy required to produce 1000 kg of aluminum metal from bauxite by this procedure are summarized in Figure 23.9▼. Due to the large amount of electrical energy needed in the Hall-Héroult process, aluminum smelters are invariably located in areas with access to low cost sources of electricity. In fact, the aluminum industry consumes about 10% of the world's hydroelectric power. However, recycled aluminum only requires 5% of the energy needed to produce “new” aluminum. Therefore, considerable energy

▶ **Figure 23.8 The Hall-Héroult process.** An electrolysis cell used to form aluminum metal through reduction. Because molten aluminum is denser than the mixture of cryolite (Na<sub>3</sub>AlF<sub>6</sub>) and Al<sub>2</sub>O<sub>3</sub>, the metal collects at the bottom of the cell.

▲ **Figure 23.9** What it takes to produce 1000 kg of aluminum.

savings can be realized by increasing the amount of aluminum that is recycled. In the United States approximately 42% of post-consumer aluminum is recycled, while in Europe the rate is estimated to be 52%. Much higher rates of recycling are possible. In Norway, for example, the aluminum recycling rate is 93%.

The electrodes represent another challenge surrounding aluminum manufacture. The carbon anode is consumed in the process, generating a variety of pollutants, including  $\text{CO}_2$ . Approximately  $3.8 \times 10^{10}$  kg of  $\text{CO}_2$  are emitted each year from aluminum manufacture. It is a significant challenge to find electrodes that are conducting and chemically inert at elevated temperatures in molten cryolite.

### GIVE IT SOME THOUGHT

Does molten cryolite conduct electricity through the movement of electrons (electronic conductivity) or the movement of ions (ionic conductivity)?

## Electrorefining of Copper

Copper is widely used to make electrical wiring and in other applications that utilize its high electrical conductivity. Crude copper, which is usually obtained by pyrometallurgical methods, is not suitable to serve in electrical applications because impurities greatly reduce the metal's conductivity.

Purification of copper is achieved by electrolysis, as illustrated in Figure 23.11. Large slabs of crude copper serve as the anodes in the cell, and thin sheets of pure copper serve as the cathodes. The electrolyte consists of an acidic solution of  $\text{CuSO}_4$ . Application of a suitable voltage to the electrodes causes oxidation of copper metal at the anode and reduction of  $\text{Cu}^{2+}$  to form copper metal at the cathode. This strategy can be used because copper is both oxidized and reduced more readily than water. The relative ease of reduction of  $\text{Cu}^{2+}$  and  $\text{H}_2\text{O}$  is seen by comparing their standard reduction potentials:

## A Closer Look

CHARLES M. HALL

Charles M. Hall (Figure 23.10) began to work on the problem of reducing aluminum in about 1885 after he had learned from a professor of the difficulty of reducing ores of very active metals. Before the development of Hall's electrolytic process, aluminum was obtained by a chemical reduction using sodium or potassium as the reducing agent. Because the procedure was very costly, aluminum metal was very expensive. As late as 1852, the cost of aluminum was \$545 per pound, far greater than the cost of gold. During the Paris Exposition in 1855, aluminum was exhibited as a rare metal, even though it is the third most abundant element in Earth's crust.

Hall, who was 21 years old when he began his research, utilized handmade and borrowed equipment in his studies and used a woodshed near his Ohio home as his laboratory. In about a year's time he was able to solve the problem of reducing aluminum. His procedure consisted of finding an ionic compound that could be melted to form a conducting medium that would dissolve  $\text{Al}_2\text{O}_3$  but would not interfere in the electrolysis reactions. The relatively rare mineral cryolite,  $(\text{Na}_3\text{AlF}_6)$ , found in Greenland, met these criteria. Ironically,

◀ **Figure 23.10** Charles M. Hall (1863–1914) as a young man.

Paul Héroult, who was the same age as Hall, independently made the same discovery in France at about the same time. Because of the research of these two unknown young scientists, large-scale production of aluminum became commercially feasible, and aluminum became a common and familiar metal.

The impurities in the copper anode include lead, zinc, nickel, arsenic, selenium, tellurium, and several precious metals, including gold and silver. Metallic impurities that are more active than copper are readily oxidized at the anode but do not plate out at the cathode because their reduction potentials are more negative than that for  $\text{Cu}^{2+}$ . Less active metals, however, are not oxidized at the anode. Instead they collect below the anode as a sludge that is collected and processed to recover the valuable metals. The anode sludges from copper-refining cells provide one-fourth of U.S. silver production and about one-eighth of U.S. gold production.

▲ **Figure 23.11** Electrolysis cell for refining copper. As the anodes dissolve away, the cathodes on which the pure metal is deposited grow larger.

### GIVE IT SOME THOUGHT

Which ions carry the current in the electrorefining of copper?

#### SAMPLE EXERCISE 23.2 | Impurities in Electrorefining

Nickel is one of the chief impurities in the crude copper that is subjected to electrorefining. What happens to this nickel in the course of the electrolytic process?

#### SOLUTION

**Analyze:** We are asked to predict whether nickel can be oxidized at the anode and reduced at the cathode during the electrorefining of copper.

**Plan:** We need to compare the standard reduction potentials of  $\text{Ni}^{2+}$  and  $\text{Cu}^{2+}$ . The more negative the reduction potential, the less readily the ion is reduced but the more readily the metal itself is oxidized. (Section 20.4)

**Solve:** The standard reduction potential for  $\text{Ni}^{2+}$  is more negative than that for  $\text{Cu}^{2+}$ :

As a result, nickel is more readily oxidized than copper, assuming standard conditions. Although we do not have standard conditions in the electrolytic cell, we nevertheless expect that nickel is preferentially oxidized at the anode. Because the reduction of  $\text{Ni}^{2+}$  occurs less readily than the reduction of  $\text{Cu}^{2+}$ , the  $\text{Ni}^{2+}$  accumulates in the electrolyte solution, while the  $\text{Cu}^{2+}$  is reduced at the cathode. After a time it is necessary to recycle the electrolyte solution to remove the accumulated metal ion impurities, such as  $\text{Ni}^{2+}$ .

#### PRACTICE EXERCISE

Zinc is another common impurity in copper. Using standard reduction potentials, determine whether zinc will accumulate in the anode sludge or in the electrolytic solution during the electrorefining of copper.

**Answer:** It is found in the electrolytic solution because the standard reduction potential of  $\text{Zn}^{2+}$  is more negative than that of  $\text{Cu}^{2+}$ .

## 23.5 METALLIC BONDING

In our discussion of metallurgy we have confined ourselves to discussing the methods employed for obtaining metals in pure form. Metallurgy is also concerned with understanding the properties of metals and with developing useful new materials. As with any branch of science and engineering, our ability to make advances is coupled with our understanding of the fundamental properties of the systems with which we work. At several places in the text we have referred to the differences in physical and chemical behavior between metals and non-metals. Let's now consider the distinctive properties of metals and relate these properties to a model for metallic bonding.

▲ **Figure 23.12 Malleability and ductility.** Gold leaf (left) demonstrates the characteristic malleability of metals, and copper wire (right) demonstrates their ductility.

## Physical Properties of Metals

You have probably held a length of copper wire or an iron bolt. Perhaps you have even seen the surface of a freshly cut piece of sodium metal. These substances, although distinct from one another, share certain similarities that enable us to classify them as metallic. A clean metal surface has a characteristic luster. In addition, metals that we can handle with bare hands have a characteristic cold feeling related to their high heat conductivity. Metals also have high electrical conductivities; electrical current flows easily through them. Current flow occurs without any displacement of atoms within the metal structure and is due to the flow of electrons within the metal. The heat conductivity of a metal usually parallels its electrical conductivity. Silver and copper, for example, which possess the highest electrical conductivities among the elements, also possess the highest heat conductivities. This observation suggests that the two types of conductivity have the same origin in metals, which we will soon discuss.

Most metals are *malleable*, which means that they can be hammered into thin sheets, and *ductile*, which means that they can be drawn into wires (Figure 23.12 ◀). These properties indicate that the atoms are capable of slipping with respect to one another. Ionic solids or crystals of most covalent compounds do not exhibit such behavior. These types of solids are typically brittle and fracture easily. Consider, for example, the difference between dropping an ice cube and a block of aluminum metal onto a concrete floor.

Most metals form solid structures in which the atoms are arranged as close-packed spheres. In these structures each atom is in contact with 12 neighboring atoms. ∞ (Section 11.7) This arrangement of atoms is very different from the structures of the nonmetallic elements. Consider for example the structures of elements of the third period (Na–Ar). Argon with eight valence electrons has a complete octet; as a result it does not form any bonds. Chlorine, sulfur, and phosphorus form molecules ( $\text{Cl}_2$ ,  $\text{S}_8$ , and  $\text{P}_4$ ) where the atoms make one, two, and three bonds, respectively. ∞ (Chapter 22) Silicon forms an extended network solid where each atom is bonded to four equidistant neighbors (Figure 12.3). Each of these elements forms 8–N bonds, where N is the number of valence electrons. This behavior can easily be understood through application of the octet rule.

If the trend were to continue as we move left across the periodic table, we would expect aluminum to form five bonds. But, like many other metals including magnesium, titanium and gold, aluminum adopts a close-packed structure with 12 near neighbors. Clearly there is a change in the preferred bonding mechanism as the number of valence electrons decreases. As a general rule, metals do not have enough valence-shell electrons to satisfy their bonding requirements through the formation of localized electron pair bonds. In response to this deficiency, the valence electrons are collectively shared. A close-packed lattice of atoms facilitates a delocalized sharing of electrons among all atoms in the lattice.

## Electron-Sea Model for Metallic Bonding

One very simple model that accounts for some of the most important characteristics of metals is the **electron-sea model**. ∞ (Section 11.8) In this model the metal is pictured as an array of metal cations in a “sea” of valence electrons, as illustrated in Figure 23.13 ◀. The electrons are confined to the metal by electrostatic attractions to the cations, and they are uniformly distributed throughout the structure. The electrons are mobile, however, and no individual electron is confined to any particular metal ion. When a metal wire is connected to the terminals of a battery, electrons flow through the metal toward the positive terminal and into the metal from the battery at the negative terminal. The high heat conductivity of metals is also accounted for by the mobility of the electrons, which permits ready transfer of kinetic energy throughout the solid. The ability of metals to deform (their malleability and ductility) can be explained by the fact that metal atoms form bonds to many neighbors. Changes in the positions of the atoms brought about in reshaping the metal are partly accommodated by a redistribution of electrons.

▲ **Figure 23.13 Electron-sea model.** Schematic illustration of the electronic structure of metals. Each gray sphere is a positively charged metal ion.

▲ **Figure 23.14** The (a) melting and (b) boiling points of metallic elements.

The electron-sea model, however, does not adequately explain all properties. According to the model, for example, the strength of bonding between metal atoms should increase as the number of valence electrons increases, resulting in a corresponding increase in the melting and boiling points. However, the elements found near the middle of the transition metal series, rather than those at the end, have the highest melting and boiling points in their respective periods (Figure 23.14▲), which implies that the strength of metallic bonding first increases with increasing number of electrons and then decreases. Similar trends are seen in other physical properties of the metals, such as the heat of fusion and hardness.

### Molecular-Orbital Model for Metals

To obtain a more accurate picture of the bonding in metals we turn to molecular-orbital theory. In Sections 9.7 and 9.8 we learned how molecular orbitals are created from the overlap of atomic orbitals. In Section 12.2 we saw that in extended solids (such as covalent network solids and metals) the presence of a large number of atoms results in a large number of closely spaced molecular orbitals. These closely spaced orbitals form continuous *bands* of allowed energy states. ∞ (Section 12.2)

The band structure for a typical metal is shown schematically in Figure 23.15▶. The electron filling depicted corresponds to nickel metal, but the basic features of other metals are similar. The electron configuration of a nickel atom is  $[\text{Ar}]3d^84s^2$ , as shown on the left side of the figure. The energy bands that form from these orbitals are shown on the right side of the figure. The  $4s$ ,  $4p$ , and  $3d$  orbitals are treated independently, each giving rise to a band of molecular orbitals. In practice, these overlapping bands are not independent of each other, but for our purposes this simplification is reasonable.

▲ **Figure 23.15** The electronic band structure of nickel. The left side of the figure shows the electron configuration of a single Ni atom, while the right-hand side of the figure shows how these orbital energy levels broaden into energy bands in bulk nickel. The horizontal dashed gray line denotes the position of the Fermi Level, which separates the occupied molecular orbitals (shaded in blue) from the unoccupied molecular orbitals.

When two atomic orbitals overlap they form two molecular orbitals: (1) a bonding molecular orbital whose energy is lowered with respect to the parent atomic orbitals and (2) an antibonding molecular orbital whose energy is raised with respect to the parent atomic orbitals. [↔ \(Chapters 9 and 12\)](#) As the overlap increases, the energy splitting between bonding and antibonding molecular orbitals increases. The  $4s$  and  $4p$  orbitals are considerably larger than the  $3d$  orbitals, which means that they overlap more effectively. This characteristic leads to a large difference in energy between the molecular orbitals at the bottom of the band, where the interactions are strongly bonding, and the molecular orbitals at the top of the band, where the interactions are strongly antibonding. The result is  $4s$  and  $4p$  bands that span a relatively wide range of energy, but due to the Pauli Exclusion Principle [↔ \(Section 6.7\)](#) these bands can hold only two and six electrons per atom, respectively.

The band that arises from overlap of the  $3d$  orbitals differs in two important ways. Because the  $3d$  orbitals are smaller, yet the interatomic distance is the same, they overlap less effectively, which reduces the strength of both the stabilizing bonding interactions and the destabilizing antibonding interactions. The result is a band that spans a much narrower range of energy. But because there are five  $3d$  orbitals on each atom, this band can hold up to ten electrons per atom. The filling of bands with electrons is akin to filling a reservoir with water. In a solid the energy of the highest filled molecular orbital is called the *Fermi level*. Only a tiny energy separates it from the energy of the lowest empty orbital. The electrons occupy the lowest energy molecular orbitals available to them, irrespective of the orbitals populated in an individual atom. The occupied molecular orbitals are shaded in blue in Figure 23.15.

Many properties of metals can be understood from the simple band structure diagram shown in Figure 23.15. Because the electrons available for bonding do not completely fill the available molecular orbitals, we can think of the energy band as a partially filled container for electrons. The incomplete filling of the energy band gives rise to characteristic metallic properties. The electrons in orbitals near the top of the occupied levels require very little energy input to be “promoted” to still higher energy orbitals that are unoccupied. Under the influence of any source of excitation, such as an applied electrical potential or an input of thermal energy, electrons move into previously vacant levels and are thus freed to move through the lattice, giving rise to electrical and thermal conductivity.

Without the overlap of energy bands, the periodic properties of metals could not be explained. In the absence of the  $d$ - and  $p$ -bands we would expect the  $s$ -band to be half filled for the alkali metals (group 1A) and completely filled for the alkali-earth metals (group 2A). If that were true, metals like magnesium, calcium, and strontium would be expected to behave as semiconductors! While the conductivity of metals can be qualitatively understood using either the electron-sea model or the molecular-orbital model, many of the physical properties of transition metals, such as the melting and boiling points plotted in Figure 23.14, can be explained only by using the latter model. The molecular-orbital model predicts that bonding will first become stronger as the number of valence electrons increases and the bonding orbitals are populated. Upon moving past the middle elements of the transition metal series, the bonds grow weaker as we fill the antibonding orbitals.

Strong bonds between atoms lead to metals with higher melting and boiling points, higher heats of fusion, higher hardness, and so forth. Metals with a small number of electrons per atom, such as Rb or Cs, have relatively few metal–metal bonding orbitals occupied. In metals with a large number of electrons per atom, such as Zn or Cd, the metal–metal bonding orbitals are filled, but at the same time a high percentage of the metal–metal antibonding orbitals are also occupied. In either case, the bonding will be much weaker compared to elements in the middle of the transition series, dramatically impacting a number of physical properties. However, we need to remember that factors other than the number of electrons (such as atomic radius, nuclear charge, and the particular packing structure of the metal) also play a role in determining the properties of metals.

### GIVE IT SOME THOUGHT

Which element, W or Hg, has the greater number of electrons in antibonding orbitals? Which one would you expect to have a higher melting point?

## 23.6 ALLOYS

An **alloy** is a material that contains more than one element and has the characteristic properties of metals. The alloying of metals is of great importance because it is one of the primary ways of modifying the properties of pure metallic elements. Nearly all the common uses of iron, for example, involve alloy compositions. Bronze is formed by alloying copper and tin, while brass is an alloy of copper and zinc. Copper is the majority element in both alloys. Pure gold is too soft to be used in jewelry, but alloys of gold and copper are quite hard. Pure gold is termed 24 karat; the common alloy used in jewelry is 14 karat, meaning that it is 58% gold ( $\frac{14}{24} \times 100\%$ ). A gold alloy of this composition has suitable hardness to be used in jewelry. The alloy can be either yellow or white, depending on the elements added. Some further examples of alloys are given in Table 23.2 ▼.

Alloys can be classified as solution alloys, heterogeneous alloys, and intermetallic compounds. **Solution alloys** are homogeneous mixtures in which components are dispersed randomly and uniformly. Atoms of the solute can take positions normally occupied by a solvent atom, thereby forming a *substitutional alloy*. Or they can occupy interstitial positions in the “holes” between the solvent atoms, thereby forming an *interstitial alloy*. These types are diagrammed in Figure 23.16 ▼.

Substitutional alloys are formed when the two metallic components have similar atomic radii and chemical-bonding characteristics. For example, silver and gold form such an alloy over the entire range of possible compositions. When two metals differ in radii by more than about 15%, solubility is more limited.

For an interstitial alloy to form, the component present in the interstitial positions between the solvent atoms must have a much smaller bonding atomic radius than the solvent atoms. Typically, an interstitial element is a nonmetal that bonds to neighboring atoms. The presence of the extra bonds provided by the interstitial component causes the metal lattice to become harder, stronger, and less ductile. For example, steel, which is much harder and stronger than pure iron, is an alloy of iron that contains up to 3% carbon. *Mild steels* contain less than 0.2% carbon; they are malleable and ductile and are used to make cables, nails, and chains. *Medium steels* contain 0.2–0.6% carbon; they are tougher than mild steels and are used to make girders and rails. *High-carbon steel*, used in cutlery, tools, and springs, contains 0.6–1.5% carbon. In all three cases other elements may be added to form *alloy steels*. Vanadium and chromium may be added to impart strength and to increase resistance to fatigue and corrosion. For example, a rail steel used in Sweden on lines bearing heavy ore carriers contains 0.7% carbon, 1% chromium, and 0.1% vanadium.

### GIVE IT SOME THOUGHT

Would you expect the alloy PdB<sub>0.15</sub> to be a substitutional alloy or an interstitial alloy?

TABLE 23.2 ■ Some Common Alloys

Primary Element	Name of Alloy	Composition by Mass	Properties	Uses
Bismuth	Wood's metal	50% Bi, 25% Pb, 12.5% Sn, 12.5% Cd	Low melting point (70 °C)	Fuse plugs, automatic sprinklers
Copper	Yellow brass	67% Cu, 33% Zn	Ductile, takes polish	Hardware items
Iron	Stainless steel	80.6% Fe, 0.4% C, 18% Cr, 1% Ni	Resists corrosion	Tableware
Lead	Plumber's solder	67% Pb, 33% Sn	Low melting point (275 °C)	Soldering joints
Silver	Sterling silver	92.5% Ag, 7.5% Cu	Bright surface	Tableware
	Dental amalgam	70% Ag, 18% Sn, 10% Cu, 2% Hg	Easily worked	Dental fillings

## THE ARRANGEMENT OF ATOMS IN TWO TYPES OF SOLUTION ALLOYS

*Solution alloys are homogenous mixtures in which the components are dispersed randomly and uniformly.*

▲ **Figure 23.16 Substitutional and interstitial alloys.** The blue spheres represent host metal; the yellow spheres represent the other components of the alloy.

One of the most important iron alloys is stainless steel, which contains about 0.4% carbon, 18% chromium, and 1% nickel. The chromium is obtained by carbon reduction of chromite ( $\text{FeCr}_2\text{O}_4$ ) in an electric furnace. The product of the reduction is *ferrochrome* ( $\text{FeCr}_2$ ), which is then added in the appropriate amount to molten iron that comes from the converter, to achieve the desired steel composition. The ratio of elements present in the steel may vary over a wide range, imparting a variety of specific physical and chemical properties to the materials.

In a **heterogeneous alloy** the components are not dispersed uniformly. In the form of steel known as pearlite, for example, two distinct phases—essentially pure iron and the compound  $\text{Fe}_3\text{C}$ , known as cementite—are present in alternating layers. In general, the properties of heterogeneous alloys depend on both the composition and the manner in which the solid is formed from the molten mixture. Rapid cooling leads to distinctly different properties than are obtained by slow cooling.

### Intermetallic Compounds

**Intermetallic compounds** are homogeneous alloys that have definite properties and compositions. Unlike substitutional and interstitial alloys, the different types of atoms in an intermetallic compound are ordered rather than randomly distributed. Examples of the atomic ordering seen in some important cubic intermetallic phases are shown in Figure 23.17. The ordering of atoms in an intermetallic compound generally leads to better structural stability and higher

◀ **Figure 23.17 Ordered intermetallic structures.** (a) The face-centered cubic unit cell of a cubic close-packed metal. (b) The ordered structure of Ni<sub>3</sub>Al with nickel atoms shown in gray and aluminum atoms in blue. (c) The ordered structure of TiAl with titanium atoms shown in red and aluminum atoms in blue. (d) The ordered structure of ZnCu with copper atoms shown in gray and zinc atoms in blue.

melting points than the constituent metals. These features can be attractive for high temperature applications. On the other hand, intermetallic compounds are often more brittle than substitutional alloys.

Intermetallic compounds play many important roles in modern society. The intermetallic compound Ni<sub>3</sub>Al is a major component of jet aircraft engines because of its strength at high temperature and its low density. Razor blades are often coated with Cr<sub>3</sub>Pt, which adds hardness, allowing the blade to stay sharp longer. Both compounds have the ordered structure shown in Figure 23.17(b). The compound Co<sub>5</sub>Sm is used in the permanent magnets in lightweight headsets and high-fidelity speakers because of its high magnetic strength per unit weight. A related compound with the same structure, LaNi<sub>5</sub>, is used as the anode in nickel-metal hydride batteries.

## A Closer Look

### SHAPE-MEMORY ALLOYS

In 1961 a naval engineer, William J. Buechler, made an unexpected and fortunate discovery. In searching for the best metal to use in missile nose cones, he tested many metal alloys. One of them, an intermetallic compound of nickel and titanium, NiTi, behaved very oddly. When he struck the cold metal, the sound was a dull thud. When he struck the metal at a higher temperature, however, it resonated like a bell. Mr. Buechler knew that the way in which sound propagates in a metal is related to its metallic structure. Clearly, the structure of the NiTi alloy had changed as it went from cold to warm. As it turned out, he had discovered an alloy that has shape memory.

Metals and metal alloys consist of many tiny crystalline areas (*crystallites*). When a metal is formed into a certain shape at high temperature, the crystallites are forced into a particular arrangement with respect to one another. Upon cooling a normal metal, the crystallites are “locked” in place by the

bonds between them. When the metal is subsequently bent, the resulting stresses are sometimes elastic, as in a spring. Often, however, the metal merely deforms (for example, when we bend a nail or crumple a sheet of aluminum foil). In these cases bending weakens the bonds that tie the crystallites together, and upon repeated flexing, the metal breaks apart.

In a shape-memory alloy, the atoms can exist in two different bonding arrangements, representing two different solid-state phases. The higher-temperature phase has strong, fixed bonds between the atoms in the crystallites. By contrast, the lower-temperature phase is quite flexible with respect to the arrangements between the atoms. Thus, when the metal is distorted at low temperature, the stresses of the distortion are absorbed *within* the crystallites by changes in the atomic lattice. In the higher-temperature phase, however, the atomic lattice is stiff, and the bonds between crystallites, as in a normal metal, absorb stresses that are due to bending.

*continues on next page*

TABLE 23.3 ■ Properties of the First Transition-Series Elements

Group	3B	4B	5B	6B	7B	8B			1B	2B
	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn
Element:	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn
Electron configuration	$3d^14s^2$	$3d^24s^2$	$3d^34s^2$	$3d^54s^1$	$3d^54s^2$	$3d^64s^2$	$3d^74s^2$	$3d^84s^2$	$3d^{10}4s^1$	$3d^{10}4s^2$
First ionization energy (kJ/mol)	631	658	650	653	717	759	758	737	745	906
Radius in metallic substances (Å)	1.64	1.47	1.35	1.29	1.37	1.26	1.25	1.25	1.28	1.37
Density (g/cm <sup>3</sup> )	3.0	4.5	6.1	7.9	7.2	7.9	8.7	8.9	8.9	7.1
Melting point (°C)	1541	1660	1917	1857	1244	1537	1494	1455	1084	420

The properties of metals vary in similar ways across each series (row). We have already seen evidence for this in the melting and boiling points of metals (Figure 23.14). Another example is shown in Figure 23.20 where the atomic radius observed in close packed metallic structures is plotted versus group number\*. The variation seen in Figure 23.20 is a result of two competing forces. On the one hand, increasing effective nuclear charge favors a steady decrease in the radius as we proceed from left to right across each transition series. On the other hand, the metallic bonding strength increases until we reach the middle of each transition series and then decreases as we fill antibonding orbitals (Section 23.5). As a general principle a bond shortens as it becomes stronger. ∞ (Section 8.8) For groups 3B through 6B these two effects work cooperatively and the result is a rapid decrease in radius. Upon moving past group 6B the two effects counteract each other, slowing the decrease and eventually leading to an increase in radius.

### GIVE IT SOME THOUGHT

Which of the following elements will have the largest bonding atomic radius: Cr, Mn, Re? Which will have the smallest?

The incomplete screening of the nuclear charge by added electrons produces an interesting and important effect in the third transition-metal series. In general, the radius increases as we move down in a family because of the increasing principal quantum number of the outer-shell electrons. ∞ (Section 7.3) Once we move beyond the group 3B elements, however, the second and third transition-series elements have virtually the same radii. In group 5B, for example, tantalum has virtually the same radius as niobium. This effect has its origin in the lanthanide series, the elements with atomic numbers 57 through 70, which occur between Ba and Lu (inside front cover). The filling of  $4f$  orbitals through the lanthanide elements causes a steady increase in the effective nuclear charge, producing a contraction in size called the **lanthanide contraction**. This contraction just offsets the increase we would expect as we go from the second to the third series. Thus, the second- and third-series transition metals in each group have about the same radii all the way across the series. Consequently, the second- and third-series metals in a given group have great similarity in their chemical properties. For example, the chemical properties of zirconium and hafnium are remarkably similar. They always occur together in nature, and they are very difficult to separate.

\*Note that the radii defined in this way, often referred to as metallic radii, differ somewhat from the covalent radii defined in Section 7.3.

▲ Figure 23.20 Radii of transition metals. The variation in the radius of transition metal atoms in close packed metallic substances as a function of position in the periodic table.

## Electron Configurations and Oxidation States

Transition metals owe their location in the periodic table to the filling of the  $d$  subshells. Many of the chemical and physical properties of transition metals, result from the unique characteristics of the  $d$  orbitals. For a given transition metal atom, the valence  $(n-1)d$  orbitals are smaller than the corresponding valence shell  $ns$  and  $np$  orbitals. In quantum mechanical terms the  $(n-1)d$  orbital wave functions drop off more rapidly upon moving away from the nucleus than do the  $ns$  and  $np$  orbital wave functions. This characteristic feature of the  $d$  orbitals limits their interaction with orbitals on neighboring atoms, but not so much that they are insensitive to surrounding atoms. As a result they behave like valence electrons in many instances but more like core electrons in other instances. The details depend upon the location of the element in the periodic table and the environment of the atom.

When transition metals are oxidized, they lose their outer  $s$  electrons before they lose electrons from the  $d$  subshell.  $\Rightarrow$  (Section 7.4) The electron configuration of Fe is  $[\text{Ar}]3d^64s^2$ , for example, whereas that of  $\text{Fe}^{2+}$  is  $[\text{Ar}]3d^6$ . Formation of  $\text{Fe}^{3+}$  requires loss of one  $3d$  electron, giving  $[\text{Ar}]3d^5$ . Most transition-metal ions contain partially occupied  $d$  subshells, which are responsible in large part for several characteristics of transition metals:

**▲ Figure 23.21** Salts of transition-metal ions and their solutions. From left to right:  $\text{Mn}^{2+}$ ,  $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$ , and  $\text{Zn}^{2+}$ .

1. They often exhibit more than one stable oxidation state.
2. Many of their compounds are colored, as shown in Figure 23.21. (We will discuss the origin of these colors in Chapter 24.)
3. Transition metals and their compounds exhibit interesting and important magnetic properties.

Figure 23.22 summarizes the common nonzero oxidation states for the first transition series. The oxidation states shown as large blue circles are those most frequently encountered either in solution or in solid compounds. The ones shown as small green circles are less common. Notice that Sc occurs only in the +3 oxidation state and Zn occurs

only in the +2 oxidation state. The other metals, however, exhibit a variety of oxidation states. For example, Mn is commonly found in solution in the +2 ( $\text{Mn}^{2+}$ ) and +7 ( $\text{MnO}_4^-$ ) oxidation states. In the solid state the +4 oxidation state (as in  $\text{MnO}_2$ ) is common. The +3, +5, and +6 oxidation states are less common.

The +2 oxidation state, which commonly occurs for most of these metals, is due to the loss of their two outer  $4s$  electrons. This oxidation state is found for all these elements except Sc, where the  $3+$  ion with an  $[\text{Ar}]$  configuration is particularly stable.

Oxidation states above +2 are due to successive losses of  $3d$  electrons. From Sc through Mn the maximum oxidation state increases from +3 to +7, equaling in each case the total number of  $4s$  plus  $3d$  electrons in the atom. Thus, manganese has a maximum oxidation state of  $2 + 5 = +7$ . As we move to the right beyond Mn in the first transition series, the maximum oxidation state decreases. This decrease is due in part to the attraction of  $d$  orbital electrons to the nucleus, which increases faster than the attraction of the  $s$  orbital electrons to

the nucleus as we move left-to-right across the periodic table. Thus, in each period the  $d$  electrons become more corelike as the atomic number increases. By the time we get to zinc, it is not possible to remove electrons from the  $3d$  orbitals

**▲ Figure 23.22** Nonzero oxidation states of the first transition series. The larger circles indicate the most common oxidation states.

through chemical oxidation. In the second and third transition series the increased size of the  $4d$  and  $5d$  orbitals makes it possible to attain maximum oxidation states as high as +8, which is achieved in  $\text{RuO}_4$  and  $\text{OsO}_4$ . In general, the maximum oxidation states are found only when the metals are combined with the most electronegative elements, especially O, F, and in some cases Cl.

## Magnetism

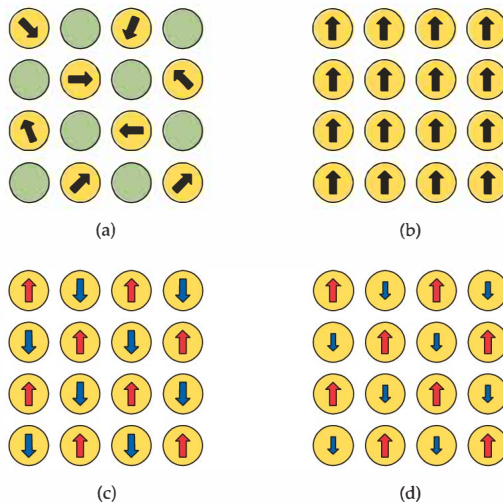

The magnetic properties of transition metals and their compounds are both interesting and important. Measurements of magnetic properties provide information about chemical bonding. In addition, many important uses are made of magnetic properties in modern technology.

An electron possesses a “spin” that gives it a magnetic moment, causing it to behave like a tiny magnet.  $\infty\infty$  (Section 9.8) In a diamagnetic solid, one in which all of the electrons in the solid are paired, the up-spin and down-spin electrons effectively cancel each other. Diamagnetic substances are generally described as nonmagnetic, but when a diamagnetic substance is placed in a magnetic field, the motions of the electrons cause the substance to be very weakly repelled by the magnet.

When an atom or ion possesses one or more unpaired electrons, the substance is said to be *paramagnetic*.  $\infty\infty$  (Section 9.8) In a paramagnetic solid the electrons on adjacent atoms or ions do not influence the unpaired electrons on neighboring atoms or ions of the solid. As a result the magnetic moments on the individual atoms or ions are randomly oriented, as shown in Figure 23.23(a)  $\blacktriangleright$ . When placed in a magnetic field, however, the magnetic moments become aligned roughly parallel to one another, producing a net attractive interaction with the magnet. Thus, a paramagnetic substance is drawn into a magnetic field.

When you think of a magnet you probably conjure up an image of a simple iron magnet (Figure 23.24  $\blacktriangleright$ ). Iron exhibits **ferromagnetism**, a much stronger form of magnetism than paramagnetism. Ferromagnetism arises when the unpaired electrons of the atoms or ions in a solid are influenced by the orientations of the electrons of their neighbors. The most stable (lowest-energy) arrangement results when the spins of electrons on adjacent atoms or ions are aligned in the same direction, as shown in Figure 23.23(b). When a ferromagnetic solid is placed in a magnetic field, the electrons tend to align strongly in a direction parallel to the magnetic field. The attraction to the magnetic field that results may be as much as one million times stronger than that for a simple paramagnetic substance. When the external magnetic field is removed, the interactions between the electrons cause the solid as a whole to maintain a magnetic moment. We then refer to it as a *permanent magnet*. The only transition metal elements that display ferromagnetism are Fe, Co, and Ni. Many alloys also exhibit ferromagnetism, which is in some cases stronger than the ferromagnetism of the pure metals. Particularly powerful magnetism is found in certain intermetallic compounds containing both transition metals and lanthanide metals. Two of the most important examples are  $\text{SmCo}_5$  and  $\text{Nd}_2\text{Fe}_{14}\text{B}$ .

Two additional types of magnetism involving ordered arrangements of unpaired electrons are depicted in Figure 23.23. In materials that exhibit **antiferromagnetism** the unpaired electrons on a given atom align so that their spins are oriented in the opposite direction as the spins on neighboring atoms, as shown in Figure 23.23(c). In an antiferromagnetic substance the up-spin and down-spin electrons cancel each other. Examples of antiferromagnetism are found among metals (such as Cr), alloys (such as FeMn), and transition metal oxides (such as  $\text{Fe}_2\text{O}_3$ ,  $\text{LaFeO}_3$  and MnO).

**▲ Figure 23.23 Types of magnetic behavior.** (a) Simple paramagnetic: centers with magnetic moments not aligned unless the substance is in a magnetic field. (b) Ferromagnetic: where the spins of coupled centers align in a common direction. (c) Antiferromagnetic: where the spins of coupled centers align in opposite directions. (d) Ferrimagnetic: where the spins of coupled centers align in opposite directions, but because the two magnetic centers have different numbers of unpaired electrons, the magnetic fields do not fully cancel.

**▲ Figure 23.24 Permanent magnets.** Permanent magnets are made from ferromagnetic and ferrimagnetic materials.

A substance that exhibits **ferrimagnetism** has characteristics of both a ferromagnet and an antiferromagnet. Like an antiferromagnet, the unpaired electrons align themselves so that they are pointing in the opposite direction of their neighbors. However, unlike an antiferromagnet the net magnetic moments of the up-spin electrons are not fully cancelled by the down-spin electrons. This can happen either because the magnetic centers have different numbers of unpaired electrons (i.e.  $\text{NiMnO}_3$ ), the number of magnetic sites aligned in one direction is larger than in the other direction (i.e.  $\text{Y}_3\text{Fe}_5\text{O}_{12}$ ), or both (i.e.  $\text{Fe}_3\text{O}_4$ ). Because the magnetic moments do not cancel, the bulk properties of ferrimagnetic materials are much like ferromagnetic materials.

All magnetically ordered materials—ferromagnets, ferrimagnets, and antiferromagnets—become paramagnetic when heated above a critical temperature. This happens when the thermal energy is sufficient to overcome the forces that are responsible for orienting the spins with respect to their neighbors. This temperature is called the *Curie temperature*,  $T_C$ , for ferromagnets and ferrimagnets, and the *Néel temperature*,  $T_N$ , for antiferromagnets. For Fe, Co, and Ni the Curie temperatures are 770 °C, 1115 °C, and 354 °C, respectively.

▲ **Figure 23.25** Two forms of the **Cr(III) ion**. The tube on the left contains the violet hydrated chromium(III) ion,  $\text{Cr}(\text{H}_2\text{O})_6^{3+}$ . The tube on the right contains the green  $[(\text{H}_2\text{O})_4\text{Cr}(\text{OH})_2\text{Cr}(\text{H}_2\text{O})_4]^{4+}$  ion.

▲ **Figure 23.26** Chromate and dichromate solutions. Solutions of sodium chromate,  $\text{Na}_2\text{CrO}_4$  (left), and potassium dichromate,  $\text{K}_2\text{Cr}_2\text{O}_7$  (right), illustrate the difference in color of the chromate and dichromate ions.

## 23.8 CHEMISTRY OF SELECTED TRANSITION METALS

Let's now briefly consider some of the chemistry of three common elements from the first transition series: chromium, iron, and copper. As you read this material, look for the trends that illustrate the generalizations outlined earlier.

### Chromium

Chromium dissolves slowly in dilute hydrochloric or sulfuric acid, liberating hydrogen. In the absence of air, the reaction results in the formation of a sky-blue solution of the chromium(II) or chromous ion:

In the presence of air, the chromium(II) ion is rapidly oxidized by  $\text{O}_2$  to form the chromium(III) ion. The reaction produces the green  $[(\text{H}_2\text{O})_4\text{Cr}(\text{OH})_2\text{Cr}(\text{H}_2\text{O})_4]^{4+}$  ion (Figure 23.25 ◀). In a strongly acidic solution, this ion reacts slowly with  $\text{H}^+$  ions to form the violet  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$  ion (Figure 23.25), which is often represented simply as  $\text{Cr}^{3+}(aq)$ . The overall reaction in acid solution is often given simply as shown in Equation 23.22.

### GIVE IT SOME THOUGHT

Would you expect the  $\text{Cr}^{3+}$  ion to contain any unpaired electrons?

Chromium is frequently encountered in aqueous solution in the +6 oxidation state. In basic solution the yellow chromate ion ( $\text{CrO}_4^{2-}$ ) is the most stable. In acidic solution the dichromate ion ( $\text{Cr}_2\text{O}_7^{2-}$ ) is formed:

Equation 23.24 is a condensation reaction in which water is split out from two  $\text{HCrO}_4^-$  ions. Similar reactions occur among the oxyanions of other elements, such as phosphorus. ⇌ (Section 22.8) The equilibrium between the dichromate and chromate ions is readily observable because  $\text{CrO}_4^{2-}$  is bright yellow and  $\text{Cr}_2\text{O}_7^{2-}$  is deep orange, as seen in Figure 23.26 ◀. The dichromate ion in acidic solution is a strong oxidizing agent, as evidenced by its large, positive reduction potential. By contrast, the chromate ion in basic solution is not a particularly strong oxidizing agent.

## Iron

We have already discussed the metallurgy of iron in considerable detail in Section 23.2. Here we consider some of its important aqueous solution chemistry. Iron exists in aqueous solution in either the +2 (ferrous) or +3 (ferric) oxidation states. It often appears in natural waters because these waters come into contact with deposits of  $\text{FeCO}_3$  ( $K_{sp} = 3.2 \times 10^{-11}$ ). Dissolved  $\text{CO}_2$  in the water can then help dissolve the mineral:

The dissolved  $\text{Fe}^{2+}$ , together with  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ , contributes to water hardness. [∞∞ \(Section 18.6\)](#)

The standard reduction potentials in Appendix E reveal much about the kind of chemical behavior we should expect to observe for iron. The potential for reduction from the +2 state to the metal is negative; however, the reduction from the +3 to the +2 state is positive. Iron, therefore, should react with acids that are not highly oxidizing such as dilute sulfuric acid or acetic acid to form  $\text{Fe}^{2+}(aq)$ , as indeed it does. In the presence of air, however,  $\text{Fe}^{2+}(aq)$  tends to be oxidized to  $\text{Fe}^{3+}(aq)$ , as shown by the positive standard emf for Equation 23.26:

### ■ SAMPLE EXERCISE 23.3 Writing Half-Reactions for an Oxidation-Reduction Reaction

Write the two balanced half-reactions for the reaction in Equation 23.26.

#### SOLUTION

**Analyze:** We are asked to write two oxidation-reduction half-reactions that together make up a given oxidation-reduction reaction.

**Plan:** We need to separate the two half-reactions that make up the given balanced reaction. We can best start by noting that Fe appears in the +2 and +3 states and that oxygen appears in the 0 and -2 oxidation states.

**Solve:** We note that iron is oxidized from the +2 to +3 oxidation state. The half-reaction for this process is

Oxygen in acidic medium is reduced:

To achieve a balanced equation, we need four  $\text{Fe}^{2+}$  for each  $\text{O}_2$ . Therefore, all we need to do to obtain Equation 23.26 is to multiply the oxidation half-reaction through by 4.

**Comment:** As noted in the text, the potential for the oxidation of  $\text{Fe}^{2+}(aq)$  is negative, but the potential for the reduction of  $\text{O}_2(g)$  in acidic aqueous solution is sufficiently positive to overcome that, leading to an overall positive potential for the reaction of Equation 23.26.

### ■ PRACTICE EXERCISE

Calculate the standard potential for the reaction of Equation 23.22.

**Answer:** 1.64 V

You may have seen instances in which water dripping from a faucet or other outlet has left a brown stain. The brown color is due to insoluble iron(III) oxide, formed by oxidation of iron(II) present in the water:

When iron metal reacts with an oxidizing acid such as warm, dilute nitric acid,  $\text{Fe}^{3+}(aq)$  is formed directly:

▲ **Figure 23.27** **Precipitation of Fe(OH)<sub>3</sub>.** Addition of NaOH solution to an aqueous solution of Fe<sup>3+</sup> causes Fe(OH)<sub>3</sub> to precipitate.

▲ **Figure 23.28** **Crystals of copper(II) sulfate pentahydrate, CuSO<sub>4</sub> · 5 H<sub>2</sub>O.**

▲ **Figure 23.29** **Precipitation of Cu(OH)<sub>2</sub>.** Addition of NaOH solution to an aqueous solution of Cu<sup>2+</sup> causes Cu(OH)<sub>2</sub> to precipitate.

In the +3 oxidation state iron is soluble in acidic solution as the hydrated ion, Fe(H<sub>2</sub>O)<sub>6</sub><sup>3+</sup>. However, this ion hydrolyzes readily  $\rightleftharpoons$  (Section 16.11):

When an acidic solution of iron(III) is made more basic, a gelatinous red-brown precipitate, most accurately described as a hydrous oxide, Fe<sub>2</sub>O<sub>3</sub> · nH<sub>2</sub>O, is formed (Figure 23.27 ◀). In this formulation *n* represents an indefinite number of water molecules, depending on the precise conditions of the precipitation. Usually, the precipitate that forms is represented merely as Fe(OH)<sub>3</sub>. The solubility of Fe(OH)<sub>3</sub> is very low ( $K_{sp} = 4 \times 10^{-38}$ ). It dissolves in strongly acidic solution but not in basic solution. The fact that it does *not* dissolve in basic solution is the basis of the Bayer process, in which aluminum is separated from impurities, primarily iron(III).  $\rightleftharpoons$  (Section 23.3)

## Copper

In its aqueous solution chemistry, copper exhibits two oxidation states: +1 (cuprous) and +2 (cupric). In the +1 oxidation state copper possesses a 3d<sup>10</sup> electron configuration. Salts of Cu<sup>+</sup> are often water insoluble and are mostly white in color. In aqueous solution the Cu<sup>+</sup> ion readily disproportionates:

Because of this reaction and because copper(I) is readily oxidized to copper(II) under most solution conditions, the +2 oxidation state is by far the more common.

Many salts of Cu<sup>2+</sup>, including Cu(NO<sub>3</sub>)<sub>2</sub>, CuSO<sub>4</sub>, and CuCl<sub>2</sub>, are water soluble. Copper sulfate pentahydrate (CuSO<sub>4</sub> · 5 H<sub>2</sub>O), a widely used salt, has four water molecules bound to the copper ion and a fifth held to the SO<sub>4</sub><sup>2-</sup> ion by hydrogen bonding. The salt is blue and is often called *blue vitriol* (Figure 23.28 ◀). Aqueous solutions of Cu<sup>2+</sup>, in which the copper ion is coordinated by water molecules, are also blue. Among the insoluble compounds of copper(II) is Cu(OH)<sub>2</sub>, which is formed when NaOH is added to an aqueous Cu<sup>2+</sup> solution (Figure 23.29 ◀). This blue compound readily loses water on heating to form black copper(II) oxide:

CuS is one of the least soluble copper(II) compounds ( $K_{sp} = 6.3 \times 10^{-36}$ ). This black substance does not dissolve in NaOH, NH<sub>3</sub>, or nonoxidizing acids such as HCl. It does dissolve in HNO<sub>3</sub>, however, which oxidizes the sulfide to sulfur:

CuSO<sub>4</sub> is often added to water to stop algae or fungal growth, and other copper preparations are used to spray or dust plants to protect them from lower organisms and insects. Copper compounds are not generally toxic to human beings, except in massive quantities. Our daily diet normally includes from 2 to 5 mg of copper.

### ■ SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

The most important commercial ore of chromium is *chromite* (FeCr<sub>2</sub>O<sub>4</sub>). (a) What is the most reasonable assignment of oxidation states to Fe and Cr in this ore? (b) Below 74 K the FeCr<sub>2</sub>O<sub>4</sub> magnetically orders so that the unpaired electrons on chromium point in the opposite direction as those on iron. What type of magnetic state describes FeCr<sub>2</sub>O<sub>4</sub> below 74 K? Would you expect the magnetism to increase or decrease as FeCr<sub>2</sub>O<sub>4</sub> is cooled through the 74 K transition? (c) Chromite can be reduced in an electric arc furnace (which provides the required heat) using coke (carbon). Write a balanced chemical equation for this reduction, which forms ferrochrome (FeCr<sub>2</sub>). (d) Two of the major forms of chromium in the +6 oxidation state are CrO<sub>4</sub><sup>2-</sup> and Cr<sub>2</sub>O<sub>7</sub><sup>2-</sup>. Draw Lewis structures for these species. (*Hint*: You may find it helpful to consider the Lewis structures of nonmetallic anions of the same formula.) (e) Chromium metal is used in alloys (for example, stainless steel) and in electroplating, but

chromium is not widely used by itself, in part because it is not ductile at ordinary temperatures. From what we have learned in this chapter about metallic bonding and properties, suggest why chromium is less ductile than most metals.

### SOLUTION

(a) Because each oxygen has an oxidation number of  $-2$ , the four oxygens represent a total of  $-8$ . If the metals have whole-number oxidation numbers, our choices are  $\text{Fe} = +4$  and  $\text{Cr} = +2$ , or  $\text{Fe} = +2$  and  $\text{Cr} = +3$ . The latter choice seems the more reasonable because a  $+4$  oxidation number for iron is unusual. (Although one alternative would be that  $\text{Fe}$  is  $+3$  and the two  $\text{Cr}$  have different oxidation states of  $+2$  and  $+3$ , the properties of chromite indicate that the two  $\text{Cr}$  have the same oxidation number.)

(b)  $\text{Fe}^{2+}$  and  $\text{Cr}^{3+}$  have electron configurations of  $[\text{Ar}]3d^6$  and  $[\text{Ar}]3d^3$ , respectively. Therefore,  $\text{Fe}^{2+}$  will have four unpaired electrons, and  $\text{Cr}^{3+}$  will have three unpaired electrons. Because they line up in opposite directions,  $\text{FeCr}_2\text{O}_4$  will either be antiferromagnetic or ferrimagnetic. Because the ions possess different numbers of unpaired electrons as well as the fact that there are twice as many  $\text{Cr}^{3+}$  ions as there are  $\text{Fe}^{2+}$  ions, their spins will not cancel each other out, and  $\text{FeCr}_2\text{O}_4$  will be ferrimagnetic below  $74\text{ K}$ . The magnetic behavior of a ferrimagnet is similar to that of a ferromagnet, so we would expect to see a large increase in the magnetism below  $74\text{ K}$ .

(c) The balanced equation is

(d) We expect that in  $\text{CrO}_4^{2-}$ , the  $\text{Cr}$  will be surrounded tetrahedrally by four oxygens. The electron configuration of the  $\text{Cr}$  atom is  $[\text{Ar}]3d^54s^1$ , giving it six electrons that can be used in bonding, much like the  $\text{S}$  atom in  $\text{SO}_4^{2-}$ . These six electrons must be shared with four  $\text{O}$  atoms, each of which has six valence-shell electrons. In addition, the ion has a  $2-$  charge. Thus, we have a total of  $6 + 4(6) + 2 = 32$  valence electrons to place in the Lewis structure. Putting one electron pair in each  $\text{Cr}-\text{O}$  bond and adding unshared electron pairs to the oxygens, we require precisely 32 electrons to achieve an octet around each atom:

In  $\text{Cr}_2\text{O}_7^{2-}$  the structure is analogous to that of the diphosphate ion ( $\text{P}_2\text{O}_7^{4-}$ ), which we discussed in Section 22.8. We can think of the  $\text{Cr}_2\text{O}_7^{2-}$  ion as formed by a condensation reaction as shown in Equation 23.24.

(e) Recall that chromium, with six electrons available for bonding, has relatively strong metallic bonding among the metals of the transition series, as evidenced by its high melting point (Figure 23.14). This means that distortions of the metallic lattice of the sort that occur when metals are drawn into wires will require more energy than for other metals with weaker metallic bonding.

## CHAPTER REVIEW

### SUMMARY AND KEY TERMS

**Section 23.1** The metallic elements are extracted from the **lithosphere**, the uppermost solid portion of our planet. Metallic elements occur in nature in **minerals**, which are solid inorganic compounds found in various deposits, or **ores**. The desired components of an ore must be separated from the undesired components, called **gangue**. **Metallurgy** is concerned with obtaining metals from these sources and with understanding and modifying the properties of metals.

**Section 23.2** **Pyrometallurgy** is the use of heat to bring about chemical reactions that convert an ore from one chemical form to another. In **calcination** an ore is heated to drive off a volatile substance, as in heating a carbonate ore to drive off  $\text{CO}_2$ . In **roasting**, the ore is heated under conditions that bring about reaction with the furnace atmosphere. For example, sulfide ores might be heated to oxidize sulfur to  $\text{SO}_2$ . In a **smelting** operation two or more layers of mutually insoluble materials form in the

furnace. One layer consists of molten metal, and the other layer (**slag**) is composed of molten silicate minerals and other ionic materials such as phosphates.

Iron, the most extensively used metal in modern society, is obtained from its oxide ores by reduction in a blast furnace. The reducing agent is carbon, in the form of coke. Limestone ( $\text{CaCO}_3$ ) is added to react with the silicates present in the crude ore to form slag. The raw iron from the blast furnace, called pig iron, is usually taken directly to a converter, where **refining** takes place to produce various kinds of steel. In the converter the molten iron reacts with pure oxygen to oxidize impurity elements.

**Section 23.3 Hydrometallurgy** is the use of chemical processes occurring in aqueous solution to separate a mineral from its ore or one particular element from others. In **leaching**, an ore is treated with an aqueous reagent to dissolve one component selectively. In the **Bayer process** aluminum is selectively dissolved from bauxite by treatment with concentrated NaOH solution.

**Section 23.4 Electrometallurgy** is the use of electrolytic methods to prepare or purify a metallic element. Sodium is prepared by electrolysis of molten NaCl in a **Downs cell**. Aluminum is obtained in the **Hall-Héroult process** by electrolysis of  $\text{Al}_2\text{O}_3$  in molten cryolite ( $\text{Na}_3\text{AlF}_6$ ). Copper is purified by electrolysis of aqueous copper sulfate solution using anodes composed of impure copper.

**Section 23.5** The properties of metals can be accounted for in a qualitative way by the **electron-sea model**, in which the electrons are visualized as being free to move throughout the metal structure. In the molecular-orbital model the valence atomic orbitals of the metal atoms interact to form energy bands that are incompletely filled by valence electrons. The bands that form from the valence shell *s*, *p*, and *d* orbitals overlap so that all metals have partially filled bands. The orbitals that constitute the energy band are delocalized over the atoms of the metal, and their energies are closely spaced. Because the energy differences between orbitals in the band are so small, promoting electrons to higher-energy orbitals requires very little energy. This gives rise to high electrical and thermal conductivity, as well as other characteristic metallic properties.

**Section 23.6** Alloys are materials that possess characteristic metallic properties and are composed of more than one element. Usually, one or more metallic elements are major components. **Solution alloys** are homogeneous alloys in which the components are distributed uniformly, while in **heterogeneous alloys** the components are not distributed uniformly; instead, two or more distinct phases with characteristic compositions are present. Solution alloys can be either *substitutional alloys*, where atoms of the different metals randomly occupy metal atoms sites in the lattice, or *interstitial alloys*, where smaller often nonmetallic atoms occupy interstitial sites between metal atoms. **Intermetallic compounds** are homogeneous alloys that have definite properties and compositions.

**Sections 23.7 and 23.8** Transition metals are characterized by incomplete filling of the *d* orbitals. The presence of *d* electrons in transition elements leads to multiple oxidation states. As we proceed through a given series of transition metals, the attraction between the nucleus and the valence electrons increases faster for electrons occupying the *d* orbitals than for electrons occupying the *s* orbitals. As a result, the later transition elements in a given row tend to adopt lower oxidation states. Although the atomic and ionic radii increase in the second series as compared to the first, the elements of the second and third series are similar with respect to these and other properties. This similarity is due to the **lanthanide contraction**.

The presence of unpaired electrons in valence orbitals leads to interesting magnetic behavior in transition metals and their compounds. In **ferromagnetic**, **ferrimagnetic**, and **antiferromagnetic** substances the unpaired electron spins on atoms in a solid are affected by those on neighboring atoms. In a ferromagnetic substance the spins all point in the same direction. In an antiferromagnetic substance the spins point in opposite directions and cancel each other. In a ferrimagnetic substance the spins point in opposite directions but do not fully cancel. Ferromagnetic and ferrimagnetic substances are used to make permanent magnets.

The chapter concluded with a concise overview of the chemistry of three of the common transition metals: chromium, iron, and copper.

## KEY SKILLS

- Understand the differences between metals, minerals, and ores.
- Be able to write balanced chemical equations to illustrate the kinds of reactions that result when a mineral undergoes calcination or roasting.
- Understand and be able to write balanced chemical equations for the processes that are used to convert iron ore into steel.
- Understand and be able to write balanced chemical equations for the Bayer process whereby aluminum is separated from other metals, most notably iron.
- Describe the electrometallurgical processes used to produce sodium, aluminum, and copper, and write balanced chemical equations for them.
- Explain the relationship between the electronic structure of metals and their physical properties.

- Use the molecular-orbital model to qualitatively predict the trends in melting point, boiling point, and hardness of metals.
- Explain how solution alloys and heterogeneous alloys differ.
- Describe the differences between substitutional alloys, interstitial alloys, and intermetallic compounds.
- Be familiar with the periodic trends in radii and oxidation states of the transition metal ions, including the origin and effect of the lanthanide contraction.
- Understand the differences between paramagnetism, ferromagnetism, antiferromagnetism, and ferrimagnetism.

## VISUALIZING CONCEPTS

- 23.1** This diagram shows the approximate enthalpy change in the roasting of ZnS. Does the roasting reaction cause an increase or a decrease in the temperature of the roasting oven? Explain. In light of your answer, is it necessary to heat the ore to produce roasting? [Section 23.2]

- 23.2** Magnesium is produced commercially by electrolysis from a molten salt using a cell similar to the one shown below. (a) What salt is used as the electrolyte? (b) Which electrode is the anode, and which one is the cathode? (c) Write the overall cell reaction and individual half-reactions. (d) What precautions would need to be taken with respect to the magnesium formed? [Section 23.4]

- 23.3** The standard enthalpy of formation of the gaseous element varies among some fourth-row metals as shown in the figure below. Would you expect gaseous molybdenum to have a larger or smaller standard enthalpy of formation than zirconium? What about gaseous cadmium? [Section 23.5]

- 23.4** Nb<sub>3</sub>Sn and SmCo<sub>5</sub> are two important intermetallic compounds. Nb<sub>3</sub>Sn is a superconductor from which the electromagnets of a magnetic resonance imaging (MRI) instrument are built, while SmCo<sub>5</sub> is used to make powerful permanent magnets. The unit cells of Nb<sub>3</sub>Sn and SmCo<sub>5</sub> are shown below. By counting the atoms in the unit cell, determine the empirical formulas corresponding to each structure. Then use this information to determine which structure corresponds to which intermetallic compound. (Hint: In both structures all of the atoms shown are located either at the corners of the unit cell, the body center of the unit cell, or the faces of the unit cell.) [Section 23.6]

- 23.5** This chart shows the variation in an important property of the metals from K through Ge. Is the property atomic radius, electronegativity, or first ionization energy? Explain your choice. [Section 23.7]

- 23.6** (a) Except for scandium, chromium is the only element in Figure 23.22 for which the +3 oxidation state is more stable in general than the +2. Explain why the +3 oxidation state is most characteristic of scandium. (b) What type of magnetism would you expect from SrCrO<sub>4</sub>? (c) By analogy with inorganic ions of the same formula type, predict the geometrical structure of the permanganate ion, MnO<sub>4</sub><sup>-</sup>. [Sections 23.7 and 23.8]

## EXERCISES

## Metallurgy

- 23.7** Two of the most heavily utilized metals are aluminum and iron. What are the most important natural sources of these elements? In what oxidation state is each metal found in nature?
- 23.8** (a) Pyrolusite ( $\text{MnO}_2$ ) is a commercially important mineral of manganese. What is the oxidation state of Mn in this metal? (b) Name some reagents that might be used to reduce this ore to the metal.
- 23.9** Explain in your own words what is meant by the statement, "This ore consists of a small concentration of chalcopyrite, together with considerable gangue."
- 23.10** What is meant by the following terms: (a) calcination, (b) leaching, (c) smelting, (d) slag?
- 23.11** Complete and balance each of the following equations:
- (a)  $\text{Cr}_2\text{O}_3(s) + \text{Na}(l) \longrightarrow$   
 (b)  $\text{PbCO}_3(s) \xrightarrow{\Delta}$   
 (c)  $\text{CdS}(s) + \text{O}_2(g) \xrightarrow{\Delta}$   
 (d)  $\text{ZnO}(s) + \text{CO}(g) \xrightarrow{\Delta}$
- 23.12** Complete and balance each equation:
- (a)  $\text{PbS}(s) + \text{O}_2(g) \xrightarrow{\Delta}$   
 (b)  $\text{CoCO}_3(s) \xrightarrow{\Delta}$   
 (c)  $\text{WO}_3(s) + \text{H}_2(g) \xrightarrow{\Delta}$   
 (d)  $\text{VCl}_3(l) + \text{K}(l) \longrightarrow$   
 (e)  $\text{BaO}(s) + \text{P}_2\text{O}_5(l) \longrightarrow$
- 23.13** A sample containing  $\text{PbSO}_4$  is to be refined to Pb metal via calcination, followed by roasting. (a) What volatile product would you expect to be produced by calcination? (b) Propose an appropriate atmosphere to accompany the roasting. (c) Write balanced chemical equations for the two steps.
- 23.14** Consider the thermodynamics of calcination. (a) The following equation is a generic reaction representing calcination of a metal carbonate:
- $$\text{MCO}_3(s) \longrightarrow \text{MO}(s) + \text{CO}_2(g)$$
- Would you expect this reaction to become more or less spontaneous as the temperature increases? (b) What is the standard free energy,  $\Delta G^\circ$ , for the reaction corresponding to the calcination of  $\text{PbCO}_3$  (Equation 23.1) at  $25^\circ\text{C}$  under standard conditions? Is this reaction spontaneous? If not, at what temperature does this reaction become spontaneous (assuming  $\Delta H^\circ$  and  $S^\circ$  values do not change with temperature)?
- 23.15** Use the thermodynamic quantities given in Appendix C to calculate  $\Delta G^\circ$ ,  $\Delta H^\circ$ , and  $\Delta S^\circ$  for the reaction corresponding to roasting of  $\text{PbO}$  in a CO atmosphere (Equation 23.5). Approximate the thermodynamic quantities of  $\text{Pb}(l)$  using the thermodynamic properties of  $\text{Pb}(s)$ . Is this reaction spontaneous at  $25^\circ\text{C}$  under standard conditions? Is it exothermic or endothermic?
- 23.16** Assess the feasibility of reducing  $\text{TiO}_2$  to titanium metal by roasting in carbon monoxide. (a) Write a reaction for this process. (b) Use the thermodynamic quantities given in Appendix C to calculate  $\Delta G^\circ$ ,  $\Delta H^\circ$ , and  $\Delta S^\circ$  for this reaction. Is this reaction spontaneous at  $25^\circ\text{C}$  under standard conditions? (c) If we assume that  $\Delta H^\circ$  and  $S^\circ$  values do not change with temperature, at what temperature would this process become spontaneous? Do you think this process would be practical?
- 23.17** What is the major reducing agent in the reduction of iron ore in a blast furnace? Write a balanced chemical equation for the reduction process.
- 23.18** Write balanced chemical equations for the reduction of  $\text{FeO}$  and  $\text{Fe}_2\text{O}_3$  by  $\text{H}_2$  and by  $\text{CO}$ .
- 23.19** What role does each of the following materials play in the chemical processes that occur in a blast furnace: (a) air, (b) limestone, (c) coke, (d) water? Write balanced chemical equations to illustrate your answers.
- 23.20** (a) In the basic oxygen process for steel formation, what reactions cause the temperature in the converter to increase? (b) Write balanced chemical equations for the oxidation of carbon, sulfur, and silicon in the converter.
- 23.21** Describe how electrometallurgy could be employed to purify crude cobalt metal. Describe the compositions of the electrodes and electrolyte, and write out all electrode reactions.
- 23.22** The element tin is generally recovered from deposits of the ore cassiterite ( $\text{SnO}_2$ ). The oxide is reduced with carbon, and the crude metal is purified by electrolysis. Write balanced chemical equations for the reduction process and for the electrode reactions in the electrolysis. (Assume that an acidic solution of  $\text{SnSO}_4$  is employed as an electrolyte in the electrolysis.)

## Metals and Alloys

- 23.23** Sodium is a highly malleable substance, whereas sodium chloride is not. Explain this difference in properties.
- 23.24** Germanium has the same crystal structure as diamond (Figure 11.41). Based on this fact, do you think germanium is likely to exhibit metallic properties? Explain your answer.
- 23.25** Explain how the electron-sea model accounts for the high electrical and thermal conductivity of metals.
- 23.26** (a) Compare the electronic structures of atomic chromium and atomic selenium. In what respects are they similar, and in what respects do they differ? (b) Chromium is a metal, and selenium is a nonmetal. What factors are important in determining this difference in properties?

- 23.27** The densities of the elements K, Ca, Sc, and Ti are 0.86, 1.5, 3.2, and 4.5 g/cm<sup>3</sup>, respectively. What factors are likely to be of major importance in determining this variation? Which factor do you think will be the most important?
- 23.28** Explain this trend in melting points: Y 1522 °C, Zr 1852 °C, Nb 2468 °C, Mo 2617 °C.
- 23.29** Which would you expect to be the more ductile element, (a) Ag or Mo, (b) Zn or Si? In each case explain your reasoning.
- 23.30** How do you account for the observation that the alkali metals, like sodium and potassium, are soft enough to be cut with a knife?
- 23.31** Tin exists in two allotropic forms: Gray tin has a diamond structure, and white tin has a close-packed structure. One of these allotropic forms is a semiconductor with a small band gap while the other is a metal. Which one is which? Which form would you expect to have the longer Sn—Sn bond distance?
- [23.32]** The electrical conductivity of titanium is approximately 2500 times greater than that of silicon. Titanium has a hexagonal close-packed structure, and silicon has the diamond structure. Explain how the structures relate to the relative electrical conductivities of the elements.
- 23.33** Define the term *alloy*. Distinguish among solution alloys, heterogeneous alloys, and intermetallic compounds.
- 23.34** Distinguish between substitutional and interstitial alloys. What conditions favor formation of substitutional alloys?
- 23.35** For each of the following alloy compositions indicate whether you would expect it to be a substitutional alloy, an interstitial alloy, or an intermetallic compound: (a) Fe<sub>0.97</sub>Si<sub>0.03</sub>, (b) Fe<sub>0.60</sub>Ni<sub>0.40</sub>, (c) Cu<sub>3</sub>Au.
- 23.36** For each of the following alloy compositions indicate whether you would expect it to be a substitutional alloy, an interstitial alloy, or an intermetallic compound: (a) Cu<sub>0.66</sub>Zn<sub>0.34</sub>, (b) Ag<sub>3</sub>Sn, (c) Ti<sub>0.99</sub>O<sub>0.01</sub>.

## Transition Metals

- 23.37** Which of the following properties are better considered characteristic of the free isolated atoms, and which are characteristic of the bulk metal: (a) electrical conductivity, (b) first ionization energy, (c) atomic radius, (d) melting point, (e) heat of vaporization, (f) electron affinity?
- 23.38** Which of the following species would you expect to possess metallic properties: (a) TiCl<sub>4</sub>, (b) NiCo alloy, (c) W, (d) Ge, (e) Hg<sub>2</sub><sup>2+</sup>? Explain in each case.
- 23.39** Zirconium and hafnium are the group 4B elements in the second and third transition series. The radii of these elements are virtually the same (Figure 23.20). Explain this similarity.
- 23.40** What is meant by the term lanthanide contraction? What properties of the transition elements are affected by the lanthanide contraction?
- 23.41** Write the formula for the fluoride corresponding to the highest expected oxidation state for (a) Sc, (b) Co, (c) Zn, (d) Mo.
- 23.42** Write the formula for the oxide corresponding to the highest expected oxidation state for (a) Cd, (b) V, (c) W, (d) Ru.
- 23.43** Why does chromium exhibit several oxidation states in its compounds, whereas aluminum exhibits only the +3 oxidation state?
- 23.44** The element vanadium exhibits multiple oxidation states in its compounds, including +2. The compound VCl<sub>2</sub> is known, whereas ScCl<sub>2</sub> is unknown. Use electron configurations and effective nuclear charges to account for this difference in behavior.
- 23.45** Write the expected electron configuration for (a) Cr<sup>3+</sup>, (b) Au<sup>3+</sup>, (c) Ru<sup>2+</sup>, (d) Cu<sup>+</sup>, (e) Mn<sup>4+</sup>, (f) Ir<sup>+</sup>.
- 23.46** What is the expected electron configuration for (a) Ti<sup>2+</sup>, (b) Co<sup>3+</sup>, (c) Pd<sup>2+</sup>, (d) Mo<sup>3+</sup>, (e) Ru<sup>3+</sup>, (f) Ni<sup>4+</sup>?
- 23.47** Which would you expect to be more easily oxidized, Ti<sup>2+</sup> or Ni<sup>2+</sup>?
- 23.48** Which would you expect to be the stronger reducing agent, Cr<sup>2+</sup> or Fe<sup>2+</sup>?
- 23.49** How does the presence of air affect the relative stabilities of ferrous and ferric ions in solution?
- 23.50** (a) Give the chemical formulas and colors of the chromate and dichromate ions. (b) Which of these ions is more stable in acidic solution? (c) What type of reaction is involved in their interconversion in solution?
- 23.51** Write balanced chemical equations for the reaction between iron and (a) hydrochloric acid, (b) nitric acid.
- 23.52** MnO<sub>2</sub> reacts with aqueous HCl to yield MnCl<sub>2</sub>(aq) and chlorine gas. (a) Write a balanced chemical equation for the reaction. (b) Is this an oxidation-reduction reaction? If yes, identify the oxidizing and reducing agents.
- 23.53** On the atomic level, what distinguishes a paramagnetic material from a diamagnetic one? How does each behave in a magnetic field?
- 23.54** On the atomic level, what distinguishes an antiferromagnetic material from a diamagnetic one?
- 23.55** (a) On the atomic level, what distinguishes ferromagnetic, ferrimagnetic, and antiferromagnetic materials from each other? (b) Which one of these types of magnetic materials *cannot* be used to make a permanent magnet?
- 23.56** The two most important iron oxide minerals are magnetite, Fe<sub>3</sub>O<sub>4</sub>, and hematite, Fe<sub>2</sub>O<sub>3</sub>. One is a ferrimagnetic material, while the other is an antiferromagnetic material. (a) Based on the oxidation states of iron, which one is more likely to be ferrimagnetic? (b) Would it be possible to use magnetic fields to separate these minerals?

## ADDITIONAL EXERCISES

- 23.57** Write a chemical equation for the reaction that occurs when PbS is roasted in air. Why might a sulfuric acid plant be located near a plant that roasts sulfide ores?
- 23.58** Explain why aluminum, magnesium, and sodium metals are obtained by electrolysis instead of by reduction with chemical reducing agents.
- 23.59** Make a list of the chemical reducing agents employed in the production of metals, as described in this chapter. For each of them, identify a metal that can be formed using that reducing agent.
- 23.60** Write balanced chemical equations for each of the following verbal descriptions: (a) Vanadium oxytrichloride ( $\text{VOCl}_3$ ) is formed by the reaction of vanadium(III) chloride with oxygen. (b) Niobium(V) oxide is reduced to the metal with hydrogen gas. (c) Iron(III) ion in aqueous solution is reduced to iron(II) ion in the presence of zinc dust. (d) Niobium(V) chloride reacts with water to yield crystals of niobic acid ( $\text{HNbO}_3$ ).
- 23.61** Write a balanced chemical equation to correspond to each of the following verbal descriptions: (a) NiO(s) can be solubilized by leaching with aqueous sulfuric acid. (b) After concentration, an ore containing the mineral carrollite ( $\text{CuCo}_2\text{S}_4$ ) is leached with aqueous sulfuric acid to produce a solution containing copper ions and cobalt ions. (c) Titanium dioxide is treated with chlorine in the presence of carbon as a reducing agent to form  $\text{TiCl}_4$ . (d) Under oxygen pressure ZnS(s) reacts at 150 °C with aqueous sulfuric acid to form soluble zinc sulfate, with deposition of elemental sulfur.
- 23.62** The crude copper that is subjected to electrorefining contains tellurium as an impurity. The standard reduction potential between tellurium and its lowest common oxidation state,  $\text{Te}^{4+}$ , is
- $$\text{Te}^{4+}(\text{aq}) + 4\text{e}^- \longrightarrow \text{Te}(\text{s}) \quad E_{\text{red}}^\circ = 0.57\text{ V}$$
- Given this information, describe the probable fate of tellurium impurities during electrorefining.
- 23.63** Why is the +2 oxidation state common among the transition metals? Why do so many transition metals exhibit a variety of oxidation states?
- [23.64]** Write balanced chemical equations that correspond to the steps in the following brief account of the metallurgy of molybdenum: Molybdenum occurs primarily as the sulfide,  $\text{MoS}_2$ . On boiling with concentrated nitric acid, a white residue of  $\text{MoO}_3$  is obtained. This is an acidic oxide; when it is dissolved in excess hot concentrated ammonia, ammonium molybdate crystallizes on cooling. On heating ammonium molybdate, white  $\text{MoO}_3$  is obtained. On further heating to 1200 °C in hydrogen, a gray powder of metallic molybdenum is obtained.
- 23.65** Antimony and niobium both possess five valence-shell electrons and are metallic conductors. Which element would you expect to be a better conductor of electricity?
- [23.66]** Introduction of carbon into a metallic lattice generally results in a harder, less ductile substance with lower electrical and thermal conductivities. Explain why this might be so.
- 23.67** The thermodynamic stabilities of the three complexes  $\text{Zn}(\text{H}_2\text{O})_4^{2+}$ ,  $\text{Zn}(\text{NH}_3)_4^{2+}$ , and  $\text{Zn}(\text{CN})_4^{2-}$  increase from the  $\text{H}_2\text{O}$  to the  $\text{NH}_3$  to the  $\text{CN}^-$  complex. How do you expect the reduction potentials of these three complexes to compare?
- 23.68** Indicate whether each of the following compounds is expected to be diamagnetic or paramagnetic, and give a reason for your answer in each case: (a)  $\text{NbCl}_5$ , (b)  $\text{CrCl}_2$ , (c)  $\text{CuCl}$ , (d)  $\text{RuO}_4$ , (e)  $\text{NiCl}_2$ .
- [23.69]** Associated with every ferromagnetic solid is a temperature known as its Curie temperature. When heated above its Curie temperature, the substance no longer exhibits ferromagnetism but rather becomes paramagnetic. Use the kinetic-molecular theory of solids to explain this observation.
- 23.70** Associated with every antiferromagnetic solid is a temperature known as its Néel temperature. When heated above its Néel temperature the magnetic behavior changes from antiferromagnetic to paramagnetic. In contrast diamagnetic substances do not generally become paramagnetic upon heating. How do you explain this difference in behavior?
- 23.71** Write balanced chemical equations for each of the following reactions characteristic of elemental manganese: (a) It reacts with aqueous  $\text{HNO}_3$  to form a solution of manganese(II) nitrate. (b) When solid manganese(II) nitrate is heated to 450 K, it decomposes to  $\text{MnO}_2$ . (c) When  $\text{MnO}_2$  is heated to 700 K, it decomposes to  $\text{Mn}_3\text{O}_4$ . (d) When solid  $\text{MnCl}_2$  is reacted with  $\text{F}_2(\text{g})$ , it forms  $\text{MnF}_3$  (one of the products is  $\text{ClF}_3$ ).
- [23.72]** Based on the chemistry described in this chapter and others, propose balanced chemical equations for the following sequence of reactions involving nickel: (a) The ore millerite, which contains NiS, is roasted in an atmosphere of oxygen to produce an oxide. (b) The oxide is reduced to the metal, using coke. (c) Dissolving the metal in hydrochloric acid produces a green solution. (d) Adding excess sodium hydroxide to the solution causes a gelatinous green material to precipitate. (e) Upon heating, the green material loses water and yields a green powder.
- [23.73]** Indicate whether each of the following solids is likely to be an insulator, a metallic conductor, or a semiconductor: (a)  $\text{TiO}_2$ , (b) Ge, (c)  $\text{Cu}_3\text{Al}$ , (d) Pd, (e) SiC, (f) Bi.

## INTEGRATIVE EXERCISES

- 23.74** (a) A charge of  $3.3 \times 10^6$  kg of material containing 27%  $\text{Cu}_2\text{S}$  and 13%  $\text{FeS}$  is added to a converter and oxidized. What mass of  $\text{SO}_2(\text{g})$  is formed? (b) What is the molar ratio of Cu to Fe in the resulting mixture of oxides? (c) What are the likely formulas of the oxides formed in the oxidation reactions, assuming an excess of oxygen? (d) Write balanced equations representing each of the oxidation reactions.

23.75 Using the concepts discussed in Chapter 13, indicate why the molten metal and slag phases formed in the blast furnace shown in Figure 23.4 are immiscible.

23.76 In an electrolytic process nickel sulfide is oxidized in a two-step reaction:

What mass of  $\text{Ni}^{2+}$  is produced in solution by passing a current of 67 A for a period of 11.0 hr, assuming the cell is 90% efficient?

[23.77] (a) Using the data in Appendix C, estimate the free-energy change for the following reaction at 1200 °C:

(b) What does this value tell you about the feasibility of carrying out this reaction at 1200 °C?

[23.78] (a) In the converter employed in steel formation (Figure 23.6), oxygen gas is blown at high temperature directly into a container of molten iron. Iron is converted to rust on exposure to air at room temperature, but the iron is not extensively oxidized in the converter. Explain why this is so. (b) The oxygen introduced into the converter reacts with various impurities, particularly with carbon, phosphorus, sulfur, silicon, and impurity metals. What are the products of these reactions, and where do they end up in the process?

23.79 Copper(I) is an uncommon oxidation state in aqueous acidic solution because  $\text{Cu}^+(\text{aq})$  disproportionates into  $\text{Cu}^{2+}$  and Cu. Use data from Appendix E to calculate the equilibrium constant for the reaction

23.80 The reduction of metal oxides is often accomplished using carbon monoxide as a reducing agent. Carbon (coke) and carbon dioxide are usually present, leading to the following reaction:

Using data from Appendix C, calculate the equilibrium constant for this reaction at 298 K and at 2000 K, assuming that the enthalpies and entropies of formation do not depend upon temperature.

23.81 An important process in the metallurgy of titanium is the reaction between titanium dioxide and chlorine in the presence of carbon, which acts as a reducing agent, leading to the formation of gaseous  $\text{TiCl}_4$ . (a) Write a balanced chemical equation for this reaction, and use it with the values listed in Appendix C to calculate the standard enthalpy change of this reaction. Is this reaction exothermic or endothermic? (b) Write a reaction for the direct reaction between titanium dioxide and chlorine to form  $\text{TiCl}_4$  and oxygen. Is this reaction exothermic or endothermic?

23.82 Magnesium is obtained by electrolysis of molten  $\text{MgCl}_2$ . (a) Why isn't an aqueous solution of  $\text{MgCl}_2$  used in the electrolysis? (b) Several cells are connected in parallel by

very large copper buses that convey current to the cells. Assuming that the cells are 96% efficient in producing the desired products in electrolysis, what mass of Mg is formed by passing a current of 97,000 A for a period of 24 hr?

23.83 Vanadium(V) fluoride is a colorless substance that melts at 19.5 °C and boils at 48.3 °C. Vanadium(III) fluoride, on the other hand, is yellow-green in color and melts at 800 °C. (a) Suggest a structure and bonding for  $\text{VF}_5$  that accounts for its melting and boiling points. Can you identify a compound of a nonmetallic element that probably has the same structure? (b)  $\text{VF}_3$  is prepared by the action of HF on heated  $\text{VCl}_3$ . Write a balanced equation for this reaction. (c) While  $\text{VF}_5$  is a known compound, the other vanadium(V) halides are unknown. Suggest why these compounds might be unstable. (*Hint:* The reasons might have to do with both size and electronic factors.)

23.84 The galvanizing of iron sheet can be carried out electrolytically using a bath containing a zinc sulfate solution. The sheet is made the cathode, and a graphite anode is used. Calculate the cost of the electricity required to deposit a 0.49-mm layer of zinc on both sides of an iron sheet 2.0 m wide and 80 m long if the current is 30 A, the voltage is 3.5 V, and the energy efficiency of the process is 90%. Assume the cost of electricity is \$0.082 per kilowatt hour. The density of zinc is 7.1 g/cm<sup>3</sup>.

23.85 As mentioned in the text,  $\text{Ni}_3\text{Al}$  is used in the turbines of aircraft engines because of its strength and low density. Nickel metal has a cubic close-packed structure with a face-centered cubic unit cell, while  $\text{Ni}_3\text{Al}$  has the ordered cubic structure shown in Figure 23.17(b). The length of the cubic unit cell edge is 3.53 Å for nickel and 3.56 Å for  $\text{Ni}_3\text{Al}$ . Use this data to calculate and compare the densities of these two materials.

[23.86] Silver is found as  $\text{Ag}_2\text{S}$  in the ore argentite. (a) By using data in Table 17.1 and Appendix D.3, determine the equilibrium constant for the cyanidation of  $\text{Ag}_2\text{S}$  to  $\text{Ag}(\text{CN})_2^-$ . (b) Based on your answer to part (a), would you consider cyanidation to be a practical means of leaching silver from argentite ore? (c) Silver is also found as  $\text{AgCl}$  in the mineral cerargyrite. Would it be feasible to use cyanidation as a leaching process for this ore?

[23.87] The heats of atomization,  $\Delta H_{\text{atom}}$ , in kJ/mol, of the first transition series of elements are as follows:

Element	Ca	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu
$\Delta H_{\text{atom}}$	178	378	471	515	397	281	415	426	431	338

(a) Write an equation for the process involved in atomization, and describe the electronic and structural changes that occur. (b)  $\Delta H_{\text{atom}}$  varies irregularly in the series following V. How can this be accounted for, at least in part, using the electronic configurations of the gaseous atoms? (*Hint:* Recall the discussions of Sections 6.8 and 6.9.)

CHAPTER  
24

# CHEMISTRY OF COORDINATION COMPOUNDS

THE GRAND CENTRAL STAINED-GLASS SKYLIGHT IN THE CONCERT HALL OF THE PAUJAU DE LA MUSICA CATALANA IN BARCELONA, SPAIN. The colors in stained glass are obtained by adding oxides of the transition metals to the molten glass before the glass sheets are formed.

## WHAT'S AHEAD

---

### 24.1 Metal Complexes

We begin by introducing the concepts of *metal complexes* and *ligands* and by providing a brief history of the development of *coordination chemistry*.

### 24.2 Ligands with More than One Donor Atom

We examine some of the common geometries exhibited by coordination complexes for different *coordination numbers*.

### 24.3 Nomenclature of Coordination Chemistry

We introduce the *nomenclature* used to name coordination compounds.

### 24.4 Isomerism

We will see that coordination compounds exhibit *isomerism*, in which two compounds have the

same composition but different structures. The types of isomerism exhibited by coordination compounds are described, including *structural isomers*, *geometric isomers*, and *optical isomers*.

### 24.5 Color and Magnetism

We discuss the basic notions of *color* and *magnetism* in coordination compounds.

### 24.6 Crystal-Field Theory

We explore how *crystal-field theory* allows us to explain some of the interesting spectral and magnetic properties of coordination compounds.

## THE COLORS ASSOCIATED WITH CHEMISTRY ARE BOTH BEAUTIFUL AND

**INFORMATIVE**—providing insights into the structure and bonding of matter. Compounds of the transition metals constitute an important group of colored substances. Some of them are used in paint pigments; others produce the colors

in glass and precious gems. For example, the colors in the stained-glass skylight shown in the chapter-opening photograph are due mainly to compounds of the transition metals. Why do these compounds have color, and why do these colors change as the ions or molecules bonded to the metal change? The chemistry we explore in this chapter will help us to answer these questions.

In earlier chapters we have seen that metal ions can function as Lewis acids, forming covalent bonds with a variety of molecules and ions that function as Lewis bases. ∞(Section 16.11) We have encountered many ions and compounds that result from such interactions. We discussed  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$  and  $[\text{Ag}(\text{NH}_3)_2]^+$ , for example, in our coverage of equilibria in Sections 16.11 and 17.5. Hemoglobin is an important iron compound responsible for the oxygen-carrying capacity of blood. ∞(Sections 13.6 and 18.4) In Section 23.3 we saw that hydrometallurgy depends on the formation of species such as  $[\text{Au}(\text{CN})_2]^-$ . In this chapter we will focus on the rich and important chemistry associated with such complex assemblies of metals surrounded by molecules and ions. Metal compounds of this kind are called *coordination compounds*.

## 24.1 METAL COMPLEXES

Species such as  $[\text{Ag}(\text{NH}_3)_2]^+$  that are assemblies of a central metal ion bonded to a group of surrounding molecules or ions are called **metal complexes**, or merely *complexes*. If the complex carries a net charge, it is generally called a *complex ion*.  $\rightleftharpoons$  (Section 17.5) Compounds that contain complexes are known as **coordination compounds**. Most of the coordination compounds that we will examine contain transition-metal ions, although ions of other metals can also form complexes.

The molecules or ions that bond to the metal ion in a complex are known as **ligands** (from the Latin word *ligare*, meaning “to bind”). There are two  $\text{NH}_3$  ligands bonded to  $\text{Ag}^+$  in  $[\text{Ag}(\text{NH}_3)_2]^+$ . Each ligand functions as a Lewis base, donating a pair of electrons to the metal to form a bond with the metal.  $\rightleftharpoons$  (Section 16.11) Thus, every ligand has at least one unshared pair of valence electrons, as illustrated in the following examples:

These examples illustrate that most ligands are either polar molecules or anions. In forming a complex, the ligands are said to *coordinate* to the metal.

### The Development of Coordination Chemistry: Werner's Theory

Because compounds of the transition metals exhibit beautiful colors, the chemistry of these elements greatly fascinated chemists even before the periodic table was introduced. During the late 1700s through the 1800s, many coordination compounds were isolated and studied. These compounds showed properties that seemed puzzling in light of the bonding theories at the time. Table 24.1  $\blacktriangledown$ , for example, lists a series of compounds that result from the reaction of cobalt(III) chloride with ammonia. These compounds have strikingly different colors. Even the last two listed, which were both formulated as  $\text{CoCl}_3 \cdot 4 \text{NH}_3$ , have different colors.

The modern formulations of these compounds are based on various lines of experimental evidence. For example, all the compounds in Table 24.1 are strong electrolytes (Section 4.1), but they yield different numbers of ions when dissolved in water. Dissolving  $\text{CoCl}_3 \cdot 6 \text{NH}_3$  in water yields four ions per formula unit (that is, the  $[\text{Co}(\text{NH}_3)_6]^{3+}$  ion and three  $\text{Cl}^-$  ions), whereas  $\text{CoCl}_3 \cdot 5 \text{NH}_3$  yields only three ions per formula unit (that is, the  $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$  ion and two  $\text{Cl}^-$  ions). Furthermore, the reaction of the compounds with excess aqueous silver nitrate leads to the precipitation of variable amounts of  $\text{AgCl}(s)$ ; the precipitation of  $\text{AgCl}(s)$  in this way is often used to test for the number of “free”  $\text{Cl}^-$  ions in an ionic compound. When  $\text{CoCl}_3 \cdot 6 \text{NH}_3$  is treated with excess  $\text{AgNO}_3(aq)$ , 3 mol of  $\text{AgCl}(s)$  are produced per mole of complex, so all three  $\text{Cl}^-$  ions in the formula can react to form  $\text{AgCl}(s)$ . By contrast, when  $\text{CoCl}_3 \cdot 5 \text{NH}_3$  is treated with  $\text{AgNO}_3(aq)$  in an analogous fashion, only 2 mol of  $\text{AgCl}(s)$  precipitate per mole of complex; one of the  $\text{Cl}^-$  ions in the compound does not react to form  $\text{AgCl}(s)$ . These results are summarized in Table 24.1.

**TABLE 24.1** ■ Properties of Some Ammonia Complexes of Cobalt(III)

Original Formulation	Color	Ions per Formula Unit	“Free” $\text{Cl}^-$ Ions per Formula Unit	Modern Formulation
$\text{CoCl}_3 \cdot 6 \text{NH}_3$	Orange	4	3	$[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$
$\text{CoCl}_3 \cdot 5 \text{NH}_3$	Purple	3	2	$[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$
$\text{CoCl}_3 \cdot 4 \text{NH}_3$	Green	2	1	<i>trans</i> - $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$
$\text{CoCl}_3 \cdot 4 \text{NH}_3$	Violet	2	1	<i>cis</i> - $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$

In 1893 the Swiss chemist Alfred Werner (1866–1919) proposed a theory that successfully explained the observations in Table 24.1. This theory became the basis for understanding coordination chemistry. Werner proposed that metal ions exhibit both “primary” and “secondary” valences. The primary valence is the oxidation state of the metal, which for the complexes in Table 24.1 is +3.  $\rightleftharpoons$  (Section 4.4) The secondary valence is the number of atoms directly bonded to the metal ion, which is also called the **coordination number**. For these cobalt complexes, Werner deduced a coordination number of 6 with the ligands in an octahedral arrangement (Figure 9.9) around the  $\text{Co}^{3+}$  ion.

Werner’s theory provided a beautiful explanation for the results in Table 24.1. The  $\text{NH}_3$  molecules in the complexes are ligands that are bonded to the  $\text{Co}^{3+}$  ion; if there are fewer than six  $\text{NH}_3$  molecules, the remaining ligands are  $\text{Cl}^-$  ions. The central metal and the ligands bound to it constitute the **coordination sphere** of the complex. In writing the chemical formula for a coordination compound, Werner suggested using square brackets to set off the groups within the coordination sphere from other parts of the compound. He therefore proposed that  $\text{CoCl}_3 \cdot 6 \text{NH}_3$  and  $\text{CoCl}_3 \cdot 5 \text{NH}_3$  are better written as  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$  and  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$ , respectively. He further proposed that the chloride ions that are part of the coordination sphere are bound so tightly that they do not dissociate when the complex is dissolved in water. Thus, dissolving  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$  in water produces a  $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$  ion and two  $\text{Cl}^-$  ions; only the two “free”  $\text{Cl}^-$  ions are able to react with  $\text{Ag}^+(\text{aq})$  to form  $\text{AgCl}(\text{s})$ .

Werner’s ideas also explained why there are two distinctly different forms of  $\text{CoCl}_3 \cdot 4 \text{NH}_3$ . Using Werner’s postulates, we formulate the compound as  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$ . As shown in Figure 24.1  $\blacktriangleright$ , there are two different ways to arrange the ligands in the  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^{+}$  complex, called the *cis* and *trans* forms. In *cis*- $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^{+}$  the two chloride ligands occupy adjacent vertices of the octahedral arrangement. In *trans*- $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^{+}$  the chlorides are opposite one another. As seen in Table 24.1, the difference in these arrangements causes the complexes to have different colors.

The insight that Werner provided into the bonding in coordination compounds is even more remarkable when we realize that his theory predated Lewis’s ideas of covalent bonding by more than 20 years! Because of his tremendous contributions to coordination chemistry, Werner was awarded the 1913 Nobel Prize in Chemistry.

**▲ Figure 24.1** The two forms (isomers) of  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^{+}$ . In (a) *cis*- $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^{+}$  the two Cl ligands occupy adjacent vertices of the octahedron, whereas in (b) *trans*- $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^{+}$  they are opposite one another.

### **SAMPLE EXERCISE 24.1** Identifying the Coordination Sphere of a Complex

Palladium(II) tends to form complexes with a coordination number of 4. One such compound was originally formulated as  $\text{PdCl}_2 \cdot 3 \text{NH}_3$ . (a) Suggest the appropriate coordination compound formulation for this compound. (b) Suppose an aqueous solution of the compound is treated with excess  $\text{AgNO}_3(\text{aq})$ . How many moles of  $\text{AgCl}(\text{s})$  are formed per mole of  $\text{PdCl}_2 \cdot 3 \text{NH}_3$ ?

#### **SOLUTION**

**Analyze:** We are given the coordination number of Pd(II) and a chemical formula indicating that  $\text{NH}_3$  and  $\text{Cl}^-$  are the potential ligands. We are asked to determine (a) what ligands are attached to Pd(II) in the compound and (b) how the compound behaves toward  $\text{AgNO}_3$  in aqueous solution.

**Plan:** (a) Because of their charge, the  $\text{Cl}^-$  ions can be either in the coordination sphere, where they are bonded directly to the metal, or outside the coordination sphere, where they are bonded ionically to the complex. Because the  $\text{NH}_3$  ligands are neutral, they must be in the coordination sphere. (b) The chlorides that are in the coordination sphere will not be precipitated as  $\text{AgCl}$ .

#### **Solve:**

(a) By analogy to the ammonia complexes of cobalt(III), we predict that the three  $\text{NH}_3$  groups of  $\text{PdCl}_2 \cdot 3 \text{NH}_3$  serve as ligands attached to the Pd(II) ion. The fourth ligand around Pd(II) is one of the chloride ions. The second chloride ion is not a ligand; it serves only as an anion in this ionic compound. We conclude that the correct formulation is  $[\text{Pd}(\text{NH}_3)_3\text{Cl}]\text{Cl}$ .

(a)

(b)

**▲ Figure 24.2 Reaction of  $\text{Fe}^{3+}(\text{aq})$  and  $\text{SCN}^{-}(\text{aq})$ .** (a) An aqueous solution of  $\text{NH}_4\text{SCN}$  is in the pipette, and an aqueous solution of  $\text{Fe}^{3+}$  is in the flask. (b) The intensely colored  $[\text{Fe}(\text{H}_2\text{O})_5\text{NCS}]^{2+}$  ion forms when the  $\text{NH}_4\text{SCN}$  is added to  $\text{Fe}^{3+}(\text{aq})$ .

(b) The chloride ion that serves as a ligand will not be precipitated as  $\text{AgCl}(\text{s})$  following the reaction with  $\text{AgNO}_3(\text{aq})$ . Thus, only the single “free”  $\text{Cl}^{-}$  can react. We therefore expect to produce 1 mol of  $\text{AgCl}(\text{s})$  per mole of complex. The balanced equation is  $[\text{Pd}(\text{NH}_3)_3\text{Cl}]\text{Cl}(\text{aq}) + \text{AgNO}_3(\text{aq}) \longrightarrow [\text{Pd}(\text{NH}_3)_3\text{Cl}]\text{NO}_3(\text{aq}) + \text{AgCl}(\text{s})$ . This is a metathesis reaction (Section 4.2) in which one of the cations is the  $[\text{Pd}(\text{NH}_3)_3\text{Cl}]^{+}$  complex ion.

### ■ PRACTICE EXERCISE

Predict the number of ions produced per formula unit in an aqueous solution of  $\text{CoCl}_2 \cdot 6 \text{H}_2\text{O}$ .

*Answer:* three (the complex ion,  $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$ , and two chloride ions)

## The Metal–Ligand Bond

The bond between a ligand and a metal ion is an example of an interaction between a Lewis base and a Lewis acid.  $\rightleftharpoons$  (Section 16.11) Because the ligands have unshared pairs of electrons, they can function as Lewis bases (electron-pair donors). Metal ions (particularly transition-metal ions) have empty valence orbitals, so they can act as Lewis acids (electron-pair acceptors). We can picture the bond between the metal ion and ligand as the result of their sharing a pair of electrons that was initially on the ligand:

The formation of metal–ligand bonds can markedly alter the properties we observe for the metal ion. A metal complex is a distinct chemical species that has physical and chemical properties different from the metal ion and the ligands from which it is formed. Complexes, for example, may have colors that differ dramatically from those of their component metal ions and ligands. Figure 24.2  $\blacktriangleleft$  shows the color change that occurs when aqueous solutions of  $\text{SCN}^{-}$  and  $\text{Fe}^{3+}$  are mixed, forming  $[\text{Fe}(\text{H}_2\text{O})_5\text{NCS}]^{2+}$ .

Complex formation can also significantly change other properties of metal ions, such as their ease of oxidation or reduction. The silver ion,  $\text{Ag}^{+}$ , for example, is readily reduced in water:

In contrast, the  $[\text{Ag}(\text{CN})_2]^{-}$  ion is not so easily reduced because complexation by  $\text{CN}^{-}$  ions stabilizes silver in the +1 oxidation state:

Hydrated metal ions are actually complex ions in which the ligand is water. Thus,  $\text{Fe}^{3+}(\text{aq})$  consists largely of  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ .  $\rightleftharpoons$  (Section 16.11) Complex ions form in aqueous solutions from reactions in which ligands such as  $\text{NH}_3$ ,  $\text{SCN}^{-}$ , and  $\text{CN}^{-}$  replace  $\text{H}_2\text{O}$  molecules in the coordination sphere of the metal ion.

### GIVE IT SOME THOUGHT

Write a balanced chemical equation for the reaction that causes the color change in Figure 24.2.

## Charges, Coordination Numbers, and Geometries

The charge of a complex is the sum of the charges on the central metal and on its surrounding ligands. In  $[\text{Cu}(\text{NH}_3)_4]\text{SO}_4$  we can deduce the charge on the complex ion if we first recognize that  $\text{SO}_4$  represents the sulfate ion and

therefore has a 2− charge. Because the compound is neutral, the complex ion must have a 2+ charge,  $[\text{Cu}(\text{NH}_3)_4]^{2+}$ . We can then use the charge of the complex ion to deduce the oxidation number of copper. Because the  $\text{NH}_3$  ligands are neutral molecules, the oxidation number of copper must be +2.

### SAMPLE EXERCISE 24.2 | Determining the Oxidation Number of a Metal in a Complex

What is the oxidation number of the central metal in  $[\text{Rh}(\text{NH}_3)_5\text{Cl}](\text{NO}_3)_2$ ?

#### SOLUTION

**Analyze:** We are given the chemical formula of a coordination compound, and we are asked to determine the oxidation number of its metal atom.

**Plan:** To determine the oxidation number of the Rh atom, we need to figure out what charges are contributed by the other groups in the substance. The overall charge is zero, so the oxidation number of the metal must balance the charge that is due to the rest of the compound.

**Solve:** The  $\text{NO}_3$  group is the nitrate anion, which has a 1− charge,  $\text{NO}_3^-$ . The  $\text{NH}_3$  ligands are neutral, and the Cl is a coordinated chloride ion, which has a 1− charge,  $\text{Cl}^-$ . The sum of all the charges must be zero.

The oxidation number of rhodium,  $x$ , must therefore be +3.

### PRACTICE EXERCISE

What is the charge of the complex formed by a platinum(II) metal ion surrounded by two ammonia molecules and two bromide ions?

*Answer:* zero

### SAMPLE EXERCISE 24.3 | Determining the Formula of a Complex Ion

A complex ion contains a chromium(III) bound to four water molecules and two chloride ions. What is its formula?

#### SOLUTION

**Analyze:** We are given a metal, its oxidation number, and the number of ligands of each kind in a complex ion containing the metal, and we are asked to write the chemical formula of the ion.

**Plan:** We write the metal first, then the ligands. We can use the charges of the metal ion and ligands to determine the charge of the complex ion. The oxidation state of the metal is +3, water is neutral, and chloride has a 1− charge.

**Solve:**

The charge on the ion is 1+,  $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]^+$ .

### PRACTICE EXERCISE

Write the formula for the complex described in the Practice Exercise accompanying Sample Exercise 24.2.

*Answer:*  $[\text{Pt}(\text{NH}_3)_2\text{Br}_2]$

► **Figure 24.3 Four-coordinate complexes.** Structures of (a)  $[\text{Zn}(\text{NH}_3)_4]^{2+}$  and (b)  $[\text{Pt}(\text{NH}_3)_4]^{2+}$ , illustrating the tetrahedral and square-planar geometries, respectively. These are the two common geometries for complexes in which the metal ion has a coordination number of 4.

Recall that the number of atoms directly bonded to the metal atom in a complex is called the *coordination number*. The atom of the ligand bound directly to the metal is called the **donor atom**. Nitrogen, for example, is the donor atom in the  $[\text{Ag}(\text{NH}_3)_2]^+$  complex shown in Equation 24.1. The silver ion in  $[\text{Ag}(\text{NH}_3)_2]^+$  has a coordination number of 2, whereas each cobalt ion in the  $\text{Co}(\text{III})$  complexes in Table 24.1 has a coordination number of 6.

Some metal ions exhibit constant coordination numbers. The coordination number of chromium(III) and cobalt(III) is invariably 6, for example, and that of platinum(II) is always 4. The coordination numbers of most metal ions vary with the ligand, however. The most common coordination numbers are 4 and 6.

The coordination number of a metal ion is often influenced by the relative sizes of the metal ion and the surrounding ligands. As the ligand gets larger, fewer ligands can coordinate to the metal ion. Thus, iron(III) is able to coordinate to six fluorides in  $[\text{FeF}_6]^{3-}$  but coordinates to only four chlorides in  $[\text{FeCl}_4]^-$ . Ligands that transfer substantial negative charge to the metal also produce reduced coordination numbers. For example, six neutral ammonia molecules can coordinate to nickel(II), forming  $[\text{Ni}(\text{NH}_3)_6]^{2+}$ , but only four negatively charged cyanide ions can coordinate, forming  $[\text{Ni}(\text{CN})_4]^{2-}$ .

Four-coordinate complexes have two common geometries—tetrahedral and square planar—as shown in Figure 24.3 ▲. The tetrahedral geometry is the more common of the two and is especially common among nontransition metals. The square-planar geometry is characteristic of transition-metal ions with eight *d* electrons in the valence shell, such as platinum(II) and gold(III).

The vast majority of six-coordinate complexes have an octahedral geometry, as shown in Figure 24.4(a) ▼. The octahedron is often represented as a planar square with ligands above and below the plane, as in Figure 24.4(b). Recall, however, that all positions on an octahedron are geometrically equivalent. ∞ (Section 9.2)

### GIVE IT SOME THOUGHT

What are the geometries most commonly associated with (a) coordination number 4, (b) coordination number 6?

► **Figure 24.4 Six-coordinate complex.** Two representations of an octahedral coordination sphere, the common geometric arrangement for complexes in which the metal ion has a coordination number of 6. In (a) the light blue polyhedron is an octahedron. Representation (b) is easier to draw than (a) and is therefore a more common way to depict an octahedral complex.

## 24.2 LIGANDS WITH MORE THAN ONE DONOR ATOM

The ligands that we have discussed so far, such as  $\text{NH}_3$  and  $\text{Cl}^-$ , are called **monodentate ligands** (from the Latin, meaning “one-toothed”). These ligands possess a single donor atom and are able to occupy only one site in a coordination sphere. Some ligands have two or more donor atoms that can simultaneously coordinate to a metal ion, thereby occupying two or more coordination sites. They are called **polydentate ligands** (“many-toothed”). Because they appear to grasp the metal between two or more donor atoms, polydentate ligands are also known as **chelating agents** (from the Greek word *chele*, “claw”). One such ligand is *ethylenediamine*:

Ethylenediamine, which is abbreviated *en*, has two nitrogen atoms (shown in color) that have unshared pairs of electrons. These donor atoms are sufficiently far apart that the ligand can wrap around a metal ion with the two nitrogen atoms simultaneously bonding to the metal in adjacent positions. The  $[\text{Co}(\text{en})_3]^{3+}$  ion, which contains three ethylenediamine ligands in the octahedral coordination sphere of cobalt(III), is shown in Figure 24.5. Notice that the ethylenediamine has been written in a shorthand notation as two nitrogen atoms connected by an arc. Ethylenediamine is a **bidentate ligand** (“two-toothed” ligand) because it can occupy two coordination sites. Table 24.2 shows several common ligands.

▲ **Figure 24.5** The  $[\text{Co}(\text{en})_3]^{3+}$  ion. Notice how each bidentate ethylenediamine ligand is able to occupy two positions in the coordination sphere.

**TABLE 24.2** ■ Some Common Ligands

Ligand Type	Examples				
Monodentate	$\text{H}_2\ddot{\text{O}}:$ Water $:\ddot{\text{F}}:^-$ Fluoride ion $[\text{C}\equiv\text{N}:]^-$ Cyanide ion $[\text{:}\ddot{\text{O}}-\text{H}]^-$ Hydroxide ion				
	$:\text{NH}_3$ Ammonia $:\ddot{\text{Cl}}:^-$ Chloride ion $[\text{:}\ddot{\text{S}}=\text{C}=\ddot{\text{N}}:]^-$ Thiocyanate ion $[\text{:}\ddot{\text{O}}-\text{N}=\ddot{\text{O}}:]^-$ Nitrite ion				
Bidentate	$\text{H}_2\text{C}-\text{CH}_2$ $\text{H}_2\text{N} \quad \text{NH}_2$ Ethylenediamine ( <i>en</i> )	Bipyridine ( <i>bipy</i> )	Ortho-phenanthroline ( <i>o-phen</i> )	$[\text{:}\ddot{\text{O}}-\text{C}(\text{:}\ddot{\text{O}})=\text{C}(\text{:}\ddot{\text{O}})-\text{O}]^{2-}$ Oxalate ion	$[\text{:}\ddot{\text{O}}-\text{C}(\text{:}\ddot{\text{O}})=\text{O}]^{2-}$ Carbonate ion
	Polydentate	$\text{H}_2\text{C}-\text{CH}_2-\text{CH}_2-\text{CH}_2$ $\text{H}_2\text{N} \quad \text{NH} \quad \text{NH}_2$ Diethylenetriamine	$[\text{:}\ddot{\text{O}}-\text{P}(\text{:}\ddot{\text{O}})-\text{O}-\text{P}(\text{:}\ddot{\text{O}})-\text{O}-\text{P}(\text{:}\ddot{\text{O}})-\text{O}]^{5-}$ Triphosphate ion	$[\text{:}\ddot{\text{O}}-\text{C}(\text{:}\ddot{\text{O}})-\text{CH}_2-\text{N}(\text{CH}_2-\text{C}(\text{:}\ddot{\text{O}})=\text{O})_2-\text{CH}_2-\text{N}(\text{CH}_2-\text{C}(\text{:}\ddot{\text{O}})=\text{O})_2-\text{CH}_2-\text{C}(\text{:}\ddot{\text{O}})=\text{O}]^{4-}$ Ethylenediaminetetraacetate ion ( $\text{EDTA}^{4-}$ )	

▲ **Figure 24.6** The [CoEDTA]<sup>-</sup> ion. Notice how the ethylenediaminetetraacetate ion, a polydentate ligand, is able to wrap around a metal ion, occupying six positions in the coordination sphere.

The ethylenediaminetetraacetate ion, abbreviated [EDTA]<sup>4-</sup>, is an important polydentate ligand that has six donor atoms:

It can wrap around a metal ion using all six of these donor atoms, as shown in Figure 24.6 ◀, although it sometimes binds to a metal using only five of its six donor atoms.

In general, chelating ligands form more stable complexes than do related monodentate ligands. The formation constants for [Ni(NH<sub>3</sub>)<sub>6</sub>]<sup>2+</sup> and [Ni(en)<sub>3</sub>]<sup>2+</sup>, shown in Equations 24.4 and 24.5, illustrate this observation:

Although the donor atom is nitrogen in both instances, [Ni(en)<sub>3</sub>]<sup>2+</sup> has a formation constant that is more than 10<sup>8</sup> times larger than that of [Ni(NH<sub>3</sub>)<sub>6</sub>]<sup>2+</sup>. The generally larger formation constants for polydentate ligands as compared with the corresponding monodentate ligands is known as the **chelate effect**. We examine the origin of this effect in greater detail in “A Closer Look: Entropy and the Chelate Effect” in this section.

Chelating agents are often used to prevent one or more of the customary reactions of a metal ion without actually removing it from solution. For example, a metal ion that interferes with a chemical analysis can often be complexed and its interference thereby removed. In a sense, the chelating agent hides the metal ion. For this reason, scientists sometimes refer to these ligands as sequestering agents. (The word *sequester* means to remove, set apart, or separate.)

Phosphates such as sodium tripolyphosphate, shown here, are used to complex or sequester metal ions such as Ca<sup>2+</sup> and Mg<sup>2+</sup> in hard water so these ions cannot interfere with the action of soap or detergents: ⇌ (Section 18.6)

▲ **Figure 24.7** Lichens growing on a rock surface. Lichens obtain the nutrients needed for growth from a variety of sources. Using chelating agents, they are able to extract needed metallic elements from the rocks on which they grow.

Chelating agents such as EDTA are used in consumer products, including many prepared foods such as salad dressings and frozen desserts, to complex trace metal ions that catalyze decomposition reactions. Chelating agents are used in medicine to remove metal ions such as Hg<sup>2+</sup>, Pb<sup>2+</sup>, and Cd<sup>2+</sup>, which are detrimental to health. One method of treating lead poisoning is to administer Na<sub>2</sub>[Ca(EDTA)]. The EDTA chelates the lead, allowing it to be removed from the body via urine. Chelating agents are also quite common in nature. Mosses and lichens secrete chelating agents to capture metal ions from the rocks they inhabit (Figure 24.7 ◀).

## GIVE IT SOME THOUGHT

Cobalt(III) has a coordination number of 6 in all of its complexes. Is the carbonate ion acting as a monodentate or as a bidentate ligand in the  $[\text{Co}(\text{NH}_3)_4\text{CO}_3]^+$  ion?

## Metals and Chelates in Living Systems

Ten of the 29 elements known to be necessary for human life are transition metals.  $\infty$  (Section 27, "Chemistry and Life: Elements Required by Living Organisms") These ten elements—V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Mo, and Cd—owe their roles in living systems mainly to their ability to form complexes with a variety of donor groups present in biological systems. Metal ions are integral parts of many enzymes, which are the body's catalysts.  $\infty$  (Section 14.7)

Although our bodies require only small quantities of metals, deficiencies can lead to serious illness. A deficiency of manganese, for example, can lead to convulsive disorders. Some epilepsy patients have been helped by the addition of manganese to their diets.

Among the most important chelating agents in nature are those derived from the *porphine* molecule, which is shown in Figure 24.8. This molecule can coordinate to a metal using the four nitrogen atoms as donors. Upon coordination to a metal, the two H atoms shown bonded to nitrogen are displaced. Complexes derived from porphine are called **porphyrins**. Different porphyrins contain different metal ions and have different substituent groups attached to the carbon atoms at the ligand's periphery. Two of the most important porphyrin or porphyrinlike compounds are *heme*, which contains Fe(II), and *chlorophyll*, which contains Mg(II).

**▲ Figure 24.8 The porphine molecule.** This molecule forms a tetradentate ligand with the loss of the two protons bound to nitrogen atoms. Porphine is the basic component of porphyrins, complexes that play a variety of important roles in nature.

## A Closer Look

## ENTROPY AND THE CHELATE EFFECT

When we examined thermodynamics in Chapter 19, we learned that the spontaneity of chemical processes is favored by a positive change in the entropy of the system and by a negative change in its enthalpy.  $\infty$  (Section 19.5) The special stability associated with the formation of chelates, called the *chelate effect*, can be explained by looking at the entropy changes that occur when polydentate ligands bind to a metal ion. To understand this effect better, let's look at some reactions in which two  $\text{H}_2\text{O}$  ligands of the square-planar  $\text{Cu}(\text{II})$  complex  $[\text{Cu}(\text{H}_2\text{O})_4]^{2+}$  are replaced by other ligands. First, let's consider replacing the  $\text{H}_2\text{O}$  ligands with  $\text{NH}_3$  ligands at  $27^\circ\text{C}$  to form  $[\text{Cu}(\text{H}_2\text{O})_2(\text{NH}_3)_2]^{2+}$ , the structure of which is shown in Figure 24.9(a):

The thermodynamic data provide us with information about the relative abilities of  $\text{H}_2\text{O}$  and  $\text{NH}_3$  to serve as ligands in these systems. In general,  $\text{NH}_3$  binds more tightly to metal ions than  $\text{H}_2\text{O}$ , so these kinds of substitution reactions are exothermic ( $\Delta H < 0$ ). The stronger bonding of the  $\text{NH}_3$  ligands also causes  $[\text{Cu}(\text{H}_2\text{O})_2(\text{NH}_3)_2]^{2+}$  to be more rigid, which

**▲ Figure 24.9 Ball-and-stick models of two related copper complexes.** The square-planar complexes (a)  $[\text{Cu}(\text{H}_2\text{O})_2(\text{NH}_3)_2]^{2+}$  and (b)  $[\text{Cu}(\text{H}_2\text{O})_2(\text{en})]^{2+}$  have the same donor atoms, but (b) has a bidentate ligand.

is probably the reason that the entropy change for the reaction is slightly negative. By using Equation 19.17, we can use the value of  $\Delta G^\circ$  to calculate the equilibrium constant of the reaction at  $27^\circ\text{C}$ . The resulting value,  $K = 3.1 \times 10^7$ , tells us that the equilibrium lies far to the right, favoring substitution of  $\text{H}_2\text{O}$  by  $\text{NH}_3$ . For this equilibrium, the change in the enthalpy is large and negative enough to overcome the negative change in the entropy.

*continues on next page*

continued

How does this situation change if instead of two  $\text{NH}_3$  ligands we use a single bidentate ethylenediamine (en) ligand and form  $[\text{Cu}(\text{H}_2\text{O})_2(\text{en})]^{2+}$  [Figure 24.9(b)]? The equilibrium reaction and thermodynamic data are

The en ligand binds slightly more strongly to a  $\text{Cu}^{2+}$  ion than two  $\text{NH}_3$  ligands, so the enthalpy change on forming  $[\text{Cu}(\text{H}_2\text{O})_2(\text{en})]^{2+}$  is slightly more negative than for  $[\text{Cu}(\text{H}_2\text{O})_2(\text{NH}_3)_2]^{2+}$ . There is a big difference in the entropy change, however. Whereas the entropy change for forming  $[\text{Cu}(\text{H}_2\text{O})_2(\text{NH}_3)_2]^{2+}$  is negative, the entropy change for forming  $[\text{Cu}(\text{H}_2\text{O})_2(\text{en})]^{2+}$  is positive. We can explain this positive value by using the concepts we discussed in Section 19.3. Because a single en ligand occupies two coordination sites, two molecules of  $\text{H}_2\text{O}$  are released upon binding one en ligand. Thus, there are three molecules on the right side of the equation, whereas there are only two on the left side, all of which are part of the same aqueous solution. The greater number of molecules on the right leads to the positive entropy change for the equilibrium. The slightly more negative value of  $\Delta H^\circ$  coupled with the positive entropy change leads to a much more negative value of  $\Delta G^\circ$  and a correspondingly larger equilibrium constant:  $K = 4.2 \times 10^{10}$ .

We can combine the earlier equations to show that the formation of  $[\text{Cu}(\text{H}_2\text{O})_2(\text{en})]^{2+}$  is thermodynamically preferred over the formation of  $[\text{Cu}(\text{H}_2\text{O})_2(\text{NH}_3)_2]^{2+}$ . If we add the second reaction to the reverse of the first reaction, we obtain

The thermochemical data for this equilibrium reaction can be obtained from those given earlier:

$$\begin{aligned} \Delta H^\circ &= (-54 \text{ kJ}) - (-46 \text{ kJ}) = -8 \text{ kJ} \\ \Delta S^\circ &= (+23 \text{ J/K}) - (-8.4 \text{ J/K}) = +31 \text{ J/K} \\ \Delta G^\circ &= (-61 \text{ kJ}) - (-43 \text{ kJ}) = -18 \text{ kJ} \end{aligned}$$

Notice that at  $27^\circ \text{C}$  (300 K), the entropic contribution ( $-T\Delta S^\circ$ ) to the free-energy change is negative and greater in magnitude than the enthalpic contribution ( $\Delta H^\circ$ ). The resulting value of the equilibrium constant,  $K$ , for this reaction,  $1.4 \times 10^3$ , shows that the formation of the chelate complex is favored.

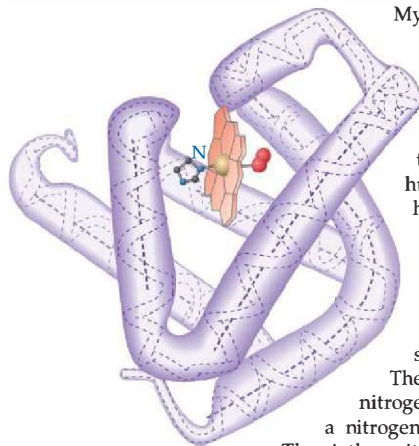

The chelate effect is important in biochemistry and molecular biology. The additional thermodynamic stabilization provided by entropic effects helps to stabilize biological metal-chelate complexes, such as porphyrins, and can allow changes in the oxidation state of the metal ion while retaining the structural integrity of the complex.

Figure 24.10  $\blacktriangledown$  shows a schematic structure of myoglobin, a protein that contains one heme group. Myoglobin is a *globular protein*, one that folds into a compact, roughly spherical shape. Globular proteins are generally soluble in water and are mobile within cells.

**► Figure 24.10 Myoglobin.**

Myoglobin is a protein that stores oxygen in cells. The molecule has a molecular weight of about 18,000 amu and contains one heme unit, shown in orange. The heme unit is bound to the protein through a nitrogen-containing ligand, as shown on the left side of the heme. In the oxygenated form an  $\text{O}_2$  molecule is coordinated to the heme group, as shown on the right side of the heme. The continuous purple cylinder represents the three-dimensional structure of the protein chain. The dashed lines denote the helical sections. The protein wraps around to make a pocket for the heme group.

Myoglobin is found in the cells of skeletal muscle, particularly in seals, whales, and porpoises.

It stores oxygen in cells until it is needed for metabolic activities. Hemoglobin, the protein that transports oxygen in human blood, is made up of four heme-containing subunits, each of which is very similar to myoglobin.

The coordination environment of the iron in myoglobin and hemoglobin is illustrated schematically in Figure 24.11  $\blacktriangleright$ .

The iron is coordinated to the four nitrogen atoms of the porphyrin and to a nitrogen atom from the protein chain.

The sixth position around the iron is occupied either by  $\text{O}_2$  (in oxyhemoglobin, the bright red form)

or by water (in deoxyhemoglobin, the purplish red form). The oxy form is shown in Figure 24.11. Some substances, such as CO, are poisonous because they bind to iron more strongly than does O<sub>2</sub>. ⇐(Section 18.4)

The **chlorophylls**, which are porphyrins that contain Mg(II), are the key components in the conversion of solar energy into forms that can be used by living organisms. This process, called **photosynthesis**, occurs in the leaves of green plants. In photosynthesis, carbon dioxide and water are converted to carbohydrate, with the release of oxygen:

The formation of one mole of glucose, C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>, requires the absorption of 48 moles of photons from sunlight or other sources of light. Chlorophyll-containing pigments in the leaves of plants absorb the photons. The structure of the most abundant chlorophyll, called chlorophyll *a*, is shown in Figure 24.12 ▶.

Chlorophylls contain a Mg<sup>2+</sup> ion bound to four nitrogen atoms arranged around the metal in a planar array. The series of alternating, or *conjugated*, double bonds in the ring surrounding the metal ion is similar to ones found in many organic dyes. This system of conjugated double bonds makes it possible for chlorophyll to absorb light strongly in the visible region of the spectrum, which corresponds to wavelengths ranging from 400–700 nm. Figure 24.13 ▼ compares the absorption spectrum of chlorophyll to the distribution of visible solar energy at Earth's surface. Chlorophyll is green because it absorbs red light (maximum absorption at 655 nm) and blue light (maximum absorption at 430 nm) and transmits green light. Plant photosynthesis is nature's solar-energy–conversion machine. All living systems on Earth depend on photosynthesis for continued existence (Figure 24.14 ▼).

### GIVE IT SOME THOUGHT

What property of the porphine ligand makes it possible for chlorophyll to play a role in plant photosynthesis?

◀ **Figure 24.13 The absorption of light by chlorophyll.** The absorption spectrum of chlorophyll (green curve) is compared with the distribution of solar radiation at ground level (red curve).

▶ **Figure 24.14 Photosynthesis.** The absorption and conversion of solar energy that occurs in leaves provides the energy necessary to drive all the living processes of the plant, including growth.

▲ **Figure 24.11 Coordination sphere of oxymyoglobin and oxyhemoglobin.** The iron is bound to four nitrogen atoms of the porphyrin, to a nitrogen from the surrounding protein, and to an O<sub>2</sub> molecule.

▼ **Figure 24.12 Chlorophyll *a*.** All chlorophyll molecules are essentially alike; they differ only in details of the side chains.

Although iron is the fourth most abundant element in Earth's crust, living systems have difficulty assimilating enough iron to satisfy their needs. Consequently, iron-deficiency anemia is a common problem in humans. Chlorosis, an iron deficiency in plants that results in yellowing of leaves, is also commonplace. Living systems have difficulty assimilating iron because most iron compounds found in nature are not very soluble in water. Microorganisms have adapted to this problem by secreting an iron-binding compound, called a *siderophore*, that forms an extremely stable water-soluble complex with iron(III). One such complex is called *ferrichrome*; its structure is shown in Figure 24.15. The iron-binding strength of a siderophore is so great that it can extract iron from Pyrex® glassware, and it readily solubilizes the iron in iron oxides.

The overall charge of ferrichrome is zero, which makes it possible for the complex to pass through the rather hydrophobic walls of cells. When a dilute solution of ferrichrome is added to a cell suspension, iron is found entirely within the cells in an hour. When ferrichrome enters the cell, the iron is removed through an enzyme-catalyzed reaction that reduces the iron(III) to iron(II). Iron in the lower oxidation state is not strongly complexed by the siderophore. Microorganisms thus acquire iron by excreting a siderophore into their immediate environment and then taking the resulting iron complex into the cell. The overall process is illustrated in Figure 24.16.

In humans, iron is assimilated from food in the intestine. A protein called *transferrin* binds iron and transports it across the intestinal wall to distribute it to other tissues in the body. The normal adult carries a total of about 4 g of iron. At any one time, about 3 g, or 75%, of this iron is in the blood, mostly in the form of hemoglobin. Most of the remainder is carried by transferrin.

▲ **Figure 24.15 Ferrichrome.** In this complex six oxygen atoms coordinate an  $\text{Fe}^{3+}$  ion. The complex is very stable; it has a formation constant of about  $10^{30}$ . The overall charge of the complex is zero.

▲ **Figure 24.16 The iron-transport system of a bacterial cell.** The iron-binding ligand, called a siderophore, is synthesized inside the cell and excreted into the surrounding medium. It reacts with  $\text{Fe}^{3+}$  ion to form ferrichrome, which is then absorbed by the cell. Inside the cell the ferrichrome is reduced, forming  $\text{Fe}^{2+}$ , which is not tightly bound by the siderophore. Having released the iron for use in the cell, the siderophore may be recycled back into the medium.

A bacterium that infects the blood requires a source of iron if it is to grow and reproduce. The bacterium excretes a siderophore into the blood to compete with transferrin for the iron it holds. The formation constants for iron binding are about the same for transferrin and siderophores. The more iron available to the bacterium, the more rapidly it can reproduce, and, thus, the more harm it can do. Several years ago, New Zealand clinics regularly gave iron supplements to infants soon after birth. However, the incidence of certain bacterial infections was eight times higher in treated than in untreated infants. Presumably, the presence of more iron in the blood than absolutely necessary makes it easier for bacteria to obtain the iron needed for growth and reproduction.

In the United States it is common medical practice to supplement infant formula with iron sometime during the first year of life. However, iron supplements are not necessary for infants who breast-feed, because breast milk contains two specialized proteins, lactoferrin and transferrin, which provide sufficient iron while denying its availability to bacteria. Even for infants fed with infant formulas, supplementing with iron during the first several months of life may be ill advised.

For bacteria to continue to multiply in the bloodstream, they must synthesize new supplies of siderophores. Synthesis of siderophores in bacteria slows, however, as the temperature is increased above the normal body temperature of  $37^\circ\text{C}$ , and it stops completely at  $40^\circ\text{C}$ . This suggests that fever in the presence of an invading microbe is a mechanism used by the body to deprive bacteria of iron.

## 24.3 NOMENCLATURE OF COORDINATION CHEMISTRY

When complexes were first discovered and few were known, they were named after the chemist who originally prepared them. A few of these names persist; for example, the dark red substance  $\text{NH}_4[\text{Cr}(\text{NH}_3)_2(\text{NCS})_4]$  is still known as Reinecke's salt. Once the structures of complexes were more fully understood, it became possible to name them in a more systematic manner. Let's consider two examples:

These examples illustrate how coordination compounds are named. The rules that govern naming of this class of substances are as follows:

1. In naming salts, the name of the cation is given before the name of the anion. Thus, in  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$  we name the  $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$  cation and then  $\text{Cl}^-$ .
2. Within a complex ion or molecule, the ligands are named before the metal. Ligands are listed in alphabetical order, regardless of charge on the ligand. Prefixes that give the number of ligands are not considered part of the ligand name in determining alphabetical order. Thus, in the  $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$  ion we name the ammonia ligands first, then the chloride, then the metal: pentaamminechlorocobalt(III). In writing the formula, however, the metal is listed first.
3. The names of the anionic ligands end in the letter o, whereas neutral ones ordinarily bear the name of the molecules. Some common ligands and their names are listed in Table 24.3. Special names are given to  $\text{H}_2\text{O}$  (aqua),  $\text{NH}_3$  (ammine), and  $\text{CO}$  (carbonyl). For example,  $[\text{Fe}(\text{CN})_2(\text{NH}_3)_2(\text{H}_2\text{O})_2]^+$  would be named as diaamminediaquacyanoiron(III) ion.

TABLE 24.3 ■ Some Common Ligands

Ligand	Name in Complexes	Ligand	Name in Complexes
Azide, $\text{N}_3^-$	Azido	Oxalate, $\text{C}_2\text{O}_4^{2-}$	Oxalato
Bromide, $\text{Br}^-$	Bromo	Oxide, $\text{O}^{2-}$	Oxo
Chloride, $\text{Cl}^-$	Chloro	Ammonia, $\text{NH}_3$	Ammine
Cyanide, $\text{CN}^-$	Cyano	Carbon monoxide, $\text{CO}$	Carbonyl
Fluoride, $\text{F}^-$	Fluoro	Ethylenediamine, en	Ethylenediamine
Hydroxide, $\text{OH}^-$	Hydroxo	Pyridine, $\text{C}_5\text{H}_5\text{N}$	Pyridine
Carbonate, $\text{CO}_3^{2-}$	Carbonato	Water, $\text{H}_2\text{O}$	Aqua

- Greek prefixes (di-, tri-, tetra-, penta-, and hexa-) are used to indicate the number of each kind of ligand when more than one is present. If the ligand itself contains a prefix of this kind (for example, ethylenediamine), or is polydentate, alternate prefixes are used (bis-, tris-, tetrakis-, pentakis-, hexakis-) and the ligand name is placed in parentheses. For example, the name for  $[\text{Co}(\text{en})_3]\text{Br}_3$  is tris(ethylenediamine)-cobalt(III) bromide.
- If the complex is an anion, its name ends in -ate. The compound  $\text{K}_4[\text{Fe}(\text{CN})_6]$  is named potassium hexacyanoferrate(II), for example, and the ion  $[\text{CoCl}_4]^{2-}$  is named tetrachlorocobaltate(II) ion.
- The oxidation number of the metal is given in parentheses in Roman numerals following the name of the metal.

The following substances and their names demonstrate the application of these rules:

$[\text{Ni}(\text{NH}_3)_6]\text{Br}_2$	Hexaamminenickel(II) bromide
$[\text{Co}(\text{en})_2(\text{H}_2\text{O})(\text{CN})]\text{Cl}_2$	Aquacyanobis(ethylenediamine)cobalt(III) chloride
$\text{Na}_2[\text{MoOCl}_4]$	Sodium tetrachlorooxomolybdate(IV)

### SAMPLE EXERCISE 24.4 | Naming Coordination Compounds

Name the following compounds: (a)  $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]\text{Cl}$ , (b)  $\text{K}_4[\text{Ni}(\text{CN})_4]$ .

#### SOLUTION

**Analyze:** We are given the chemical formulas for two coordination compounds, and we are assigned the task of naming them.

**Plan:** To name the complexes, we need to determine the ligands in the complexes, the names of the ligands, and the oxidation state of the metal ion. We then put the information together following the rules listed previously.

**Solve:** (a) As ligands, there are four water molecules, which are indicated as tetraqua, and two chloride ions, indicated as dichloro. The oxidation state of Cr is +3.

$$+3 + 4(0) + 2(-1) + (-1) = 0$$

Thus, we have chromium(III). Finally, the anion is chloride. Putting these parts together, the name of the compound is

tetraaquadichlorochromium(III) chloride

(b) The complex has four cyanide ions,  $\text{CN}^-$ , as ligands, which we indicate as tetracyano. The oxidation state of the nickel is zero.

$$4(+1) + 0 + 4(-1) = 0$$

Because the complex is an anion, the metal is indicated as nickelate(0). Putting these parts together and naming the cation first, we have

potassium tetracyanonickelate(0)

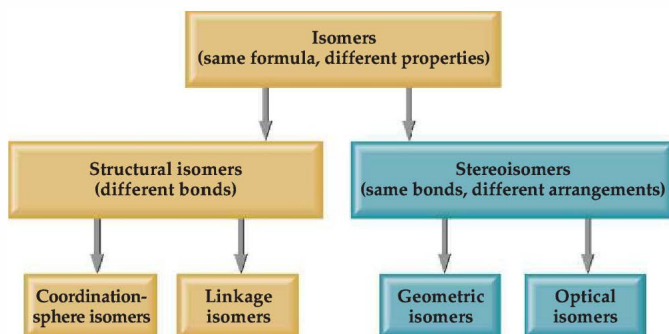

### PRACTICE EXERCISE

Name the following compounds: (a)  $[\text{Mo}(\text{NH}_3)_3\text{Br}_3]\text{NO}_3$ , (b)  $(\text{NH}_4)_2[\text{CuBr}_4]$ , (c) Write the formula for sodium diaquabis(oxalato)ruthenate(III).

**Answers:** (a) triamminetribromomolybdenum(IV) nitrate, (b) ammonium tetrabromocuprate(II) (c)  $\text{Na}[\text{Ru}(\text{H}_2\text{O})_2(\text{C}_2\text{O}_4)_2]$

## 24.4 ISOMERISM

When two or more compounds have the same composition but a different arrangement of atoms, we call them **isomers**. Isomerism—the existence of isomers—is a characteristic feature of both organic and inorganic compounds. Although isomers are composed of the same collection of atoms, they usually differ in one or more physical or chemical properties such as color, solubility, or rate of reaction with some reagent. We will consider two main kinds of

▲ Figure 24.17 Forms of isomerism in coordination compounds.

isomers in coordination compounds: **structural isomers** (which have different bonds) and **stereoisomers** (which have the same bonds but different ways in which the ligands occupy the space around the metal center). Each of these classes also has subclasses, as shown in Figure 24.17▲.

### Structural Isomerism

Many different types of structural isomerism are known in coordination chemistry. Figure 24.17 gives two examples: linkage isomerism and coordination-sphere isomerism. **Linkage isomerism** is a relatively rare but interesting type that arises when a particular ligand is capable of coordinating to a metal in two different ways. The nitrite ion,  $\text{NO}_2^-$ , for example, can coordinate through either a nitrogen or an oxygen atom, as shown in Figure 24.18▶. When it coordinates through the nitrogen atom, the  $\text{NO}_2^-$  ligand is called *nitro*; when it coordinates through the oxygen atom, it is called *nitrito* and is generally written  $\text{ONO}^-$ . The isomers shown in Figure 24.18 have different properties. The N-bonded isomer is yellow, for example, whereas the O-bonded isomer is red. Another ligand capable of coordinating through either of two donor atoms is thiocyanate,  $\text{SCN}^-$ , whose potential donor atoms are N and S.

**Coordination-sphere isomers** differ in the ligands that are directly bonded to the metal, as opposed to being outside the coordination sphere in the solid lattice. For example, there are three compounds whose chemical formula is  $\text{CrCl}_3(\text{H}_2\text{O})_6$ :  $[\text{Cr}(\text{H}_2\text{O})_6]\text{Cl}_3$  (a violet compound),  $[\text{Cr}(\text{H}_2\text{O})_5\text{Cl}]\text{Cl}_2 \cdot \text{H}_2\text{O}$  (a green compound), and  $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]\text{Cl} \cdot 2 \text{H}_2\text{O}$  (also a green compound). In the two green compounds the water has been displaced from the coordination sphere by chloride ions and occupies a site in the crystal lattice.

### Stereoisomerism

Stereoisomerism is the most important form of isomerism. **Stereoisomers** have the same chemical bonds but different spatial arrangements. In the square-planar

▲ Figure 24.18 Linkage isomerism. Yellow N-bound isomer (left) and red O-bound isomer (right) of  $[\text{Co}(\text{NH}_3)_3\text{NO}_2]^{2+}$ .

▲ **Figure 24.19 Geometric Isomerism.** (a) Cis and (b) trans geometric isomers of the square-planar  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$ .

complex  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$ , for example, the chloro ligands can be either adjacent to or opposite each other, as illustrated in Figure 24.19 ◀. This particular form of isomerism, in which the arrangement of the constituent atoms is different though the same bonds are present, is called **geometric isomerism**. The isomer in Figure 24.19(a), with like ligands in adjacent positions, is called the **cis isomer**. The isomer in Figure 24.19(b), with like ligands across from one another, is called the **trans isomer**. Geometric isomers generally have different properties, such as colors, solubilities, melting points, and boiling points. They may also have markedly different chemical reactivities. For example, *cis*- $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$ , also called *cisplatin*, is effective in the treatment of testicular, ovarian, and certain other cancers, whereas the trans isomer is ineffective.

Geometric isomerism is possible also in octahedral complexes when two or more different ligands are present. The cis and trans isomers of the tetraamminedichlorocobalt(III) ion were shown in Figure 24.1. As noted in Section 24.1 and Table 24.1, these two isomers have different colors. Their salts also possess different solubilities in water.

Because all the corners of a tetrahedron are adjacent to one another, cis-trans isomerism is not observed in tetrahedral complexes.

#### ■ SAMPLE EXERCISE 24.5 Determining the Number of Geometric Isomers

The Lewis structure of the CO molecule indicates that the molecule has a lone pair of electrons on the C atom and one on the O atom ( $:\text{C}\equiv\text{O}:$ ). When CO binds to a transition-metal atom, it nearly always does so by using the lone pair on the C atom. How many geometric isomers are there for tetracarbonyldichloroiron(II)?

#### SOLUTION

**Analyze:** We are given the name of a complex containing only monodentate ligands, and we must determine the number of isomers the complex can form.

**Plan:** We can count the number of ligands, thereby determining the coordination number of the Fe in the complex and then use the coordination number to predict the geometry of the complex. We can then either make a series of drawings with ligands in different positions to determine the number of isomers, or we can deduce the number of isomers by analogy to cases we have discussed.

**Solve:** The name indicates that the complex has four carbonyl (CO) ligands and two chloro ( $\text{Cl}^-$ ) ligands, so its formula is  $\text{Fe}(\text{CO})_4\text{Cl}_2$ . The complex therefore has a coordination number of 6, and we can assume that it has an octahedral geometry. Like  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$  (Figure 24.1), it has four ligands of one type and two of another. Consequently, it possesses two isomers: one with the  $\text{Cl}^-$  ligands across the metal from each other (*trans*- $\text{Fe}(\text{CO})_4\text{Cl}_2$ ) and one with the  $\text{Cl}^-$  ligands adjacent (*cis*- $\text{Fe}(\text{CO})_4\text{Cl}_2$ ).

In principle, the CO ligand could exhibit linkage isomerism by binding to a metal atom via the lone pair on the O atom. When bonded this way, a CO ligand is called an *isocarbonyl* ligand. Metal isocarbonyl complexes are extremely rare, and we do not normally have to consider the possibility that CO will bind in this way.

**Comment:** It is easy to overestimate the number of geometric isomers. Sometimes different orientations of a single isomer are incorrectly thought to be different isomers. If two structures can be rotated so that they are equivalent, they are not isomers of each other. The problem of identifying isomers is compounded by the difficulty we often have in visualizing three-dimensional molecules from their two-dimensional representations. It is sometimes easier to determine the number of isomers if we use three-dimensional models.

#### ■ PRACTICE EXERCISE

How many isomers exist for square-planar  $[\text{Pt}(\text{NH}_3)_2\text{ClBr}]?$

*Answer:* two

A second type of stereoisomerism is known as **optical isomerism**. Optical isomers, called **enantiomers**, are mirror images that cannot be superimposed on each other. They bear the same resemblance to each other that your left hand bears to your right hand. If you look at your left hand in a mirror, the image is

▲ **Figure 24.20 Optical isomerism.** Just as our hands are nonsuperimposable mirror images of each other (a), so too are optical isomers such as the two optical isomers of  $[\text{Co}(\text{en})_3]^{3+}$  (b).

identical to your right hand [Figure 24.20(a)▲]. No matter how hard you try, however, you cannot superimpose your two hands on one another. An example of a complex that exhibits this type of isomerism is the  $[\text{Co}(\text{en})_3]^{3+}$  ion. Figure 24.20(b) shows the two enantiomers of  $[\text{Co}(\text{en})_3]^{3+}$  and their mirror-image relationship to each other. Just as there is no way that we can twist or turn our right hand to make it look identical to our left, so also there is no way to rotate one of these enantiomers to make it identical to the other. Molecules or ions that are not superimposable on their mirror image are said to be **chiral** (pronounced KY-rul). Enzymes are among the most important chiral molecules and, as noted in Section 24.2, many enzymes contain complexed metal ions. A molecule need not contain a metal atom to be chiral, however; in Section 25.5, you will see that many organic molecules, including some of those that are important in biochemistry, are chiral.

### ■ SAMPLE EXERCISE 24.6 | Predicting Whether a Complex Has Optical Isomers

Does either *cis*- or *trans*- $[\text{Co}(\text{en})_2\text{Cl}_2]^+$  have optical isomers?

#### SOLUTION

**Analyze:** We are given the chemical formula for two structural isomers, and we are asked to determine whether either has optical isomers. The en ligand is a bidentate ligand, so the complexes are six-coordinate and octahedral.

**Plan:** We need to sketch the structures of the *cis* and *trans* isomers and their mirror images. We can draw the en ligand as two N atoms connected by a line, as is done in Figure 24.20. If the mirror image cannot be superimposed on the original structure, the complex and its mirror image are optical isomers.

**Solve:** The *trans* isomer of  $[\text{Co}(\text{en})_2\text{Cl}_2]^+$  and its mirror image is

where the dashed vertical line represents a mirror. Notice that the mirror image of the *trans* isomer is identical to the original. Consequently *trans*- $[\text{Co}(\text{en})_2\text{Cl}_2]^+$  does not exhibit optical isomerism.

The mirror image of the cis isomer of  $[\text{Co}(\text{en})_2\text{Cl}_2]^+$ , however, cannot be superimposed on the original:

Thus, the two cis structures are optical isomers (enantiomers): *cis*- $[\text{Co}(\text{en})_2\text{Cl}_2]^+$  is a chiral complex.

#### ■ PRACTICE EXERCISE

Does the square-planar complex ion  $[\text{Pt}(\text{NH}_3)(\text{N}_3)\text{ClBr}]^-$  have optical isomers?

*Answer:* no

Most of the physical and chemical properties of optical isomers are identical. The properties of two optical isomers differ only if they are in a chiral environment—that is, one in which there is a sense of right- and left-handedness. In the presence of a chiral enzyme, for example, the reaction of one optical isomer might be catalyzed, whereas the other isomer would not react. Consequently, one optical isomer may produce a specific physiological effect within the body, whereas its mirror image produces a different effect or none at all. Chiral reactions are also extremely important in the synthesis of pharmaceuticals and other industrially important chemicals.

Optical isomers are usually distinguished from each other by their interaction with plane-polarized light. If light is polarized—for example, by passage through a sheet of polarizing film—the light waves are oscillating in a single plane, as shown in Figure 24.21 ▼. If the polarized light is passed through a solution containing one optical isomer, the plane of polarization is rotated either to the right (clockwise) or to the left (counterclockwise). The isomer that rotates the plane of polarization to the right is **dextrorotatory**; it is labeled the dextro, or *d*, isomer (Latin *dexter*, “right”). Its mirror image rotates the plane of polarization to the left; it is **levorotatory** and is labeled the levo, or *l*, isomer (Latin *laevus*, “left”). The isomer of  $[\text{Co}(\text{en})_3]^{3+}$  on the left in Figure 24.20(b) is found experimentally to be the *l* isomer of this ion. Its mirror image is the *d* isomer. Because of their effect on plane-polarized light, chiral molecules are said to be **optically active**.

▲ **Figure 24.21 Optical activity.** Effect of an optically active solution on the plane of polarization of plane-polarized light. The unpolarized light is passed through a polarizer. The resultant polarized light thereafter passes through a solution containing a dextrorotatory optical isomer. As a result, the plane of polarization of the light is rotated to the right relative to an observer looking toward the light source.

### GIVE IT SOME THOUGHT

What is the similarity and what is the difference between the *d* and *l* isomers of a compound?

When a substance with optical isomers is prepared in the laboratory, the chemical environment during the synthesis is not usually chiral. Consequently, equal amounts of the two isomers are obtained; the mixture is said to be **racemic**. A racemic mixture will not rotate polarized light because the rotatory effects of the two isomers cancel each other.

## 24.5 COLOR AND MAGNETISM

Studies of the colors and magnetic properties of transition-metal complexes have played an important role in the development of modern models for metal–ligand bonding. We have discussed the various types of magnetic behavior in Section 23.7, and we have discussed the interaction of radiant energy with matter in Section 6.3. Let's briefly examine the significance of these two properties for transition-metal complexes before we try to develop a model for metal–ligand bonding.

### Color

In Figure 23.21 we saw the diverse range of colors exhibited by salts of transition-metal ions and their aqueous solutions. ∞ (Section 23.7) In these examples water molecules occupy the coordination sphere about the metal. In general, the color of a complex depends on the particular element, its oxidation state, and the ligands bound to the metal. Figure 24.22 ▼ shows how the pale blue color characteristic of  $[\text{Cu}(\text{H}_2\text{O})_4]^{2+}$  changes to a deep blue color as  $\text{NH}_3$  ligands replace  $\text{H}_2\text{O}$  ligands to form  $[\text{Cu}(\text{NH}_3)_4]^{2+}$ .

For a compound to have color, it must absorb visible light. Visible light consists of electromagnetic radiation with wavelengths ranging from approximately 400 to 700 nm. ∞ (Section 6.1) White light contains all wavelengths in this

▲ **Figure 24.22 Effect of ligands on color.** An aqueous solution of  $\text{CuSO}_4$  is pale blue because of  $[\text{Cu}(\text{H}_2\text{O})_4]^{2+}$  (left). When  $\text{NH}_3(aq)$  is added (middle and right), the deep blue  $[\text{Cu}(\text{NH}_3)_4]^{2+}$  ion forms.

▲ **Figure 24.23 Visible spectrum.** The relationship between color and wavelength for visible light. (See also Figure 6.4.)

visible region. It can be dispersed into a spectrum of colors, each of which has a characteristic range of wavelengths, as shown in Figure 24.23 ▲. The energy of this or any other electromagnetic radiation is inversely proportional to its wavelength:  $\infty$  (Section 6.2)

$$E = h\nu = h(c/\lambda) \quad [24.7]$$

A compound will absorb visible radiation when that radiation possesses the energy needed to move an electron from its lowest energy (ground) state to some excited state.  $\infty$  (Section 6.3) Thus, the particular energies of radiation that a substance absorbs dictate the colors that it exhibits.

When a sample absorbs visible light, the color we perceive is the sum of the remaining colors that are reflected or transmitted by an object and strike our eyes. An opaque object reflects light, whereas a transparent one transmits it. If an object absorbs all wavelengths of visible light, none reaches our eyes from that object. Consequently, it appears black. If it absorbs no visible light, it is white or colorless. If it absorbs all but orange light, the material appears orange. We also perceive an orange color, however, when visible light of all colors except blue strikes our eyes. Orange and blue are **complementary colors**; the removal of blue from white light makes the light look orange, and vice versa. Thus, an object has a particular color for one of two reasons: (1) It reflects or transmits light of that color; (2) it absorbs light of the complementary color. Complementary colors can be determined using an artist's color wheel, shown in Figure 24.24 ◀. The wheel shows the colors of the visible spectrum, from red to violet. Complementary colors, such as orange and blue, appear as wedges opposite each other on the wheel.

▲ **Figure 24.24 Artist's color wheel.** Colors with approximate wavelength ranges are shown as wedges. The colors that are complementary to each other lie opposite each other.

#### ■ SAMPLE EXERCISE 24.7 | Relating Color Absorbed to Color Observed

The complex ion  $\text{trans-}[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$  absorbs light primarily in the red region of the visible spectrum (the most intense absorption is at 680 nm). What is the color of the complex?

#### ■ SOLUTION

**Analyze:** We need to relate the color absorbed by a complex (red) to the color observed for the complex.

**Plan:** The color observed for a substance is complementary to the color it absorbs. We can use the color wheel of Figure 24.24 to determine the complementary color.

**Solve:** From Figure 24.24, we see that green is complementary to red, so the complex appears green.

**Comment:** As noted in Section 24.1, in the text discussing Table 24.1, this green complex was one of those that helped Werner establish his theory of coordination. The other geometric isomer of this complex,  $\text{cis-}[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ , absorbs yellow light and therefore appears violet.

#### ■ PRACTICE EXERCISE

The  $[\text{Cr}(\text{H}_2\text{O})_6]^{2+}$  ion has an absorption band at about 630 nm. Which of the following colors—sky blue, yellow, green, or deep red—is most likely to describe this ion?  
*Answer:* sky blue

▲ **Figure 24.25 Experimental determination of an absorption spectrum.** The prism is rotated so that different wavelengths of light pass through the sample. The detector measures the amount of light reaching it, and this information can be displayed as the absorbance at each wavelength. The absorbance is a measure of the amount of light absorbed.

The amount of light absorbed by a sample as a function of wavelength is known as its **absorption spectrum**. The visible absorption spectrum of a transparent sample can be determined as shown in Figure 24.25▲. The spectrum of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ , which we will discuss in Section 24.6, is shown in Figure 24.26▶. The absorption maximum of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  is at about 500 nm, but the band is broad. Because the sample absorbs most strongly in the green and yellow regions of the visible spectrum, it appears red-violet.

## Magnetism

Many transition-metal complexes exhibit simple paramagnetism, as described in Sections 9.8 and 23.7. In such compounds the individual metal ions possess some number of unpaired electrons. It is possible to determine the number of unpaired electrons per metal ion from the degree of paramagnetism. The experiments reveal some interesting comparisons. Compounds of the complex ion  $[\text{Co}(\text{CN})_6]^{3-}$  have no unpaired electrons, for example, but compounds of the  $[\text{CoF}_6]^{3-}$  ion have four unpaired electrons per metal ion. Both complexes contain Co(III) with a  $3d^6$  electron configuration. ∞ (Section 7.4) Clearly, there is a major difference in the ways in which the electrons are arranged in the metal orbitals in these two cases. Any successful bonding theory must explain this difference, and we will present such a theory in Section 24.6.

### GIVE IT SOME THOUGHT

What is the electron configuration for (a) the Co atom and (b) the  $\text{Co}^{3+}$  ion? How many unpaired electrons does each possess? (See Section 7.4 to review electron configurations of ions.)

## 24.6 CRYSTAL-FIELD THEORY

Scientists have long recognized that many of the magnetic properties and colors of transition-metal complexes are related to the presence of *d* electrons in metal orbitals. In this section we will consider a model for bonding in transition-metal complexes, called the **crystal-field theory**, that accounts for many of the observed properties of these substances.\*

The ability of a metal ion to attract ligands such as water around itself is a Lewis acid–base interaction. ∞ (Section 16.11) The base—that is, the ligand—donates a pair of electrons into a suitable empty orbital on the metal, as shown

(a)

(b)

▶ **Figure 24.26 The color of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ .** (a) A solution containing the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion. (b) The visible absorption spectrum of the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion.

\*The name crystal field arose because the theory was first developed to explain the properties of solid crystalline materials, such as ruby. The same theoretical model applies to complexes in solution.

▲ **Figure 24.27 Metal–ligand bond formation.** The ligand, which acts as a Lewis base, donates charge to the metal via a metal hybrid orbital. The bond that results is strongly polar, with some covalent character. It is often sufficient to assume that the metal–ligand interaction is entirely electrostatic in character, as is done in the crystal-field model.

in Figure 24.27 ◀. Much of the attractive interaction between the metal ion and the surrounding ligands is due, however, to the electrostatic forces between the positive charge on the metal and negative charges on the ligands. If the ligand is ionic, as in the case of  $\text{Cl}^-$  or  $\text{SCN}^-$ , the electrostatic interaction occurs between the positive charge

on the metal center and the negative charge on the ligand. When the ligand is neutral, as in the case of  $\text{H}_2\text{O}$  or  $\text{NH}_3$ , the negative ends of these polar molecules, which contain an unshared electron pair, are directed toward the metal. In this case the attractive interaction is of the ion–dipole type. ◀◀ (Section 11.2) In either case the result is the same: The ligands are attracted strongly toward the metal center. Because of the electrostatic attraction between the positive metal ion and the electrons of the ligands, the complex formed by the metal ion and the ligands has a lower energy than the fully separated metal and ligands.

Although the positive metal ion is attracted to the electrons in the ligands, the  $d$  electrons on the metal ion feel a repulsion from the ligands (negative charges repel one another). Let's examine this effect more closely, and particularly for the case in which the ligands form an octahedral array around the metal ion. For the crystal-field model, we consider the ligands to be negative points of charge that repel the electrons in the  $d$  orbitals. Figure 24.28 ◀ shows the effects of these point charges on the energies of the  $d$  orbitals in two steps. In the first step the *average* energy of the  $d$  orbitals is raised by the presence of the point charges. Hence, all five  $d$  orbitals are raised in energy by the same amount. In the second step we consider what happens to the energies of the individual  $d$  orbitals when the ligands sit in an octahedral arrangement.

In a six-coordinate octahedral complex we can envision the ligands approaching along the  $x$ -,  $y$ -, and  $z$ -axes, as shown in Figure 24.29(a) ▶; this arrangement is called an *octahedral crystal field*. Because the  $d$  orbitals on the metal ion have different shapes, they do not all have the same energy under the influence of the crystal field. To see why, we must consider the shapes of the  $d$  orbitals and how their lobes are oriented relative to the ligands.

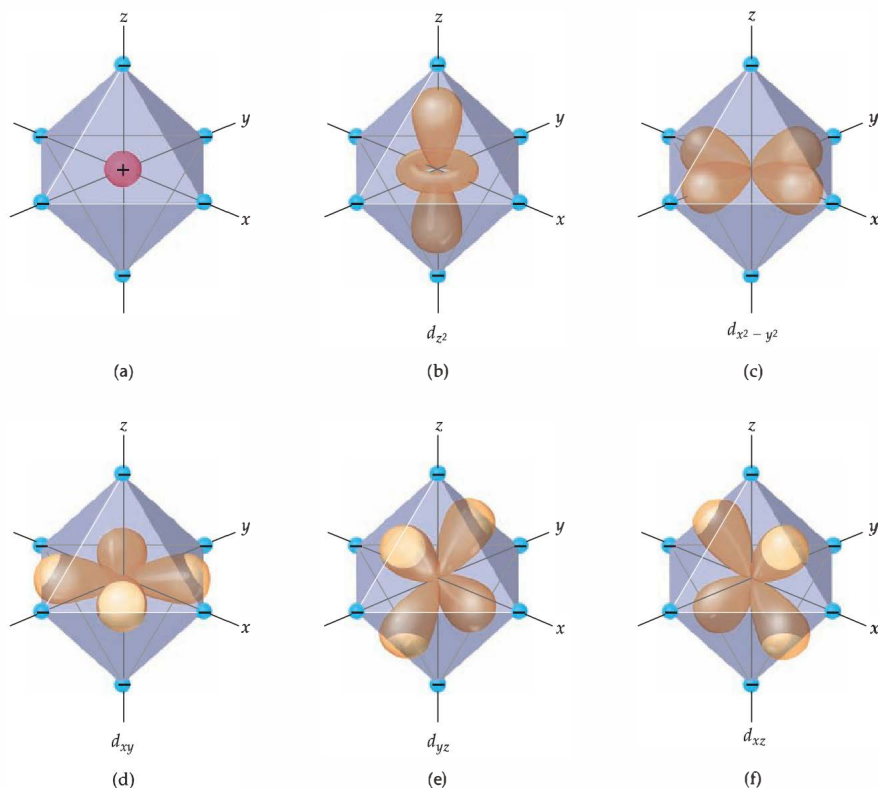

Figure 24.29(b–f) shows the five  $d$  orbitals in an octahedral crystal field. Notice that the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals have lobes directed *along* the  $x$ -,  $y$ -, and  $z$ -axes pointing *toward* the point charges, whereas the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals have lobes that are directed *between* the axes along which the charges approach. The high symmetry of the octahedral crystal field dictates that the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals experience the same amount of repulsion from the crystal field. Those two orbitals therefore have the same energy in the presence of the crystal field. Likewise, the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals experience exactly the same repulsion, so those three orbitals remain together in energy.

Because their lobes point directly at the negative ligand charges, electrons in the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals experience stronger repulsions than those in the  $d_{xy}$ ,  $d_{xz}$ ,  $d_{yz}$  orbitals. As a result, an energy separation, or splitting, occurs between the three lower-energy  $d$  orbitals (called the  $t_2$  set of orbitals) and the two higher-energy ones (called the  $e$  set),\* as shown on the right side of Figure 24.28. The energy gap between the two sets of  $d$  orbitals is labeled  $\Delta$ , a quantity that is often called the *crystal-field splitting energy*.

▼ **Figure 24.28 Energies of  $d$  orbitals in an octahedral crystal field.** On the left the energies of the  $d$  orbitals of a free ion are shown. When negative charges are brought up to the ion, the average energy of the  $d$  orbitals increases (center). On the right the splitting of the  $d$  orbitals that is due to the octahedral field is shown. Because the repulsion felt by the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals is greater than that felt by the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals, the five  $d$  orbitals split into a lower-energy set of three (the  $t_2$  set) and a higher-energy set of two (the  $e$  set).

\*The labels  $t_2$  for the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals and  $e$  for the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals come from the application of a branch of mathematics called group theory to crystal-field theory. Group theory can be used to analyze the effects of symmetry on molecular properties.

▲ **Figure 24.29** The five  $d$  orbitals in an octahedral crystal field. (a) An octahedral array of negative charges approaching a metal ion. (b–f) The orientations of the  $d$  orbitals relative to the negative charges. Notice that the lobes of the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals (b and c) point toward the charges, whereas the lobes of the  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$  orbitals (d–f) point between the charges.

### GIVE IT SOME THOUGHT

Which  $d$  orbitals have lobes that point directly toward the negative charges in an octahedral crystal field?

The crystal-field model helps us account for the observed colors in transition-metal complexes. The energy gap between the  $d$  orbitals,  $\Delta$ , is of the same order of magnitude as the energy of a photon of visible light. It is therefore possible for a transition-metal complex to absorb visible light, which excites an electron from the lower-energy  $d$  orbitals into the higher-energy ones. In the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion, for example, the Ti(III) ion has an  $[\text{Ar}]3d^1$  electron configuration (recall that when determining the electron configurations of transition-metal ions, we remove the  $s$  electrons first).  $\rightleftharpoons$  (Section 7.4) Ti(III) is thus called a “ $d^1$  ion.” In the ground state of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  the single  $3d$  electron resides in one of the three lower-energy orbitals in the  $t_2$  set. Absorption of light with a wavelength of 495 nm (242 kJ/mol) excites the  $3d$  electron from the lower  $t_2$  set to the upper  $e$  set of orbitals, as shown in Figure 24.30, generating the absorption spectrum shown in Figure 24.26. Because this transition involves exciting an electron from one set of  $d$  orbitals to the other, we call it a  $d$ - $d$  transition. As noted earlier, the absorption of visible radiation that produces this  $d$ - $d$  transition causes the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion to appear red-violet.

▲ **Figure 24.30** Electronic transition accompanying absorption of light. The  $3d$  electron of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  is excited from the lower-energy  $d$  orbitals to the higher-energy ones when irradiated with light of 495-nm wavelength.

## GIVE IT SOME THOUGHT

Why are compounds of Ti(IV) colorless?

The magnitude of the energy gap,  $\Delta$ , and consequently the color of a complex depend on both the metal and the surrounding ligands. For example,  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$  is light violet,  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$  is violet, and  $[\text{Cr}(\text{NH}_3)_6]^{3+}$  is yellow. Ligands can be arranged in order of their abilities to increase the energy gap,  $\Delta$ . The following is an abbreviated list of common ligands arranged in order of increasing  $\Delta$ :

This list is known as the **spectrochemical series**. The magnitude of  $\Delta$  increases by roughly a factor of 2 from the far left to the far right of the spectrochemical series.

Ligands that lie on the low- $\Delta$  end of the spectrochemical series are termed *weak-field ligands*; those on the high- $\Delta$  end are termed *strong-field ligands*. Figure 24.31  $\blacktriangledown$  shows schematically what happens to the crystal-field splitting

**▲ Figure 24.31** Effect of ligand on crystal-field splitting. This series of octahedral chromium(III) complexes illustrates how  $\Delta$ , the energy gap between the  $t_2$  and  $e$  orbitals, increases as the field strength of the ligand increases.

when the ligand is varied in a series of chromium(III) complexes. Because a Cr atom has an  $[\text{Ar}]3d^54s^1$  electron configuration,  $\text{Cr}^{3+}$  has an  $[\text{Ar}]3d^3$  electron configuration; Cr(III), therefore, is a  $d^3$  ion. Consistent with Hund's rule, the three  $3d$  electrons occupy the  $t_2$  set of orbitals, with one electron in each orbital and all the spins the same.  $\rightleftharpoons$  (Section 6.8) As the field exerted by the six surrounding ligands increases, the splitting of the metal  $d$  orbitals increases. Because the absorption spectrum is related to this energy separation, these complexes vary in color.

### SAMPLE EXERCISE 24.8 Using the Spectrochemical Series

Which of the following complexes of  $\text{Ti}^{3+}$  exhibits the shortest wavelength absorption in the visible spectrum:  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ ,  $[\text{Ti}(\text{en})_3]^{3+}$ , or  $[\text{TiCl}_6]^{3-}$ ?

#### SOLUTION

**Analyze:** We are given three octahedral complexes, each containing Ti in the +3 oxidation state. We need to predict which complex absorbs the shortest wavelength of visible light.

**Plan:** Ti(III) is a  $d^1$  ion, so we anticipate that the absorption is due to a  $d-d$  transition in which the  $3d$  electron is excited from the lower-energy  $t_2$  set to the higher-energy  $e$  set. The wavelength of the light absorbed is determined by the magnitude of the energy difference,  $\Delta$ . Thus, we use the position of the ligands in the spectrochemical series to predict the relative values of  $\Delta$ . The larger the energy, the shorter the wavelength (Equation 24.7).

**Solve:** Of the three ligands involved— $\text{H}_2\text{O}$ , en, and  $\text{Cl}^-$ —we see that ethylenediamine (en) is highest in the spectrochemical series and will therefore cause the largest splitting,  $\Delta$ , of the  $t_2$  and  $e$  sets of orbitals. The larger the splitting, the shorter the wavelength of the light absorbed. Thus, the complex that absorbs the shortest-wavelength light is  $[\text{Ti}(\text{en})_3]^{3+}$ .

#### PRACTICE EXERCISE

The absorption spectrum of  $[\text{Ti}(\text{NCS})_6]^{3-}$  shows a band that lies intermediate in wavelength between those for  $[\text{TiCl}_6]^{3-}$  and  $[\text{TiF}_6]^{3-}$ . What can we conclude about the place of  $\text{NCS}^-$  in the spectrochemical series?

**Answer:** It lies between  $\text{Cl}^-$  and  $\text{F}^-$ ; that is,  $\text{Cl}^- < \text{NCS}^- < \text{F}^-$ .

▲ **Figure 24.32 Electron configurations in octahedral complexes.** Orbital occupancies are shown for complexes with one, two, and three  $d$  electrons in an octahedral crystal field.

### Electron Configurations in Octahedral Complexes

The crystal-field model also helps us understand the magnetic properties and some important chemical properties of transition-metal ions. From Hund's rule, we expect that electrons will always occupy the lowest-energy vacant orbitals first and that they will occupy a set of degenerate orbitals one at a time with their spins parallel. ∞ (Section 6.8) Thus, if we have a  $d^1$ ,  $d^2$ , or  $d^3$  octahedral complex, the electrons will go into the lower-energy  $t_2$  set of orbitals, with their spins parallel, as shown in Figure 24.32 ▲. When a fourth electron must be added, a problem arises. If the electron is added to a lower-energy  $t_2$  orbital, an energy gain of magnitude  $\Delta$  is realized, as compared with placing the electron in a higher-energy  $e$  orbital. There is a penalty for doing this, however, because the electron must now be paired up with the electron already occupying the orbital. The energy required to do this, relative to putting it in another orbital with parallel spin, is called the **spin-pairing energy**. The spin-pairing energy arises from the greater electrostatic repulsion of two electrons that share an orbital as compared with two that are in different orbitals with the same electron spin.

The ligands that surround the metal ion and the charge on the metal ion often play major roles in determining which of the two electronic arrangements arises. In both the  $[\text{CoF}_6]^{3-}$  and  $[\text{Co}(\text{CN})_6]^{3-}$  ions, the ligands have a  $1-$  charge. The  $\text{F}^-$  ion, however, is on the low end of the spectrochemical series, so it is a weak-field ligand. The  $\text{CN}^-$  ion is on the high end of the spectrochemical series, so it is a strong-field ligand. It produces a larger energy gap than the  $\text{F}^-$  ion. The splittings of the  $d$ -orbital energies in these two complexes are compared in Figure 24.33 ►.

Cobalt(III) has an  $[\text{Ar}]3d^6$  electron configuration, so these are both  $d^6$  complexes. Let's imagine that we add these six electrons one at a time to the  $d$  orbitals of the  $\text{CoF}_6^{3-}$  ion. The first three will go into the lower-energy  $t_2$  orbitals with their spins parallel. The fourth electron could go into one of the  $t_2$  orbitals, pairing up with one of those already present. Doing so would result in an energy gain of  $\Delta$  as compared with putting the electron in one of the higher-energy  $e$  orbitals. However, it would cost energy in an amount equal to the spin-pairing energy. Because  $\text{F}^-$  is a weak-field ligand,  $\Delta$  is small, and the more stable arrangement is the one in which the electron is placed in one of the  $e$  orbitals. Similarly, the fifth electron we add goes into the other  $e$  orbital. With all of the orbitals containing at least one electron, the sixth must be paired up, and it goes into a lower-energy  $t_2$  orbital; we end up with four of the electrons in the  $t_2$  set of orbitals and two electrons in the  $e$  set. In the case of the  $[\text{Co}(\text{CN})_6]^{3-}$  complex, the crystal-field splitting is much larger. The spin-pairing energy is smaller than  $\Delta$ , so all six electrons are paired in the  $t_2$  orbitals, as illustrated in Figure 24.33.

The  $[\text{CoF}_6]^{3-}$  complex is a **high-spin complex**; that is, the electrons are arranged so that they remain unpaired as much as possible. The  $[\text{Co}(\text{CN})_6]^{3-}$  ion, on the other hand, is a **low-spin complex**; that is, the electrons are arranged so that they remain paired as much as possible. These two different electronic arrangements can be readily distinguished by measuring the magnetic properties of the complex, as described earlier. The absorption spectrum also shows characteristic features that indicate the electronic arrangement.

Metal ions of the second and third transition series (those with  $4d$  and  $5d$  electrons) have larger  $d$ -orbitals than those from the first series ( $3d$  electrons). Thus, these ions interact more strongly with ligands, resulting in a larger crystal-field splitting. Consequently, metal ions of the second and third transition series are invariably low spin in an octahedral crystal field.

▲ **Figure 24.33 High-spin and low-spin complexes.** Populations of  $d$  orbitals are compared for the high-spin  $[\text{CoF}_6]^{3-}$  ion (small  $\Delta$ ) and the low-spin  $[\text{Co}(\text{CN})_6]^{3-}$  ion (large  $\Delta$ ). Both complexes contain cobalt(III), which has six  $3d$  electrons,  $3d^6$ .

### ■ SAMPLE EXERCISE 24.9 Predicting the Number of Unpaired Electrons in an Octahedral Complex

Predict the number of unpaired electrons in six-coordinate high-spin and low-spin complexes of  $\text{Fe}^{3+}$ .

#### SOLUTION

**Analyze:** We must determine how many unpaired electrons there are in the high-spin and low-spin complexes of the metal ion  $\text{Fe}^{3+}$ .

**Plan:** We need to consider how the electrons populate  $d$  orbitals for  $\text{Fe}^{3+}$  when the metal is in an octahedral complex. There are two possibilities: one giving a high-spin complex and the other giving a low-spin complex. The electron configuration of  $\text{Fe}^{3+}$  gives us the number of  $d$  electrons. We then determine how these electrons populate the  $t_2$  set and  $e$  set of  $d$  orbitals. In the high-spin case, the energy difference between the  $t_2$  and  $e$  orbitals is small, and the complex has the maximum number of unpaired electrons. In the low-spin case, the energy difference between the  $t_2$  and  $e$  orbitals is large, causing the  $t_2$  orbitals to be filled before any electrons occupy the  $e$  orbitals.

**Solve:**  $\text{Fe}^{3+}$  is a  $d^5$  ion. In a high-spin complex, all five of these electrons are unpaired, with three in the  $t_2$  orbitals and two in the  $e$  orbitals. In a low-spin complex, all five electrons reside in the  $t_2$  set of  $d$  orbitals, so there is one unpaired electron:

#### ■ PRACTICE EXERCISE

For which  $d$  electron configurations in octahedral complexes is it possible to distinguish between high-spin and low-spin arrangements?

*Answer:*  $d^4, d^5, d^6, d^7$

▲ **Figure 24.34** Energies of the  $d$  orbitals in a tetrahedral crystal field.

▲ **Figure 24.35** Energies of the  $d$  orbitals in a square-planar crystal field. The boxes on the left show the energies of the  $d$  orbitals in an octahedral crystal field. As the two negative charges along the  $z$ -axis are removed, the energies of the  $d$  orbitals change, as indicated by the lines between the boxes. When the charges are completely removed, the square-planar geometry results, giving the splitting of  $d$ -orbital energies represented by the boxes on the right.

## Tetrahedral and Square-Planar Complexes

Thus far we have considered the crystal-field model only for complexes having an octahedral geometry. When there are only four ligands about the metal, the geometry is generally tetrahedral, except for the special case of metal ions with a  $d^8$  electron configuration, which we will discuss in a moment. The crystal-field splitting of the metal  $d$  orbitals in tetrahedral complexes differs from that in octahedral complexes. Four equivalent ligands can interact with a central metal ion most effectively by approaching along the vertices of a tetrahedron. It turns out—and this is not easy to explain in just a few sentences—that the splitting of the metal  $d$  orbitals in a tetrahedral crystal is just the opposite of that for the octahedral case. That is, the three metal  $d$  orbitals in the  $t_2$  set are raised in energy, and the two orbitals in the  $e$  set are lowered, as illustrated in Figure 24.34 ◀. Because there are only four ligands instead of six, as in the octahedral case, the crystal-field splitting is much smaller for tetrahedral complexes. Calculations show that for the same metal ion and ligand set, the crystal-field splitting for a tetrahedral complex is only four-ninths as large as for the octahedral complex. For this reason, all tetrahedral complexes are high spin; the crystal field is never large enough to overcome the spin-pairing energies.

Square-planar complexes, in which four ligands are arranged about the metal ion in a plane, can be envisioned as formed by removing two ligands from along the vertical  $z$ -axis of the octahedral complex. The changes that occur in the energy levels of the  $d$  orbitals are illustrated in Figure 24.35 ◀. Note in particular that the  $d_{z^2}$  orbital is now considerably lower in energy than the  $d_{x^2-y^2}$  orbital because the ligands along the vertical  $z$ -axis have been removed.

Square-planar complexes are characteristic of metal ions with a  $d^8$  electron configuration. They are nearly always low spin; that is, the eight  $d$  electrons are spin-paired to form a diamagnetic complex. Such an electronic arrangement is particularly common among the ions of heavier metals, such as  $\text{Pd}^{2+}$ ,  $\text{Pt}^{2+}$ ,  $\text{Ir}^+$ , and  $\text{Au}^{3+}$ .

### GIVE IT SOME THOUGHT

Why is the energy of the  $d_{xz}$  and  $d_{yz}$  orbitals lower than that of the  $d_{xy}$  orbital in square-planar complexes?

#### SAMPLE EXERCISE 24.10 | Populating $d$ Orbitals in Tetrahedral and Square-Planar Complexes

Four-coordinate nickel(II) complexes exhibit both square-planar and tetrahedral geometries. The tetrahedral ones, such as  $[\text{NiCl}_4]^{2-}$ , are paramagnetic; the square-planar ones, such as  $[\text{Ni}(\text{CN})_4]^{2-}$ , are diamagnetic. Show how the  $d$  electrons of nickel(II) populate the  $d$  orbitals in the appropriate crystal-field splitting diagram in each case.

#### SOLUTION

**Analyze:** We are given two complexes containing  $\text{Ni}^{2+}$ , a tetrahedral one and a square-planar one. We are asked to use the appropriate crystal-field diagrams to describe how the  $d$  electrons populate the  $d$  orbitals in each case.

**Plan:** We need to first determine the number of  $d$  electrons possessed by  $\text{Ni}^{2+}$  and then use Figure 24.34 for the tetrahedral complex and Figure 24.35 for the square-planar complex.

**Solve:** Nickel(II) has an electron configuration of  $[\text{Ar}]3d^8$ . The population of the  $d$  electrons in the two geometries is

**Comment:** Notice that the tetrahedral complex is paramagnetic with two unpaired electrons, whereas the square-planar complex is diamagnetic. Nickel(II) forms octahedral complexes more frequently than square-planar ones, whereas heavier  $d^8$  metals tend to favor square planar coordination.

#### PRACTICE EXERCISE

How many unpaired electrons do you predict for the tetrahedral  $[\text{CoCl}_4]^{2-}$  ion?

**Answer:** three

We have seen that the crystal-field model provides a basis for explaining many features of transition-metal complexes. In fact, it can be used to explain many observations in addition to those we have discussed. Many lines of evidence show, however, that the bonding between transition-metal ions and ligands must have some covalent character. Molecular-orbital theory (Sections 9.7 and 9.8) can also be used to describe the bonding in complexes, although the application of molecular-orbital theory to coordination compounds is beyond the scope of our discussion. The crystal-field model, although not entirely accurate in all details, provides an adequate and useful first description of the electronic structure of complexes.

## A Closer Look

## CHARGE-TRANSFER COLOR

▲ **Figure 24.36 Effect of charge-transfer transitions.** The compounds  $\text{KMnO}_4$ ,  $\text{K}_2\text{CrO}_4$ , and  $\text{KClO}_4$  are shown from left to right. The  $\text{KMnO}_4$  and  $\text{K}_2\text{CrO}_4$  are intensely colored because of ligand-to-metal charge transfer (LMCT) transitions in the  $\text{MnO}_4^-$  and  $\text{CrO}_4^{2-}$  anions. There are no valence  $d$  orbitals on Cl, so the charge-transfer transition for  $\text{ClO}_4^-$  requires ultraviolet light and  $\text{KClO}_4$  is white.

In the laboratory portion of your course, you have probably seen many colorful compounds of the transition metals. Many of these exhibit color because of  $d-d$  transitions, in which visible light excites electrons from one  $d$  orbital to another. There are other colorful transition-metal complexes, however, that derive their color from a rather different type of excitation involving the  $d$  orbitals. Two such common substances are the deep violet permanganate ion ( $\text{MnO}_4^-$ ) and the bright yellow chromate ion ( $\text{CrO}_4^{2-}$ ), salts of which are shown in Figure 24.36 ▲. Both  $\text{MnO}_4^-$  and  $\text{CrO}_4^{2-}$  are tetrahedral complexes.

The permanganate ion strongly absorbs visible light with a maximum absorption at a wavelength of 565 nm. The strong absorption in the yellow portion of the visible spectrum is responsible for the violet appearance of salts and solutions of the ion (violet is the complementary color to yellow). What is happening during this absorption? The  $\text{MnO}_4^-$  ion is a complex of Mn(VII), which has a  $d^0$  electron configuration. As such, the absorption in the complex cannot be due to a  $d-d$  transition because there are no  $d$  electrons to excite! That does not mean, however, that the  $d$  orbitals are not involved in the transition. The excitation in the  $\text{MnO}_4^-$  ion is due to a *charge-transfer transition*, in which an electron on one of the oxygen ligands is excited into a vacant  $d$  orbital on the Mn atom (Figure 24.37 ►). In essence, an electron is transferred from a ligand to the metal, so this transition is called a *ligand-to-metal charge-transfer (LMCT) transition*. An LMCT transition is also responsible for the color of the  $\text{CrO}_4^{2-}$ , which is a  $d^0$  Cr(VI) complex. Also shown in Figure 24.36 is a salt of the perchlorate ion ( $\text{ClO}_4^-$ ). Like  $\text{MnO}_4^-$ , the  $\text{ClO}_4^-$  is tetrahedral and has

its central atom in the +7 oxidation state. However, because the Cl atom does not have low-lying  $d$  orbitals, exciting an electron requires a more energetic photon than for  $\text{MnO}_4^-$ . The first absorption for  $\text{ClO}_4^-$  is in the ultraviolet portion of the spectrum, so all the visible light is transmitted and the salt appears white.

Other complexes exhibit charge-transfer excitations in which an electron from the metal atom is excited to an empty orbital on a ligand. Such an excitation is called a *metal-to-ligand charge-transfer (MLCT) transition*.

Charge-transfer transitions are generally more intense than  $d-d$  transitions. Many metal-containing pigments used for oil painting, such as cadmium yellow ( $\text{CdS}$ ), chrome yellow ( $\text{PbCrO}_4$ ), and red ochre ( $\text{Fe}_2\text{O}_3$ ) have intense colors because of charge-transfer transitions.

**Related Exercise:** 24.64

◀ **Figure 24.37 Ligand-to-metal charge transfer (LMCT) transition in  $\text{MnO}_4^-$ .** As shown by the blue arrow, an electron is excited from a nonbonding pair on O into one of the empty  $d$  orbitals on Mn.

### SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

The oxalate ion has the Lewis structure shown in Table 24.2. (a) Show the geometrical structure of the complex formed by coordination of oxalate to cobalt(II), forming  $[\text{Co}(\text{C}_2\text{O}_4)(\text{H}_2\text{O})_4]$ . (b) Write the formula for the salt formed upon coordination of three oxalate ions to Co(II), assuming that the charge-balancing cation is  $\text{Na}^+$ . (c) Sketch all the possible geometric isomers for the cobalt complex formed in part (b). Are any of these isomers chiral? Explain. (d) The equilibrium constant for the formation of the cobalt(II) complex produced by coordination of three oxalate anions, as in part (b), is  $5.0 \times 10^9$ . By comparison, the formation constant for formation of the cobalt(II) complex with three molecules of *ortho*-phenanthroline (Table 24.2) is  $9 \times 10^{19}$ .

From these results, what conclusions can you draw regarding the relative Lewis base properties of the two ligands toward cobalt(II)? (e) Using the approach described in Sample Exercise 17.14, calculate the concentration of free aqueous Co(II) ion in a solution initially containing 0.040 M oxalate ion and 0.0010 M  $\text{Co}^{2+}(\text{aq})$ .

### SOLUTION

(a) The complex formed by coordination of one oxalate ion is octahedral:

(b) Because the oxalate ion has a charge of  $2^-$ , the net charge of a complex with three oxalate anions and one  $\text{Co}^{2+}$  ion is  $4^-$ . Therefore, the coordination compound has the formula  $\text{Na}_4[\text{Co}(\text{C}_2\text{O}_4)_3]$ .

(c) There is only one geometric isomer. The complex is chiral, however, in the same way as the  $[\text{Co}(\text{en})_3]^{3+}$  complex, shown in Figure 24.20(b). These two mirror images are not superimposable, so there are two enantiomers:

(d) The *ortho*-phenanthroline ligand is bidentate, like the oxalate ligand, so they both exhibit the chelate effect. Thus, we can conclude that *ortho*-phenanthroline is a stronger Lewis base toward  $\text{Co}^{2+}$  than oxalate. This conclusion is consistent with what we learned about bases in Section 16.7, namely that nitrogen bases are generally stronger than oxygen bases. (Recall, for example, that  $\text{NH}_3$  is a stronger base than  $\text{H}_2\text{O}$ .)

(e) The equilibrium we must consider involves three moles of oxalate ion (represented as  $\text{Ox}^{2-}$ ).

The formation-constant expression is

$$K_f = \frac{[\text{Co}(\text{Ox})_3]^{4-}}{[\text{Co}^{2+}][\text{Ox}^{2-}]^3}$$

Because  $K_f$  is so large, we can assume that essentially all of the  $\text{Co}^{2+}$  is converted to the oxalato complex. Under that assumption, the final concentration of  $[\text{Co}(\text{Ox})_3]^{4-}$  is 0.0010 M and that of oxalate ion is  $[\text{Ox}^{2-}] = (0.040) - 3(0.0010) = 0.037 \text{ M}$  (three  $\text{Ox}^{2-}$  ions react with each  $\text{Co}^{2+}$  ion).

We then have

$$[\text{Co}^{2+}] = x \text{ M}, [\text{Ox}^{2-}] \cong 0.037 \text{ M}, [[\text{Co}(\text{Ox})_3]^{4-}] \cong 0.0010 \text{ M}$$

Inserting these values into the equilibrium-constant expression, we have

$$K_f = \frac{(0.0010)}{x(0.037)^3} = 5 \times 10^9$$

Solving for  $x$ , we obtain  $4 \times 10^{-9} \text{ M}$ . From this, we can see that the oxalate has complexed all but a tiny fraction of the  $\text{Co}^{2+}$  present in solution.

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Section 24.1** Coordination compounds are substances that contain **metal complexes**. Metal complexes contain metal ions bonded to several surrounding anions or molecules known as **ligands**. The metal ion and its ligands comprise the **coordination sphere** of the complex. The atom of the ligand that bonds to the metal ion is the **donor atom**. The number of donor atoms attached to the metal ion is the **coordination number** of the metal ion. The most common coordination numbers are 4 and 6; the most common coordination geometries are tetrahedral, square planar, and octahedral.

**Sections 24.2 and 24.3** Ligands that occupy only one site in a coordination sphere are called **monodentate ligands**. If a ligand has several donor atoms that can coordinate simultaneously to the metal ion, it is a **polydentate ligand** and is referred to as a **chelating agent**. Two common examples are ethylenediamine, denoted en, which is a **bidentate ligand**, and the ethylenediaminetetraacetate ion,  $[\text{EDTA}]^{4-}$ , which has six potential donor atoms. In general, chelating agents form more stable complexes than do related monodentate ligands, an observation known as the **chelate effect**. Many biologically important molecules, such as the **porphyrins**, are complexes of chelating agents. A related group of plant pigments known as **chlorophylls** are important in **photosynthesis**, the process by which plants use solar energy to convert  $\text{CO}_2$  and  $\text{H}_2\text{O}$  into carbohydrates.

As in the nomenclature of other inorganic compounds, specific rules are followed for naming coordination compounds. In general, the number and type of ligands attached to the metal ion are specified, as is the oxidation state of the metal ion.

**Section 24.4** **Isomers** are compounds with the same composition but different arrangements of atoms and therefore different properties. **Structural isomers** differ in the bonding arrangements of the ligands. One simple form of structural isomerism, known as **linkage isomerism**, occurs when a ligand is capable of coordinating to a metal ion through either of two donor atoms. **Coordination-sphere isomers** contain different ligands in the coordination sphere.

**Stereoisomers** are isomers with the same chemical bonding arrangements but different spatial arrangements of ligands. The most common forms of stereoisomerism are **geometric isomerism** and **optical isomerism**. Geometric isomers differ from one another in the relative locations of donor atoms in the coordination sphere; the most common are *cis-trans* isomers. Optical isomers are nonsuperimposable mirror images of one another. Geometric isomers differ from one another in their chemical and physical properties; optical isomers or **enantiomers** are **chiral**, however, meaning that they have a specific

“handedness” and they differ only in the presence of a chiral environment. Optical isomers can be distinguished from one another by their interactions with plane-polarized light; solutions of one isomer rotate the plane of polarization to the right (**dextrorotatory**), and solutions of its mirror image rotate the plane to the left (**levorotatory**). Chiral molecules, therefore, are **optically active**. A 50–50 mixture of two optical isomers does not rotate plane-polarized light and is said to be **racemic**.

**Section 24.5** Studies of the colors and magnetic properties of transition-metal complexes have played important roles in the formulation of bonding theories for these compounds. A substance has a particular color because it either (1) reflects or transmits light of that color or (2) absorbs light of the **complementary color**. The amount of light absorbed by a sample as a function of wavelength is known as its **absorption spectrum**. The light absorbed provides the energy to excite electrons to higher-energy states.

It is possible to determine the number of unpaired electrons in a complex from its degree of paramagnetism. Compounds with no unpaired electrons are diamagnetic.

**Section 24.6** The **crystal-field theory** successfully accounts for many properties of coordination compounds, including their color and magnetism. In this model the interaction between metal ion and ligand is viewed as electrostatic. Because some *d* orbitals are pointing right at the ligands whereas others point between them, the ligands split the energies of the metal *d* orbitals. For an octahedral complex, the *d* orbitals are split into a lower-energy set of three degenerate orbitals (the  $t_2$  set) and a higher-energy set of two degenerate orbitals (the *e* set). Visible light can cause a ***d-d* transition**, in which an electron is excited from a lower-energy *d* orbital to a higher-energy *d* orbital. The **spectrochemical series** lists ligands in order of their ability to split the *d*-orbital energies in octahedral complexes.

Strong-field ligands create a splitting of *d*-orbital energies that is large enough to overcome the **spin-pairing energy**. The *d* electrons then preferentially pair up in the lower-energy orbitals, producing a **low-spin complex**. When the ligands exert a weak crystal field, the splitting of the *d* orbitals is small. The electrons then occupy the higher-energy *d* orbitals in preference to pairing up in the lower-energy set, producing a **high-spin complex**.

The crystal-field model also applies to tetrahedral and square-planar complexes, which leads to different *d*-orbital splitting patterns. In a tetrahedral crystal field, the splitting of the *d* orbitals is exactly opposite that of the octahedral case. The splitting by a tetrahedral crystal field is much smaller than that of an octahedral crystal field, so tetrahedral complexes are always high-spin complexes.

## KEY SKILLS

- Determine the oxidation number and number of  $d$  electrons for metal ions in complexes.
- Name coordination compounds given their formula and write their formula given their name.
- Recognize and draw the geometric isomers of a complex.
- Recognize and draw the optical isomers of a complex.
- Use crystal-field theory to explain the colors and to determine the number of unpaired electrons in a complex.

## VISUALIZING CONCEPTS

**24.1** (a) Draw the structure for  $\text{Pt}(\text{en})\text{Cl}_2$ . (b) What is the coordination number for platinum in this complex, and what is the coordination geometry? (c) What is the oxidation state of the platinum? [Section 24.1]

**24.2** Draw the Lewis structure for the ligand shown below. (a) Which atoms can serve as donor atoms? Classify this ligand as monodentate, bidentate, or tridentate. (b) How many of these ligands are needed to fill the coordination sphere in an octahedral complex? [Section 24.2]

**24.3** The complex ion shown below has a  $1-$  charge. Name the complex ion. [Section 24.3]

**24.4** There are two geometric isomers of octahedral complexes of the type  $\text{MA}_3\text{X}_3$ , where M is a metal and A and X are monodentate ligands. Of the complexes shown here, which are identical to (1) and which are the geometric isomers of (1)? [Section 24.4]

**24.5** Which of the following complexes are chiral? Explain. [Section 24.4]

**24.6** Assume that the two solutions shown below have an absorption spectrum with a single absorption peak like that shown in Figure 24.26. What color does each solution absorb most strongly? [Section 24.5]

**24.7** Consider the following crystal-field splitting diagrams. Select the one that fits each of the following descriptions: (a) a weak-field octahedral complex of  $\text{Fe}^{3+}$ , (b) a strong-field octahedral complex of  $\text{Fe}^{3+}$ , (c) a tetrahedral complex of  $\text{Fe}^{3+}$ , (d) a tetrahedral complex of  $\text{Ni}^{2+}$ . (The diagrams do not indicate the relative magnitudes of  $\Delta$ .) [Section 24.6]

- 24.8 Consider the accompanying linear crystal field, in which the negative charges are on the  $z$ -axis. Using Figure 24.29 as a guide, predict which  $d$  orbital has lobes closest to the charges. Which two have lobes farthest from the charges? Predict the crystal-field splitting of the  $d$  orbitals in linear complexes. [Section 24.6]

## EXERCISES

### Introduction to Metal Complexes

- 24.9 (a) What is the difference between Werner's concepts of *primary valence* and *secondary valence*? What terms do we now use for these concepts? (b) Why can the  $\text{NH}_3$  molecule serve as a ligand but the  $\text{BH}_3$  molecule cannot?
- 24.10 (a) What is the meaning of the term *coordination number* as it applies to metal complexes? (b) Generally speaking, what structural feature characterizes substances that can serve as ligands in metal complexes? Give an example of a ligand that is neutral and one that is negatively charged. (c) Would you expect ligands that are positively charged to be common? Explain. (d) What type of chemical bonding is characteristic of coordination compounds? Illustrate with the compound  $\text{Co}(\text{NH}_3)_6\text{Cl}_3$ .
- 24.11 A complex is written as  $\text{NiBr}_2 \cdot 6 \text{NH}_3$  (a) What is the oxidation state of the Ni atom in this complex? (b) What is the likely coordination number for the complex? (c) If the complex is treated with excess  $\text{AgNO}_3(aq)$ , how many moles of  $\text{AgBr}$  will precipitate per mole of complex?
- 24.12 A certain complex of metal M is formulated as  $\text{MCl}_3 \cdot 3 \text{H}_2\text{O}$ . The coordination number of the complex is not known but is expected to be 4 or 6. (a) Would conductivity measurements provide information about the coordination number? (b) In using conductivity measurements to test which ligands are bound to the metal ion, what assumption is made about the rate at which ligands enter or leave the coordination sphere of the metal?
- 24.13 Indicate the coordination number of the metal and the oxidation number of the metal in each of the following complexes:
- $\text{Na}_2[\text{CdCl}_4]$
  - $\text{K}_2[\text{MoOCl}_4]$
  - $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$
  - $[\text{Ni}(\text{CN})_5]^{3-}$
  - $\text{K}_3[\text{V}(\text{C}_2\text{O}_4)_3]$
  - $[\text{Zn}(\text{en})_2]\text{Br}_2$
- 24.14 Indicate the coordination number of the metal and the oxidation number of the metal in each of the following complexes:
- $\text{K}_3[\text{Co}(\text{CN})_6]$
  - $\text{Na}_2[\text{CdBr}_4]$
  - $[\text{Pt}(\text{en})_3](\text{ClO}_4)_4$
  - $[\text{Co}(\text{en})_2(\text{C}_2\text{O}_4)]^+$
  - $\text{NH}_4[\text{Cr}(\text{NH}_3)_2(\text{NCS})_4]$
  - $[\text{Cu}(\text{bipy})_2]\text{I}$
- 24.15 Determine the number and type of each donor atom in each of the complexes in Exercise 24.13.
- 24.16 What are the number and types of donor atoms in each of the complexes in Exercise 24.14?

### Polydentate Ligands; Nomenclature

- 24.17 (a) What is the difference between a monodentate ligand and a bidentate ligand? (b) How many bidentate ligands are necessary to fill the coordination sphere of a six-coordinate complex? (c) You are told that a certain molecule can serve as a tridentate ligand. Based on this statement, what do you know about the molecule?
- 24.18 For each of the following polydentate ligands, determine (i) the maximum number of coordination sites that the ligand can occupy on a single metal ion and (ii) the number and type of donor atoms in the ligand: (a) ethylenediamine (en), (b) bipyridine (bipy), (c) the oxalate anion ( $\text{C}_2\text{O}_4^{2-}$ ), (d) the 2<sup>-</sup> ion of the porphine molecule (Figure 24.8); (e)  $[\text{EDTA}]^{4-}$ .
- 24.19 Polydentate ligands can vary in the number of coordination positions they occupy. In each of the following, identify the polydentate ligand present and indicate the probable number of coordination positions it occupies:
- $[\text{Co}(\text{NH}_3)_4(o\text{-phen})]\text{Cl}_3$
  - $[\text{Cr}(\text{C}_2\text{O}_4)(\text{H}_2\text{O})_4]\text{Br}$
  - $[\text{Cr}(\text{EDTA})(\text{H}_2\text{O})]^-$
  - $[\text{Zn}(\text{en})_2](\text{ClO}_4)_2$
- 24.20 Indicate the likely coordination number of the metal in each of the following complexes:
- $[\text{Rh}(\text{bipy})_3](\text{NO}_3)_3$
  - $\text{Na}_3[\text{Co}(\text{C}_2\text{O}_4)_2\text{Cl}_2]$
  - $[\text{Cr}(o\text{-phen})_3](\text{CH}_3\text{COO})_3$
  - $\text{Na}_2[\text{Co}(\text{EDTA})\text{Br}]$

**24.21** (a) What is meant by the term *chelate effect*? (b) What thermodynamic factor is generally responsible for the chelate effect? (c) Why are polydentate ligands often called *sequestering agents*?

**24.22** Pyridine ( $C_5H_5N$ ), abbreviated py, is the following molecule:

- (a) Why is pyridine referred to as a monodentate ligand?  
 (b) Consider the following equilibrium reaction:

What would you predict for the magnitude of the equilibrium constant for this equilibrium? Explain the basis for your answer.

**24.23** Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:

- (a) hexaamminechromium(III) nitrate  
 (b) tetraamminecarbonatocobalt(III) sulfate  
 (c) dichlorobis(ethylenediamine)platinum(IV) bromide  
 (d) potassium diaquatetabromovanadate(III)  
 (e) bis(ethylenediamine)zinc(II) tetraiodomercurate(II)

## Isomerism

**24.27** By writing formulas or drawing structures related to any one of these three complexes,

illustrate (a) geometric isomerism, (b) linkage isomerism, (c) optical isomerism, (d) coordination-sphere isomerism.

**24.28** (a) Draw the two linkage isomers of  $[Co(NH_3)_5SCN]^{2+}$ .  
 (b) Draw the two geometric isomers of  $[Co(NH_3)_3Cl_3]^{2+}$ .  
 (c) Two compounds with the formula  $Co(NH_3)_5ClBr$  can be prepared. Use structural formulas to show how they differ. What kind of isomerism does this illustrate?

**24.24** Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:

- (a) tetraaquadibromomanganese(III) perchlorate  
 (b) bis(bipyridyl)cadmium(II) chloride  
 (c) potassium tetrabromo(*ortho*-phenanthroline)-cobaltate (III)  
 (d) cesium diamminetetracyanochromate(III)  
 (e) tris(ethylenediamine)rhodium(III) tris(oxalato)-cobaltate(III)

**24.25** Write the names of the following compounds, using the standard nomenclature rules for coordination complexes:

- (a)  $[Rh(NH_3)_4Cl_2]Cl$   
 (b)  $K_2[TiCl_6]$   
 (c)  $MoOCl_4$   
 (d)  $[Pt(H_2O)_4(C_2O_4)]Br_2$

**24.26** Write names for the following coordination compounds:

- (a)  $[Cd(en)Cl_2]$   
 (b)  $K_4[Mn(CN)_6]$   
 (c)  $[Cr(NH_3)_5CO_3]Cl$   
 (d)  $[Ir(NH_3)_4(H_2O)_2](NO_3)_3$

## Color; Magnetism; Crystal-Field Theory

**24.33** (a) To the closest 100 nm, what are the largest and smallest wavelengths of visible light? (b) What is meant by the term *complementary color*? (c) What is the significance of complementary colors in understanding the colors of metal complexes? (d) If a complex absorbs light at 610 nm, what is the energy of this absorption in kJ/mol?

**24.34** (a) A complex absorbs light with wavelength of 530 nm. Do you expect it to have color? (b) A solution of a compound appears green. Does this observation necessarily mean that all colors of visible light other than green are absorbed by the solution? Explain. (c) What information is usually presented in a *visible absorption spectrum* of a compound? (d) What energy is associated with the absorption at 530 nm in kJ/mol?

**24.35** In crystal-field theory, ligands are modeled as if they are point negative charges. What is the basis of this assumption, and how does it relate to the nature of metal-ligand bonds?

**24.29** A four-coordinate complex  $MA_2B_2$  is prepared and found to have two different isomers. Is it possible to determine from this information whether the complex is square planar or tetrahedral? If so, which is it?

**24.30** Consider an octahedral complex  $MA_3B_3$ . How many geometric isomers are expected for this compound? Will any of the isomers be optically active? If so, which ones?

**24.31** Sketch all the possible stereoisomers of (a) tetrahedral  $[Cd(H_2O)_2Cl_2]$ , (b) square-planar  $[IrCl_2(PH_3)_2]^-$ , (c) octahedral  $[Fe(o-phen)_2Cl_2]^+$ .

**24.32** Sketch all the possible stereoisomers of (a)  $[Rh(bipy)(o-phen)_2]^{3+}$ , (b)  $[Co(NH_3)_3(bipy)Br]^{2+}$ , (c) square-planar  $[Pd(en)(CN)_2]$ .

**24.36** Explain why the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals lie lower in energy than the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals in the presence of an octahedral arrangement of ligands about the central metal ion.

**24.37** (a) Sketch a diagram that shows the definition of the *crystal-field splitting energy* ( $\Delta$ ) for an octahedral crystal field. (b) What is the relationship between the magnitude of  $\Delta$  and the energy of the  $d-d$  transition for a  $d^1$  complex? (c) Calculate  $\Delta$  in kJ/mol if a  $d^1$  complex has an absorption maximum at 590 nm.

**24.38** As shown in Figure 24.26, the  $d-d$  transition of  $[Ti(H_2O)_6]^{3+}$  produces an absorption maximum at a wavelength of about 500 nm. (a) What is the magnitude of  $\Delta$  for  $[Ti(H_2O)_6]^{3+}$  in kJ/mol? (b) What is the *spectrochemical series*? How would the magnitude of  $\Delta$  change if the  $H_2O$  ligands in  $[Ti(H_2O)_6]^{3+}$  were replaced with  $NH_3$  ligands?

- 24.39** Explain why many cyano complexes of divalent transition-metal ions are yellow, whereas many aqua complexes of these ions are blue or green.
- 24.40** The  $[\text{Ni}(\text{H}_2\text{O})_6]^{2+}$  ion has an absorption maximum at about 725 nm, whereas the  $[\text{Ni}(\text{NH}_3)_6]^{2+}$  ion absorbs at about 570 nm. Predict the color of each ion. (b) The  $[\text{Ni}(\text{en})_3]^{2+}$  ion absorption maximum occurs at about 545 nm, and that of the  $[\text{Ni}(\text{bipy})_3]^{2+}$  ion occurs at about 520 nm. From these data, indicate the relative strengths of the ligand fields created by the four ligands involved.
- 24.41** Give the number of  $d$  electrons associated with the central metal ion in each of the following complexes: (a)  $\text{K}_3[\text{TiCl}_6]$ , (b)  $\text{Na}_3[\text{Co}(\text{NO}_2)_6]$ , (c)  $[\text{Ru}(\text{en})_3]\text{Br}_3$ , (d)  $[\text{Mo}(\text{EDTA})]\text{ClO}_4$ , (e)  $\text{K}_3[\text{ReCl}_6]$ .
- 24.42** Give the number of  $d$  electrons associated with the central metal ion in each of the following complexes: (a)  $\text{K}_3[\text{Fe}(\text{CN})_6]$ , (b)  $[\text{Mn}(\text{H}_2\text{O})_6](\text{NO}_3)_2$ , (c)  $\text{Na}[\text{Ag}(\text{CN})_2]$ , (d)  $[\text{Cr}(\text{NH}_3)_4\text{Br}_2]\text{ClO}_4$ , (e)  $[\text{Sr}(\text{EDTA})]^{2-}$ .
- 24.43** For each of the following metals, write the electronic configuration of the atom and its  $2+$  ion: (a) Mn, (b) Ru, (c) Rh. Draw the crystal-field energy-level diagram for the  $d$  orbitals of an octahedral complex, and show the placement of the  $d$  electrons for each  $2+$  ion, assuming a strong-field complex. How many unpaired electrons are there in each case?
- 24.44** For each of the following metals, write the electronic configuration of the atom and its  $3+$  ion: (a) Ru, (b) Mo, (c) Co. Draw the crystal-field energy-level diagram for the  $d$  orbitals of an octahedral complex, and show the placement of the  $d$  electrons for each  $3+$  ion, assuming a weak-field complex. How many unpaired electrons are there in each case?
- 24.45** Draw the crystal-field energy-level diagrams and show the placement of  $d$  electrons for each of the following: (a)  $[\text{Cr}(\text{H}_2\text{O})_6]^{2+}$  (four unpaired electrons), (b)  $[\text{Mn}(\text{H}_2\text{O})_6]^{2+}$  (high spin), (c)  $[\text{Ru}(\text{NH}_3)_5\text{H}_2\text{O}]^{2+}$  (low spin), (d)  $[\text{IrCl}_6]^{2-}$  (low spin), (e)  $[\text{Cr}(\text{en})_3]^{3+}$ , (f)  $[\text{NiF}_6]^{4-}$ .
- 24.46** Draw the crystal-field energy-level diagrams and show the placement of electrons for the following complexes: (a)  $[\text{VCl}_6]^{3-}$ , (b)  $[\text{FeF}_6]^{3-}$  (a high-spin complex), (c)  $[\text{Ru}(\text{bipy})_3]^{2+}$  (a low-spin complex), (d)  $[\text{NiCl}_4]^{2-}$  (tetrahedral), (e)  $[\text{PtBr}_6]^{2-}$ , (f)  $[\text{Ti}(\text{en})_3]^{2+}$ .
- 24.47** The complex  $[\text{Mn}(\text{NH}_3)_6]^{2+}$  contains five unpaired electrons. Sketch the energy-level diagram for the  $d$  orbitals, and indicate the placement of electrons for this complex ion. Is the ion a high-spin or a low-spin complex?
- 24.48** The ion  $[\text{Fe}(\text{CN})_6]^{3-}$  has one unpaired electron, whereas  $[\text{Fe}(\text{NCS})_6]^{3-}$  has five unpaired electrons. From these results, what can you conclude about whether each complex is high spin or low spin? What can you say about the placement of  $\text{NCS}^-$  in the spectrochemical series?

## ADDITIONAL EXERCISES

- 24.49** Based on the molar conductance values listed here for the series of platinum(IV) complexes, write the formula for each complex so as to show which ligands are in the coordination sphere of the metal. By way of example, the molar conductances of  $0.050\text{ M}$   $\text{NaCl}$  and  $\text{BaCl}_2$  are  $107\text{ ohm}^{-1}$  and  $197\text{ ohm}^{-1}$ , respectively.

Complex	Molar Conductance ( $\text{ohm}^{-1}$ )* of $0.050\text{ M}$ Solution
$\text{Pt}(\text{NH}_3)_6\text{Cl}_4$	523
$\text{Pt}(\text{NH}_3)_4\text{Cl}_4$	228
$\text{Pt}(\text{NH}_3)_3\text{Cl}_4$	97
$\text{Pt}(\text{NH}_3)_2\text{Cl}_4$	0
$\text{KPt}(\text{NH}_3)\text{Cl}_5$	108

\*The  $\text{ohm}$  is a unit of resistance; conductance is the inverse of resistance.

- 24.50** (a) A compound with formula  $\text{RuCl}_3 \cdot 5\text{H}_2\text{O}$  is dissolved in water, forming a solution that is approximately the same color as the solid. Immediately after forming the solution, the addition of excess  $\text{AgNO}_3(aq)$  forms 2 mol of solid  $\text{AgCl}$  per mole of complex. Write the formula for the compound, showing which ligands are likely to be present in the coordination sphere. (b) After a solution of  $\text{RuCl}_3 \cdot 5\text{H}_2\text{O}$  has stood for about a year, addition of  $\text{AgNO}_3(aq)$  precipitates 3 mol of  $\text{AgCl}$  per mole of complex. What has happened in the ensuing time?
- 24.51** Sketch the structure of the complex in each of the following compounds:  
 (a)  $\text{cis-}[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2](\text{NO}_3)_2$   
 (b)  $\text{Na}_2[\text{Ru}(\text{H}_2\text{O})\text{Cl}_5]$
- (c)  $\text{trans-}[\text{Co}(\text{C}_2\text{O}_4)_2(\text{H}_2\text{O})_2]$   
 (d)  $\text{cis-}[\text{Ru}(\text{en})_2\text{Cl}_2]$
- 24.52** (a) Give the full name for each of the compounds in Exercise 24.51. (b) Will any of the complexes be optically active? Explain.
- 24.53** The molecule *dimethylphosphinoethane*  $[(\text{CH}_3)_2\text{PCH}_2\text{-CH}_2\text{P}(\text{CH}_3)_2]$ , which is abbreviated *dmpe* is used as a ligand for some complexes that serve as catalysts. A complex that contains this ligand is  $\text{Mo}(\text{CO})_4(\text{dmpe})$ . (a) Draw the Lewis structure for *dmpe*, and compare it with ethylenediamine as a coordinating ligand. (b) What is the oxidation state of Mo in  $\text{Na}_2[\text{Mo}(\text{CN})_2(\text{CO})_2(\text{dmpe})]$ ? (c) Sketch the structure of the  $[\text{Mo}(\text{CN})_2(\text{CO})_2(\text{dmpe})]^{2-}$  ion, including all the possible isomers.
- 24.54** Although the *cis* configuration is known for  $[\text{Pt}(\text{en})\text{Cl}_2]$ , no *trans* form is known. (a) Explain why the *trans* compound is not possible. (b) Suggest what type of ligand would be required to form a *trans*-bidentate coordination to a metal atom.
- [24.55]** The acetylacetonate ion forms very stable complexes with many metallic ions. It acts as a bidentate ligand, coordinating to the metal at two adjacent positions. Suppose that one of the  $\text{CH}_3$  groups of the ligand is replaced by a  $\text{CF}_3$  group, as shown here,

Sketch all possible isomers for the complex with three fac ligands on cobalt(III). (You can use the symbol  $\bullet\bigcirc$  to represent the ligand.)

- 24.56 Give brief statements about the relevance of the following complexes in living systems: (a) hemoglobin, (b) chlorophylls, (c) siderophores.

24.57 Write balanced chemical equations to represent the following observations. (In some instances the complex involved has been discussed previously in the text.) (a) Solid silver chloride dissolves in an excess of aqueous ammonia. (b) The green complex  $[\text{Cr}(\text{en})_2\text{Cl}_2]\text{Cl}$ , on treatment with water over a long time, converts to a brown-orange complex. Reaction of  $\text{AgNO}_3$  with a solution of the product precipitates 3 mol of  $\text{AgCl}$  per mole of  $\text{Cr}$  present. (Write two chemical equations.) (c) When an  $\text{NaOH}$  solution is added to a solution of  $\text{Zn}(\text{NO}_3)_2$ , a precipitate forms. Addition of excess  $\text{NaOH}$  solution causes the precipitate to dissolve. (Write two chemical equations.) (d) A pink solution of  $\text{Co}(\text{NO}_3)_2$  turns deep blue on addition of concentrated hydrochloric acid.

24.58 Some metal complexes have a coordination number of 5. One such complex is  $\text{Fe}(\text{CO})_5$ , which adopts a *trigonal bipyramidal* geometry (see Figure 9.8). (a) Write the name for  $\text{Fe}(\text{CO})_5$ , using the nomenclature rules for coordination compounds. (b) What is the oxidation state of  $\text{Fe}$  in this compound? (c) Suppose one of the  $\text{CO}$  ligands is replaced with a  $\text{CN}^-$  ligand, forming  $[\text{Fe}(\text{CO})_4(\text{CN})]^-$ . How many geometric isomers would you predict this complex could have?

24.59 Which of the following objects is chiral? (a) a left shoe, (b) a slice of bread, (c) a wood screw, (d) a molecular model of  $\text{Zn}(\text{en})\text{Cl}_2$ , (e) a typical golf club.

24.60 The complexes  $[\text{V}(\text{H}_2\text{O})_6]^{3+}$  and  $[\text{VF}_6]^{3-}$  are both known. (a) Draw the *d*-orbital energy-level diagram for  $\text{V}(\text{III})$  octahedral complexes. (b) What gives rise to the colors of these complexes? (c) Which of the two complexes would you expect to absorb light of higher energy? Explain.

[24.61] One of the more famous species in coordination chemistry is the Creutz–Taube complex,

It is named for the two scientists who discovered it and initially studied its properties. The central ligand is pyrazine, a planar six-membered ring with nitrogens at opposite sides. (a) How can you account for the fact that the complex, which has only neutral ligands, has an odd overall charge? (b) The metal is in a low-spin configuration in both cases. Assuming octahedral coordination, draw the *d*-orbital energy-level diagram for each metal. (c) In many experiments the two metal ions appear to be in exactly equivalent states. Can you think of a reason that this might appear to be so, recognizing that electrons move very rapidly compared to nuclei?

24.62 Solutions of  $[\text{Co}(\text{NH}_3)_6]^{2+}$ ,  $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$  (both octahedral), and  $[\text{CoCl}_4]^{2-}$  (tetrahedral) are colored. One is pink, one is blue, and one is yellow. Based on the

spectrochemical series and remembering that the energy splitting in tetrahedral complexes is normally much less than that in octahedral ones, assign a color to each complex.

24.63 Oxyhemoglobin, with an  $\text{O}_2$  bound to iron, is a low-spin  $\text{Fe}(\text{II})$  complex; deoxyhemoglobin, without the  $\text{O}_2$  molecule, is a high-spin complex. (a) Assuming that the coordination environment about the metal is octahedral, how many unpaired electrons are centered on the metal ion in each case? (b) What ligand is coordinated to the iron in place of  $\text{O}_2$  in deoxyhemoglobin? (c) Explain in a general way why the two forms of hemoglobin have different colors (hemoglobin is red, whereas deoxyhemoglobin has a bluish cast). (d) A 15-minute exposure to air containing 400 ppm of  $\text{CO}$  causes about 10% of the hemoglobin in the blood to be converted into the carbon monoxide complex, called carboxyhemoglobin. What does this suggest about the relative equilibrium constants for binding of carbon monoxide and  $\text{O}_2$  to hemoglobin?

[24.64] Consider the tetrahedral anions  $\text{VO}_4^{3-}$  (orthovanadate ion),  $\text{CrO}_4^{2-}$  (chromate ion), and  $\text{MnO}_4^-$  (permanganate ion). (a) These anions are *isoelectronic*. What does this statement mean? (b) Would you expect these anions to exhibit *d-d* transitions? Explain. (c) As mentioned in “A Closer Look” on charge-transfer color, the violet color of  $\text{MnO}_4^-$  is due to a *ligand-to-metal charge transfer* (LMCT) transition. What is meant by this term? (d) The LMCT transition in  $\text{MnO}_4^-$  occurs at a wavelength of 565 nm. The  $\text{CrO}_4^{2-}$  ion is yellow. Is the wavelength of the LMCT transition for chromate larger or smaller than that for  $\text{MnO}_4^-$ ? Explain. (e) The  $\text{VO}_4^{3-}$  ion is colorless. Is this observation consistent with the wavelengths of the LMCT transitions in  $\text{MnO}_4^-$  and  $\text{CrO}_4^{2-}$ ?

[24.65] The red color of ruby is due to the presence of  $\text{Cr}(\text{III})$  ions at octahedral sites in the close-packed oxide lattice of  $\text{Al}_2\text{O}_3$ . Draw the crystal-field-splitting diagram for  $\text{Cr}(\text{III})$  in this environment. Suppose that the ruby crystal is subjected to high pressure. What do you predict for the variation in the wavelength of absorption of the ruby as a function of pressure? Explain.

24.66 In 2001, chemists at SUNY-Stony Brook succeeded in synthesizing the complex *trans*- $[\text{Fe}(\text{CN})_4(\text{CO})_2]^{2-}$ , which could be a model of complexes that may have played a role in the origin of life. (a) Sketch the structure of the complex. (b) The complex is isolated as a sodium salt. Write the complete name of this salt. (c) What is the oxidation state of  $\text{Fe}$  in this complex? How many *d* electrons are associated with the  $\text{Fe}$  in this complex? (d) Would you expect this complex to be high spin or low spin? Explain.

[24.67] When Alfred Werner was developing the field of coordination chemistry, it was argued by some that the optical activity he observed in the chiral complexes he had prepared was because of the presence of carbon atoms in the molecule. To disprove this argument, Werner synthesized a chiral complex of cobalt that had no carbon atoms in it, and he was able to resolve it into its enantiomers. Design a cobalt(III) complex that would be chiral if it could be synthesized and that contains no carbon atoms. (It may not be possible to synthesize the complex you design, but we won't worry about that for now.)

[24.68] Generally speaking, for a given metal and ligand, the stability of a coordination compound is greater for the metal in the 3+ rather than in the 2+ oxidation state. Furthermore, for a given ligand the complexes of the bivalent metal ions of the first transition series tend to increase in stability in the order  $\text{Mn(II)} < \text{Fe(II)} < \text{Co(II)} < \text{Ni(II)} < \text{Cu(II)}$ . Explain how these two observations are consistent with one another and also consistent with a crystal-field picture of coordination compounds.

24.69 Many trace metal ions exist in the bloodstream as complexes with amino acids or small peptides. The anion of the amino acid glycine, symbol gly<sup>-</sup>, is capable of acting as a bidentate ligand, coordinating to the metal through nitrogen and oxygen atoms.

How many isomers are possible for (a)  $[\text{Zn}(\text{gly})_2]$  (tetrahedral), (b)  $[\text{Pt}(\text{gly})_2]$  (square-planar), (c)  $[\text{Co}(\text{gly})_3]$  (octahedral)? Sketch all possible isomers. Use  $\text{N}$  and  $\text{O}$  to represent the ligand.

[24.70] Suppose that a transition-metal ion was in a lattice in which it was in contact with just two nearby anions, located on opposite sides of the metal. Diagram the splitting of the metal  $d$  orbitals that would result from such a crystal field. Assuming a strong field, how many unpaired electrons would you expect for a metal ion with six  $d$  electrons? (Hint: Consider the linear axis to be the  $z$ -axis).

## INTEGRATIVE EXERCISES

24.71 Metallic elements are essential components of many important enzymes operating within our bodies. *Carbonic anhydrase*, which contains  $\text{Zn}^{2+}$ , is responsible for rapidly interconverting dissolved  $\text{CO}_2$  and bicarbonate ion,  $\text{HCO}_3^-$ . The zinc in carbonic anhydrase is coordinated by three nitrogen-containing groups and a water molecule. The enzyme's action depends on the fact that the coordinated water molecule is more acidic than the bulk solvent molecules. Explain this fact in terms of Lewis acid-base theory (Section 16.11).

24.72 Two different compounds have the formulation  $\text{CoBr}(\text{SO}_4) \cdot 5 \text{NH}_3$ . Compound A is dark violet, and compound B is red-violet. When compound A is treated with  $\text{AgNO}_3(\text{aq})$ , no reaction occurs, whereas compound B reacts with  $\text{AgNO}_3(\text{aq})$  to form a white precipitate. When compound A is treated with  $\text{BaCl}_2(\text{aq})$ , a white precipitate is formed, whereas compound B has no reaction with  $\text{BaCl}_2(\text{aq})$ . (a) Is Co in the same oxidation state in these complexes? (b) Explain the reactivity of compounds A and B with  $\text{AgNO}_3(\text{aq})$  and  $\text{BaCl}_2(\text{aq})$ . (c) Are compounds A and B isomers of one another? If so, which category from Figure 24.17 best describes the isomerism observed for these complexes? (d) Would compounds A and B be expected to be strong electrolytes, weak electrolytes, or nonelectrolytes?

24.73 A manganese complex formed from a solution containing potassium bromide and oxalate ion is purified and analyzed. It contains 10.0% Mn, 28.6% potassium, 8.8% carbon, and 29.2% bromine by mass. The remainder of the compound is oxygen. An aqueous solution of the complex has about the same electrical conductivity as an equimolar solution of  $\text{K}_4[\text{Fe}(\text{CN})_6]$ . Write the formula of the compound, using brackets to denote the manganese and its coordination sphere.

[24.74] The  $E^\circ$  values for two iron complexes in acidic solution are as follows:

(a) What do the relative  $E^\circ$  values tell about the relative stabilities of the Fe(II) and Fe(III) complexes in each case? (b) Account for the more positive  $E^\circ$  value for the

(*o-phen*) complex. Both of the Fe(II) complexes are low spin. (Hint: consider the charges carried by the ligands in the two cases.)

24.75 A palladium complex formed from a solution containing bromide ion and pyridine,  $\text{C}_5\text{H}_5\text{N}$  (a good electron-pair donor), is found on elemental analysis to contain 37.6% bromine, 28.3% carbon, 6.60% nitrogen, and 2.37% hydrogen by mass. The compound is slightly soluble in several organic solvents; its solutions in water or alcohol do not conduct electricity. It is found experimentally to have a zero dipole moment. Write the chemical formula, and indicate its probable structure.

24.76 (a) In early studies it was observed that when the complex  $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{Br}$  was placed in water, the electrical conductivity of a 0.05 M solution changed from an initial value of  $191 \text{ ohm}^{-1}$  to a final value of  $374 \text{ ohm}^{-1}$  over a period of an hour or so. Suggest an explanation for the observed results. (See Exercise 24.49 for relevant comparison data.) (b) Write a balanced chemical equation to describe the reaction. (c) A 500-mL solution is made up by dissolving 3.87 g of the complex. As soon as the solution is formed, and before any change in conductivity has occurred, a 25.00-mL portion of the solution is titrated with 0.0100 M  $\text{AgNO}_3$  solution. What volume of  $\text{AgNO}_3$  solution do you expect to be required to precipitate the free  $\text{Br}^-(\text{aq})$ ? (d) Based on the response you gave to part (b), what volume of  $\text{AgNO}_3$  solution would be required to titrate a fresh 25.00-mL sample of  $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{Br}$  after all conductivity changes have occurred?

24.77 The total concentration of  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  in a sample of hard water was determined by titrating a 0.100-L sample of the water with a solution of  $\text{EDTA}^{4-}$ . The  $\text{EDTA}^{4-}$  chelates the two cations:

It requires 31.5 mL of 0.0104 M  $[\text{EDTA}]^{4-}$  solution to reach the end point in the titration. A second 0.100-L sample was then treated with sulfate ion to precipitate  $\text{Ca}^{2+}$  as calcium sulfate. The  $\text{Mg}^{2+}$  was then titrated with 18.7 mL of 0.0104 M  $[\text{EDTA}]^{4-}$ . Calculate the concentrations of  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  in the hard water in mg/L.

- 24.78 Carbon monoxide is toxic because it binds more strongly to the iron in hemoglobin (Hb) than does  $O_2$ , as indicated by these approximate standard free-energy changes in blood:

Using these data, estimate the equilibrium constant at 298 K for the equilibrium

- [24.79] The molecule *methylamine* ( $\text{CH}_3\text{NH}_2$ ) can act as a monodentate ligand. The following are equilibrium reactions and the thermochemical data at 298 K for reactions of methylamine and en with  $\text{Cd}^{2+}(\text{aq})$ :

$\Delta H^\circ = -56.5 \text{ kJ}$ ;  $\Delta S^\circ = +14.1 \text{ J/K}$ ;  $\Delta G^\circ = -60.7 \text{ kJ}$

(a) Calculate  $\Delta G^\circ$  and the equilibrium constant  $K$  for the following *ligand exchange* reaction:

(b) Based on the value of  $K$  in part (a), what would you conclude about this reaction? What concept is demonstrated? (c) Determine the magnitudes of the enthalpic ( $\Delta H^\circ$ ) and the entropic ( $-T\Delta S^\circ$ ) contributions to  $\Delta G^\circ$  for the ligand exchange reaction. Explain the relative magnitudes. (d) Based on information in this exercise and in the "A Closer Look" box on the chelate effect, predict the sign of  $\Delta H^\circ$  for the following hypothetical reaction:

- 24.80 The value of  $\Delta$  for the  $[\text{CrF}_6]^{3-}$  complex is 182 kJ/mol. Calculate the expected wavelength of the absorption corresponding to promotion of an electron from the lower-energy to the higher-energy  $d$ -orbital set in this complex. Should the complex absorb in the visible range? (You may need to review Sample Exercise 6.3; remember to divide by Avogadro's number.)

- [24.81] A Cu electrode is immersed in a solution that is 1.00 M in  $[\text{Cu}(\text{NH}_3)_4]^{2+}$  and 1.00 M in  $\text{NH}_3$ . When the cathode is a standard hydrogen electrode, the emf of the cell is found to be +0.08 V. What is the formation constant for  $[\text{Cu}(\text{NH}_3)_4]^{2+}$ ?

- [24.82] The complex  $[\text{Ru}(\text{EDTA})(\text{H}_2\text{O})]^-$  undergoes substitution reactions with several ligands, replacing the water molecule with the ligand.

The rate constants for several ligands are as follows:

Ligand, L	$k$ ( $M^{-1}s^{-1}$ )
Pyridine	$6.3 \times 10^3$
$\text{SCN}^-$	$2.7 \times 10^2$
$\text{CH}_3\text{CN}$	$3.0 \times 10$

- (a) One possible mechanism for this substitution reaction is that the water molecule dissociates from the complex in the rate-determining step, and then the ligand L fills the void in a rapid second step. A second possible mechanism is that L approaches the complex, begins to form a new bond to the metal, and displaces the water molecule, all in a single concerted step. Which of these two mechanisms is more consistent with the data? Explain. (b) What do the results suggest about the relative basicities of the three ligands toward Ru(III)? (c) Assuming that the complexes are all low spin, how many unpaired electrons are in each?

## WHAT'S AHEAD

---

- 25.1** Some General Characteristics of Organic Molecules  
We begin with a brief review of the structures and reactivities of organic compounds.
- 25.2** Introduction to Hydrocarbons  
We consider the *hydrocarbons*, compounds containing only C and H.
- 25.3** Alkanes, Alkenes, and Alkynes  
We next explore three classes of hydrocarbons: those in which all bonds are single bonds called *alkanes*, those with one or more C=C bonds called *alkenes*, and those with one or more C≡C bonds called *alkynes*. *Aromatic* hydrocarbons have at least one planar ring with delocalized  $\pi$  electrons. One reason for the huge number of organic compounds is the existence of *isomers*, compounds with identical compositions whose molecules have different structures.
- 25.4** Organic Functional Groups  
We recognize that a central organizing principle of organic chemistry is the *functional group*, a group of atoms at which most of the compound's chemical reactions occur. Common organic functional groups that include oxygen and nitrogen atoms are described.
- 25.5** Chirality in Organic Chemistry  
We learn that compounds with nonsuperimposable mirror images are *chiral*. Chirality plays very important roles in organic and biological chemistry.
- 25.6** Introduction to Biochemistry  
We introduce the chemistry of living organisms, known as *biochemistry*, *biological chemistry*, or *chemical biology*. Important classes of compounds that occur in living systems are *proteins*, *carbohydrates*, *lipids*, and *nucleic acids*.
- 25.7** Proteins  
We learn that proteins are polymers of *amino acids* linked with *amide* (also called *peptide*) bonds. Proteins are used for structural support (muscles, cartilage), molecular transporters (hemoglobin, which transports oxygen in blood), and enzymes (proteins that catalyze many metabolic reactions).
- 25.8** Carbohydrates  
We observe that carbohydrates are sugars and polymers of sugars that are primarily used as fuel for organisms (glucose) or as structural supports in plants (cellulose).
- 25.9** Lipids  
We recognize that lipids are a large class of molecules that are primarily used for energy storage in organisms (fats, oils).
- 25.10** Nucleic Acids  
Finally, we learn that nucleic acids are polymers of nucleotides that comprise an organism's genetic information. *Deoxyribonucleic acid* (DNA) and *ribonucleic acid* (RNA) are polymers composed of *nucleotides*.

### MANY CANS OF DIET SOFT DRINK CARRY THE WARNING

**“PHENYLKETONURICS: CONTAINS PHENYLALANINE.”** Phenylalanine is one of the essential amino acids, which means that we must have it in our diets to survive. However, in about one out of 10,000 to 20,000 Caucasian or Asian births, an enzyme

that converts phenylalanine to another amino acid, tyrosine, is completely or nearly completely deficient because of a genetic defect. The result is that phenylalanine accumulates in the blood and in body tissues. The disease that results is called phenylketonuria (PKU), which causes mental retardation and seizures. Newborns are now routinely tested for PKU at about 3 days of age. The disease can be managed by a diet that provides just enough phenylalanine for proper nutrition, without exceeding the limit. Hence, the government requires warnings on diet drink containers.

Although biological systems are almost unimaginably complex, they are nevertheless constructed of molecules of quite modest size, put together in nature to form a host of complex, interacting structures. The example of phenylalanine and PKU illustrates the point that to understand biology, we need to understand the chemical behaviors of molecules of low molar mass. This chapter is about the molecules, composed mainly of carbon, hydrogen, oxygen, and nitrogen, that form the basis of both organic and biological chemistry.

The element carbon forms a vast number of compounds. Over 16 million carbon-containing compounds are known. Chemists make thousands of new compounds every year, about 90% of which contain carbon. The study of carbon compounds constitutes a separate branch of chemistry known as **organic chemistry**. This term arose from the eighteenth-century belief that organic compounds could be formed only by living systems. This idea was disproved in 1828 by the German chemist Friedrich Wöhler when he synthesized urea ( $\text{H}_2\text{NCONH}_2$ ), an organic substance found in the urine of mammals, by heating ammonium cyanate ( $\text{NH}_4\text{OCN}$ ), an inorganic substance.

The study of the chemistry of living species is called *biological chemistry*, *chemical biology*, or **biochemistry**. In this final chapter we present a brief view of some of the elementary aspects of organic chemistry and biochemistry. Many of you will study these subjects in greater detail by taking additional courses devoted entirely to these topics. As you read the material that follows, you will notice that many of the concepts important for understanding the fundamentals of organic chemistry and biochemistry have been developed in earlier chapters.

## 25.1 SOME GENERAL CHARACTERISTICS OF ORGANIC MOLECULES

What is it about carbon that leads to the tremendous diversity in its compounds, and allows it to play such crucial roles in biology and society? Let's consider some general features of organic molecules, and as we do, let's review some principles that we learned in earlier chapters.

### The Structures of Organic Molecules

The three-dimensional structures of organic and biochemical molecules play an essential role in determining their physical and chemical behaviors. Because carbon has four valence electrons ( $[\text{He}]2s^22p^2$ ), it forms four bonds in virtually all its compounds. When all four bonds are single bonds, the electron pairs are disposed in a tetrahedral arrangement. [☞ \(Section 9.2\)](#) In the hybridization model the carbon  $2s$  and  $2p$  orbitals are then  $sp^3$  hybridized. [☞ \(Section 9.5\)](#) When there is one double bond, the arrangement is trigonal planar ( $sp^2$  hybridization). With a triple bond, it is linear ( $sp$  hybridization). Examples are shown in Figure 25.1 ▼.

► **Figure 25.1 Carbon geometries.** These molecular models show the three common geometries around carbon: (a) tetrahedral in methane ( $\text{CH}_4$ ), where the carbon is bonded to four other atoms; (b) trigonal planar in formaldehyde ( $\text{CH}_2\text{O}$ ), where the carbon is bonded to three other atoms; and (c) linear in acetonitrile ( $\text{CH}_3\text{CN}$ ), where the top carbon is bonded to two atoms.

C—H bonds occur in almost every organic molecule. Because the valence shell of H can hold only two electrons, hydrogen forms only one covalent bond. As a result, hydrogen atoms are always located on the surface of organic molecules, as in the propane molecule:

The C—C bonds form the backbone, or skeleton, of the molecule, while the H atoms are on the surface, or “skin,” of the molecule.

The bonding arrangements about individual atoms are important in determining overall molecular shape. In turn, the overall shapes of organic and biochemical molecules are important in determining how they will react with other molecules, and how rapidly. They also determine important physical properties.

### The Stabilities of Organic Substances

In Section 8.8 we learned about the average strengths of various chemical bonds, including those that are characteristic of organic molecules, such as C—H, C—C, C—N, C—O, and C=O bonds. Carbon forms strong bonds with a variety of elements, especially H, O, N, and the halogens. Carbon also has an exceptional ability to bond to itself, forming a variety of molecules with chains or rings of carbon atoms. As we saw in Chapter 8, double bonds are generally stronger than single bonds, and triple bonds are stronger than double bonds. Increasing bond strength with bond order is accompanied by a shortening of the bond. Thus, carbon–carbon bond lengths decrease in the order C—C > C=C > C≡C.

We know from calorimetric measurements that reaction of a simple organic substance such as methane (CH<sub>4</sub>) with oxygen is highly exothermic. (Sections 5.6, 5.7, and 5.8) Indeed, the combustion of methane (natural gas) keeps many of our homes warm during the winter months! Although the reactions of most organic compounds with oxygen are exothermic, great numbers of them are stable indefinitely at room temperature in the presence of air because the activation energy required for combustion is large.

Most reactions with low or moderate activation barriers begin when a region of high electron density on one molecule encounters a region of low electron density on another molecule. The regions of high electron density may be due to the presence of a multiple bond or to the more electronegative atom in a polar bond. Because of their strength and lack of polarity, C—C single bonds are relatively unreactive. C—H bonds are also largely unreactive for the same reasons. The C—H bond is nearly nonpolar because the electronegativities of C (2.5) and H (2.1) are close. To better understand the implications of these facts, consider ethanol:

The differences in the electronegativity values of C (2.5) and O (3.5) and those of O and H (2.1) indicate that the C—O and O—H bonds are quite polar. Thus, the chemical reactions of ethanol involve these bonds. A group of atoms such as the C—O—H group, which determines how an organic molecule functions or reacts, is called a **functional group**. The functional group is the center of reactivity in an organic molecule.

#### GIVE IT SOME THOUGHT

Which of these bond types is most likely to be the seat of a chemical reaction: C=N, C—C, or C—H?

▲ **Figure 25.2 Water-soluble organic molecules.** (a) Glucose ( $C_6H_{12}O_6$ ), a simple sugar; (b) ascorbic acid ( $HC_6H_7O_6$ ), known as vitamin C; (c) the stearate ion ( $C_{17}H_{35}COO^-$ ), an ion that functions as a surfactant. (To fit this illustration in the allocated space, the scale at which the surfactant molecule is drawn is different from the scale used for the glucose and ascorbic acid molecules.)

## Solubility and Acid–Base Properties of Organic Substances

In most organic substances, the most prevalent bonds are carbon–carbon and carbon–hydrogen, which have low polarity. For this reason, the overall polarity of organic molecules is often low. They are generally soluble in nonpolar solvents and not very soluble in water. ∞ (Section 13.3) Molecules that are soluble in polar solvents such as water are those that have polar groups on the surface of the molecule, such as found in glucose [Figure 25.2(a) ◀] or ascorbic acid [vitamin C, Figure 25.2(b)]. Surfactant organic molecules have a long, nonpolar part that extends into a nonpolar medium and a polar, ionic “head group” that extends into a polar medium, such as water [Figure 25.2(c)]. ∞ (Section 13.6) This type of structure is found in many biochemically important substances, as well as soaps and detergents.

Many organic substances contain acidic or basic groups. The most important acidic substances are the carboxylic acids, which bear the functional group  $-\text{COOH}$ . ∞ (Section 4.3 and Section 16.10) The most important basic substances are amines, which bear the  $-\text{NH}_2$ ,  $-\text{NHR}$ , or  $-\text{NR}_2$  groups, where R is an organic group consisting of some combination of C–C and C–H bonds, such as  $-\text{CH}_3$  or  $-\text{C}_2\text{H}_5$ . ∞ (Section 16.7)

As you read this chapter, you will find many concept links to related materials in earlier chapters, many of them to the sections just discussed. *We strongly encourage you to follow these links and review the earlier materials.* Doing so will definitely enhance your understanding and appreciation of organic chemistry and biochemistry.

## 25.2 INTRODUCTION TO HYDROCARBONS

Because the compounds of carbon are so numerous, it is convenient to organize them into families that exhibit structural similarities. The simplest class of organic compounds is the *hydrocarbons*, compounds composed only of carbon and hydrogen. The key structural feature of hydrocarbons (and of most other organic substances) is the presence of stable carbon–carbon bonds. Carbon is the only element capable of forming stable, extended chains of atoms bonded through single, double, or triple bonds.

Hydrocarbons can be divided into four general types, depending on the kinds of carbon–carbon bonds in their molecules. Figure 25.3 ▶ shows an example of each of the four types: alkanes, alkenes, alkynes, and aromatic hydrocarbons. In these hydrocarbons, as well as in other organic compounds, each C atom invariably has four bonds (four single bonds, two single bonds and one double bond, or one single bond and one triple bond).

**Alkanes** are hydrocarbons that contain only single bonds, as in ethane ( $C_2H_6$ ). Because alkanes contain the largest possible number of hydrogen atoms per carbon atom, they are called *saturated hydrocarbons*. **Alkenes**, also known as *olefins*, are hydrocarbons that contain at least one C=C double bond, as in ethylene ( $C_2H_4$ ). **Alkynes** contain at least one C≡C triple bond, as in acetylene ( $C_2H_2$ ). In **aromatic hydrocarbons** the carbon atoms are connected in a planar ring structure, joined by both  $\sigma$  and  $\pi$  bonds between carbon atoms. Benzene ( $C_6H_6$ ) is the best-known example of an aromatic hydrocarbon. Alkenes, alkynes, and aromatic hydrocarbons are called *unsaturated hydrocarbons* because they contain less hydrogen than an alkane with the same number of carbon atoms.

The members of these different classes of hydrocarbons exhibit different chemical behaviors, as we will see shortly. Their physical properties, however, are similar in many ways. Because carbon and hydrogen do not differ greatly in electronegativity, hydrocarbon molecules are relatively nonpolar. Thus, they are

▲ **Figure 25.3** The four hydrocarbon types. Names, molecular formulas, and geometrical structures for examples of each type of hydrocarbon.

almost completely insoluble in water, but they dissolve readily in other nonpolar solvents. Their melting points and boiling points are determined by London dispersion forces. Hence, hydrocarbons tend to become less volatile with increasing molar mass. [↔ \(Section 11.2\)](#) As a result, hydrocarbons of very low molecular weight, such as  $\text{C}_2\text{H}_6$  (bp =  $-89^\circ\text{C}$ ), are gases at room temperature; those of moderate molecular weight, such as  $\text{C}_6\text{H}_{14}$  (bp =  $69^\circ\text{C}$ ), are liquids; and those of high molecular weight, such as  $\text{C}_{22}\text{H}_{46}$  (mp =  $44^\circ\text{C}$ ), are solids.

## 25.3 ALKANES, ALKENES, AND ALKYNES

Table 25.1 ▼ lists several of the simplest alkanes. Many of these substances are familiar because they are used so widely. Methane is a major component of natural gas and is used for home heating and in gas stoves and water heaters. Propane is the major component of bottled gas used for home heating and cooking in areas where natural gas is not available. Butane is used in disposable lighters and in fuel canisters for gas camping stoves and lanterns. Alkanes with from 5 to 12 carbon atoms per molecule are found in gasoline.

The formulas for the alkanes given in Table 25.1 are written in a notation called *condensed structural formulas*. This notation reveals the way in which atoms are bonded to one another but does not require drawing in all the bonds.

TABLE 25.1 ■ First Several Members of the Straight-Chain Alkane Series

Molecular Formula	Condensed Structural Formula	Name	Boiling Point (°C)
CH <sub>4</sub>	CH <sub>4</sub>	Methane	-161
C <sub>2</sub> H <sub>6</sub>	CH <sub>3</sub> CH <sub>3</sub>	Ethane	-89
C <sub>3</sub> H <sub>8</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>3</sub>	Propane	-44
C <sub>4</sub> H <sub>10</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	Butane	-0.5
C <sub>5</sub> H <sub>12</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	Pentane	36
C <sub>6</sub> H <sub>14</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	Hexane	68
C <sub>7</sub> H <sub>16</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	Heptane	98
C <sub>8</sub> H <sub>18</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	Octane	125
C <sub>9</sub> H <sub>20</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	Nonane	151
C <sub>10</sub> H <sub>22</sub>	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>3</sub>	Decane	174

For example, the Lewis structure and the condensed structural formulas for butane (C<sub>4</sub>H<sub>10</sub>) are

We will frequently use either Lewis structures or condensed structural formulas to represent organic compounds. Notice that each carbon atom in an alkane has four single bonds, whereas each hydrogen atom forms one single bond. Notice also that each succeeding compound in the series listed in Table 25.1 has an additional CH<sub>2</sub> unit.

### GIVE IT SOME THOUGHT

How many C—H and C—C bonds are formed by the middle carbon atom of propane, Table 25.1?

### Structures of Alkanes

The Lewis structures and condensed structural formulas for alkanes do not tell us anything about the three-dimensional structures of these substances. According to the VSEPR model, the geometry about each carbon atom in an alkane is tetrahedral; that is, the four groups attached to each carbon are located at the vertices of a tetrahedron. [∞ \(Section 9.2\)](#) The three-dimensional structures can be represented as shown for methane in Figure 25.4 [▼](#). The bonding may be described as involving sp<sup>3</sup>-hybridized orbitals on the carbon. [∞ \(Section 9.5\)](#)

▲ Figure 25.4 Representations of the three-dimensional arrangement of bonds about carbon in methane.

Rotation about a carbon–carbon single bond is relatively easy, and it occurs very rapidly at room temperature. To visualize such rotation, imagine grasping either methyl group in Figure 25.5 ▶, which shows the structure of propane, and spinning it relative to the rest of the structure. Because motion of this sort occurs very rapidly in alkanes, a long-chain alkane molecule is constantly undergoing motions that cause it to change its shape, something like a length of chain that is being shaken.

### Structural Isomers

The alkanes listed in Table 25.1 are called *straight-chain hydrocarbons* because all the carbon atoms are joined in a continuous chain. Alkanes consisting of four or more carbon atoms can also form *branched chains* called *branched-chain hydrocarbons*. Figure 25.6 ▼ shows space-filling models, full structural formulas, and

▲ **Figure 25.5** Rotation about a C–C bond. Either representation of propane ( $C_3H_8$ ) can help you visualize rotation about a C–C single bond.

▲ **Figure 25.6** Hydrocarbon isomers. There are two structural isomers having the formula  $C_4H_{10}$ : butane and isobutane. For the formula  $C_5H_{12}$ , there are three structural isomers: pentane, isopentane, and neopentane. In general, the number of structural isomers increases as the number of carbons in the hydrocarbon increases.

condensed structural formulas for all the possible structures of alkanes containing four or five carbon atoms. There are two ways that four carbon atoms can be joined to give  $C_4H_{10}$ : as a straight chain (left) or a branched chain (right). For alkanes with five carbon atoms ( $C_5H_{12}$ ), there are three different arrangements.

Compounds with the same molecular formula but with different bonding arrangements (and hence different structures) are called **structural isomers**. The structural isomers of a given alkane differ slightly from one another in physical properties. Note the melting and boiling points of the isomers of butane and pentane, given in Figure 25.6. The number of possible structural isomers increases rapidly with the number of carbon atoms in the alkane. There are 18 possible isomers having the molecular formula  $C_8H_{18}$ , for example, and 75 possible isomers with the molecular formula  $C_{10}H_{22}$ .

## Nomenclature of Alkanes

The first names given to the structural isomers shown in Figure 25.6 are the so-called common names. The isomer in which one  $CH_3$  group is branched off the major chain is labeled the *iso-* isomer (for example, isobutane). As the number of isomers grows, however, it becomes impossible to find a suitable prefix to denote each isomer. The need for a systematic means of naming organic compounds was recognized early in the history of organic chemistry. In 1892 an organization called the International Union of Chemistry met in Geneva, Switzerland, to formulate rules for systematic naming of organic substances. Since that time the task of updating the rules for naming compounds has fallen to the International Union of Pure and Applied Chemistry (IUPAC). Chemists everywhere, regardless of their nationality, subscribe to a common system for naming compounds.

The IUPAC names for the isomers of butane and pentane are the ones given in parentheses for each compound in Figure 25.6. These names as well as those of other organic compounds have three parts to them:

The following steps summarize the procedures used to arrive at the names of alkanes, which all have names ending with the suffix *-ane*. We use a similar approach to write the names of other organic compounds.

1. Find the longest continuous chain of carbon atoms, and use the name of this chain (Table 25.1) as the base name of the compound. The longest chain may not always be written in a straight line, as seen in the following example:

Because this compound has a chain of six C atoms, it is named as a substituted hexane. Groups attached to the main chain are called *substituents* because they are substituted in place of an H atom on the main chain.

2. Number the carbon atoms in the longest chain, beginning with the end of the chain that is nearest to a substituent. In our example we number the C atoms from the upper right because that places the  $CH_3$  substituent on the second C atom of the chain; if we number from the lower right, the  $CH_3$  would be on the fifth C atom. The chain is numbered from the end that gives the lowest number for the substituent position.

3. Name and give the location of each substituent group. A substituent group that is formed by removing an H atom from an alkane is called an **alkyl group**. Alkyl groups are named by replacing the *-ane* ending of the alkane name with *-yl*. The methyl group (CH<sub>3</sub>), for example, is derived from methane (CH<sub>4</sub>). Likewise, the ethyl group (C<sub>2</sub>H<sub>5</sub>) is derived from ethane (C<sub>2</sub>H<sub>6</sub>). Table 25.2 lists several common alkyl groups. The name 2-methylhexane indicates the presence of a methyl (CH<sub>3</sub>) group on the second carbon atom of a hexane (six-carbon) chain.

### GIVE IT SOME THOUGHT

What is the chemical formula of the propyl group?

4. When two or more substituents are present, list them in alphabetical order. When there are two or more of the same substituent, the number of substituents of that type is indicated by a prefix: *di-* (two), *tri-* (three), *tetra-* (four), *penta-* (five), and so forth. Notice how the following example is named:

3-Ethyl-2,4,5-trimethylheptane

TABLE 25.2 Condensed Structural Formulas and Common Names for Several Alkyl Groups

Group	Name
CH <sub>3</sub> —	Methyl
CH <sub>3</sub> CH <sub>2</sub> —	Ethyl
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> —	Propyl
CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> —	Butyl
$\begin{array}{c} \text{CH}_3 \\   \\ \text{HC}— \\   \\ \text{CH}_3 \end{array}$	Isopropyl
$\begin{array}{c} \text{CH}_3 \\   \\ \text{CH}_3—\text{C}— \\   \\ \text{CH}_3 \end{array}$	<i>tert</i> -Butyl

### SAMPLE EXERCISE 25.1 Naming Alkanes

Give the systematic name for the following alkane:

### SOLUTION

**Analyze:** We are given the structural formula of an alkane and asked to give its name.

**Plan:** Because the hydrocarbon is an alkane, its name ends in *-ane*. The name of the parent hydrocarbon is based on the longest continuous chain of carbon atoms, as summarized in Table 25.1. Branches are alkyl groups, named after the number of C atoms in the branch and located by counting C atoms along the longest continuous chain.

**Solve:** The longest continuous chain of C atoms extends from the upper left CH<sub>3</sub> group to the lower left CH<sub>3</sub> group and is seven C atoms long:

The parent compound is thus heptane. There are two CH<sub>3</sub> (methyl) groups that branch off the main chain. Hence, this compound is a dimethylheptane. To specify the location of the two methyl groups, we must number the C atoms from the end that gives the lowest number possible to the carbons bearing side chains. This means that we should start numbering with the upper left carbon. There is a methyl group on carbon 3, and one on carbon 4. The compound is thus 3,4-dimethylheptane.

**PRACTICE EXERCISE**

Name the following alkane:

*Answer:* 2,4-dimethylpentane**SAMPLE EXERCISE 25.2** Writing Condensed Structural Formulas

Write the condensed structural formula for 3-ethyl-2-methylpentane.

**SOLUTION****Analyze:** We are given the systematic name for a hydrocarbon and asked to write its structural formula.**Plan:** Because the compound's name ends in *-ane*, it is an alkane, meaning that all the carbon-carbon bonds are single bonds. The parent hydrocarbon is pentane, indicating five C atoms (Table 25.1). There are two alkyl groups specified, an ethyl group (two carbon atoms, C<sub>2</sub>H<sub>5</sub>) and a methyl group (one carbon atom, CH<sub>3</sub>). Counting from left to right along the five-carbon chain, the ethyl group will be attached to the third C atom and the methyl group will be attached to the second C atom.**Solve:** We begin by writing a string of five C atoms attached to each other by single bonds. These represent the backbone of the parent pentane chain:

We next place a methyl group on the second C and an ethyl group on the third C atom of the chain. We then add hydrogens to all the other C atoms to make the four bonds to each carbon, giving the following condensed structure:

The formula can be written even more concisely in the following style:

In this formula the branching alkyl groups are indicated in parentheses.

**PRACTICE EXERCISE**

Write the condensed structural formula for 2,3-dimethylhexane.

**Cycloalkanes**

Alkanes can form rings or cycles. Alkanes with this form of structure are called **cycloalkanes**. Figure 25.7 illustrates a few cycloalkanes. Cycloalkane structures are sometimes drawn as simple polygons in which each corner of the polygon represents a CH<sub>2</sub> group. This method of representation is similar to that used for benzene rings.  $\rightleftharpoons$  (Section 8.6) (Remember from our benzene discussion that in aromatic structures each vertex represents a CH group, not a CH<sub>2</sub> group.)

Carbon rings containing fewer than five carbon atoms are strained because the C—C—C bond angle in the smaller rings must be less than the 109.5° tetrahedral angle. The amount of strain increases as the rings get smaller. In cyclopropane, which has the shape of an equilateral triangle, the angle is only 60°; this molecule is therefore much more reactive than propane, its straight-chain analog.

◀ **Figure 25.7** Condensed structural formulas and line structures for three cycloalkanes.

Cycloalkanes, particularly the small-ring compounds, sometimes behave chemically like unsaturated hydrocarbons, which we will discuss shortly. The general formula for cycloalkanes,  $C_nH_{2n}$ , differs from the general formula for straight-chain alkanes,  $C_nH_{2n+2}$ .

### Reactions of Alkanes

Because they contain only C—C and C—H bonds, most alkanes are relatively unreactive. At room temperature, for example, they do not react with acids, bases, or strong oxidizing agents, and they are not even attacked by boiling nitric acid. Their low chemical reactivity is due primarily to the strength and lack of polarity of C—C and C—H bonds.

Alkanes are not completely inert, however. One of their most commercially important reactions is *combustion* in air, which is the basis of their use as fuels. ∞ (Section 3.2) For example, the complete combustion of ethane proceeds as follows:

In the following sections we will see that hydrocarbons can be modified to impart greater reactivity by introducing unsaturation into the carbon-carbon framework and by attaching other reactive groups to the hydrocarbon backbone.

## Chemistry Put to Work

### GASOLINE

Petroleum, or crude oil, is a complex mixture of organic compounds, mainly hydrocarbons, with smaller quantities of other organic compounds containing nitrogen, oxygen, or sulfur. The tremendous demand for petroleum to meet the world's energy needs has led to the tapping of oil wells in such forbidding places as the North Sea and northern Alaska.

The usual first step in the *refining*, or processing, of petroleum is to separate it into fractions on the basis of boiling point. The fractions commonly taken are shown in Table 25.3 ▼.

Because gasoline is the most commercially important of these fractions, various processes are used to maximize its yield.

*Gasoline* is a mixture of volatile hydrocarbons containing varying amounts of aromatic hydrocarbons in addition to alkanes. In a traditional automobile engine a mixture of air and gasoline vapor is compressed by a piston and then ignited by a spark plug. The burning of the gasoline should create a strong, smooth expansion of gas, forcing the piston outward and imparting force along the drive shaft of the engine. If the gas

**TABLE 25.3** ■ Hydrocarbon Fractions from Petroleum

Fraction	Size Range of Molecules	Boiling-Point Range (°C)	Uses
Gas	C <sub>1</sub> to C <sub>5</sub>	−160 to 30	Gaseous fuel, production of H <sub>2</sub>
Straight-run gasoline	C <sub>5</sub> to C <sub>12</sub>	30 to 200	Motor fuel
Kerosene, fuel oil	C <sub>12</sub> to C <sub>18</sub>	180 to 400	Diesel fuel, furnace fuel, cracking
Lubricants	C <sub>16</sub> and up	350 and up	Lubricants

Asphalt	C <sub>36</sub> and up	Gummy residues	Surfacing roads

*continues on next page*

continued

▲ **Figure 25.8 Octane rating.** The octane rating of gasoline measures its resistance to knocking when burned in an engine. The octane rating of this gasoline is 89, as shown on the face of the pump.

burns too rapidly, the piston receives a single hard slam rather than a strong, smooth push. The result is a “knocking” or “pinging” sound and a reduction in the efficiency with which energy produced by the combustion is converted to work.

The *octane number* of a gasoline is a measure of its resistance to knocking. Gasolines with high octane numbers burn more smoothly and are thus more effective fuels (Figure 25.8▲). Branched alkanes and aromatic hydrocarbons have higher octane numbers than the straight-chain alkanes. The octane number of gasoline is obtained by comparing its knocking characteristics with those of “isooctane” (2,2,4-trimethylpentane) and heptane. Isooctane is assigned an octane number of 100, whereas heptane is assigned 0. Gasoline with the same knocking characteristics as a mixture of 91% isooctane and 9% heptane is rated as 91 octane.

The gasoline obtained directly from fractionation of petroleum (called *straight-run* gasoline) contains mainly straight-chain hydrocarbons and has an octane number around 50. It is therefore subjected to a process called *reforming*, which converts the straight-chain alkanes into more desirable branched-chain ones (Figure 25.9▶). *Cracking* is used to produce aromatic hydrocarbons and to convert some of the less volatile kerosene and fuel-oil fraction into compounds with lower molecular weights that are suitable for use as automobile fuel. In the cracking process the hydrocarbons are mixed with a catalyst and heated to 400 °C to 500 °C. The catalysts used are naturally occurring clay minerals or synthetic  $\text{Al}_2\text{O}_3$ - $\text{SiO}_2$  mixtures. In addition to forming molecules more suitable for gasoline, cracking results in the formation of hydrocarbons of lower molecular weight, such as ethylene and propene. These substances are used in a variety of reactions to form plastics and other chemicals.

▲ **Figure 25.9 Fractional distillation.** Petroleum is separated into fractions by distillation and is subjected to catalytic cracking in a refinery, as shown here.

Adding certain compounds called *antiknock agents* or octane enhancers increases the octane rating of gasoline. Until the mid-1970s the principal antiknock agent was tetraethyl lead,  $(\text{C}_2\text{H}_5)_4\text{Pb}$ . It is no longer used, however, because of the environmental hazards of lead and because it poisons catalytic converters. ⇄(Section 14.7: “Chemistry Put to Work: Catalytic Converters”) Aromatic compounds such as toluene ( $\text{C}_6\text{H}_5\text{CH}_3$ ) and oxygenated hydrocarbons such as ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) and methyl *tert*-butyl ether (MTBE, shown below) are now generally used as antiknock agents.

The use of MTBE has been banned in several states, however, because it finds its way into drinking-water supplies from spills and leaking storage tanks, giving the water a bad smell and taste and perhaps producing adverse health effects.

*Related Exercises:* 25.29 and 25.30

## Alkenes

Alkenes are unsaturated hydrocarbons that contain at least one  $\text{C}=\text{C}$  bond. The simplest alkene is  $\text{CH}_2=\text{CH}_2$ , called ethene (IUPAC) or ethylene. Ethylene is a plant hormone. It plays important roles in seed germination and fruit ripening. The next member of the series is  $\text{CH}_3-\text{CH}=\text{CH}_2$ , called propene or propylene. For alkenes with four or more carbon atoms, several isomers exist for each molecular formula. For example, there are four isomers of  $\text{C}_4\text{H}_8$ , as shown in Figure 25.10▶. Notice both their structures and their names.

▲ **Figure 25.10**  $\text{C}_4\text{H}_8$  structural isomers. Full structural formulas, names, and boiling points of alkenes having the molecular formula  $\text{C}_4\text{H}_8$ .

The names of alkenes are based on the longest continuous chain of carbon atoms that contains the double bond. The name given to the chain is obtained from the name of the corresponding alkane (Table 25.1) by changing the ending from *-ane* to *-ene*. The compound on the left in Figure 25.10, for example, has a double bond as part of a three-carbon chain; thus, the parent alkene is propene.

The location of the double bond along an alkene chain is indicated by a prefix number that designates the number of the carbon atom that is part of the double bond and is nearest an end of the chain. The chain is always numbered from the end that brings us to the double bond sooner and hence gives the smallest-numbered prefix. In propene the only possible location for the double bond is between the first and second carbons; thus, a prefix indicating its location is unnecessary. For butene (Figure 25.10) there are two possible positions for the double bond, either after the first carbon (1-butene) or after the second carbon (2-butene).

### GIVE IT SOME THOUGHT

How many distinct locations are there for one double bond in a five-carbon linear chain?

If a substance contains two or more double bonds, each is located by a numerical prefix. The ending of the name is altered to identify the number of double bonds: diene (two), triene (three), and so forth. For example,  $\text{CH}_2=\text{CH}-\text{CH}_2-\text{CH}=\text{CH}_2$  is 1,4-pentadiene.

The two isomers on the right in Figure 25.10 differ in the relative locations of their terminal methyl groups. These two compounds are **geometric isomers**, compounds that have the same molecular formula and the same groups bonded to one another, but differ in the spatial arrangement of these groups. ∞ (Section 24.4) In the *cis* isomer the two methyl groups are on the same side of the double bond, whereas in the *trans* isomer they are on opposite sides. Geometric isomers possess distinct physical properties and often differ significantly in their chemical behavior.

Geometric isomerism in alkenes arises because, unlike the  $\text{C}-\text{C}$  bond, the  $\text{C}=\text{C}$  bond resists twisting. Recall that the double bond between two carbon atoms consists of a  $\sigma$  and a  $\pi$  bond. ∞ (Section 9.6) Figure 25.11 shows a *cis* alkene. The carbon-carbon bond axis and the bonds to the hydrogen atoms and to the alkyl groups (designated R) are all in a plane. The  $p$  orbitals that overlap sideways to form the  $\pi$  bond are perpendicular to the molecular plane. As Figure 25.11 shows, rotation around the carbon-carbon double bond requires the  $\pi$  bond to be broken, a process that requires considerable energy (about 250 kJ/mol). While rotation about a double bond does not occur easily, it is a key process in the chemistry of vision. ∞ (Section 9.6: "Chemistry and Life: Chemistry of Vision")

▲ **Figure 25.11** Rotation about a carbon-carbon double bond. In an alkene, the overlap of the  $p$  orbitals that form the  $\pi$  bond is lost in the rotation. For this reason, rotation about carbon-carbon double bonds does not occur readily.

The addition reactions of alkynes resemble those of alkenes, as shown in the following examples:

### SAMPLE EXERCISE 25.5 Identifying the Product of a Hydrogenation Reaction

Write the structural formula for the product of the hydrogenation of 3-methyl-1-pentene.

#### SOLUTION

**Analyze:** We are asked to predict the compound formed when a particular alkene undergoes hydrogenation (reaction with  $\text{H}_2$ ).

**Plan:** To determine the structural formula of the reaction product, we must first write the structural formula or Lewis structure of the reactant. In the hydrogenation of the alkene,  $\text{H}_2$  adds to the double bond, producing an alkane. (That is, each carbon atom of the double bond forms a bond to an H atom, and the double bond is converted to a single bond.)

**Solve:** The name of the starting compound tells us that we have a chain of five C atoms with a double bond at one end (position 1) and a methyl group on the third C from that end (position 3):

Hydrogenation—the addition of two H atoms to the carbons of the double bond—leads to the following alkane:

**Comment:** The longest chain in the product alkane has five carbon atoms; its name is therefore 3-methylpentane.

#### PRACTICE EXERCISE

Addition of HCl to an alkene forms 2-chloropropane. What is the alkene?

*Answer:* propene

## Mechanism of Addition Reactions

As the understanding of chemistry has grown, chemists have been able to advance from simply cataloging reactions known to occur to explaining *how* they occur. An explanation of how a reaction proceeds is called a *mechanism*. [∞ \(Section 14.6\)](#)

In Equation 25.3 we considered the addition reaction between HBr and an alkene. This reaction is thought to proceed in two steps. In the first step, which is rate determining [[∞ \(Section 14.6\)](#)], the HBr molecule attacks the electron-rich double bond, transferring a proton to one of the two alkene carbons.

In the reaction of 2-butene with HBr, for example, the first step proceeds as follows:

The pair of electrons that formed the  $\pi$  bond between the carbon atoms in the alkene is used to form the new C—H bond.

The second step, involving the addition of  $\text{Br}^-$  to the positively charged carbon, is faster:

In this reaction the bromide ion ( $\text{Br}^-$ ) donates a pair of electrons to the carbon, forming the new C—Br bond.

Because the first rate-determining step in the reaction involves both the alkene and acid, the rate law for the reaction is second order, first order each in the alkene and HBr:

$$\text{Rate} = -\frac{\Delta[\text{CH}_3\text{CH}=\text{CHCH}_3]}{\Delta t} = k[\text{CH}_3\text{CH}=\text{CHCH}_3][\text{HBr}] \quad [25.9]$$

The energy profile for the reaction is shown in Figure 25.12  $\blacktriangledown$ . The first energy maximum represents the transition state in the first step of the mechanism. The second maximum represents the transition state for the second step. Notice that there is an energy minimum between the first and second steps of the reaction. This energy minimum corresponds to the energies of the intermediate species,  $\text{CH}_3\overset{+}{\text{C}}\text{H}-\text{CH}_2\text{CH}_3$  and  $\text{Br}^-$ .

$\blacktriangleleft$  **Figure 25.12** Energy profile for addition of HBr to 2-butene. The chemical formulas given in brackets in Equations 25.7 and 25.8 are the transition states.

To show electron movement in reactions like these, chemists often use curved arrows, which point in the direction of the electron flow (from a negative charge toward a positive charge). For the addition of HBr to 2-butene, the shifts in electron positions are

## Aromatic Hydrocarbons

Aromatic hydrocarbons are a large and important class of hydrocarbons. The simplest member of the series is benzene ( $\text{C}_6\text{H}_6$ ), whose structure is shown in Figure 25.3. The planar, highly symmetrical structure of benzene, with its  $120^\circ$  bond angles, suggests a high degree of unsaturation. You might therefore expect benzene to resemble the unsaturated hydrocarbons and to be highly reactive. The chemical behavior of benzene, however, is unlike that of alkenes or alkynes. Benzene and the other aromatic hydrocarbons are much more stable than alkenes and alkynes because the  $\pi$  electrons are delocalized in the  $\pi$  orbitals. [☞ \(Section 9.6\)](#)

We can estimate the stabilization of the  $\pi$  electrons in benzene by comparing the energy required to add hydrogen to benzene to form a saturated compound with the energy required to hydrogenate certain alkenes. The hydrogenation of benzene to form cyclohexane can be represented as

The enthalpy change in this reaction is  $-208 \text{ kJ/mol}$ . The heat of hydrogenation of the cyclic alkene cyclohexene is  $-120 \text{ kJ/mol}$ :

Similarly, the heat released on hydrogenating 1,4-cyclohexadiene is  $-232 \text{ kJ/mol}$ :

From these last two reactions, it appears that the heat of hydrogenating each double bond is roughly  $116 \text{ kJ/mol}$  for each bond. Benzene contains the equivalent of three double bonds. We might expect, therefore, that the heat of hydrogenating benzene would be about 3 times  $-116$ , or  $-348 \text{ kJ/mol}$ , if benzene behaved as though it were “cyclohexatriene”; that is, if it behaved as though it had three isolated double bonds in a ring. Instead, the heat released is  $140 \text{ kJ}$  less than this, indicating that benzene is more stable than would be expected for three double bonds. The difference of  $140 \text{ kJ/mol}$  between the “expected” heat of hydrogenation,  $-348 \text{ kJ/mol}$ , and the observed heat of hydrogenation,  $-208 \text{ kJ/mol}$ , is due to stabilization of the  $\pi$  electrons through delocalization in the  $\pi$  orbitals that extend around the ring in this aromatic compound.

Each aromatic ring system is given a common name as shown in Figure 25.13 [◀](#). Although aromatic hydrocarbons are unsaturated, they do not readily undergo addition reactions. The delocalized  $\pi$  bonding causes aromatic compounds

**▲ Figure 25.13 Condensed structural formulas and common names of several aromatic compounds.** The aromatic rings are represented by hexagons with a circle inscribed inside to denote aromatic character. Each corner represents a carbon atom. Each carbon is bound to three other atoms—either three carbons or two carbons and a hydrogen. The hydrogen atoms are not shown.

to behave quite differently from alkenes and alkynes. Benzene, for example, does not add  $\text{Cl}_2$  or  $\text{Br}_2$  to its double bonds under ordinary conditions. In contrast, aromatic hydrocarbons undergo **substitution reactions** relatively easily. In a substitution reaction one atom of a molecule is removed and replaced (substituted) by another atom or group of atoms. When benzene is warmed in a mixture of nitric and sulfuric acids, for example, hydrogen is replaced by the nitro group,  $\text{NO}_2$ :

More vigorous treatment results in substitution of a second nitro group into the molecule:

There are three possible isomers of benzene with two nitro groups attached. These three isomers are named *ortho*-, *meta*-, and *para*-dinitrobenzene:

Mainly the *meta* isomer is formed in the reaction of nitric acid with nitrobenzene.

The bromination of benzene, which is carried out using  $\text{FeBr}_3$  as a catalyst, is another substitution reaction:

In a similar reaction, called the *Friedel-Crafts reaction*, alkyl groups can be substituted onto an aromatic ring by reaction of an alkyl halide with an aromatic compound in the presence of  $\text{AlCl}_3$  as a catalyst:

### GIVE IT SOME THOUGHT

When naphthalene is reacted with nitric and sulfuric acids, two compounds containing one nitro group are formed. Draw the structures of these two compounds.

If you look up the U.S. Environmental Protection Agency's list of priority pollutants, you will find "PAHs" among the top 25. PAHs are "polycyclic aromatic hydrocarbons," a term which refers to an entire class of molecules whose structures are fused benzene rings, such as naphthalene and anthracene (Figure 25.13). Traditionally, molecules with three fused benzene rings or more are considered PAHs; some examples are shown below.

Tetracene

Chrysene

Pyrene

Benzo[a]pyrene

Pentacene

Coronene

You will notice that only one representative resonance structure is shown for each molecule, and that all these molecules resemble graphite. [↔ \(Section 11.8\)](#) PAHs are found in coal and tars, and occur as side products of combustion of carbon-containing compounds. Therefore, PAHs can be found as particulate matter in air, water, and adsorbed to sediments and soil. They are relatively insoluble in water, as you would expect; the larger the molecule, the less water soluble, but more fat soluble, it is. Many PAHs are carcinogenic, meaning that they are known to cause cancer. Benzo[a]pyrene was the first chemical carcinogen discovered; it is one of the many components of cigarette smoke.

In spite of the toxicity of PAHs, there is great scientific interest in their electronic properties. Tetracene and pentacene are large enough that their delocalized  $\pi$  electrons provide a very high conductivity in the plane of the rings, but these molecules are also small enough that they are chemically easier to work with compared to larger PAHs. Tetracene is yellow, and pentacene is dark blue, due to their delocalized  $\pi$  electron systems. [↔ \(Section 9.6\)](#) Pentacene is being explored as a component in organic thin-film transistors and solar energy conversion devices. [↔ \(Section 12.3\)](#)

## 25.4 ORGANIC FUNCTIONAL GROUPS

The reactivity of organic compounds can be attributed to particular atoms or groups of atoms within the molecules. A site of reactivity in an organic molecule is called a *functional group* because it controls how the molecule behaves or functions. [↔ \(Section 25.1\)](#) As we have seen, the presence of  $C=C$  double bonds or  $C\equiv C$  triple bonds in a hydrocarbon markedly increases its reactivity. Furthermore, these functional groups each undergo characteristic reactions. Each distinct kind of functional group often undergoes the same kinds of reactions in every molecule, regardless of the size and complexity of the molecule. Thus, the chemistry of an organic molecule is largely determined by the functional groups it contains.

Table 25.4 [▶](#) lists the most common functional groups and gives examples of each. Notice that in addition to  $C=C$  double bonds or  $C\equiv C$  triple bonds, there are also many functional groups that contain elements other than just C and H. Many of the functional groups contain other nonmetals such as O and N.

We can think of organic molecules as being composed of functional groups that are bonded to one or more alkyl groups. The alkyl groups, which are made of  $C-C$  and  $C-H$  single bonds, are the less reactive portions of the organic molecules. In describing general features of organic compounds, chemists often use the designation R to represent any alkyl group: methyl, ethyl, propyl, and so on. Alkanes, for example, which contain no functional group, are represented as  $R-H$ . Alcohols, which contain the  $-OH$ , or alcohol functional group, are represented as  $R-OH$ . If two or more different alkyl groups are present in a

TABLE 25.4 Common Functional Groups in Organic Compounds

Functional Group	Type of Compound	Suffix or Prefix	Example	Systematic Name (common name)
	Alkene	-ene		Ethene (Ethylene)
	Alkyne	-yne		Ethyne (Acetylene)
	Alcohol	-ol		Methanol (Methyl alcohol)
	Ether	ether		Dimethyl ether
	Haloalkane	halo-		Chloromethane (Methyl chloride)
<small>(X = halogen)</small>				
	Amine	-amine		Ethylamine
	Aldehyde	-al		Ethanal (Acetaldehyde)
	Ketone	-one		Propanone (Acetone)
	Carboxylic acid	-oic acid		Ethanoic acid (Acetic acid)
	Ester	-oate		Methyl ethanoate (Methyl acetate)
	Amide	-amide		Ethanamide (Acetamide)

molecule, we will designate them as R, R', R'', and so forth. In this section we examine the structure and chemical properties of two functional groups, alcohols and ethers. Later in this section we consider some additional functional groups that contain C=O bonds.

▲ **Figure 25.14** Structural formulas of six important alcohols. Common names are given in blue.

▲ **Figure 25.15** Everyday alcohols. Many of the products we use every day—from rubbing alcohol and throat lozenges to hair spray and antifreeze—are composed either entirely or mainly of alcohols.

## Alcohols

Alcohols are hydrocarbon derivatives in which one or more hydrogens of a parent hydrocarbon have been replaced by a *hydroxyl* or *alcohol* functional group, —OH. Figure 25.14 ◀ shows the structural formulas and names of several alcohols. Note that the name for an alcohol ends in *-ol*. The simple alcohols are named by changing the last letter in the name of the corresponding alkane to *-ol*—for example, ethane becomes ethanol. Where necessary, the location of the OH group is designated by an appropriate numeral prefix that indicates the number of the carbon atom bearing the OH group, as shown in many of the examples in Figure 25.14.

The O—H bond is polar, so alcohols are much more soluble in polar solvents such as water than are hydrocarbons. The —OH functional group can also participate in hydrogen bonding. As a result, the boiling points of alcohols are much higher than those of their parent alkanes.

Figure 25.15 ◀ shows several familiar commercial products that consist entirely or in large part of an organic alcohol. Let's consider how some of the more important alcohols are formed and used.

The simplest alcohol, methanol (methyl alcohol), has many important industrial uses and is produced on a large scale. Carbon monoxide and hydrogen are heated together under pressure in the presence of a metal oxide catalyst:

Because methanol has a very high octane rating as an automobile fuel, it is used as a gasoline additive and as a fuel in its own right.

Ethanol (ethyl alcohol,  $\text{C}_2\text{H}_5\text{OH}$ ) is a product of the fermentation of carbohydrates such as sugar and starch. In the absence of air, yeast cells convert carbohydrates into a mixture of ethanol and  $\text{CO}_2$ , as shown in Equation 25.15. In the process, yeast derives energy necessary for growth.

This reaction is carried out under carefully controlled conditions to produce beer, wine, and other beverages in which ethanol is the active ingredient.

Many polyhydroxyl alcohols (those containing more than one OH group) are known. The simplest of these is 1,2-ethanediol (ethylene glycol,  $\text{HOCH}_2\text{CH}_2\text{OH}$ ). This substance is the major ingredient in automobile antifreeze. Another common polyhydroxyl alcohol is 1,2,3-propanetriol [glycerol,  $\text{HOCH}_2\text{CH(OH)CH}_2\text{OH}$ ]. It is a viscous liquid that dissolves readily in water and is widely used as a skin softener in cosmetic preparations. It is also used in foods and candies to keep them moist.

Phenol is the simplest compound with an OH group attached to an aromatic ring. One of the most striking effects of the aromatic group is the greatly increased acidity of the OH group. Phenol is about 1 million times more acidic in water than a typical nonaromatic alcohol such as ethanol. Even so, it is not a very strong acid ( $K_a = 1.3 \times 10^{-10}$ ). Phenol is used industrially to make several kinds of plastics and dyes. It is also used as a topical anesthetic in many sore throat sprays.

Cholesterol, shown in Figure 25.14, is a biochemically important alcohol. The OH group forms only a small component of this rather large molecule, so cholesterol is only slightly soluble in water (0.26 g per 100 mL of  $\text{H}_2\text{O}$ ). Cholesterol is a normal component of our bodies; when present in excessive amounts, however,

it may precipitate from solution. It precipitates in the gallbladder to form crystalline lumps called *gallstones*. It may also precipitate against the walls of veins and arteries and thus contribute to high blood pressure and other cardiovascular problems. The amount of cholesterol in our blood is determined by how much cholesterol we eat and by total dietary intake. There is evidence that excessive caloric intake leads the body to synthesize excessive cholesterol.

## Ethers

Compounds in which two hydrocarbon groups are bonded to one oxygen are called **ethers**. Ethers can be formed from two molecules of alcohol by splitting out a molecule of water. The reaction is catalyzed by sulfuric acid, which takes up water to remove it from the system:

A reaction in which water is split out from two substances is called a *condensation reaction*. [↔](#)(Sections 12.4 and 22.8)

Ethers are used as solvents. Both diethyl ether and the cyclic ether tetrahydrofuran are common solvents for organic reactions:

## Aldehydes and Ketones

Several of the functional groups listed in Table 25.4 contain a C=O double bond. This particular group of atoms is called a **carbonyl group**. The carbonyl group, together with the atoms that are attached to the carbon of the carbonyl group, defines several important functional groups that we consider in this section. In **aldehydes** the carbonyl group has at least one hydrogen atom attached, as in the following examples:

In **ketones** the carbonyl group occurs at the interior of a carbon chain and is therefore flanked by carbon atoms:

Aldehydes and ketones can be prepared by carefully controlled oxidation of alcohols. It is fairly easy to oxidize alcohols. Complete oxidation results in formation of CO<sub>2</sub> and H<sub>2</sub>O, as in the burning of methanol:

Controlled partial oxidation to form other organic substances, such as aldehydes and ketones, is carried out by using various oxidizing agents such as air, hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), ozone (O<sub>3</sub>), and potassium dichromate (K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>).

(a)

(b)

▲ **Figure 25.16** **Everyday carboxylic acids and esters.** (a) Spinach and some cleaners contain oxalic acid; vinegar contains acetic acid; vitamin C is ascorbic acid; citrus fruits contain citric acid; and aspirin is acetylsalicylic acid (which is both an acid and an ester). (b) Many sunburn lotions contain the ester benzocaine; some nail polish remover is ethyl acetate; vegetable oils are also esters.

### GIVE IT SOME THOUGHT

Write the condensed formula for the ketone that would result from partial oxidation of this alcohol.

Many compounds found in nature possess an aldehyde or ketone functional group. Vanilla and cinnamon flavorings are naturally occurring aldehydes. Two isomers of the ketone carvone impart the characteristic flavors of spearmint leaves or caraway seeds.

Ketones are less reactive than aldehydes and are used extensively as solvents. Acetone, which boils at 56 °C, is the most widely used ketone. The carbonyl functional group imparts polarity to the solvent. Acetone is completely miscible with water, yet it dissolves a wide range of organic substances. 2-Butanone ( $\text{CH}_3\text{COCH}_2\text{CH}_3$ ), which boils at 80 °C, is also used industrially as a solvent.

### Carboxylic Acids and Esters

We discussed carboxylic acids in Sections 4.3 and 16.10. **Carboxylic acids** contain the *carboxyl* functional group, which is often written as  $\text{COOH}$ . These weak acids are widely distributed in nature and are common in consumer products [Figure 25.16(a)◀]. They are also important in the manufacture of polymers used to make fibers, films, and paints. Figure 25.17▼ shows the structural formulas of several carboxylic acids. Notice that oxalic acid and citric acid contain two and three carboxyl groups, respectively. The common names of many carboxylic acids are based on their historical origins. Formic acid, for example, was first prepared by extraction from ants; its name is derived from the Latin word *formica*, meaning “ant.”

Carboxylic acids can be produced by oxidation of alcohols in which the OH group is attached to a  $\text{CH}_2$  group, such as ethanol or propanol. Under appropriate conditions the corresponding aldehyde may be isolated as the first product of oxidation. These transformations are shown for ethanol in the following equations, in which (O) represents an oxidant that can provide oxygen atoms:

► **Figure 25.17**  
**Structural formulas of common carboxylic acids.** The IUPAC names are given in black type for the monocarboxylic acids, but they are generally referred to by their common names (blue type).

The air oxidation of ethanol to acetic acid is responsible for causing wines to turn sour, producing vinegar.

Acetic acid can also be produced by the reaction of methanol with carbon monoxide in the presence of a rhodium catalyst:

This reaction involves, in effect, the insertion of a carbon monoxide molecule between the CH<sub>3</sub> and OH groups. A reaction of this kind is called *carbonylation*.

Carboxylic acids can undergo condensation reactions with alcohols to form **esters**:

Esters are compounds in which the H atom of a carboxylic acid is replaced by a carbon-containing group:

Figure 25.16(b) shows some common esters, which are named by using first the group from which the alcohol is derived and then the group from which the acid is derived. For example:

Esters generally have very pleasant odors. They are largely responsible for the pleasant aromas of fruit. Pentyl acetate (CH<sub>3</sub>COOCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub>), for example, is responsible for the odor of bananas.

When esters are treated with an acid or a base in aqueous solution, they are hydrolyzed; that is, the molecule is split into its alcohol and acid components:

In this example the hydrolysis was carried out in basic medium. The products of the reaction are the sodium salt of the carboxylic acid and the alcohol.

**SAMPLE EXERCISE 25.6** Naming Esters and Predicting Hydrolysis Products

In a basic aqueous solution, esters react with hydroxide ion to form the salt of the carboxylic acid and the alcohol from which the ester is constituted. Name each of the following esters, and indicate the products of their reaction with aqueous base.

**SOLUTION**

**Analyze:** We are given two esters and asked to name them and to predict the products formed when they undergo hydrolysis (split into an alcohol and carboxylate ion) in basic solution.

**Plan:** Esters are formed by the condensation reaction between an alcohol and a carboxylic acid. To name an ester, we must analyze its structure and determine the identities of the alcohol and acid from which it is formed. We can identify the alcohol by adding an OH to the alkyl group attached to the O atom of the carboxyl (COO) group. We can identify the acid by adding an H group to the O atom of the carboxyl group. We have learned that the first part of an ester name indicates the alcohol portion and the second indicates the acid portion. The name conforms to how the ester undergoes hydrolysis in base, reacting with base to form an alcohol and a carboxylate anion.

**Solve:**

(a) This ester is derived from ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) and benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ). Its name is therefore ethyl benzoate. The net ionic equation for reaction of ethyl benzoate with hydroxide ion is

The products are benzoate ion and ethanol.

(b) This ester is derived from phenol ( $\text{C}_6\text{H}_5\text{OH}$ ) and butanoic acid (commonly called butyric acid) ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{COOH}$ ). The residue from the phenol is called the phenyl group. The ester is therefore named phenyl butyrate. The net ionic equation for the reaction of phenyl butyrate with hydroxide ion is

The products are butyrate ion and phenol.

**PRACTICE EXERCISE**

Write the structural formula for the ester formed from propyl alcohol and propionic acid.

**Amines and Amides**

Amines are organic bases.  $\infty$  (Section 16.7) They have the general formula  $\text{R}_3\text{N}$ , where R may be H or a hydrocarbon group, as in the following examples:

Amines containing a hydrogen bonded to nitrogen can undergo condensation reactions with carboxylic acids to form **amides**:

We may consider the amide functional group to be derived from a carboxylic acid with an  $\text{NR}_2$  group replacing the  $\text{OH}$  of the acid, as in these additional examples:

The amide linkage

where  $\text{R}$  and  $\text{R}'$  are organic groups, is the key functional group in the structures of proteins, as we will see in Section 25.7.

## 25.5 CHIRALITY IN ORGANIC CHEMISTRY

A molecule possessing a nonsuperimposable mirror image is termed **chiral** (Greek *cheir*, "hand").  $\infty$  (Section 24.4) *Compounds containing carbon atoms with four different attached groups are inherently chiral.* A carbon atom with four different attached groups is called a *chiral center*. For example, the structural formula of 2-bromopentane is

**▲ Figure 25.20** The two enantiomeric forms of 2-bromopentane. The mirror-image isomers are not superimposable on each other.

All four groups attached to the second carbon are different, making that carbon a chiral center. Figure 25.20  $\blacktriangleleft$  illustrates the two nonsuperimposable mirror images of this molecule.

If you imagine trying to move the left-hand molecule to the right and turning it in every possible way, you will conclude that it cannot be superimposed on the right-hand molecule. Nonsuperimposable mirror images are called optical isomers or *enantiomers*.  $\infty$  (Section 24.4)

Organic chemists use the labels *R* and *S* to distinguish the two forms. We need not go into the rules for deciding on the labels.

Enantiomers, such as the two forms of 2-bromopentane shown in Figure 25.20, have identical physical properties, such as melting and boiling points, and identical chemical properties when they react with nonchiral reagents. Only in a chiral environment do they exhibit different behaviors. One of the more interesting properties of chiral substances is that their solutions may rotate the plane of polarized light, as explained in Section 24.4.

Chirality is very common in organic substances. It is not often observed, however, because when a chiral substance is synthesized in a typical chemical reaction, the two enantiomeric species are formed in precisely the same quantity.

The resulting mixture of isomers is called a *racemic* mixture. A racemic mixture of enantiomers does not rotate the plane of polarized light because the two forms rotate the light to equal extents in opposite directions. ∞ (Section 24.4)

Naturally occurring substances often are found as just one enantiomer. An example is tartaric acid, which has the structural formula\*

This compound has not one, but two chiral centers. Both the inner carbon atoms are attached to four different groups. Tartaric acid is found in nature, either as the free acid or as a salt of calcium or potassium, in fruit extracts and especially as crystals deposited during wine fermentation. The naturally occurring form is optically active in solution. Tartaric acid is typical; many biologically important molecules are chiral. In Section 25.7 we will examine the amino acids, all of which (except for glycine) are chiral and found in nature as just one of the enantiomers.

Many drugs of importance in human medicine are chiral substances. When a drug is administered as a racemic mixture, it often turns out that only one of the enantiomers has beneficial results. The other is either inert or nearly so, or may even have a harmful effect. For this reason, a great deal of attention has been given in recent years to methods for synthesizing the desired enantiomer of chiral drugs. Synthesizing just one enantiomer of a chiral substance can be very difficult and costly, but the rewards are worth the effort. Worldwide sales of single-enantiomer drugs amount to over \$125 billion annually! As an example of the different behavior of enantiomers, the drug (*R*)-albuterol (Figure 25.21 ►) is an effective bronchodilator used to relieve the symptoms of asthma. The enantiomer (*S*)-albuterol is not only ineffective as a bronchodilator but actually counters the effects of (*R*)-albuterol. As another example, the nonsteroidal analgesic ibuprofen (marketed under the trade names Advil™, Motrin™, and Nuprin™) is a chiral molecule usually sold as the racemic mixture. However, a preparation consisting of just the more active enantiomer, (*S*)-ibuprofen (Figure 25.22 ▼), relieves pain and reduces inflammation more rapidly than the racemic mixture. For this reason, the chiral version of the drug may in time come to replace the racemic mixture.

▲ **Figure 25.21 (*R*)-Albuterol.** This compound, which acts as a bronchodilator in patients with asthma, is one member of a pair of optical isomers. The other member, (*S*)-albuterol, does not have the same physiological effect.

### GIVE IT SOME THOUGHT

What are the requirements on the four groups attached to a carbon atom in order that it be a chiral center?

▲ **Figure 25.22 (*S*)-Ibuprofen.** For relieving pain and reducing inflammation, the ability of this enantiomer far outweighs that of the (*R*) isomer.

\*Louis Pasteur discovered chirality while he was studying crystalline samples of salts of tartaric acid.

## 25.6 INTRODUCTION TO BIOCHEMISTRY

---

The several types of organic functional groups discussed in Section 25.4 generate a vast array of molecules with very specific chemical reactivities. Nowhere is this specificity more apparent than in *biochemistry*—the chemistry of living organisms.

Before we discuss specific biochemical molecules, we can make some general observations. As we will see, many biologically important molecules are quite large. The synthesis of these molecules is a remarkable aspect of biochemistry, one that places large demands on the chemical systems in living organisms. Organisms build biomolecules from much smaller and simpler substances that are readily available in the biosphere. The synthesis of large molecules requires energy because most of the reactions are endothermic. The ultimate source of this energy is the Sun. Mammals and other animals have essentially no capacity for using solar energy directly; rather, they depend on plant photosynthesis to supply the bulk of their energy needs. [∞ \(Section 24.2\)](#)

In addition to requiring large amounts of energy, living organisms are highly organized. The complexity of all the substances that make up even the simplest single-cell organisms and the relationships among all the many chemical processes that occur are truly amazing. In thermodynamic terms this high degree of organization means that the entropy of living systems is much lower than the entropy of the random mix of raw materials from which the systems formed. Thus, living systems must continuously work against the spontaneous tendency toward increased entropy that is characteristic of all organized systems. Maintaining a high degree of order places additional energetic requirements on organisms. (You may want to review the second law of thermodynamics in Section 19.3 and the “Chemistry and Life” box there.)

We have introduced you to some important biochemical applications of fundamental chemical ideas in the “Chemistry and Life” essays that appear throughout this text. A complete listing of the topics covered and their locations in the text are included in the table of contents. The remainder of this chapter will serve as only a brief introduction to other aspects of biochemistry. Nevertheless, you will see some patterns emerging. Hydrogen bonding [∞ \(Section 11.2\)](#), for example, is critical to the function of many biochemical systems, and the geometry of molecules can govern their biological importance and activity. Many of the large molecules in living systems are polymers (Section 12.6) of much smaller molecules. These **biopolymers** can be classified into three broad categories: proteins, polysaccharides (carbohydrates), and nucleic acids. Lipids are another common class of molecules in living systems, but they are usually large molecules, not biopolymers.

## 25.7 PROTEINS

---

**Proteins** are macromolecular substances present in all living cells. About 50% of your body’s dry weight is protein. Proteins serve as the major structural components in animal tissues; they are a key part of skin, nails, cartilage, and muscles. Other proteins catalyze reactions, transport oxygen, serve as hormones to regulate specific body processes, and perform other tasks. Whatever their function, all proteins are chemically similar, being composed of the same basic building blocks, called **amino acids**.

### Amino Acids

*The building blocks of all proteins are  $\alpha$ -amino acids, which are substances in which the amino group is located on the carbon atom immediately adjacent to the carboxylic acid group. Thus, there is always one carbon atom between the*

amino group and the carboxylic acid group. The general formula for an  $\alpha$ -amino acid is represented in the following ways:

The doubly ionized form, called the zwitterion, usually predominates at near-neutral values of pH. This form is a result of the transfer of a proton from the carboxylic acid group to the basic amine group.  $\rightleftharpoons$  (Section 16.10: "Chemistry and Life: The Amphiprotic Behavior of Amino Acids")

Amino acids differ from one another in the nature of their R groups. Twenty-two amino acids have been identified in nature. Figure 25.23  $\blacktriangledown$  shows the structural formulas of the 20 amino acids found in the proteins of our bodies. Those amino acids for which the side group is relatively nonpolar are shown in Figure 25.23(a). Those that contain a relatively polar or charged side group are shown in Figure 25.23(b)  $\blacktriangledown$ . Our bodies can synthesize ten of the amino acids in sufficient amounts for our needs. The other ten must be ingested and are called *essential amino acids* because they are necessary components of our diet.

**▲ Figure 25.23(a) The 9 amino acids found in the human body that contain relatively nonpolar, hydrophobic side groups.** The acids are shown in the zwitterionic form in which they exist in water at near-neutral pH. The names for each amino acid are given with their three-letter codes and one-letter codes in parentheses.

## ► Figure 25.23(b)

**The 11 amino acids found in the human body that contain polar side groups.**

The acids are shown in the zwitterionic form in which they exist in water at a near-neutral pH. The names for each amino acid are given with their three-letter codes and one-letter codes in parentheses.

(b)

## ▲ Figure 25.24 Alanine

**enantiomers.** The middle carbon of alanine is chiral, and therefore there are two enantiomers, which by definition are nonsuperimposable mirror images of each other.

The  $\alpha$ -carbon atom of the amino acids, which bears both the ammonium and carboxylate groups, has four different groups attached to it. The amino acids are thus chiral (except for glycine, which has two hydrogens attached to the central carbon). Figure 25.24 ◀ shows the two enantiomers of the amino acid alanine. For historical reasons, the two enantiomeric forms of amino acids are often distinguished by the labels D (from the Latin *dexter*, “right”) and L (from the Latin *laevus*, “left”). Nearly all amino acids normally found in living organisms are “left-handed”; that is, all have the L configuration at the chiral center (except for glycine, which is not chiral because its central carbon has two hydrogens attached). The principal exception to the dominance of L amino acids in nature are the proteins that make up the cell walls of bacteria, which can contain considerable quantities of the D isomers.

**Polypeptides and Proteins**

Amino acids are linked together into proteins by amide groups, one of the functional groups introduced in Section 25.4:

Each of these amide groups is called a **peptide bond** when it is formed by amino acids. A peptide bond is formed by a condensation reaction between the carboxyl group of one amino acid and the amino group of another amino acid.

Alanine and glycine, for example, can react to form the dipeptide glycylalanine:

The amino acid that furnishes the carboxyl group for peptide-bond formation is named first, with a *-yl* ending; then the amino acid furnishing the amino group is named. Based on the three-letter codes for the amino acids from Figure 25.23, glycylalanine can be abbreviated Gly-Ala, or as GA using the one-letter codes for the amino acids. In this notation it is understood that the unreacted amino group is on the left and the unreacted carboxyl group on the right. The artificial sweetener *aspartame* (Figure 25.25▶) is the methyl ester of the dipeptide of aspartic acid and phenylalanine:

▲ **Figure 25.25 Sweet stuff.** The artificial sweetener aspartame is the methyl ester of a dipeptide.

### SAMPLE EXERCISE 25.7 | Drawing the Structural Formula of a Tripeptide

Draw the full structural formula for alanyl-glycylserine, or AGS.

#### SOLUTION

**Analyze:** We are given the name of a substance with peptide bonds and asked to write its full structural formula.

**Plan:** The name of this substance suggests that three amino acids—alanine, glycine, and serine—have been linked together, forming a *tripeptide*. Note that the ending *-yl* has been added to each amino acid except for the last one, serine. By convention, the sequence of amino acids that make up peptides and proteins are written from the nitrogen end to the carbon end: the first-named amino acid (alanine, in this case) has a free amino group and the last-named one (serine) has a free carboxyl group. Thus, we can construct the structural formula of the tripeptide from its amino acid building blocks (Figure 25.23).

**Solve:** We first combine the carboxyl group of alanine with the amino group of glycine to form a peptide bond and then the carboxyl group of glycine with the amino group of serine to form another peptide group. The resulting tripeptide consists of three “building blocks” connected by peptide bonds:

We can abbreviate this tripeptide as Ala-Gly-Ser, or AGS.

## PRACTICE EXERCISE

Name the dipeptide that has the following structure, and give its abbreviation:

Answer: serylaspartic acid; Ser-Asp, or SD.

▲ **Figure 25.26**  $\alpha$ -Helix structure for a protein. The symbol R represents any one of the several side chains shown in Figure 25.23.

▲ **Figure 25.27**  $\beta$ -Sheet structure for a protein. The symbol R represents any one of the several side chains shown in Figure 25.23.

**Polypeptides** are formed when a large number of amino acids are linked together by peptide bonds. Proteins are linear (that is, unbranched) polypeptide molecules with molecular weights ranging from about 6000 to over 50 million amu. Because up to 22 different amino acids are linked together in proteins and because proteins consist of hundreds of amino acids, the number of possible arrangements of amino acids within proteins is virtually limitless.

## Protein Structure

The arrangement, or sequence, of amino acids along a protein chain is called its **primary structure**. The primary structure gives the protein its unique identity. A change in even one amino acid can alter the biochemical characteristics of the protein. For example, sickle-cell anemia is a genetic disorder resulting from a single replacement in a protein chain in hemoglobin. The chain that is affected contains 146 amino acids. The substitution of a single amino acid with a hydrocarbon side chain for one that has an acidic functional group in the side chain alters the solubility properties of the hemoglobin, and normal blood flow is impeded. [☞ \(Section 13.6: “Chemistry and Life: Sickle-Cell Anemia”\)](#)

Proteins in living organisms are not simply long, flexible chains with random shapes. Rather, the chains self-assemble into particular structures based on the same kinds of intermolecular forces we learned about in Chapter 11. The **secondary structure** of a protein refers to how segments of the protein chain are oriented in a regular pattern.

One of the most important and common secondary structure arrangements is the  $\alpha$  helix, first proposed by Linus Pauling and R. B. Corey. The helix arrangement is shown in schematic form in Figure 25.26 ◀. Imagine winding a long protein chain in a helical fashion around a long cylinder. The helix is held in position by hydrogen-bond interactions between N—H bonds and the oxygens of nearby carbonyl groups in the amide backbone of the protein; the R groups are not involved. The pitch of the helix and the diameter of the cylinder must be such that (1) no bond angles are strained and (2) the N—H and C=O functional groups on adjacent turns are in proper position for hydrogen bonding. An arrangement of this kind is possible for some amino acids along the chain, but not for others. Large protein molecules may contain segments of the chain that have the  $\alpha$ -helical arrangement interspersed with sections in which the chain is in a random coil.

Another common structural motif in proteins is the beta ( $\beta$ ) sheet. Beta sheets are made of two strands of peptides that hydrogen bond their backbone amide groups more like a zipper than an alpha-helical spiral (Figure 25.27 ◀). A single protein chain can form a  $\beta$  sheet if it has a flexible loop connecting the two  $\beta$  sheet partners.

## GIVE IT SOME THOUGHT

If you heat a protein to break the intramolecular hydrogen bonds, will you maintain the  $\alpha$  helical or  $\beta$  sheet structure?

Proteins are not active biologically unless they are in a particular shape in solution. The process by which the protein adopts its biologically active shape is called **folding**. The overall shape of a protein in its folded form—determined by all the bends, kinks, and sections of rodlike  $\alpha$ -helical,  $\beta$ -sheet, or flexible coil components—is called the **tertiary structure**. Figure 24.11 shows the tertiary structure of myoglobin, a protein with a molecular weight of about 18,000 amu and containing one heme group. [∞ \(Section 24.2\)](#) Notice that some sections of the protein consist of  $\alpha$ -helices.

Myoglobin is a *globular protein*, one that folds into a compact, roughly spherical shape. Globular proteins are generally soluble in water and are mobile within cells. They have nonstructural functions, such as combating the invasion of foreign objects, transporting and storing oxygen, and acting as catalysts. The *fibrous proteins* form a second class of proteins. In these substances the long coils align themselves in a more-or-less parallel fashion to form long, water-insoluble fibers. Fibrous proteins provide structural integrity and strength to many kinds of tissue and are the main components of muscle, tendons, and hair. The largest known proteins, in excess of 27,000 amino acids long, are muscle proteins called the titins.

The tertiary structure of a protein is maintained by many different interactions. Certain foldings of the protein chain lead to lower-energy (more stable) arrangements than do other folding patterns. For example, a globular protein dissolved in aqueous solution folds in such a way that the nonpolar hydrocarbon portions are tucked within the molecule, away from the polar water molecules. Most of the more polar acidic and basic side chains, however, project into the solution where they can interact with water molecules through ion-dipole, dipole-dipole, or hydrogen-bonding interactions.

One of the most important classes of proteins is *enzymes*, large protein molecules that serve as catalysts. [∞ \(Section 14.7\)](#) Enzymes usually catalyze only very specific reactions. Their tertiary structure generally dictates that only certain substrate molecules can interact with the active site of the enzyme (Figure 25.28 ▶).

▼ **Figure 25.28 An enzyme and its substrate.** A computer-generated structure of an enzyme showing the carbon backbone as a green ribbon. The substrate (violet) is shown at the active site.

## Chemistry and Life

### THE ORIGINS OF CHIRALITY IN LIVING SYSTEMS

The presence of a “handedness” in the molecules that make up living systems is a key feature of life on Earth. The insistence of nature on just one chiral form in the molecules of life is called *homochirality*. How did the dominance of the L-amino acids arise? Why are the naturally occurring helices of protein and DNA, which we will discuss in Section 25.10, all right-turn helices? Homochirality could have arisen by chance in the course of evolution or because it was “seeded” in some way at the beginnings of life. One theory is that chirality was introduced early in Earth’s evolutionary history, through seeding by chiral amino acids that fell on the planet from outer space.

Examination of the Murchison meteorite, which fell to Earth in 1969, has revealed the presence of amino acids. For some of the acids, there appears to be a surplus of the L form. One theory proposes that the chiral amino acids could have been synthesized in interstellar space by the action of circularly

polarized starlight.\* Astronomers in Australia have recently observed circular polarization in the infrared light from a region of intense star birth in the Orion nebula. These workers calculate that a similar degree of circular polarization could be present in the visible and ultraviolet light from this source. Light that has the energy required to break chemical bonds, if circularly polarized, could give rise to new chiral molecules with a preference for one enantiomer over the other. Perhaps the homochirality we observe on Earth today arose, through a process of amplification and refinement in the course of evolutionary development, from molecules that were formed in interstellar space when the planet was young.

\*Circularly polarized light is like plane-polarized light, as shown in Figure 24.21, except that the plane continuously rotates either to the left or to the right. Thus, in a sense, circularly polarized light is chiral.

## 25.8 CARBOHYDRATES

▲ **Figure 25.29** Linear structure of glucose and fructose.

Carbohydrates are an important class of naturally occurring substances found in both plant and animal matter. The name **carbohydrate** (hydrate of carbon) comes from the empirical formulas for most substances in this class, which can be written as  $C_x(H_2O)_y$ . For example, **glucose**, the most abundant carbohydrate, has the molecular formula  $C_6H_{12}O_6$ , or  $C_6(H_2O)_6$ . Carbohydrates are not really hydrates of carbon; rather, they are polyhydroxy aldehydes and ketones. Glucose, for example, is a six-carbon aldehyde sugar; whereas **fructose**, the sugar that occurs widely in fruit, is a six-carbon ketone sugar (Figure 25.29 ◀).

Glucose, having both alcohol and aldehyde functional groups and having a reasonably long and flexible backbone, can react with itself to form a six-member-ring structure, as shown in Figure 25.30 ▼. In fact, only a small percentage of the glucose molecules are in the open-chain form in aqueous solution. Although the ring is often drawn as if it were planar, the molecules are actually nonplanar because of the tetrahedral bond angles around the C and O atoms of the ring.

Figure 25.30 shows that the ring structure of glucose can have two relative orientations. In the  $\alpha$  form the OH group on carbon 1 and the  $CH_2OH$  group on carbon 5 point in opposite directions. In the  $\beta$  form they point in the same direction. Although the difference between the  $\alpha$  and  $\beta$  forms might seem small, it has enormous biological consequences. As we will soon see, this one small change in structure accounts for the vast difference in properties between starch and cellulose.

Fructose can cyclize to form either five- or six-member rings. The five-member ring forms when the OH group on carbon 5 reacts with the carbonyl group on carbon 2:

The six-member ring results from the reaction between the OH group on carbon 6 and the carbonyl group on carbon 2.

► **Figure 25.30** Cyclic glucose.

The carbonyl group of a glucose molecule can react with one of the hydroxyl groups to form either of two six-member-ring structures, designated  $\alpha$  and  $\beta$ .

**SAMPLE EXERCISE 25.8** Identifying Chiral Centers

How many chiral carbon atoms are there in the open-chain form of glucose (Figure 25.29)?

**SOLUTION**

**Analyze:** We are given the structure of glucose and asked to determine the number of chiral carbons in the molecule.

**Plan:** A chiral carbon has four different groups attached (Section 25.5). We need to identify those carbon atoms in glucose.

**Solve:** The carbon atoms numbered 2, 3, 4, and 5 each have four different groups attached to them, as indicated here:

Thus, there are four chiral carbon atoms in the glucose molecule.

**PRACTICE EXERCISE**

How many chiral carbon atoms are there in the open-chain form of fructose (Figure 25.29)?

**Answer:** three

**Disaccharides**

Both glucose and fructose are examples of **monosaccharides**, simple sugars that cannot be broken into smaller molecules by hydrolysis with aqueous acids. Two monosaccharide units can be linked together by a condensation reaction to form a **disaccharide**. The structures of two common disaccharides, *sucrose* (table sugar) and *lactose* (milk sugar), are shown in Figure 25.31 ▼.

The word *sugar* makes us think of sweetness. All sugars are sweet, but they differ in the degree of sweetness we perceive when we taste them. Sucrose is about six times sweeter than lactose, slightly sweeter than glucose, but only about half as sweet as fructose. Disaccharides can be reacted with water (hydrolyzed) in the presence of an acid catalyst to form monosaccharides.

▲ **Figure 25.31** Two disaccharides. The structures of sucrose (left) and lactose (right).

When sucrose is hydrolyzed, the mixture of glucose and fructose that forms, called *invert sugar*,\* is sweeter to the taste than the original sucrose. The sweet syrup present in canned fruits and candies is largely invert sugar formed from hydrolysis of added sucrose.

### Polysaccharides

**Polysaccharides** are made up of many monosaccharide units joined together by a bonding arrangement similar to those shown for the disaccharides in Figure 25.31. The most important polysaccharides are starch, glycogen, and cellulose, which are formed from repeating glucose units.

▲ **Figure 25.32 Structure of a starch molecule.** The molecule consists of many units of the kind enclosed in brackets, joined by linkages of the  $\alpha$  form. (That is, the C—O bonds on the linking carbons are on the opposite side of the ring from the  $\text{CH}_2\text{OH}$  groups.)

**Starch** is not a pure substance. The term refers to a group of polysaccharides found in plants. Starches serve as a major method of food storage in plant seeds and tubers. Corn, potatoes, wheat, and rice all contain substantial amounts of starch. These plant products serve as major sources of needed food energy for humans. Enzymes within the digestive system catalyze the hydrolysis of starch to glucose.

Some starch molecules are unbranched chains, whereas others are branched. Figure 25.32 ◀ illustrates an unbranched starch structure. Notice, in particular, that the glucose units are in the  $\alpha$  form (that is, the bridging oxygen atom is opposite the  $\text{CH}_2\text{OH}$  group on the adjacent carbon).

**Glycogen** is a starchlike substance synthesized in the animal body. Glycogen molecules vary in molecular weight from about 5000 to more than 5 million amu. Glycogen acts as a kind of energy bank in the body. It is concentrated in the muscles and liver. In muscles it serves as an immediate source of energy; in the liver it serves as a storage place for glucose and helps to maintain a constant glucose level in the blood.

**Cellulose** forms the major structural unit of plants. Wood is about 50% cellulose; cotton fibers are almost entirely cellulose. Cellulose consists of an unbranched chain of glucose units, with molecular weights averaging more than 500,000 amu. The structure of cellulose is shown in Figure 25.33 ▼. At first glance this structure looks very similar to that of starch. In cellulose, however, the glucose units are in the  $\beta$  form (that is, the bridging oxygen atom is on the same side as the  $\text{CH}_2\text{OH}$  groups).

The distinction between starch and cellulose is made clearer when we examine their structures in a more realistic three-dimensional representation, as shown in Figure 25.34 ▶. The individual glucose units have different relationships to one another in the two structures. Because of this fundamental difference, enzymes

▲ **Figure 25.33 Structure of cellulose.** Like starch, cellulose is a polymer. The repeating unit is shown between brackets. The linkage in cellulose is of the  $\beta$  form, different from that in starch (see Figure 25.32).

\*The term *invert sugar* comes from the fact that rotation of the plane of polarized light by the glucose-fructose mixture is in the opposite direction, or inverted, from that of the sucrose solution.

▲ **Figure 25.36 Structure of phospholipids.** Phospholipids are closely related to fats. They form bilayers that are the key components of cell membranes.

▲ **Figure 25.37 The cell membrane.**

Living cells are encased in membranes that are typically made of phospholipid bilayers. The bilayer structure is stabilized by the favorable interactions of the hydrophobic tails of the phospholipids away from water, while the charged headgroups face the water that is both outside and inside the cell.

Oleic acid is also an example of a *monounsaturated* fatty acid, meaning that there is one carbon-carbon double bond in the chain. In contrast, *polyunsaturated* fatty acids have more than one carbon-carbon double bond in the chain.

For humans, *trans* fats are not nutritionally required, which is why some governments are moving to ban them in foods. How, then, did *trans* fats end up in our food? The process that converts unsaturated fats (such as oils) into saturated fats (such as shortening) is hydrogenation. ⇌ (Section 25.3) The by-products of this hydrogenation process include *trans* fats. If we eat food that has been cooked in *trans* fats, we inevitably ingest some *trans* fats.

Some fatty acids that are essential for human health must be available in our diets, because our metabolism is incapable of synthesizing them from other substances. These essential fatty acids are ones that have the carbon-carbon double bonds either three carbons or six carbons away from the  $-\text{CH}_3$  end of the chain. These are called omega-3 and omega-6 fatty acids, where omega refers to the last carbon in the chain (the carboxylic acid carbon is considered the first, or alpha, one).

**Phospholipids** are similar in chemical structure to fats and oils, with the important addition of a charged phosphate group to the glycerol (Figure 25.36▲). In water, phospholipids cluster together with their charged polar heads facing the water and their nonpolar tails facing inward. ⇌ (Section 13.6) The phospholipids thus form a bilayer that is a key component of cell membranes (Figure 25.37◀).

## 25.10 NUCLEIC ACIDS

**Nucleic acids** are a class of biopolymers that are the chemical carriers of an organism's genetic information. **Deoxyribonucleic acids (DNA)** are huge molecules [Figure 1.2(c)] whose molecular weights may range from 6 million to 16 million amu. **Ribonucleic acids (RNA)** are smaller molecules, with molecular weights in the range of 20,000 to 40,000 amu. Whereas DNA is found primarily in the nucleus of the cell, RNA is found mostly outside the nucleus in the *cytoplasm*, the nonnuclear material enclosed within the cell membrane. The DNA stores the genetic information of the cell and specifies which proteins the cell can synthesize. The RNA carries the information stored by DNA out of the nucleus of the cell into the cytoplasm, where the information is used in protein synthesis.

The monomers of nucleic acids, called **nucleotides**, are formed from the following units:

1. A phosphoric acid molecule,  $\text{H}_3\text{PO}_4$
2. A five-carbon sugar
3. A nitrogen-containing organic base

The sugar component of RNA is *ribose*, whereas that in DNA is *deoxyribose*.

*Deoxyribose* differs from *ribose* only in having one fewer oxygen atom at carbon 2.

The following nitrogen bases are found in DNA and RNA:

The base is attached to a ribose or deoxyribose molecule through a bond to the nitrogen atom shown in color above. An example of a nucleotide in which the base is adenine and the sugar is deoxyribose is shown in Figure 25.38 ▼.

Nucleic acids are polynucleotides formed by condensation reactions between an OH group of the phosphoric acid unit on one nucleotide and an OH group of the sugar of another nucleotide. Figure 25.39 ► shows a portion of the polymeric chain of a DNA molecule.

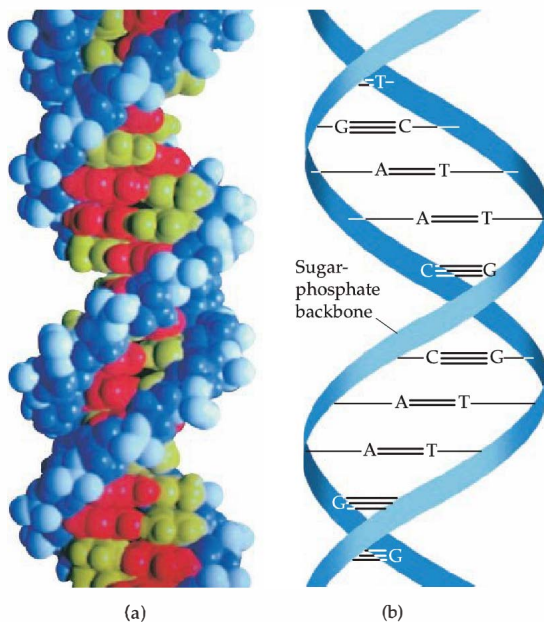

▲ **Figure 25.38** A nucleotide. Structure of deoxyadenylic acid, a nucleotide formed from phosphoric acid, deoxyribose, and the organic base adenine.

◀ **Figure 25.39** Structure of a polynucleotide. Because the sugar in each nucleotide is deoxyribose, this polynucleotide is of the form found in DNA.

► **Figure 25.40 Two views of DNA.**

(a) A computer-generated model of a DNA double helix. The dark blue and light blue atoms represent the sugar-phosphate chains that wrap around the outside. Inside the chains are the bases, shown in red and yellow-green. (b) A schematic illustration of the double helix showing the hydrogen-bond interactions between complementary base pairs.

DNA molecules consist of two deoxyribonucleic acid chains or strands that are wound together in the form of a **double helix**, as shown in Figure 25.40▲. The drawing in Figure 25.40(b) has been simplified to show the essential features of the structure. The sugar and phosphate groups form the backbone of each strand. The bases (represented by the letters T, A, C, and G) are attached to the sugars. The two strands are held together by attractions between the bases in one strand and those in the other strand. These attractions involve London dispersion interactions, dipole-dipole and hydrogen bonds. ∞ (Section 11.2) As shown in Figure 25.41▼, the structures of thymine (T) and adenine (A) make them perfect partners for hydrogen bonding. Likewise, cytosine (C) and guanine (G) form ideal hydrogen-bonding partners. In the double-helix structure, therefore, each thymine on one strand is opposite an adenine on the other strand. Likewise, each cytosine is opposite a guanine. The double-helix structure with complementary bases on the two strands is the key to understanding how DNA functions.

The two strands of DNA unwind during cell division, and new complementary strands are constructed on the unraveling strands (Figure 25.42►).

▲ **Figure 25.41 Hydrogen bonding between complementary base pairs.** The hydrogen bonds are responsible for formation of the double-stranded helical structure of DNA.

◀ **Figure 25.42 DNA replication.** The original DNA double helix partially unwinds, and new nucleotides line up on each strand in complementary fashion. Hydrogen bonds help align the new nucleotides with the original DNA chain. When the new nucleotides are joined by condensation reactions, two identical double-helix DNA molecules result.

This process results in two identical double-helix DNA structures, each containing one strand from the original structure and one newly synthesized strand. This replication process allows genetic information to be transmitted when cells divide. The structure of DNA is also the key to understanding protein synthesis, the means by which viruses infect cells, and many other problems of central importance to modern biology. These themes are beyond the scope of this book. If you take courses in the life sciences, however, you will learn a good deal about such matters.

### SAMPLE INTEGRATIVE EXERCISE | Putting Concepts Together

Pyruvic acid has the following structure:

It is formed in the body from carbohydrate metabolism. In the muscle it is reduced to lactic acid in the course of exertion. The acid-dissociation constant for pyruvic acid is  $3.2 \times 10^{-3}$ . (a) Why does pyruvic acid have a higher acid-dissociation constant than acetic acid? (b) Would you expect pyruvic acid to exist primarily as the neutral acid or as dissociated ions in muscle tissue, assuming a pH of about 7.4 and an acid concentration of  $2 \times 10^{-4} M$ ? (c) What would you predict for the solubility properties of pyruvic acid? Explain. (d) What is the hybridization of each carbon atom in pyruvic acid? (e) Assuming H atoms as the reducing agent, write a balanced chemical equation for the reduction of pyruvic acid to lactic acid (Figure 25.17). (Although H atoms do not exist as such in biochemical systems, biochemical reducing agents deliver hydrogen for such reductions.)

**SOLUTION**

(a) The acid ionization constant for pyruvic acid should be somewhat greater than that of acetic acid because the carbonyl function on the  $\alpha$ -carbon atom exerts an electron-withdrawing effect on the carboxylic acid group. In the C—O—H bond system the electrons are shifted from hydrogen, facilitating loss of the hydrogen as a proton.  $\rightleftharpoons$  (Section 16.10)

(b) To determine the extent of ionization, we first set up the ionization equilibrium and equilibrium-constant expression. Using HPv as the symbol for the acid, we have

Let  $[\text{Pv}^-] = x$ . Then the concentration of undissociated acid is  $2 \times 10^{-4} - x$ . The concentration of  $[\text{H}^+]$  is fixed at  $4.0 \times 10^{-8}$  (the antilog of the pH value). Substituting, we obtain

$$3.2 \times 10^{-3} = \frac{[4.0 \times 10^{-8}][x]}{[2 \times 10^{-4} - x]}$$

Solving for  $x$ , we obtain  $x[3.2 \times 10^{-3} + 4.0 \times 10^{-8}] = 6.4 \times 10^{-7}$ .

The second term in the brackets is negligible compared to the first, so  $x = [\text{Pv}^-] = 6.4 \times 10^{-7} / 3.2 \times 10^{-3} = 2 \times 10^{-4} \text{ M}$ . This is the initial concentration of acid, which means that essentially all the acid has dissociated. We might have expected this result because the acid is quite dilute and the acid-dissociation constant is fairly high.

(c) Pyruvic acid should be quite soluble in water because it has polar functional groups and a small hydrocarbon component. It is miscible with water, ethanol, and diethyl ether.

(d) The methyl group carbon has  $sp^3$  hybridization. The carbon carrying the carbonyl group has  $sp^2$  hybridization because of the double bond to oxygen. Similarly, the carboxylic acid carbon is  $sp^2$  hybridized.

(e) The balanced chemical equation for this reaction is

Essentially, the ketonic functional group has been reduced to an alcohol.

**Strategies in Chemistry****WHAT NOW?**

If you are reading this box, you have made it to the end of our text. We congratulate you on the tenacity and dedication that you have exhibited to make it this far!

As an epilogue, we offer the ultimate study strategy in the form of a question: What do you plan to do with the knowledge of chemistry that you have gained thus far in your studies? Many of you will enroll in additional courses in chemistry as part of your required curriculum. For others, this will be the last formal course in chemistry that you will take. Regardless of the career path you plan to take—whether it is chemistry, one of the biomedical fields, engineering, the liberal arts, or another field—we hope that this text has increased your appreciation of the chemistry in the world around you. If you pay attention, you will be aware of encounters with chemistry on a daily basis, from food and pharmaceutical labels to gasoline pumps, sports equipment to news reports.

We have also tried to give you a sense that chemistry is a dynamic, continuously changing science. Research chemists synthesize new compounds, develop new reactions, uncover chemical properties that were previously unknown, find new applications for known compounds, and refine theories. The understanding of biological systems in terms of the underlying chemistry has become increasingly important as new levels of complexity are uncovered. You may wish to participate in the fascinating venture of chemical research by taking part in an undergraduate research program. Given all the answers that chemists seem to have, you may be surprised at the large number of questions that they still find to ask.

Finally, we hope you have enjoyed using this textbook. We certainly enjoyed putting so many of our thoughts about chemistry on paper. We truly believe it to be the central science, one that benefits all who learn about it and from it.

## CHAPTER REVIEW

## SUMMARY AND KEY TERMS

**Introduction and Section 25.1** This chapter introduces **organic chemistry**, which is the study of carbon compounds (typically compounds containing carbon-carbon bonds), and **biochemistry**, which is the study of the chemistry of living organisms. We have encountered many aspects of organic chemistry in earlier chapters. Carbon forms four bonds in its stable compounds. The C—C single bonds and the C—H bonds tend to have low reactivity. Those bonds that have a high electron density (such as multiple bonds or bonds with an atom of high electronegativity) tend to be the sites of reactivity in an organic compound. These sites of reactivity are called **functional groups**.

**Section 25.2** The simplest types of organic compounds are hydrocarbons, those composed of only carbon and hydrogen. There are four major kinds of hydrocarbons: alkanes, alkenes, alkynes, and aromatic hydrocarbons. **Alkanes** are composed of only C—H and C—C single bonds. **Alkenes** contain one or more carbon-carbon double bonds. **Alkynes** contain one or more carbon-carbon triple bonds. **Aromatic hydrocarbons** contain cyclic arrangements of carbon atoms bonded through both  $\sigma$  and delocalized  $\pi$  bonds. Alkanes are saturated hydrocarbons; the others are unsaturated.

**Section 25.3** Alkanes may form straight-chain, branched-chain, and cyclic arrangements. Isomers are substances that possess the same molecular formula, but differ in the arrangements of atoms. In **structural isomers** the bonding arrangements of the atoms differ. Different isomers are given different systematic names. The naming of hydrocarbons is based on the longest continuous chain of carbon atoms in the structure. The locations of **alkyl groups**, which branch off the chain, are specified by numbering along the carbon chain. Alkanes with ring structures are called **cycloalkanes**. Alkanes are relatively unreactive. They do, however, undergo combustion in air, and their chief use is as sources of heat energy produced by combustion.

The names of alkenes and alkynes are based on the longest continuous chain of carbon atoms that contains the multiple bond, and the location of the multiple bond is specified by a numerical prefix. Alkenes exhibit not only structural isomerism but geometric (cis-trans) isomerism as well. In **geometric isomers** the bonds are the same, but the molecules have different geometries. Geometric isomerism is possible in alkenes because rotation about the C=C double bond is restricted.

Alkenes and alkynes readily undergo **addition reactions** to the carbon-carbon multiple bonds. Additions of acids, such as HBr, proceed via a rate-determining step in which a proton is transferred to one of the alkene or alkyne carbon atoms. Addition reactions are difficult to carry out

with aromatic hydrocarbons, but **substitution reactions** are easily accomplished in the presence of catalysts.

**Section 25.4** The chemistry of organic compounds is dominated by the nature of their functional groups. The functional groups we have considered are

R, R', and R'' represent hydrocarbon groups—for example, methyl (CH<sub>3</sub>) or phenyl (C<sub>6</sub>H<sub>5</sub>).

**Alcohols** are hydrocarbon derivatives containing one or more OH groups. **Ethers** are formed by a condensation reaction of two molecules of alcohol. Several functional groups contain the **carbonyl (C=O) group**, including **aldehydes, ketones, carboxylic acids, esters, and amides**. Aldehydes and ketones can be produced by oxidation of certain alcohols. Further oxidation of the aldehydes produces carboxylic acids. Carboxylic acids can form esters by a condensation reaction with alcohols, or they can form amides by a condensation reaction with amines. Esters undergo hydrolysis (**saponification**) in the presence of strong bases.

**Section 25.5** Molecules that possess nonsuperimposable mirror images are termed **chiral**. The two nonsuperimposable forms of a chiral molecule are called **enantiomers**. In carbon compounds a chiral center is created when all four groups bonded to a central carbon atom are different, as in 2-bromobutane. Many of the molecules occurring in living systems, such as the amino acids, are chiral and exist in nature in only one enantiomeric form. Many drugs of importance in human medicine are chiral, and the enantiomers may produce very different biochemical effects. For this reason, synthesis of only the effective isomers of chiral drugs has become a high priority.

**Sections 25.6 and 25.7** Many of the molecules that are essential for life are large natural polymers that are constructed from smaller molecules called monomers. Three of these **biopolymers** were considered in this chapter: proteins, polysaccharides (carbohydrates), and nucleic acids.

**Proteins** are polymers of **amino acids**. They are the major structural materials in animal systems. All naturally occurring proteins are formed from 22 amino acids are formed from 22 amino acids, although only 20 are common. The amino acids are linked by **peptide bonds**. A **polypeptide** is a polymer formed by linking many amino acids by peptide bonds.

Amino acids are chiral substances. Usually only one of the enantiomers is found to be biologically active. Protein structure is determined by the sequence of amino acids in the chain (its **primary structure**), the coiling or stretching of the chain (its **secondary structure**), and the overall shape of the complete molecule (its **tertiary structure**). Two important secondary structures are the  $\alpha$  **helix** and the  $\beta$  **sheet**. The process by which a protein assumes its biologically active tertiary structure is called **folding**.

**Sections 25.8 and 25.9** **Carbohydrates**, which are polyhydroxy aldehydes and ketones, are the major structural constituents of plants and are a source of energy in both plants and animals. **Glucose** is the most common

**monosaccharide**, or simple sugar. Two monosaccharides can be linked together by means of a condensation reaction to form a disaccharide. **Polysaccharides** are complex carbohydrates made up of many monosaccharide units joined together. The three most important polysaccharides are **starch**, which is found in plants; **glycogen**, which is found in mammals; and **cellulose**, which is also found in plants. **Lipids** are small molecules derived from glycerol and fatty acids that comprise fats, oils, and **phospholipids**. Fatty acids can be *saturated*, *unsaturated*, *cis*, or *trans* depending on their chemical formulas and structures.

**Section 25.10** **Nucleic acids** are biopolymers that carry the genetic information necessary for cell reproduction; they also control cell development through control of protein synthesis. The building blocks of these biopolymers are **nucleotides**. There are two types of nucleic acids, the **ribonucleic acids (RNA)** and the **deoxyribonucleic acids (DNA)**. These substances consist of a polymeric backbone of alternating phosphate and ribose or deoxyribose sugar groups, with organic bases attached to the sugar molecules. The DNA polymer is a double-stranded helix (a **double helix**) held together by hydrogen bonding between matching organic bases situated across from one another on the two strands. The hydrogen bonding between specific base pairs is the key to gene replication and protein synthesis.

## KEY CONCEPTS

- Draw hydrocarbon structures based on their names and name hydrocarbons based on their structures.
- Know the structures of the functional groups: alkene, alkyne, alcohol, carbonyl, ether, aldehyde, ketone, carboxylic acid, amine, amide.
- Distinguish between addition reactions and substitution reactions.
- Understand what makes a compound chiral and be able to recognize a chiral substance.
- Recognize the amino acids and understand how they form peptides and proteins via amide bond formation.
- Understand the difference between primary, secondary, and tertiary structure of proteins.
- Be able to explain the difference between  $\alpha$  helix and  $\beta$  sheet peptide and protein structures.
- Understand the distinction between starch and cellulose structures.
- Classify molecules as saccharides or lipids based on their structures.
- Understand the difference between *cis* and *trans*, and saturated and unsaturated fatty acids.
- Understand the structure of nucleic acids.

## VISUALIZING CONCEPTS

**25.1** Which of the following molecules is unsaturated? [Section 25.2]

(a)

(b)

(c)

(d)

**25.2** Which of the following molecules will most readily undergo an addition reaction? [Section 25.3]

(a)

(b)

(c)

(d)

25.3 Which of the following compounds would you expect to have the highest boiling point? Explain. [Section 25.4]

25.4 Which of the following compounds is capable of possessing isomerism? In each case where isomerism is possible, identify the type or types of isomerism. [Sections 25.3 and 25.4]

25.5 From examination of the following ball-and-stick molecular models, choose the substance that (a) can be hydrolyzed to form a solution containing glucose, (b) is capable of forming a zwitterion, (c) is one of the four bases present in DNA, (d) reacts with an acid to form an ester, (e) is a lipid. [Sections 25.6–25.10]

25.6 All the structures that follow have the same molecular formula,  $\text{C}_8\text{H}_{18}$ . Which structures are the same molecule? (*Hint*: One way to do this is to determine the chemical name for each.) [Section 25.3]

## EXERCISES

### Introduction to Organic Compounds; Hydrocarbons

25.7 Predict the ideal values for the bond angles about each carbon atom in the following molecule. Indicate the hybridization of orbitals for each carbon.

25.8 Identify the carbon atom(s) in the structure shown that has (have) each of the following hybridizations: (a)  $sp^3$ , (b)  $sp$ , (c)  $sp^2$ .

**25.9** Are carbon monoxide or ammonia considered organic molecules? Why or why not?

**25.10** Organic compounds containing C—O and C—Cl bonds are more reactive than simple alkane hydrocarbons. Considering the comparative values of C—H, C—C, C—O, and C—Cl bond energies (Table 8.4), why is this so?

**25.11** (a) What is the difference between a straight-chain and branched-chain alkane? (b) What is the difference between an alkane and an alkyl group? (c) Why are alkanes said to be saturated? (d) Give an example of an unsaturated molecule.

**25.12** What structural features help us identify a compound as (a) an alkane, (b) a cycloalkane, (c) an alkene, (d) an alkyne, (e) a saturated hydrocarbon, (f) an aromatic hydrocarbon?

**25.13** Give the molecular formula of a hydrocarbon containing five carbon atoms that is (a) an alkane, (b) a cycloalkane, (c) an alkene, (d) an alkyne. Which are saturated and which are unsaturated hydrocarbons?

**25.14** Give the molecular formula of a cyclic alkane, a cyclic alkene, a linear alkyne, and an aromatic hydrocarbon that in each case contains six carbon atoms. Which are saturated and which are unsaturated hydrocarbons?

**25.15** Eneidyne are a class of compounds that include some antibiotic drugs. Draw the structure of an "enediyn" fragment that contains six carbons in a row. (*Hint*: "di" means "two".)

**25.16** Give the general formula for any cyclic alkene, that is, a cyclic hydrocarbon with one double bond.

**25.17** Write the condensed structural formulas for as many alkenes and alkynes as you can think of that have the molecular formula  $C_6H_{10}$ .

**25.18** Draw all the possible noncyclic structural isomers of  $C_5H_{10}$ . Name each compound.

**25.19** What are the characteristic hybrid orbitals employed by (a) carbon in an alkane, (b) carbon in a double bond in an alkene, (c) carbon in the benzene ring, (d) carbon in a triple bond in an alkyne?

**25.20** What are the approximate bond angles (a) about carbon in an alkane, (b) about a doubly bonded carbon atom in an alkene, (c) about a triply bonded carbon atom in an alkyne?

**25.21** Draw the structural formula or give the name, as appropriate, for the following:

(c) 2-methylheptane

(d) 4-ethyl-2,3-dimethyloctane

(e) 1,2-dimethylcyclohexane

**25.22** Draw the structural formula or give the name, as appropriate, for the following:

(c) 2,5,6-trimethylnonane

(d) 3-propyl-4,5-methyldecane

(e) 1-ethyl-3-methylcyclohexane

**25.23** Name the following compounds:

**25.24** Name the following compounds:

(c) *trans*- $\text{CH}_3\text{CH}=\text{CHCH}_2\text{CH}_2\text{CH}_3$

(e) *cis*- $\text{CH}_2=\text{CH}-\text{CH}=\text{CH}-\text{CH}_2\text{Cl}$

**25.25** Why is geometric isomerism possible for alkenes, but not for alkanes and alkynes?

**25.26** Draw all structural and geometric isomers of butene and name them.

**25.27** Indicate whether each of the following molecules is capable of geometrical (cis-trans) isomerism. For those that are, draw the structures: (a) 1,1-dichloro-1-butene, (b) 2,4-dichloro-2-butene, (c) 1,4-dichlorobenzene, (d) 4,5-dimethyl-2-pentyne.

**25.28** Draw all the distinct geometric isomers of 2,4-hexadiene.

**25.29** What is the octane number of a mixture of 35% heptane and 65% isooctane?

**25.30** Describe two ways in which the octane number of a gasoline consisting of alkanes can be increased.

## Reactions of Hydrocarbons

- 25.31** (a) What is the difference between a substitution reaction and an addition reaction? Which one is commonly observed with alkenes, and which one with aromatic hydrocarbons? (b) Using condensed structural formulas, write the balanced equation for the addition reaction of 2-pentene with  $\text{Br}_2$  and name the resulting compound. (c) Write a balanced chemical equation for the substitution reaction of  $\text{Cl}_2$  with benzene to make *para*-dichlorobenzene in the presence of  $\text{FeCl}_3$  as a catalyst.
- 25.32** Using condensed structural formulas, write a balanced chemical equation for each of the following reactions: (a) hydrogenation of cyclohexene; (b) addition of  $\text{H}_2\text{O}$  to *trans*-2-pentene using  $\text{H}_2\text{SO}_4$  as a catalyst (two products); (c) reaction of 2-chloropropane with benzene in the presence of  $\text{AlCl}_3$ .
- 25.33** (a) When cyclopropane is treated with HI, 1-iodopropane is formed. A similar type of reaction does not occur with cyclopentane or cyclohexane. How do you account for the reactivity of cyclopropane? (b) Suggest a method of preparing ethylbenzene, starting with benzene and ethylene as the only organic reagents.
- 25.34** (a) One test for the presence of an alkene is to add a small amount of bromine, a red-brown liquid, and look for the disappearance of the red-brown color. This test

does not work for detecting the presence of an aromatic hydrocarbon. Explain. (b) Write a series of reactions leading to *para*-bromoethylbenzene, beginning with benzene and using other reagents as needed. What isomeric side products might also be formed?

- 25.35** The rate law for addition of  $\text{Br}_2$  to an alkene is first order in  $\text{Br}_2$  and first order in the alkene. Does this fact prove that the mechanism of addition of  $\text{Br}_2$  to an alkene proceeds in the same manner as for addition of  $\text{HBr}$ ? Explain.
- 25.36** Describe the intermediate that is thought to form in the addition of a hydrogen halide to an alkene, using cyclohexene as the alkene in your description.
- 25.37** The molar heat of combustion of gaseous cyclopropane is  $-2089 \text{ kJ/mol}$ ; that for gaseous cyclopentane is  $-3317 \text{ kJ/mol}$ . Calculate the heat of combustion per  $\text{CH}_2$  group in the two cases, and account for the difference.
- 25.38** The heat of combustion of decahydronaphthalene ( $\text{C}_{10}\text{H}_{18}$ ) is  $-6286 \text{ kJ/mol}$ . The heat of combustion of naphthalene ( $\text{C}_{10}\text{H}_8$ ) is  $-5157 \text{ kJ/mol}$ . (In both cases  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$  are the products.) Using these data and data in Appendix C, calculate the heat of hydrogenation of naphthalene. Does this value provide any evidence for aromatic character in naphthalene?

## Functional Groups and Chirality

- 25.39** Identify the functional groups in each of the following compounds:

- 25.40** Identify the functional groups in each of the following compounds:

- 25.41** Give the structural formula for (a) an aldehyde that is an isomer of acetone, (b) an ether that is an isomer of 1-propanol.
- 25.42** (a) Give the empirical formula and structural formula for a cyclic ether containing four carbon atoms in the ring. (b) Write the structural formula for a straight-chain compound that is a structural isomer of your answer to part (a).
- 25.43** The IUPAC name for a carboxylic acid is based on the name of the hydrocarbon with the same number of carbon atoms. The ending *-oic* is appended, as in ethanoic acid, which is the IUPAC name for acetic acid. Draw the structure of the following acids: (a) methanoic acid, (b) pentanoic acid, and (c) 2-chloro-3-methyldecanoic acid.
- 25.44** Aldehydes and ketones can be named in a systematic way by counting the number of carbon atoms (including the carbonyl carbon) that they contain. The name of the aldehyde or ketone is based on the hydrocarbon with the same number of carbon atoms. The ending *-al* for aldehyde or *-one* for ketone is added as appropriate. Draw the structural formulas for the following aldehydes or ketones: (a) propanal, (b) 2-pentanone, (c) 3-methyl-2-butanone, (d) 2-methylbutanal.

- 25.45** Draw the condensed structure of the compounds formed by condensation reactions between (a) benzoic acid and ethanol, (b) ethanoic acid and methylamine, (c) acetic acid and phenol. Name the compound in each case.
- 25.46** Draw the condensed structures of the compounds formed from (a) butanoic acid and methanol, (b) benzoic acid and 2-propanol, (c) propanoic acid and dimethylamine. Name the compound in each case.
- 25.47** Write a balanced chemical equation using condensed structural formulas for the saponification (base hydrolysis) of (a) methyl propionate, (b) phenyl acetate.
- 25.48** Write a balanced chemical equation using condensed structural formulas for (a) the formation of butyl propionate from the appropriate acid and alcohol, (b) the saponification (base hydrolysis) of methyl benzoate.
- 25.49** Would you expect pure acetic acid to be a strongly hydrogen-bonded substance? How do the melting and boiling points of the substance (see the "Chemistry Put to Work" box on p. 1076 for data) support your answer?
- 25.50** Acetic anhydride is formed from acetic acid in a condensation reaction that involves the removal of a molecule of water from between two acetic acid molecules. Write the chemical equation for this process, and show the structure of acetic anhydride.
- 25.51** Write the condensed structural formula for each of the following compounds: (a) 2-pentanol, (b) 1,2-propanediol, (c) ethyl acetate, (d) diphenyl ketone, (e) methyl ethyl ether.
- 25.52** Write the condensed structural formula for each of the following compounds: (a) 3,3-dichlorobutyraldehyde, (b) methyl phenyl ketone, (c) *para*-bromobenzoic acid, (d) methyl-*trans*-2-butenyl ether, (e) *N, N*-dimethylbenzamide.
- 25.53** Draw the structure for 2-bromo-2-chloro-3-methylpentane, and indicate any chiral carbons in the molecule.
- 25.54** Does 3-chloro-3-methylhexane have optical isomers? Why or why not?

## Proteins

- 25.55** (a) What is an  $\alpha$ -amino acid? (b) How do amino acids react to form proteins? (c) Draw the bond that links amino acids together in proteins. What is this called?
- 25.56** What properties of the side chains (R groups) of amino acids are important in affecting the amino acid's overall biochemical behavior? Give examples to illustrate your reply.
- 25.57** Draw the two possible dipeptides formed by condensation reactions between leucine and tryptophan.
- 25.58** Write a chemical equation for the formation of methionyl glycine from the constituent amino acids.
- 25.59** (a) Draw the condensed structure of the tripeptide Gly-Gly-His. (b) How many different tripeptides can be made from the amino acids glycine and histidine? Give the abbreviations for each of these tripeptides, using the three-letter and one-letter codes for the amino acids.
- 25.60** (a) What amino acids would be obtained by hydrolysis of the following tripeptide?

(b) How many different tripeptides can be made from the amino acids glycine, serine, and glutamic acid? Give the abbreviation for each of these tripeptides, using the three-letter codes and one-letter codes for the amino acids.

- [25.61]** (a) Describe the primary, secondary, and tertiary structures of proteins. (b) *Quaternary structures* of proteins arise if two or more smaller polypeptides or proteins associate with each other to make an overall much larger protein structure. The association is due to the same hydrogen bonding, electrostatic, and dispersion forces we have seen before. Hemoglobin, the protein used to transport oxygen molecules in our blood, is an example of a protein that has quaternary structure. Hemoglobin is a tetramer; it is made of four smaller polypeptides, two "alphas" and two "betas." (These names do not imply anything about the number of alpha helices or beta sheets in the individual polypeptides.) What kind of experiments would provide sound evidence that hemoglobin exists as a tetramer and not as one enormous polypeptide chain? You may need to look into the chemical literature to discover techniques that chemists and biochemists use to make these decisions.
- 25.62** What is the difference between the  $\alpha$  helix and  $\beta$  sheet secondary structures in proteins?

## Carbohydrates and Lipids

- 25.63** In your own words, define the following terms: (a) carbohydrate, (b) monosaccharide, (c) disaccharide, (d) polysaccharide.
- 25.64** What is the difference between  $\alpha$ -glucose and  $\beta$ -glucose? Show the condensation of two glucose molecules to form a disaccharide with an  $\alpha$  linkage; with a  $\beta$  linkage.

**25.65** What is the empirical formula of cellulose? What is the unit that forms the basis of the cellulose polymer? What form of linkage joins these monomeric units?

**25.66** What is the empirical formula of glycogen? What is the unit that forms the basis of the glycogen polymer? What form of linkage joins these monomeric units?

**25.67** The structural formula for the linear form of D-mannose is:

(a) How many chiral carbons are present in the molecule? (b) Draw the structure of the six-member-ring form of this sugar.

**25.68** The structural formula for the linear form of galactose is:

(a) How many chiral carbons are present in the molecule? (b) Draw the structure of the six-member-ring form of this sugar.

**25.69** Describe the chemical structures of lipids and phospholipids. Why can phospholipids form a bilayer in water?

**25.70** Using data from Table 8.4 on bond energies, show that the more C—H bonds a molecule has compared to C—O and O—H bonds, the more energy it can store.

## Nucleic Acids

**25.71** Adenine and guanine are members of a class of molecules known as *purines*; they have two rings in their structure. Thymine and cytosine, on the other hand, are *pyrimidines*, and have only one ring in their structure. Predict which have larger dispersion forces in aqueous solution, the purines or the pyrimidines.

**25.72** A nucleoside consists of an organic base of the kind shown in Section 25.10, bound to ribose or deoxyribose. Draw the structure for deoxyguanosine, formed from guanine and deoxyribose.

**25.73** Just as the amino acids in a protein are listed in the order from the amine end to the carboxylic acid end (the *protein sequence*), the bases in nucleic acids are listed in the order 5' to 3', where the numbers refer to the position of the carbons in the sugars (shown here for deoxyribose):

The base is attached to the sugar at the 1' carbon. The 5' end of a DNA sequence is a phosphate of an OH group, and the 3' end of a DNA sequence is the OH group. What is the DNA sequence for the molecule shown here?

**25.74** When samples of double-stranded DNA are analyzed, the quantity of adenine present equals that of thymine. Similarly, the quantity of guanine equals that of cytosine. Explain the significance of these observations.

**25.75** Imagine a single DNA strand containing a section with the following base sequence: 5'-GCATTGGC-3'. What is the base sequence of the complementary strand? (The two strands of DNA will come together in an *antiparallel* fashion: that is, 5'-TAG-3' will bind to 3'-ATC-5'.)

**25.76** Explain the chemical differences between DNA and RNA.

## ADDITIONAL EXERCISES

- 25.77** Draw the condensed structural formulas for two different molecules with the formula  $C_3H_4O$ .
- 25.78** How many structural isomers are there for a five-member straight carbon chain with one double bond? For a six-member straight carbon chain with two double bonds?
- 25.79** There are no known stable cyclic compounds with ring sizes of seven or less that have an alkyne linkage in the ring. Why is this? Could a ring with a larger number of carbon atoms accommodate an alkyne linkage? Explain.
- 25.80** Draw the condensed structural formulas for the cis and trans isomers of 2-pentene. Can cyclopentene exhibit cis-trans isomerism? Explain.
- 25.81** Although there are silicon analogs of alkanes, silicon analogs of alkenes or alkynes are virtually unknown. Suggest an explanation.
- 25.82** If a molecule is an "ene-one," what functional groups must it have?
- 25.83** Write the structural formulas for as many alcohols as you can think of that have empirical formula  $C_3H_6O$ .
- [25.84]** Dinitromethane,  $CH_2(NO_2)_2$ , is a dangerously reactive substance that decomposes readily on warming. On the other hand, dichloromethane is relatively unreactive. Why is the nitro compound so reactive compared to the chloro compound? (*Hint*: Consider the oxidation numbers of the atoms involved and the possible products of decomposition.)
- 25.85** Identify each of the functional groups in the following molecules:

- 25.86** Write a condensed structural formula for each of the following: (a) an acid with the formula  $C_4H_8O_2$ , (b) a cyclic ketone with the formula  $C_5H_8O$ , (c) a dihydroxy compound with formula  $C_3H_8O_2$ , (d) a cyclic ester with formula  $C_5H_8O_2$ .
- 25.87** Although carboxylic acids and alcohols both contain an  $-OH$  group, one is acidic in water and the other is not. Explain the difference.
- [25.88]** Indole smells rather terrible in high concentrations but has a pleasant floral-like odor when highly diluted. It has the following structure:

Indole is a planar molecule. The nitrogen is a very weak base, with a  $K_b$  of  $2 \times 10^{-12}$ . Explain how this information indicates that the indole molecule is aromatic in character.

- 25.89** Locate the chiral carbon atoms, if any, in each of the following substances:

- 25.90** Which of the following peptides have a net positive charge at pH 7? (a) Gly-Ser-Lys, (b) Pro-Leu-Ile, (c) Phe-Tyr-Asp.
- 25.91** Glutathione is a tripeptide found in most living cells. Partial hydrolysis yields Cys-Gly and Glu-Cys. What structures are possible for glutathione?
- 25.92** Starch, glycogen, and cellulose are all polymers of glucose. What are the structural differences among them?
- 25.93** Monosaccharides can be categorized in terms of the number of carbon atoms (pentoses have five carbons and hexoses have six carbons) and according to whether they contain an aldehyde (*aldo-* prefix, as in aldopentose) or ketone group (*keto-* prefix, as in ketopentose). Classify glucose and fructose in this way.
- 25.94** Can a DNA strand bind to a complementary RNA strand? Explain.

## INTEGRATIVE EXERCISES

- 25.95** Explain why the boiling point of ethanol (78 °C) is much higher than that of its isomer, dimethyl ether (−25 °C) and why the boiling point of  $\text{CH}_2\text{F}_2$  (−52 °C) is far above that of  $\text{CH}_4$  (−128 °C).
- [25.96]** An unknown organic compound is found on elemental analysis to contain 68.1% carbon, 13.7% hydrogen, and 18.2% oxygen by mass. It is slightly soluble in water. Upon careful oxidation it is converted into a compound that behaves chemically like a ketone and contains 69.7% carbon, 11.7% hydrogen, and 18.6% oxygen by mass. Indicate two or more reasonable structures for the unknown.
- 25.97** An organic compound is analyzed and found to contain 66.7% carbon, 11.2% hydrogen, and 22.1% oxygen by mass. The compound boils at 79.6 °C. At 100 °C and 0.970 atm, the vapor has a density of 2.28 g/L. The compound has a carbonyl group and cannot be oxidized to a carboxylic acid. Suggest a structure for the compound.
- [25.98]** An unknown substance is found to contain only carbon and hydrogen. It is a liquid that boils at 49 °C at 1 atm pressure. Upon analysis it is found to contain 85.7% carbon and 14.3% hydrogen by mass. At 100 °C and 735 torr, the vapor of this unknown has a density of 2.21 g/L. When it is dissolved in hexane solution and bromine water is added, no reaction occurs. What is the identity of the unknown compound?
- 25.99** The standard free energy of formation of solid glycine is  $-369 \text{ kJ/mol}$ , whereas that of solid glycyglycine is  $-488 \text{ kJ/mol}$ . What is  $\Delta G^\circ$  for the condensation of glycine to form glycyglycine?
- 25.100** One of the most important molecules in biochemical systems is adenosine triphosphate (ATP), for which the structure is

ATP

ATP is the principal carrier of biochemical energy. It is considered an energy-rich compound because the hydrolysis of ATP to yield adenosine diphosphate (ADP) and inorganic phosphate is spontaneous under aqueous biochemical conditions. (a) Write a balanced equation for the reaction of ATP with water to yield ADP and inorganic phosphate ion. [Hint: Hydrolysis reactions are just the reverse of condensation reactions (Section 22.8).] (b) What would you expect for the sign of the free-energy change for this reaction? (c) ADP can undergo further hydrolysis. What would you expect for the product of that reaction?

- 25.101** A typical amino acid with one amino group and one carboxylic acid group, such as serine (Figure 25.23), can exist in water in several ionic forms. (a) Suggest the forms of the amino acid at low pH and at high pH. (b) Amino acids generally have two  $\text{pK}_a$  values, one in the range of 2 to 3 and the other in the range of 9 to 10. Serine, for example, has  $\text{pK}_a$  values of 2.19 and 9.21. Using species such as acetic acid and ammonia as models, suggest the origin of the two  $\text{pK}_a$  values. (c) Glutamic acid is an amino acid that has three  $\text{pK}_a$ 's: 2.10, 4.07, and 9.47. Draw the structure of glutamic acid, and assign each  $\text{pK}_a$  to the appropriate part of the molecule.
- [25.102]** The protein ribonuclease A in its native, or most stable, form is folded into a compact globular shape. (a) Does the native form have a lower or higher free energy than the denatured form, in which the protein is an extended chain? (b) What is the sign of the entropy change in going from the denatured to the folded form? (c) In the folded form the ribonuclease A has four  $-\text{S}-\text{S}-$  bonds that bridge between parts of the chain, as shown in the accompanying figure. What effect do you predict that these four linkages have on the free energy and entropy of the folded form as compared with a hypothetical folded structure that does not possess the four  $-\text{S}-\text{S}-$  linkages? Explain. (d) A gentle reducing agent converts the four  $-\text{S}-\text{S}-$  linkages to eight  $-\text{S}-\text{H}$  bonds. What effect do you predict this would have on the tertiary structure and entropy of the protein? (e) Which amino acid must be present for  $-\text{SH}$  bonds to exist in ribonuclease A?

Native ribonuclease A

- 25.103** The monoanion of adenosine monophosphate (AMP) is an intermediate in phosphate metabolism:

where A = adenosine. If the  $\text{pK}_a$  for this anion is 7.21, what is the ratio of  $[\text{AMP}-\text{OH}^-]$  to  $[\text{AMP}-\text{O}^{2-}]$  in blood at pH 7.4?

# Answers to Selected Exercises

## Chapter 1

1.1 (a) Pure element; i, v (b) mixture of elements; vi (c) pure compound; iv (d) mixture of an element and a compound; ii, iii 1.4 The aluminum sphere (density =  $2.70 \text{ g/cm}^3$ ) is lightest, then nickel (density =  $8.90 \text{ g/cm}^3$ ), then silver (density =  $10.49 \text{ g/cm}^3$ ). 1.6 (a) 7.5 cm, 2 significant figures (sig figs) (b)  $140^\circ\text{C}$ , 2 sig figs 1.8 (a) 2 significant figures (sig figs) (b) 2 sig figs 1.11 (a) Heterogeneous mixture (b) homogeneous mixture (heterogeneous if there are undissolved particles) (c) pure substance (d) homogeneous mixture. 1.13 (a) S (b) Mg (c) K (d) Cl (e) Cu (f) fluorine (g) nickel (h) sodium (i) aluminum (j) silicon 1.15 C is a compound; it contains carbon and oxygen. A is a compound; it contains at least carbon and oxygen. B is not defined by the data given; it is probably a compound because few elements exist as white solids. 1.17 Physical properties: silvery white; lustrous; melting point =  $649^\circ\text{C}$ ; boiling point =  $1105^\circ\text{C}$ ; density at  $20^\circ\text{C}$  =  $1.738 \text{ g/cm}^3$ ; pounded into sheets; drawn into wires; good conductor. Chemical properties: burns in air; reacts with  $\text{Cl}_2$ . 1.19 (a) Chemical (b) physical (c) physical (d) chemical (e) chemical 1.21 (a) Add water to dissolve the sugar; filter this mixture, collecting the sand on filter paper and the sugar water in a flask. Evaporate water from the flask to recover solid sugar. (b) Heat the mixture until sulfur melts, then decant the liquid sulfur. 1.23 (a)  $1 \times 10^{-1}$  (b)  $1 \times 10^{-2}$  (c)  $1 \times 10^{-15}$  (d)  $1 \times 10^{-6}$  (e)  $1 \times 10^6$  (f)  $1 \times 10^3$  (g)  $1 \times 10^{-9}$  (h)  $1 \times 10^{-3}$  (i)  $1 \times 10^{-12}$  1.25 (a)  $17^\circ\text{C}$  (b)  $422.1^\circ\text{F}$  (c)  $506 \text{ K}$  (d)  $108^\circ\text{F}$  (e)  $1644 \text{ K}$  1.27 (a)  $1.59 \text{ g/mL}$ . Carbon tetrachloride,  $1.59 \text{ g/mL}$ , is more dense than water,  $1.00 \text{ g/mL}$ ; carbon tetrachloride will sink rather than float on water. (b)  $1.609 \text{ kg}$  (c)  $50.35 \text{ cm}^3$  1.29 (a) Calculated density =  $0.86 \text{ g/mL}$ . The substance is probably toluene, density =  $0.866 \text{ g/mL}$ . (b)  $40.4 \text{ mL}$  ethylene glycol (c)  $1.11 \times 10^3 \text{ g}$  nickel 1.31  $4.6 \times 10^{-6} \text{ m}$ ;  $46 \text{ nm}$  1.33 Exact: (c), (d), and (f) 1.35 (a) 3 (b) 2 (c) 5 (d) 3 (e) 5 1.37 (a)  $1.025 \times 10^2$  (b)  $6.570 \times 10^5$  (c)  $8.543 \times 10^{-3}$  (d)  $2.579 \times 10^{-4}$  (e)  $-3.572 \times 10^{-2}$  1.39 (a) 21.11 (b) 237.4 (c) 652 (d)  $7.66 \times 10^{-2}$  1.41 (a)  $1 \times 10^6 \text{ nm/mm}$  (b)  $1 \times 10^{-6} \text{ kg/mg}$  (c)  $3.28 \times 10^3 \text{ km/ft}$  (d)  $16.4 \text{ cm}^3/\text{in}^3$  1.43 (a)  $76 \text{ mL}$  (b)  $50. \text{ nm}$  (c)  $6.88 \times 10^{-4} \text{ s}$  (d)  $2.3 \times 10^2 \text{ g}$  (e)  $1.55 \text{ g/L}$  (f)  $6.151 \times 10^{-3} \text{ L/s}$  1.45 (a)  $4.32 \times 10^3 \text{ s}$  (b)  $88.5 \text{ m}$  (c)  $\$0.499/\text{L}$  (d)  $46.6 \text{ km/hr}$  (e)  $1.420 \text{ L/s}$  (f)  $707.9 \text{ cm}^3$  1.47 (a)  $1.2 \times 10^4 \text{ L}$  (b)  $4 \times 10^2 \text{ mg}$  (c)  $9.64 \text{ km/L}$  (d)  $26 \text{ mL}$  1.49  $52 \text{ kg air}$  1.51 Use the cm as a unit for comparison ( $1 \text{ in.} \approx 2.5 \text{ cm}$ ).  $57 \text{ cm} = 57 \text{ cm}$ ;  $14 \text{ in.} \approx 35 \text{ cm}$ ;  $1.1 \text{ m} = 110 \text{ cm}$ . The order of length from shortest to longest is  $14 \text{ in.} < 57 \text{ cm} < 1.1 \text{ m}$ . 1.53 (a)  $\$0.91$  (b) Since coins come in integer numbers, 3 coins are required. 1.55 Composition is the contents of a substance; structure is the arrangement of these contents. 1.58  $8.47 \text{ g O}$ ; the law of constant composition 1.61 (a) Volume (b) area (c) volume (d) density (e) time (f) length (g) temperature 1.64 (a)  $1.13 \times 10^5$  quarters (b)  $6.41 \times 10^5 \text{ g}$  (c)  $\$2.83 \times 10^4$  (d)  $3.1 \times 10^8$  stacks (approximately 310 million stacks!) 1.67 The most dense liquid, Hg, will sink; the least dense, cyclohexane, will float;  $\text{H}_2\text{O}$  will be in the middle. 1.70 Density of solid =  $1.63 \text{ g/mL}$  1.73 (a) Density of peat =  $0.13 \text{ g/cm}^3$ , density of topsoil =  $2.5 \text{ g/cm}^3$ . It is not correct to say that peat is "lighter" than topsoil. Volumes must be specified in order to compare masses. (b) Buy 7 bags of peat (6.9 are needed). 1.76 The inner diameter of the tube is  $1.13 \text{ cm}$ . 1.79 The separation is successful if two distinct spots are seen on the paper. To quantify

the characteristics of the separation, calculate a reference value for each spot: distance travelled by spot/distance travelled by solvent. If the values for the two spots are fairly different, the separation is successful. 1.81 (a) Density =  $1.04 \text{ g/mL}$  (b)  $52 \times 10^3 \text{ g}$  propylene glycol provide the same antifreeze protection as  $1.00 \text{ gal}$  of ethylene glycol. (c)  $1.3 \text{ gal}$  propylene glycol provide the same antifreeze protection as  $1.00 \text{ gal}$  of ethylene glycol.

## Chapter 2

2.1 (a) The path of the charged particle bends because it is repelled by the negatively charged plate and attracted to the positively charged plate. (b) (-) (c) increase (d) decrease 2.4 The particle is an ion.  $^{56}_{26}\text{Fe}^{2-}$  2.6 Formula:  $\text{IF}_5$ ; name: iodine pentafluoride; the compound is molecular. 2.9 Postulate 4 of the atomic theory states that the relative number and kinds of atoms in a compound are constant, regardless of the source. Therefore,  $1.0 \text{ g}$  of pure water should always contain the same relative amounts of hydrogen and oxygen, no matter where or how the sample is obtained. 2.11 (a)  $0.5711 \text{ g O/1 g N}$ ;  $1.142 \text{ g O/1 g N}$ ;  $2.284 \text{ g O/1 g N}$ ;  $2.855 \text{ g O/1 g N}$  (b) The numbers in part (a) obey the law of multiple proportions. Multiple proportions arise because atoms are the indivisible entities combining, as stated in Dalton's atomic theory. 2.13 (1) Electric and magnetic fields deflected the rays in the same way they would deflect negatively charged particles. (2) A metal plate exposed to cathode rays acquired a negative charge. 2.15 (a) If the positive plate were lower than the negative plate, the oil drops "coated" with negatively charged electrons would be attracted to the positively charged plate and would descend much more quickly. (b) The more times a measurement is repeated, the better the chance of detecting and compensating for experimental errors. Millikan wanted to demonstrate the validity of his result via its reproducibility. 2.17 (a)  $0.19 \text{ nm}$ ;  $1.9 \times 10^2$  or  $190 \text{ pm}$  (b)  $2.6 \times 10^{16}$  Kr atoms (c)  $2.9 \times 10^{-23} \text{ cm}^3$  2.19 (a) Proton, neutron, electron (b) proton =  $+1$ , neutron =  $0$ , electron =  $-1$  (c) The neutron is most massive. (The neutron and proton have very similar masses.) (d) The electron is least massive. 2.21 (a) Atomic number is the number of protons in the nucleus of an atom. Mass number is the total number of nuclear particles, protons plus neutrons, in an atom. (b) mass number 2.23 (a)  $^{40}\text{Ar}$ :  $18 \text{ p}$ ,  $22 \text{ n}$ ,  $18 \text{ e}$  (b)  $^{65}\text{Zn}$ :  $30 \text{ p}$ ,  $35 \text{ n}$ ,  $30 \text{ e}$  (c)  $^{70}\text{Ga}$ :  $31 \text{ p}$ ,  $39 \text{ n}$ ,  $31 \text{ e}$  (d)  $^{80}\text{Br}$ :  $35 \text{ p}$ ,  $45 \text{ n}$ ,  $35 \text{ e}$  (e)  $^{184}\text{W}$ :  $74 \text{ p}$ ,  $110 \text{ n}$ ,  $74 \text{ e}$  (f)  $^{243}\text{Am}$ :  $95 \text{ p}$ ,  $148 \text{ n}$ ,  $95 \text{ e}$

Molecular: C<sub>4</sub>H<sub>10</sub>  
 Empirical: C<sub>2</sub>H<sub>5</sub>

2.77 (a) Functional groups are groups of specific atoms that are constant from one molecule to the next. (b) —OH

2.79 (a) Dalton postulated the atomic theory, which is based on the indivisible atom as the smallest unit of an element that can combine with other elements. (b) Thomson measured the mass-to-charge ratio of the electron and proposed the "plum pudding" model of the atom. (c) Millikan measured the charge of an electron. (d) Rutherford postulated the nuclear atom, where most of the mass of the atom is concentrated in a small, dense nucleus and electrons move through space around the nucleus. 2.82 (a) 2 protons, 1 neutron, 2 electrons (b) Tritium, <sup>3</sup>H, is more massive. (c) A precision of 1 × 10<sup>-27</sup> g would be required to differentiate between <sup>3</sup>H and <sup>3</sup>He.

2.85 Arrangement A, 4.1 × 10<sup>14</sup> atoms/cm<sup>2</sup> (b) Arrangement B, 4.7 × 10<sup>14</sup> atoms/cm<sup>2</sup> (c) The ratio of atoms going from arrangement B to arrangement A is 1.2 to 1. In three dimensions, arrangement B leads to a greater density for Rb metal. 2.88 (a) <sup>16</sup>O, <sup>17</sup>O, <sup>18</sup>O (b) All isotopes are atoms of the same element, oxygen, with the same atomic number, 8 protons in the nucleus and 8 electrons. We expect their electron arrangements to be the same and their chemical properties to be very similar. Each has a different number of neutrons, a different mass number, and a different atomic mass. 2.91 (a) <sup>31</sup>Ga, 31 protons, 38 neutrons; <sup>31</sup>Ga, 31 protons, 40 neutrons (b) <sup>69</sup>Ga, 60.3%, <sup>71</sup>Ga, 39.7%. 2.94 (a) 5 significant figures (b) An electron

is 0.05444% of the mass of an  $^1\text{H}$  atom. **2.98** (a) Nickel(II) oxide, 2+ (b) manganese(IV) oxide, 4+ (c) chromium(III) oxide, 3+ (d) molybdenum(VI) oxide, 6+ **2.102** (a) Sodium chloride (b) sodium bicarbonate (or sodium hydrogen carbonate) (c) sodium hypochlorite (d) sodium hydroxide (e) ammonium carbonate (f) calcium sulfate **2.104** (a)  $\text{CaS}$ ,  $\text{Ca}(\text{HS})_2$  (b)  $\text{HBr}$ ,  $\text{HBrO}_3$  (c)  $\text{AlN}$ ,  $\text{Al}(\text{NO}_2)_3$  (d)  $\text{FeO}$ ,  $\text{Fe}_2\text{O}_3$  (e)  $\text{NH}_3$ ,  $\text{NH}_4^+$  (f)  $\text{K}_2\text{SO}_3$ ,  $\text{KHSO}_3$  (g)  $\text{Hg}_2\text{Cl}_2$ ,  $\text{HgCl}_2$  (h)  $\text{HClO}_3$ ,  $\text{HClO}_4$

### Chapter 3

**3.1** Equation (a) best fits the diagram. **3.3** (a)  $\text{NO}_2$  (b) No, because we have no way of knowing whether the empirical and molecular formulas are the same.  $\text{NO}_2$  represents the simplest ratio of atoms in a molecule but not the only possible molecular formula. **3.5** (a)  $\text{C}_2\text{H}_5\text{NO}_2$  (b) 75.0 g/mol (c) 225 g (d) Mass %N in glycine is 18.7%.

**3.7**

$\text{N}_2 + 3 \text{H}_2 \longrightarrow 2 \text{NH}_3$ . Eight N atoms (4  $\text{N}_2$  molecules) require 24 H atoms (12  $\text{H}_2$  molecules) for complete reaction. Only 9  $\text{H}_2$  molecules are available, so  $\text{H}_2$  is the limiting reactant. Nine  $\text{H}_2$  molecules (18 H atoms) determine that 6  $\text{NH}_3$  molecules are produced. One  $\text{N}_2$  molecule is in excess.

**3.9** (a) Conservation of mass (b) Subscripts in chemical formulas should not be changed when balancing equations, because changing the subscript changes the identity of the compound (*law of constant composition*). (c)  $\text{H}_2\text{O}(\text{g})$ ,  $\text{H}_2\text{O}(\text{g})$ ,  $\text{NaCl}(\text{aq})$ ,  $\text{NaCl}(\text{s})$

**3.11** (a)  $2 \text{CO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{CO}_2(\text{g})$   
 (b)  $\text{N}_2\text{O}_5(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{HNO}_3(\text{aq})$   
 (c)  $\text{CH}_4(\text{g}) + 4 \text{Cl}_2(\text{g}) \longrightarrow \text{CCl}_4(\text{l}) + 4 \text{HCl}(\text{g})$   
 (d)  $\text{Al}_4\text{C}_3(\text{s}) + 12 \text{H}_2\text{O}(\text{l}) \longrightarrow 4 \text{Al}(\text{OH})_3(\text{s}) + 3 \text{CH}_4(\text{g})$   
 (e)  $2 \text{C}_5\text{H}_{10}\text{O}_2(\text{l}) + 13 \text{O}_2(\text{g}) \longrightarrow 10 \text{CO}_2(\text{g}) + 10 \text{H}_2\text{O}(\text{l})$   
 (f)  $2 \text{Fe}(\text{OH})_3(\text{s}) + 3 \text{H}_2\text{SO}_4(\text{aq}) \longrightarrow \text{Fe}_2(\text{SO}_4)_3(\text{aq}) + 6 \text{H}_2\text{O}(\text{l})$   
 (g)  $\text{Mg}_3\text{N}_2(\text{s}) + 4 \text{H}_2\text{SO}_4(\text{aq}) \longrightarrow$

**3.13** (a)  $\text{CaC}_2(\text{s}) + 2 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{Ca}(\text{OH})_2(\text{aq}) + \text{C}_2\text{H}_2(\text{g})$

(b)  $2 \text{KClO}_3(\text{s}) \xrightarrow{\Delta} 2 \text{KCl}(\text{s}) + 3 \text{O}_2(\text{g})$   
 (c)  $\text{Zn}(\text{s}) + \text{H}_2\text{SO}_4(\text{aq}) \longrightarrow \text{ZnSO}_4(\text{aq}) + \text{H}_2(\text{g})$   
 (d)  $\text{PCl}_3(\text{l}) + 3 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_3\text{PO}_3(\text{aq}) + 3 \text{HCl}(\text{aq})$   
 (e)  $3 \text{H}_2\text{S}(\text{g}) + 2 \text{Fe}(\text{OH})_3(\text{s}) \longrightarrow \text{Fe}_2\text{S}_3(\text{s}) + 6 \text{H}_2\text{O}(\text{g})$

**3.15** (a) Determine the formula by balancing the positive and negative charges in the ionic product. All ionic compounds are solids.  $2 \text{Na}(\text{s}) + \text{Br}_2(\text{l}) \longrightarrow 2 \text{NaBr}(\text{s})$  (b) The second reactant is  $\text{O}_2(\text{g})$ . The products are  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ .

$2 \text{C}_6\text{H}_6(\text{l}) + 15 \text{O}_2(\text{g}) \longrightarrow 12 \text{CO}_2(\text{g}) + 6 \text{H}_2\text{O}(\text{l})$

**3.17** (a)  $\text{Mg}(\text{s}) + \text{Cl}_2(\text{g}) \longrightarrow \text{MgCl}_2(\text{s})$

(b)  $\text{BaCO}_3(\text{s}) \xrightarrow{\Delta} \text{BaO}(\text{s}) + \text{CO}_2(\text{g})$   
 (c)  $\text{C}_8\text{H}_8(\text{l}) + 10 \text{O}_2(\text{g}) \longrightarrow 8 \text{CO}_2(\text{g}) + 4 \text{H}_2\text{O}(\text{l})$   
 (d)  $\text{C}_2\text{H}_6\text{O}(\text{l}) + 3 \text{O}_2(\text{g}) \longrightarrow 2 \text{CO}_2(\text{g}) + 3 \text{H}_2\text{O}(\text{l})$

**3.19** (a)  $2 \text{Al}(\text{s}) + 3 \text{Cl}_2(\text{g}) \longrightarrow 2 \text{AlCl}_3(\text{s})$  combination

(b)  $\text{C}_2\text{H}_4(\text{g}) + 3 \text{O}_2(\text{g}) \longrightarrow 2 \text{CO}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l})$  combustion

(c)  $6 \text{Li}(\text{s}) + \text{N}_2(\text{g}) \longrightarrow 2 \text{Li}_3\text{N}(\text{s})$  combination

(d)  $\text{PbCO}_3(\text{s}) \longrightarrow \text{PbO}(\text{s}) + \text{CO}_2(\text{g})$  decomposition

(e)  $\text{C}_7\text{H}_8\text{O}(\text{l}) + 8 \text{O}_2(\text{g}) \longrightarrow 7 \text{CO}_2(\text{g}) + 4 \text{H}_2\text{O}(\text{l})$  combustion

**3.21** (a) 63.0 amu (b) 158.0 amu (c) 310.3 amu (d) 60.1 amu

(e) 235.7 amu (f) 392.3 amu (g) 137.5 amu **3.23** (a) 16.8% (b) 16.1% (c) 21.1% (d) 28.8% (e) 27.2% (f) 26.5% **3.25** (a) 79.2% (b) 63.2% (c) 64.6% **3.27** (a)  $6.022 \times 10^{23}$  (b) The formula

weight of a substance in amu has the same numerical value as the molar mass expressed in grams. **3.29** 23 g Na contains 1 mol of atoms; 0.5 mol  $\text{H}_2\text{O}$  contains 1.5 mol atoms;  $6.0 \times 10^{23}$  molecules contains 2 mol of atoms.

**3.31**  $4.37 \times 10^{25}$  kg (assuming 160 lb has 3 significant

figures). One mole of people weighs 7.31 times as much as

Earth. **3.33** (a) 35.9 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  (b) 0.7577 mol  $\text{Zn}(\text{NO}_3)_2$

## Chapter 4

4.1 Diagram (c) represents  $\text{Li}_2\text{SO}_4$ . 4.3 (a) AX is a nonelectrolyte. (b) AY is a weak electrolyte. (c) AZ is a strong electrolyte. 4.5 Solid A is NaOH, solid B is AgBr, and solid C is glucose. 4.7 (b)  $\text{NO}_3^-$  and (c)  $\text{NH}_4^+$  will always be spectator ions. 4.9 In a redox reaction, electrons are transferred from the oxidized substance to the reduced substance. In an acid-base reaction, protons are transferred from an acid to a base. 4.11 No. Electrolyte solutions conduct electricity because the dissolved ions carry charge through the solution from one electrode to the other. 4.13 Although  $\text{H}_2\text{O}$  molecules are electrically neutral, there is an unequal distribution of electrons throughout the molecule. The partially positive ends of  $\text{H}_2\text{O}$  molecules are attracted to anions in the solid, while the partially negative ends are attracted to cations. Thus, both cations and anions in an ionic solid are surrounded and separated (dissolved) by  $\text{H}_2\text{O}$ .

4.17  $\text{HCOOH}$  molecules,  $\text{H}^+$  ions, and  $\text{HCOO}^-$  ions;  $\text{HCOOH}(aq) \rightarrow \text{H}^+(aq) + \text{HCOO}^-(aq)$  4.19 (a) Soluble (b) insoluble (c) soluble (d) insoluble (e) insoluble

4.27

Compound	$\text{Ba}(\text{NO}_3)_2$ Result	$\text{NaCl}$ Result
$\text{AgNO}_3(aq)$	No ppt	$\text{AgCl}$ ppt
$\text{CaCl}_2(aq)$	No ppt	No ppt

This sequence of tests would definitely identify the bottle contents. 4.29  $\text{LiOH}$  is a strong base,  $\text{HI}$  is a strong acid, and  $\text{CH}_3\text{OH}$  is a molecular compound and nonelectrolyte. The strong acid  $\text{HI}$  will have the greatest concentration of solvated protons. 4.31 (a) A monoprotic acid has one ionizable (acidic) H, whereas a diprotic acid has two. (b) A strong acid is completely ionized in aqueous solution, whereas only a fraction of weak acid molecules are ionized. (c) An acid is an  $\text{H}^+$  donor, and a base is an  $\text{H}^+$  acceptor. 4.33 As strong acids,  $\text{HCl}$ ,  $\text{HBr}$  and  $\text{HI}$  are completely ionized in aqueous solution. They exist exclusively as  $\text{H}^+(aq)$  and  $\text{Cl}^-(aq)$ ,  $\text{H}^+(aq)$  and  $\text{Br}^-(aq)$ ,  $\text{H}^+(aq)$  and  $\text{I}^-(aq)$ , respectively. As a weak acid,  $\text{HF}$  is only partially ionized. In solution it exists as a mixture of neutral  $\text{HF}(aq)$  molecules,  $\text{H}^+(aq)$  and  $\text{F}^-(aq)$ . 4.35 (a) Acid, mixture of ions and molecules (weak electrolyte) (b) none of the above, entirely molecules (nonelectrolyte) (c) salt, entirely ions (strong electrolyte) (d) base, entirely ions (strong electrolyte) 4.37 (a)  $\text{H}_2\text{SO}_3$ , weak electrolyte (b)  $\text{C}_2\text{H}_5\text{OH}$ , nonelectrolyte (c)  $\text{NH}_3$ , weak electrolyte (d)  $\text{KClO}_3$ , strong electrolyte (e)  $\text{Cu}(\text{NO}_3)_2$ , strong electrolyte 4.39 (a)  $2\text{HBr}(aq) + \text{Ca}(\text{OH})_2(aq) \rightarrow \text{CaBr}_2(aq) + 2\text{H}_2\text{O}(l)$ ;  $\text{H}^+(aq) + \text{OH}^-(aq) \rightarrow \text{H}_2\text{O}(l)$  (b)  $\text{Cu}(\text{OH})_2(s) + 2\text{HClO}_4(aq) \rightarrow \text{Cu}(\text{ClO}_4)_2(aq) + 2\text{H}_2\text{O}(l)$ ;  $\text{Cu}(\text{OH})_2(s) + 2\text{H}^+(aq) \rightarrow 2\text{H}_2\text{O}(l) + \text{Cu}^{2+}(aq)$  (c)  $\text{Al}(\text{OH})_3(s) + 3\text{HNO}_3(aq) \rightarrow \text{Al}(\text{NO}_3)_3(aq) + 3\text{H}_2\text{O}(l)$ ;  $\text{Al}(\text{OH})_3(s) + 3\text{H}^+(aq) \rightarrow 3\text{H}_2\text{O}(l) + \text{Al}^{3+}(aq)$  4.41 (a)  $\text{CdS}(s) + \text{H}_2\text{SO}_4(aq) \rightarrow \text{CdSO}_4(aq) + \text{H}_2\text{S}(g)$ ;  $\text{Cd}(s) + 2\text{H}^+(aq) \rightarrow \text{H}_2\text{S}(g) + \text{Cd}^{2+}(aq)$  (b)  $\text{MgCO}_3(s) + 2\text{HClO}_4(aq) \rightarrow \text{Mg}(\text{ClO}_4)_2(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$ ;  $\text{MgCO}_3(s) + 2\text{H}^+(aq) \rightarrow$

oxidation is the loss of electrons by a substance and reduction is the gain of electrons (LEO says GER). (b) Relative to oxidation numbers, when a substance is oxidized, its oxidation number increases. When a substance is reduced, its oxidation number decreases. 4.47 Metals in region A are most easily oxidized. Nonmetals in region D are least easily oxidized. 4.49 (a) +4 (b) +4 (c) +7 (d) +1 (e) 0 (f) -1 4.51 (a)  $\text{N}_2 \rightarrow 2\text{NH}_3$ , N is reduced;  $3\text{H}_2 \rightarrow 2\text{NH}_3$ , H is oxidized (b)  $\text{Fe}^{2+} \rightarrow \text{Fe}$ , Fe is reduced;  $\text{Al} \rightarrow \text{Al}^{3+}$ , Al is oxidized (c)  $\text{Cl}_2 \rightarrow 2\text{Cl}^-$ , Cl is reduced;  $2\text{I}^- \rightarrow \text{I}_2$  I is oxidized (d)  $\text{S}^{2-} \rightarrow \text{SO}_4^{2-}$ , S is oxidized;  $\text{H}_2\text{O}_2 \rightarrow \text{H}_2\text{O}$ ; O is reduced

Zn and Ni on the activity series. (c) Place an iron strip in  $\text{CdCl}_2(aq)$ . If  $\text{Cd}(s)$  is deposited, Cd is less active than Fe; if there is no reaction, Cd is more active than Fe. Do the same test with Co if Cd is less active than Fe or with Cr if Cd is more active than Fe. 4.59 (a) Intensive; the ratio of amount of solute to total amount of solution is the same, regardless of how much solution is present. (b) The term 0.50 mol HCl defines an amount (~18 g) of the pure substance HCl. The term

0.50 M HCl is a ratio; it indicates that there are 0.50 mol of HCl solute in 1.0 liter of solution. 4.61 (a) 0.0500 M  $\text{NH}_4\text{Cl}$

(b) 0.125 mol  $\text{HNO}_3$  (c) 183 mL of 1.50 M KOH

4.63 16 g  $\text{Na}^+(aq)$  4.65 BAC of 0.08 = 0.02 M  $\text{CH}_3\text{CH}_2\text{OH}$

(alcohol) 4.67 (a) 5.21 g KBr (b) 0.06537 M  $\text{Ca}(\text{NO}_3)_2$

(c) 10.2 mL of 1.50 M  $\text{Na}_3\text{PO}_4$  4.69 (a) 0.15 M  $\text{K}_2\text{CrO}_4$  has the

highest  $\text{K}^+$  concentration. (b) 30.0 mL of 0.15 M  $\text{K}_2\text{CrO}_4$  has

more  $\text{K}^+$  ions. 4.71 (a) 0.25 M  $\text{Na}^+$ , 0.25 M  $\text{NO}_3^-$

(b)  $1.3 \times 10^{-2}$  M  $\text{Mg}^{2+}$ ,  $1.3 \times 10^{-2}$  M  $\text{SO}_4^{2-}$  (c) 0.0150 M

$\text{C}_6\text{H}_{12}\text{O}_6$  (d) 0.111 M  $\text{Na}^+$ , 0.111 M  $\text{Cl}^-$ , 0.0292 M  $\text{NH}_4^+$ ,

0.0146 M  $\text{CO}_3^{2-}$  4.73 (a) 16.9 mL 14.8 M  $\text{NH}_3$  (b) 0.296 M  $\text{NH}_3$

4.75 (a) Add 21.4 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  to a 250-mL volumetric flask,

dissolve in a small volume of water, and add water to the

mark on the neck of the flask. Agitate thoroughly to ensure

total mixing. (b) Thoroughly rinse, clean, and fill a 50-mL buret

with the 1.50 M  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ . Dispense 23.3 mL of this solution

into a 350-mL volumetric container, add water to the mark,

and mix thoroughly. 4.77 1.398 M  $\text{HC}_2\text{H}_3\text{O}_2$  4.79 0.227 g KCl

4.81 (a) 38.0 mL of 0.115 M  $\text{HClO}_4$  (b) 769 mL of 0.128 M HCl

(c) 0.408 M  $\text{AgNO}_3$  (d) 0.275 g KOH 4.83 27 g  $\text{NaHCO}_3$

4.85  $1.22 \times 10^{-2}$  M  $\text{Ca}(\text{OH})_2$  solution; the solubility of  $\text{Ca}(\text{OH})_2$

is 0.0904 g in 100 mL solution. 4.87 (a)  $\text{NiSO}_4(aq) +$

is the limiting reactant. (d) 0.927 g  $\text{Ni}(\text{OH})_2$  (e) 0.0667 M  $\text{Ni}^{2+}(aq)$ ,

0.0667 M  $\text{K}^+(aq)$ , 0.100 M  $\text{SO}_4^{2-}(aq)$  4.89 91.40%  $\text{Mg}(\text{OH})_2$

4.93 The first precipitate is  $\text{AgCl}(s)$ , the second is  $\text{SrSO}_4(s)$ .

Since no precipitate forms on addition of  $\text{OH}^-(aq)$  to the remaining solution,  $\text{Ni}^{2+}$  and  $\text{Mn}^{2+}$  must be absent from the original solution. 4.94 (a, b) Expt. 1: NR; Expt. 2:  $2\text{Ag}^+(aq) +$

Expt. 4:  $2 \text{Ag}^+(aq) + \text{C}_2\text{O}_4^{2-}(aq) \longrightarrow \text{Ag}_2\text{C}_2\text{O}_4(s)$  white precipitate; Expt. 5:  $\text{Ca}^{2+}(aq) + \text{C}_2\text{O}_4^{2-}(aq) \longrightarrow \text{CaC}_2\text{O}_4(s)$  white precipitate; Expt. 6:  $\text{Ag}^+(aq) + \text{Cl}^-(aq) \longrightarrow \text{AgCl}(s)$  white precipitate. (c) Chromate salts appear to be more soluble than oxalate salts. **4.100** 1.42 M KBr **4.104** 0.496 M  $\text{H}_2\text{O}_2$   
**4.106** (a) The molar mass of the acid is 136 g/mol. (b) The molecular formula is  $\text{C}_8\text{H}_8\text{O}_2$ . **4.109** (a)  $\text{Mg}(\text{OH})_2(s) + 2 \text{HNO}_3(aq) \longrightarrow \text{Mg}(\text{NO}_3)_2(aq) + 2 \text{H}_2\text{O}(l)$  (b)  $\text{HNO}_3$  is the limiting reactant. (c) 0.0923 mol  $\text{Mg}(\text{OH})_2$ , 0 mol  $\text{HNO}_3$ , and 0.00250 mol  $\text{Mg}(\text{NO}_3)_2$  are present. **4.113** 1.766%  $\text{Cl}^-$  by mass **4.115**  $2.8 \times 10^{-5}$  g  $\text{Na}_3\text{AsO}_4$  in 1.00 L  $\text{H}_2\text{O}$

## Chapter 5

**5.1** As the book falls, potential energy decreases and kinetic energy increases. At the instant before impact, all potential energy has been converted to kinetic energy, so the book's total kinetic energy is 85 J, assuming no transfer of energy as heat.  
**5.4** (a) No. The distance traveled to the top of a mountain depends on the path taken by the hiker. Distance is a path function, not a state function. (b) Yes. Change in elevation depends only on the location of the base camp and the height of the mountain, not on the path to the top. Change in elevation is a state function, not a path function. **5.6** (a) The temperatures of the system and surroundings will equalize, so the temperature of the hotter system will decrease and the temperature of the colder surroundings will increase. The sign of  $q$  is (-); the process is exothermic. (b) If neither volume nor pressure of the system changes,  $w = 0$  and  $\Delta E = q = \Delta H$ . The change in internal energy is equal to the change in enthalpy.  
**5.9** (a)  $\Delta H_A = \Delta H_B + \Delta H_C$ . The diagram and equation both show that the net enthalpy change for a process is independent of path, that  $\Delta H$  is a state function. (b)  $\Delta H_Z = \Delta H_X + \Delta H_Y$ . (c) Hess's law states that the enthalpy change for net reaction Z is the sum of the enthalpy changes for steps X and Y, regardless of whether the reaction actually occurs via this path. The diagrams are a visual statement of Hess's law. **5.11** An object can possess energy by virtue of its motion or position. Kinetic energy depends on the mass of the object and its velocity. Potential energy depends on the position of the object relative to the body with which it interacts. **5.13** (a) 84 J (b) 20 cal (c) As the ball hits the sand, its speed (and hence its kinetic energy) drops to zero. Most of the kinetic energy is transferred to the sand, which deforms when the ball lands. Some energy is released as heat through friction between the ball and the sand.  
**5.15** 1 Btu = 1054 J **5.17** (a) The system is the well-defined part of the universe whose energy changes are being studied. (b) A closed system can exchange heat but not mass with its surroundings. **5.19** (a) Work is a force applied over a distance. (b) The amount of work done is the magnitude of the force times the distance over which it is applied.  $w = F \times d$ .  
**5.21** (a) Gravity; work is done because the force of gravity is opposed and the pencil is lifted. (b) Mechanical force; work is done because the force of the coiled spring is opposed as the spring is compressed over a distance. **5.23** (a) In any chemical or physical change, energy can be neither created nor destroyed; energy is conserved. (b) The internal energy ( $E$ ) of a system is the sum of all the kinetic and potential energies of the system components. (c) Internal energy of a closed system increases when work is done on the system and when heat is transferred to the system. **5.25** (a)  $\Delta E = 76$  kJ, endothermic (b)  $\Delta E = 0.84$  kJ, endothermic (c)  $\Delta E = -80.0$  kJ, exothermic  
**5.27** (a) Since no work is done by the system in case (2), the gas will absorb most of the energy as heat; the case (2) gas will have the higher temperature. (b) In case (2)  $w = 0$  and  $q = 100$  J. In case (1) energy will be used to do work on the surroundings ( $-w$ ), but some will be absorbed as heat ( $+q$ ). (c)  $\Delta E$  is greater for case (2) because the entire 100 J increases the internal energy of the system, rather than a part of the energy

doing work on the surroundings. **5.29** (a) A state function is a property that depends only on the physical state (pressure, temperature, etc.) of the system, not on the route used to get to the current state. (b) Internal energy is a state function; heat is not a state function. (c) Work is not a state function. The amount of work required to move from one state to another depends of the specific series of processes or path used to accomplish the change. **5.31** (a)  $\Delta H$  is usually easier to measure than  $\Delta E$  because at constant pressure  $\Delta H = q$ . The heat flow associated with a process at constant pressure can easily be measured as a change in temperature, while measuring  $\Delta E$  requires a means to measure both  $q$  and  $w$ . (b) The process is exothermic. **5.33** At constant pressure,  $\Delta E = \Delta H - P \Delta V$ . The values of either  $P$  and  $\Delta V$  or  $T$  and  $\Delta n$  must be known to calculate  $\Delta E$  from  $\Delta H$ . **5.35**  $\Delta E = -97$  kJ;  $\Delta H = -79$  kJ  
**5.37** (a)  $\text{CH}_3\text{COOH}(l) + 2 \text{O}_2(g) \longrightarrow 2 \text{H}_2\text{O}(l) + 2 \text{CO}_2(g)$ ,  $\Delta H = -871.7$  kJ

$$\Delta H = -871.7 \text{ kJ}$$

**5.39** The reactant, 2 Cl(g), has the higher enthalpy.  
**5.41** (a) Exothermic (b) -59 kJ heat transferred (c) 6.43 g MgO produced (d) 112 kJ heat absorbed **5.43** (a) -13.1 kJ (b) -1.14 kJ (c) 9.83 J **5.45** (a)  $\Delta H = 726.5$  kJ (b)  $\Delta H = -1453$  kJ (c) The exothermic forward reaction is more likely to be thermodynamically favored. (d) Vaporization is endothermic. If the product were  $\text{H}_2\text{O}(g)$ , the reaction would be more endothermic and would have a smaller negative  $\Delta H$ .  
**5.47** (a) J/mol $\cdot$ °C or J/mol $\cdot$ K (b) J/g $\cdot$ °C or J/g $\cdot$ K (c) To calculate heat capacity from specific heat, the mass of the particular piece of copper pipe must be known. **5.49** (a) 4.184 J/g $\cdot$ K (b) 75.40 J/mol $\cdot$ °C (c) 774 J/°C (d) 904 kJ **5.51**  $3.00 \times 10^4$  J **5.53**  $\Delta H = -457$  kJ/mol NaOH **5.55**  $\Delta E_{\text{rxn}} = -25.5$  kJ/g  $\text{C}_6\text{H}_4\text{O}_2$  or  $-2.75 \times 10^3$  kJ/mol  $\text{C}_6\text{H}_4\text{O}_2$  **5.57** (a) Heat capacity of the complete calorimeter = 14.4 kJ/°C (b) 5.40 °C  
**5.59** Hess's law is a consequence of the fact that enthalpy is a state function. Since  $\Delta H$  is independent of path, we can describe a process by any series of steps that add up to the overall process.  $\Delta H$  for the process is the sum of  $\Delta H$  values for the steps. **5.61**  $\Delta H = -1300.0$  kJ **5.63**  $\Delta H = -2.49 \times 10^3$  kJ  
**5.65** (a) Standard conditions for enthalpy changes are  $P = 1$  atm and some common temperature, usually 298 K. (b) Enthalpy of formation is the enthalpy change that occurs when a compound is formed from its component elements. (c) Standard enthalpy of formation  $\Delta H_f^\circ$  is the enthalpy change that accompanies formation of one mole of a substance from elements in their standard states. **5.67** (a)  $\frac{1}{2} \text{N}_2(g) + \frac{3}{2} \text{H}_2(g) \longrightarrow \text{NH}_3(g)$ ,  $\Delta H_f^\circ = -46.19$  kJ (b)  $\text{S}(s) + \text{O}_2(g) \longrightarrow \text{SO}_2(g)$ ,  $\Delta H_f^\circ = -296.9$  kJ (c)  $\text{Rb}(s) + \frac{1}{2} \text{Cl}_2(g) + \frac{3}{2} \text{O}_2(g) \longrightarrow \text{RbClO}_3(s)$ ,  $\Delta H_f^\circ = -392.4$  kJ (d)  $\text{N}_2(g) + 2 \text{H}_2(g) + \frac{3}{2} \text{O}_2(g) \longrightarrow \text{NH}_4\text{NO}_3(s)$ ,  $\Delta H_f^\circ = -365.6$  kJ **5.69**  $\Delta H_{\text{rxn}}^\circ = -847.6$  kJ  
**5.71** (a)  $\Delta H_{\text{rxn}}^\circ = -196.6$  kJ (b)  $\Delta H_{\text{rxn}}^\circ = 37.1$  kJ (c)  $\Delta H_{\text{rxn}}^\circ = -976.94$  kJ (d)  $\Delta H_{\text{rxn}}^\circ = -68.3$  kJ  
**5.73**  $\Delta H_f^\circ = -248$  kJ **5.75** (a)  $\text{C}_8\text{H}_{18}(l) + \frac{25}{2} \text{O}_2(g) \longrightarrow 8 \text{CO}_2(g) + 9 \text{H}_2\text{O}(g)$ ,  $\Delta H = -5064.9$  kJ (b)  $8 \text{C}(s, \text{graphite}) + 9 \text{H}_2(g) \longrightarrow \text{C}_8\text{H}_{18}(l)$  (c)  $\Delta H_f^\circ = -259.5$  kJ  
**5.77** (a)  $\text{C}_2\text{H}_5\text{OH}(l) + 3 \text{O}_2(g) \longrightarrow 2 \text{CO}_2(g) + 3 \text{H}_2\text{O}(g)$  (b)  $\Delta H_{\text{rxn}}^\circ = -1234.8$  kJ (c)  $2.11 \times 10^4$  kJ/L heat produced (d) 0.071284 g  $\text{CO}_2$ /kJ heat emitted **5.79** (a) Fuel value is the amount of heat produced when 1 g of a substance (fuel) is combusted. (b) 5 g of fat **5.81** 104 or  $1 \times 10^2$  Cal/serving

5.83 59.7 Cal 5.85 (a)  $\Delta H_{\text{comb}} = -1850 \text{ kJ/mol C}_3\text{H}_4$ ,  $-1926 \text{ kJ/mol C}_3\text{H}_6$ ,  $-2044 \text{ kJ/mol C}_3\text{H}_8$  (b)  $\Delta H_{\text{comb}} = -4.616 \times 10^4 \text{ kJ/kg C}_3\text{H}_4$ ,  $-4.578 \times 10^4 \text{ kJ/kg C}_3\text{H}_6$ ,  $-4.635 \times 10^4 \text{ kJ/kg C}_3\text{H}_8$  (c) These three substances yield nearly identical quantities of heat per unit mass, but propane is marginally higher than the other two. 5.87 (a) 469.4 m/s (b)  $5.124 \times 10^{-21} \text{ J}$  (c) 3.086 kJ/mol 5.90 The spontaneous air bag reaction is probably exothermic, with  $-\Delta H$  and thus  $-q$ . When the bag inflates, work is done by the system, so the sign of  $w$  is also negative. 5.93  $\Delta H = 38.95 \text{ kJ}$ ;  $\Delta E = 36.48 \text{ kJ}$  5.96 (a)  $8.0 \times 10^{10} \text{ kJ energy released}$  (b)  $1.9 \times 10^4 \text{ ton dynamite}$  5.100 4.90 g  $\text{CH}_4$  5.103 (a)  $\Delta H_f^\circ = 35.4 \text{ kJ}$  (b) We need to measure the heat of combustion of  $\text{B}_2\text{H}_6(l)$ . 5.105 (a)  $\Delta H^\circ = -631.1 \text{ kJ}$  (b) 3 mol of acetylene gas has greater enthalpy. (c) Fuel values are 50 kJ/g  $\text{C}_2\text{H}_2(g)$ , 42 kJ/g  $\text{C}_6\text{H}_6(l)$ . 5.109 If all work is used to increase the man's potential energy, the stair-climbing uses 58 Cal and will not compensate for the extra order of 245 Cal fries. (More than 58 Cal will be required to climb the stairs, because some energy is used to move limbs and some will be lost as heat.) 5.112 (a) 1479  $\times 10^{-19} \text{ J/molecule}$  (b)  $1 \times 10^{13} \text{ J/photon}$ . The X-ray has approximately 1000 times more energy than is produced by the combustion of 1 molecule of  $\text{CH}_4(g)$ . 5.115 (a)  $\Delta H^\circ$  for neutralization of the acids is  $\text{HNO}_3$ ,  $-55.8 \text{ kJ}$ ;  $\text{HCl}$ ,  $-56.1 \text{ kJ}$ ;  $\text{NH}_4^+$ ,  $-4.1 \text{ kJ}$ . (b)  $\text{H}^+(aq) + \text{OH}^-(aq) \rightarrow \text{H}_2\text{O}(l)$  is the net ionic equation for the first two reactions.  $\text{NH}_4^+(aq) + \text{OH}^-(aq) \rightarrow \text{NH}_3(aq) + \text{H}_2\text{O}(l)$  (c) The  $\Delta H^\circ$  values for the first two reactions are nearly identical,  $-55.9 \text{ kJ}$  and  $-56.2 \text{ kJ}$ . Since spectator ions do not change during a reaction and these two reactions have the same net ionic equation, it is not surprising that they have the same  $\Delta H^\circ$ . (d) Strong acids are more likely than weak acids to donate  $\text{H}^+$ . Neutralization of the two strong acids is energetically favorable, while the third reaction is barely so.  $\text{NH}_4^+$  is likely a weak acid. 5.117 (a)  $\Delta H^\circ = -65.7 \text{ kJ}$  (b)  $\Delta H^\circ$  for the complete molecular equation will be the same as  $\Delta H^\circ$  for the net ionic equation. Since the overall enthalpy change is the enthalpy of products minus the enthalpy of reactants, the contributions of spectator ions cancel. (c)  $\Delta H_f^\circ$  for  $\text{AgNO}_3(aq)$  is  $-100.4 \text{ kJ/mol}$ .

## Chapter 6

6.2 (a) 0.1 m or 10 cm (b) No. Visible radiation has wavelengths much shorter than 0.1 m. (c) Energy and wavelength are inversely proportional. Photons of the longer 0.1 m radiation have less energy than visible photons. (d) Radiation with  $\lambda = 0.1 \text{ m}$  is in the low energy portion of the microwave region. The appliance is probably a microwave oven. 6.5 (a)  $n = 1, l = 4$  (b)  $n = 1, l = 2$  (c) In order of increasing wavelength and decreasing energy: (iii) < (iv) < (ii) < (i) 6.8 (a) In the left-most box, the two electrons cannot have the same spin. (b) Flip one of the arrows in the left-most box, so that one points up and the other down. (c) Group 6A 6.9 (a) Meters (b) 1/second (c) meters/second 6.11 (a) True (b) False. The frequency of radiation decreases as the wavelength increases. (c) False. Ultraviolet light has shorter wavelengths than visible light. (d) False. X-rays travel at the same speed as microwaves. (e) False. Electromagnetic radiation and sound waves travel at different speeds. 6.13 Wavelength of X-rays < ultraviolet < green light < red light < infrared < radio waves 6.15 (a)  $3.0 \times 10^{15} \text{ s}^{-1}$  (b)  $5.45 \times 10^{-7} \text{ m} = 545 \text{ nm}$  (c) The radiation in (b) is visible, the radiation in (a) is not. (d)  $1.50 \times 10^4 \text{ m}$  6.17  $5.64 \times 10^{14} \text{ s}^{-1}$ ; green. 6.19 Quantization means that energy changes can happen only in certain allowed increments. If the human growth quantum is one foot, growth occurs instantaneously in one-foot increments. The child experiences growth spurts of one foot; her height can change only by one-foot increments.

6.21 (a)  $4.61 \times 10^{14} \text{ s}^{-1}$  (b)  $1.84 \times 10^5 \text{ J}$  (c)  $\Delta E = 3.06 \times 10^{-19} \text{ J}$  6.23 (a)  $\lambda = 3.3 \mu\text{m}$ ,  $E = 6.0 \times 10^{-20} \text{ J}$ ;  $\lambda = 0.154 \text{ nm}$ ,  $E = 1.29 \times 10^{-15} \text{ J}$  (b) The 3.3  $\mu\text{m}$  photon is in the infrared and the 0.154 nm photon is in the X-ray region; the X-ray photon has the greater energy. 6.25 (a)  $6.11 \times 10^{-19} \text{ J/photon}$  (b) 368 kJ/mol (c)  $1.64 \times 10^{15}$  photons (d) 368 kJ/mol 6.27 (a) The  $\sim 1 \times 10^{-6} \text{ m}$  radiation is in the infrared portion of the spectrum. (b)  $8.1 \times 10^{16}$  photons/s 6.29 (a)  $E_{\text{min}} = 7.22 \times 10^{-19} \text{ J}$  (b)  $\lambda = 275 \text{ nm}$  (c)  $E_{120} = 1.66 \times 10^{-18} \text{ J}$ . The excess energy of the 120 nm photon is converted into the kinetic energy of the emitted electron.  $E_k = 9.3 \times 10^{-19} \text{ J/electron}$ . 6.31 When applied to atoms, the notion of quantized energies means that only certain values of  $\Delta E$  are allowed. These are represented by the lines in the emission spectra of excited atoms. 6.33 (a) Emitted (b) absorbed (c) emitted 6.35 (a)  $E_2 = -5.45 \times 10^{-19} \text{ J}$ ;  $E_6 = -0.606 \times 10^{-19} \text{ J}$ ;  $\Delta E = 4.84 \times 10^{-19} \text{ J}$ ;  $\lambda = 410 \text{ nm}$ ; visible, violet. (b)  $E_1 = -2.18 \times 10^{-18} \text{ J}$ ;  $E_{\infty} = 0$ ;  $\Delta E = 2.18 \times 10^{-18} \text{ J/electron} = 1.31 \times 10^3 \text{ kJ/mol}$  (c) The ionization energy of hydrogen calculated from the Bohr model agrees with the experimental result to three significant figures. 6.37 (a) Only lines with  $n_f = 2$  represent  $\Delta E$  values and wavelengths that lie in the visible portion of the spectrum. Lines with  $n_f = 1$  have shorter wavelengths and lines with  $n_f > 2$  have longer wavelengths than visible radiation. (b)  $n_i = 3, n_f = 2$ ;  $\lambda = 6.56 \times 10^{-7} \text{ m}$ ; this is the red line at 656 nm.  $n_i = 4, n_f = 2$ ;  $\lambda = 4.86 \times 10^{-7} \text{ m}$ ; this is the blue line at 486 nm.  $n_i = 5, n_f = 2$ ;  $\lambda = 4.34 \times 10^{-7} \text{ m}$ ; this is the violet line at 434 nm. 6.39 (a) Ultra-violet region (b)  $n_i = 6, n_f = 1$  6.41 (a)  $\lambda = 5.6 \times 10^{-37} \text{ m}$  (b)  $\lambda = 2.65 \times 10^{-34} \text{ m}$  (c)  $\lambda = 2.3 \times 10^{-13} \text{ m}$  (d)  $\lambda = 1.51 \times 10^{-11} \text{ m}$  6.43  $4.14 \times 10^3 \text{ m/s}$  6.45 (a)  $\Delta x \geq 4 \times 10^{-27} \text{ m}$  (b)  $\Delta x \geq 3 \times 10^{-10} \text{ m}$  6.47 (a) The uncertainty principle states that there is a limit to how precisely we can simultaneously know the position and momentum (a quantity related to energy) of an electron. The Bohr model states that electrons move about the nucleus in precisely circular orbits of known radius and energy. This violates the uncertainty principle. (b) De Broglie stated that electrons demonstrate the properties of both particles and waves, that each particle has a wave associated with it. A wave function is the mathematical description of the matter wave of an electron. (c) Although we cannot predict the exact location of an electron in an allowed energy state, we can determine the probability of finding an electron at a particular position. This statistical knowledge of electron location is the *probability density* and is a function of  $\Psi^2$ , the square of the wave function  $\Psi$ . 6.49 (a)  $n = 4, l = 3, 2, 1, 0$  (b)  $l = 2, m_l = -2, -1, 0, 1, 2$  (c)  $m_l = 2, l \geq 2$  or  $l = 2, 3$  or 4 6.51 (a)  $3p: n = 3, l = 1$  (b)  $2s: n = 2, l = 0$  (c)  $4f: n = 4, l = 3$  (d)  $5d: n = 5, l = 2$  6.53 (a) impossible, 1p (b) possible (c) possible (d) impossible, 2d

6.57 (a) The hydrogen atom 1s and 2s orbitals have the same overall spherical shape, but the 2s orbital has a larger radial extension and one more node than the 1s orbital. (b) A single 2p orbital is directional in that its electron density is concentrated along one of the three Cartesian axes of the atom. The  $d_{x^2-y^2}$  orbital has electron density along both the x- and y-axes, while the  $p_x$  orbital has electron density only along the x-axis. (c) The average distance of an electron from the nucleus in a 3s orbital is greater than for an electron in a 2s orbital.

(d)  $1s < 2p < 3d < 4f < 6s$  6.59 (a) In the hydrogen atom, orbitals with the same principal quantum number,  $n$ , have the same energy. (b) In a many-electron atom, for a given  $n$  value, orbital energy increases with increasing  $l$  value:  $s < p < d < f$ . 6.61 (a) There are two main pieces of experimental evidence for electron "spin." The Stern-Gerlach experiment shows that atoms with a single unpaired electron interact differently with an inhomogeneous magnetic field. Examination of the fine details of emission line spectra of multi-electron atoms reveals that each line is really a close pair of lines. Both observations can be rationalized if electrons have the property of spin.

6.63 (a) 6 (b) 10 (c) 2 (d) 14 6.65 (a) "Valence electrons" are those involved in chemical bonding. They are part or all of the outer-shell electrons listed after the core. (b) "Core electrons" are inner shell electrons that have the electron configuration of the nearest noble-gas element. (c) Each box represents an orbital. (d) Electron spin is represented by the direction of the half-arrows. 6.67 (a) Cs, [Xe]6s<sup>1</sup> (b) Ni, [Ar]4s<sup>2</sup>3d<sup>8</sup> (c) Se, [Ar]4s<sup>2</sup>3d<sup>10</sup>4p<sup>4</sup> (d) Cd, [Kr]5s<sup>2</sup>4d<sup>10</sup> (e) U, [Rn]5f<sup>3</sup>6d<sup>1</sup>7s<sup>2</sup> (f) Pb, [Xe]6s<sup>2</sup>4f<sup>14</sup>5d<sup>10</sup>6p<sup>2</sup> 6.69 (a) F<sup>-</sup>, [He]2s<sup>2</sup>2p<sup>6</sup> or [Ne] (b) I<sup>-</sup>, [Kr]5s<sup>2</sup>5p<sup>6</sup> or [Xe] (c) O<sup>2-</sup>, [He]2s<sup>2</sup>2p<sup>6</sup> or [Ne] (d) K<sup>+</sup>, [Ne]3s<sup>2</sup>3p<sup>6</sup> or [Ar] (e) Mg<sup>2+</sup>, [He]2s<sup>2</sup>2p<sup>6</sup> or [Ne] (f) Al<sup>3+</sup>, [He]2s<sup>2</sup>2p<sup>6</sup> or [Ne] 6.71 (a) He (b) O (c) Cr (d) Te (e) H 6.73 (a) The fifth electron would fill the 2p subshell before the 3s. (b) Either the core is [He], or the outer electron configuration should be 3s<sup>2</sup>3p<sup>3</sup>. (c) The 3p subshell would fill before the 3d. 6.75 (a)  $\lambda_A = 3.6 \times 10^{-8}$  m,  $\lambda_B = 8.0 \times 10^{-8}$  m (b)  $\nu_A = 8.4 \times 10^{15}$  s<sup>-1</sup>,  $\nu_B = 3.7 \times 10^{15}$  s<sup>-1</sup> (c) A, ultraviolet; B, ultraviolet 6.77 66.7 min 6.80 430–490 nm 6.84 (a) The Paschen series lies in the infrared. (b)  $n_i = 4$ ,  $\lambda = 1.87 \times 10^{-6}$  m;  $n_i = 5$ ,  $\lambda = 1.28 \times 10^{-6}$  m;  $n_i = 6$ ,  $\lambda = 1.09 \times 10^{-6}$  m 6.87  $\nu = 1.02 \times 10^7$  m/s 6.90 (a)  $l$  (b)  $n$  and  $l$  (c)  $m_l$  (d)  $m_l$  6.96 If  $m_l$  had three allowed values instead of two, each orbital would hold three electrons instead of two. Assuming that there is no change in the  $n$ ,  $l$ , and  $m_l$  values, the number of elements in each of the first four rows would be: 1st row, 3 elements; 2nd row, 12 elements; 3rd row, 12 elements; 4th row, 27 elements 6.99 (a)  $1.7 \times 10^{28}$  photons (b) 34 s 6.103 (a) Bohr's theory was based on the Rutherford nuclear model of the atom: a dense positive charge at the center and a diffuse negative charge surrounding it. Bohr's theory then specified the nature of the diffuse negative charge. The prevailing theory before the nuclear model was Thomson's plum pudding model: discrete electrons scattered about a diffuse positive charge cloud. Bohr's theory could not have been based on the Thomson model of the atom. (b) De Broglie's hypothesis is that electrons exhibit both particle and wave properties. Thomson's conclusion that electrons have mass is a particle property, while the nature of cathode rays is a wave property. De Broglie's hypothesis actually rationalizes these two seemingly contradictory observations about the properties of electrons.

## Chapter 7

7.2 The billiard ball is a more appropriate analogy for the nonbonding atomic radius. The billiard ball has a definite "hard" boundary, and can be used to model nonbonding interactions in which there is no penetration of electron clouds. If we use the billiard ball to represent the bonding atomic radius of a fluorine atom, we overestimate this radius. When atoms bond, attractive interactions cause their electron clouds to penetrate

each other, bringing the nuclei closer together than during a nonbonding (billiard ball) collision. 7.5 The energy change for the reaction is the ionization energy of A plus the electron affinity of A. The process is endothermic for both chlorine and sodium. 7.7 Mendeleev placed elements with similar chemical and physical properties within a family or column of his table. For undiscovered elements, he left blanks. He predicted properties for the "blanks" based on properties of other elements in the family and on either side. 7.9 Even though Si is the second most abundant element in Earth's crust, its abundant forms are compounds. In order to be "discovered," elemental Si had to be chemically removed from one of its compounds. Discovery awaited more sophisticated chemical techniques available in the nineteenth century.

7.11 (a) Effective nuclear charge,  $Z_{\text{eff}}$ , is a representation of the average electrical field experienced by a single electron. It is the average environment created by the nucleus and the other electrons in the molecule, expressed as a net positive charge at the nucleus. (b) Going from left to right across a period, effective nuclear charge increases. 7.13 (a) For both Na and K,  $Z_{\text{eff}} = 1$ . (b) For both Na and K,  $Z_{\text{eff}} = 2.2$ . (c) Slater's rules give values closer to the detailed calculations: Na, 2.51; K, 3.49. (d) Both approximations give the same value of  $Z_{\text{eff}}$  for Na and K; neither accounts for the gradual increase in  $Z_{\text{eff}}$  moving down a group. 7.15 The  $n = 3$  electrons in Kr experience a greater effective nuclear charge and thus have a greater probability of being closer to the nucleus. 7.17 (a) Atomic radii are determined by measuring distances between atoms in various situations. (b) Bonding radii are calculated from the internuclear separation of two atoms joined by a chemical bond. Nonbonding radii are calculated from the internuclear separation between two gaseous atoms that collide and move apart but do not bond. (c) For a given element, the nonbonding radius is always larger than the bonding radius. 7.19 1.37 Å 7.21 From the sum of the atomic radii,  $A - I = 2.52$  Å. This is very close to the experimental value of 2.55 Å. 7.23 (a) Decrease (b) increase (c)  $F < S < P < As$  7.25 (a)  $Be < Mg < Ca$  (b)  $Br < Ge < Ga$  (c)  $Si < Al < Ti$  7.27 (a) Electrostatic repulsions are reduced by removing an electron from a neutral atom, effective nuclear charge increases, and the cation is smaller. (b) The additional electrostatic repulsion produced by adding an electron to a neutral atom decreases the effective nuclear charge experienced by the valence electrons, and increases the size of the anion. (c) Going down a column, valence electrons are further from the nucleus, and they experience greater shielding by core electrons. The greater radial extent of the valence electrons outweighs the increase in  $Z$ . 7.29 The red sphere is a metal; its size decreases on reaction, characteristic of the change in radius when a metal atom forms a cation. The blue sphere is a nonmetal; its size increases on reaction, characteristic of the change in radius when a nonmetal atom forms an anion. 7.31 (a) An isoelectronic series is a group of atoms or ions that have the same number of electrons and the same electron configuration. (b) (i) Al<sup>3+</sup>; Ne (ii) Ti<sup>4+</sup>; Ar (iii) Br<sup>-</sup>; Kr (iv) Sn<sup>2+</sup>; Cd 7.33 (a) Na<sup>+</sup> (b) Assume a He core of 2 electrons. F<sup>-</sup>:  $Z_{\text{eff}} = 7$ ; Na<sup>+</sup>:  $Z_{\text{eff}} = 9$ . (c) F<sup>-</sup>:  $Z_{\text{eff}} = 4.85$ ; Na<sup>+</sup>:  $Z_{\text{eff}} = 6.85$ . (d) For isoelectronic ions, electron configurations and therefore shielding values ( $S$ ) are the same. As nuclear charge ( $Z$ ) increases, effective nuclear charge ( $Z_{\text{eff}}$ ) increases and ionic radius decreases. 7.35 Cl < S < K (b) K<sup>+</sup> < Cl<sup>-</sup> < S<sup>2-</sup> (c) In the neutral atoms, the  $n$ -value of the outer electron in K is larger than the  $n$ -value of valence electrons in S and Cl, so K atoms are largest. When the 4s electron is removed, K<sup>+</sup> is isoelectronic with Cl<sup>-</sup> and S<sup>2-</sup>, so the ion with the largest  $Z$  value, K<sup>+</sup>, is smallest. 7.37 (a) O<sup>2-</sup> is larger than O because increased repulsions that accompany addition of electrons cause the electron cloud to expand. (b) S<sup>2-</sup> is larger than O<sup>2-</sup>, because for particles with like charges, size increases going down a family. (c) S<sup>2-</sup> is larger than K<sup>+</sup> because the two

ions are isoelectronic and  $K^+$  has the larger  $Z$  and  $Z_{\text{eff}}$ . (d)  $K^+$  is larger than  $Ca^{2+}$ , because for isoelectronic particles, the ion with the smaller  $Z$  has the larger radius. 7.39  $B(g) \rightarrow B^+(g) + e^-$ ;  $B^-(g) \rightarrow B^{2+}(g) + e^-$ ;  $B^{2+}(g) \rightarrow B^{3+}(g) + e^-$ . 7.41 (a) The electrons in any atom are bound to the atom by their electrostatic attraction to the nucleus. Therefore, energy must be added in order to remove an electron from an atom. The ionization energy,  $\Delta E$  for this process, is thus positive. (b) F has a greater first ionization energy than O because F has a greater  $Z_{\text{eff}}$  and the outer electrons in both elements are approximately the same distance from the nucleus. (c) The second ionization energy of an element is greater than the first because more energy is required to overcome the larger  $Z_{\text{eff}}$  of the  $1+$  cation than that of the neutral atom. 7.43 (a) The smaller the atom, the larger its first ionization energy. (b) Of the nonradioactive elements, He has the largest, and Cs the smallest first ionization energy. 7.45 (a) Ar (b) Be (c) Co (d) S (e) Te 7.47 (a)  $In^{3+}$ ,  $[Kr]4d^{10}$  (b)  $Sb^{3+}$ ,  $[Kr]5s^24d^{10}$  (c)  $Te^{2-}$ ,  $[Kr]5s^24d^{10}5p^6$  or  $[Xe]$  (d)  $Te^{6+}$ ,  $[Kr]4d^{10}$  (e)  $Hg^{2+}$ ,  $[Xe]4f^{14}5d^{10}$  (f)  $Rh^{3+}$ ,  $[Kr]4d^6$ . 7.49 (a)  $Ni^{2+}$ ,  $[Ar]3d^8$ , 2 unpaired electrons (b)  $Sn^{2+}$ ,  $[Kr]5s^24d^{10}$ , 0 unpaired electrons 7.51 Positive, endothermic, values for ionization energy and electron affinity mean that energy is required to either remove or add electrons. Valence electrons in Ar experience the largest  $Z_{\text{eff}}$  of any element in the third row, resulting in a large, positive ionization energy. When an electron is added to Ar, the  $n = 3$  electrons become core electrons which screen the extra electron so effectively that Ar<sup>-</sup> has a higher energy than an Ar atom and a free electron. This results in a large positive electron affinity. 7.53 Electron affinity of Br:  $Br(g) + 1e^- \rightarrow Br^-(g)$ ;  $[Ar]4s^23d^{10}4p^5 \rightarrow [Ar]4s^23d^{10}4p^6$ ; electron affinity of Kr:  $Kr(g) + 1e^- \rightarrow Kr^-(g)$ ;  $[Ar]4s^23d^{10}4p^6 \rightarrow [Ar]4s^23d^{10}4p^65s^1$ . Br<sup>-</sup> adopts the stable electron configuration of Kr; the added electron experiences essentially the same  $Z_{\text{eff}}$  and stabilization as the other valence electrons and electron affinity is negative. In Kr<sup>-</sup> ion, the added electron occupies the higher energy 5s orbital. A 5s electron is farther from the nucleus, effectively shielded by the spherical Kr core and not stabilized by the nucleus; electron affinity is positive. 7.55 (a) Ionization energy ( $I_1$ ) of Ne:  $Ne(g) \rightarrow Ne^+(g) + 1e^-$ ;  $[He]2s^22p^6 \rightarrow [He]2s^22p^5$ ; electron affinity ( $E_1$ ) of F:  $F(g) + 1e^- \rightarrow F^-(g)$ ;  $[He]2s^22p^5 \rightarrow [He]2s^22p^6$ . (b)  $I_1$  of Ne is positive;  $E_1$  of F is negative. (c) One process is apparently the reverse of the other, with one important difference. Ne has a greater  $Z$  and  $Z_{\text{eff}}$ , so we expect  $I_1$  for Ne to be somewhat greater in magnitude and opposite in sign to  $E_1$  for F. 7.57 The smaller the first ionization energy of an element, the greater the metallic character of that element. 7.59 Based on ionization energies, the metallic character of Al is similar to that of Ca and Sr; it is clearly more metallic than the metalloids in groups 4A and 5A. 7.61 Ionic: MgO, Li<sub>2</sub>O, Y<sub>2</sub>O<sub>3</sub>; molecular: SO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O, XeO<sub>3</sub>. Ionic compounds are formed by combining a metal and a nonmetal; molecular compounds are formed by two or more nonmetals. 7.61 Ionic: MgO, Li<sub>2</sub>O, Y<sub>2</sub>O<sub>3</sub>; molecular: SO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O, XeO<sub>3</sub>. Ionic compounds are formed by combining a metal and a nonmetal; molecular compounds are formed by two or more nonmetals. 7.63 (a) An acidic oxide dissolved in water produces an acidic solution; a basic oxide dissolved in water produces a basic solution. (b) Oxides of nonmetals, such as SO<sub>3</sub>, are acidic; oxides of metals, such as CaO, are basic. 7.65 (a) Dichlorine-septoxide (b) 2 Cl<sub>2</sub>(g) + 7 O<sub>2</sub>(g) → 2 Cl<sub>2</sub>O<sub>7</sub>(l) (c) While most nonmetal oxides we have seen, such as CO<sub>2</sub> or SO<sub>2</sub>, are gases, a boiling point of 81 °C is not totally unexpected for a large molecule like Cl<sub>2</sub>O<sub>7</sub>. (d) Cl<sub>2</sub>O<sub>7</sub> is an acidic oxide, so it will be more reactive to base, OH<sup>-</sup>. 7.67 (a) BaO(s) + H<sub>2</sub>O(l) → Ba(OH)<sub>2</sub>(aq) (b) FeO(s) + 2 HClO<sub>4</sub>(aq) → Fe(ClO<sub>4</sub>)<sub>2</sub>(aq) + H<sub>2</sub>O(l) (c) SO<sub>3</sub>(g) + H<sub>2</sub>O(l) → H<sub>2</sub>SO<sub>4</sub>(aq) (d) CO<sub>2</sub>(g) + 2 NaOH(aq) → Na<sub>2</sub>CO<sub>3</sub>(aq) + H<sub>2</sub>O(l) 7.69 (a) Na, [Ne]3s<sup>1</sup>;

Mg, [Ne]3s<sup>2</sup> (b) When forming ions, both adopt the stable configuration of Ne; Na loses one electron and Mg two electrons to achieve this configuration. (c) The effective nuclear charge of Mg is greater, so its ionization energy is greater. (d) Mg is less reactive because it has a higher ionization energy. (e) The atomic radius of Mg is smaller because its effective nuclear charge is greater. 7.71 (a) Ca is more reactive because it has a lower ionization energy than Mg. (b) K is more reactive because it has a lower ionization energy than Ca. 7.73 (a) 2 K(s) + Cl<sub>2</sub>(g) → 2 KCl(s) (b) SrO(s) + H<sub>2</sub>O(l) → Sr(OH)<sub>2</sub>(aq) (c) 4 Li(s) + O<sub>2</sub>(g) → 2 Li<sub>2</sub>O(s) (d) 2 Na(s) + S(l) → Na<sub>2</sub>S(s) 7.75 (a) The ionization energy of H fits between those of C and N. (b) The ionization energy of Li fits between those of Na and Mg. (c) These series are consistent with the assignment of H as a nonmetal and Li as a metal. 7.77 (a) F, [He]2s<sup>2</sup>2p<sup>5</sup>; Cl, [Ne]3s<sup>2</sup>3p<sup>5</sup> (b) F and Cl are in the same group, and both adopt a 1- ionic charge. (c) The 2p valence electrons in F are closer to the nucleus and more tightly held than are the 3p electrons of Cl, so the ionization energy of F is greater. (d) The high ionization energy of F coupled with a relatively large exothermic electron affinity makes it more reactive than Cl toward H<sub>2</sub>O. (e) While F has approximately the same effective nuclear charge as Cl, its small atomic radius gives rise to large repulsions when an extra electron is added, so the overall electron affinity of F is less exothermic than that of Cl. (f) The 2p valence electrons in F are closer to the nucleus so the atomic radius is smaller than that of Cl. 7.79 (a) The term "inert" was dropped because it no longer described all the Group 8A elements. (b) In the 1960s, scientists discovered that Xe would react with substances having a strong tendency to remove electrons, such as F<sub>2</sub>. Thus, Xe could not be categorized as an "inert" gas. (c) The group is now called the noble gases. 7.81 (a) 2 O<sub>3</sub>(g) → 3 O<sub>2</sub>(g) (b) Xe(g) + F<sub>2</sub>(g) → XeF<sub>2</sub>(g); Xe(g) + 2 F<sub>2</sub>(g) → XeF<sub>4</sub>(s); Xe(g) + 3 F<sub>2</sub>(g) → XeF<sub>6</sub>(s) (c) S(s) + H<sub>2</sub>(g) → H<sub>2</sub>S(g) (d) 2 F<sub>2</sub>(g) + 2 H<sub>2</sub>O(l) → 4 HF(aq) + O<sub>2</sub>(g) 7.83 Up to Z = 82, there are three instances where atomic weights are reversed relative to atomic numbers: Ar and K; Co and Ni; Te and I. In each case the most abundant isotope of the element with the larger atomic number has one more proton, but fewer neutrons than the element with the smaller atomic number. The smaller number of neutrons causes the element with the larger Z to have a smaller than expected atomic weight. 7.85 (a) 5+ (b) 4.8+ (c) Shielding is greater for 3p electrons, owing to penetration by 3s electrons, so  $Z_{\text{eff}}$  for 3p electrons is less than that for 3s electrons. (d) The first electron lost is a 3p electron, because it has a smaller  $Z_{\text{eff}}$  and experiences less attraction for the nucleus than a 3s electron does. 7.88 Moving across the representative elements, electrons added to ns or np valence orbitals do not effectively screen each other. The increase in Z is not accompanied by a similar increase in S.  $Z_{\text{eff}}$  increases and atomic size decreases. Moving across the transition elements, electrons are added to (n - 1)d orbitals, which do significantly screen the ns valence electrons. The increase in Z is accompanied by a corresponding increase in S.  $Z_{\text{eff}}$  increases more slowly and atomic size decreases more slowly. 7.91 The completed 4f subshell in Hf leads to a much larger change in Z and  $Z_{\text{eff}}$  going from Zr to Hf than in going from Y to La. This larger increase in  $Z_{\text{eff}}$  going from Zr to Hf leads to a smaller increase in atomic radius than in going from Y to La. 7.94  $I_1$  through  $I_4$  represent loss of the 2p and 2s electrons from the outer shell of the atom. Z is constant while removal of each electron reduces repulsion between the remaining electrons, so  $Z_{\text{eff}}$  increases and  $I$  increases.  $I_5$  and  $I_6$  represent loss of the 1s core electrons. These electrons are closer to the nucleus and experience the full nuclear charge, so the values of  $I_5$  and  $I_6$  are significantly greater than  $I_1 - I_4$ .  $I_6$  is larger than  $I_5$  because all electron-electron repulsion has been eliminated.

The third electron would be added to the 3s orbital, which is farther from the nucleus and more strongly shielded by the [Ne] core. The overall attraction of this 3s electron for the oxygen nucleus is not large enough for  $\text{O}^{3-}$  to be a stable particle.

7.98 (a) The group 2B metals have complete  $(n-1)d$  subshells. An additional electron would occupy an  $np$  subshell and be substantially shielded by both  $ns$  and  $(n-1)d$  electrons. This is not a lower energy state than the neutral atom and a free electron. (b) Group 1B elements have the generic electron configuration  $ns^1(n-1)d^{10}$ . An additional electron would complete the  $ns$  subshell and experience repulsion with the other  $ns$  electron. Going down the group, size of the  $ns$  subshell increases and repulsion effects decrease, so effective nuclear charge increases and electron affinities become more negative.

7.101  $\text{O}_2 < \text{Br}_2 < \text{K} < \text{Mg}$ .  $\text{O}_2$  and  $\text{Br}_2$  are nonpolar nonmetals.  $\text{O}_2$ , with the much lower molar mass, should have the lower melting point. K and Mg are metallic solids with higher melting points than the two nonmetals. Since alkaline earth metals are typically harder, more dense, and higher melting than alkali metals, Mg should have the highest melting point of the group. This order of melting points is confirmed by data in Tables 7.4, 7.5, 7.6, and 7.7. 7.106 (a) Li,  $[\text{He}]2s^1$ ;  $Z_{\text{eff}} \approx 1+$ . (b)  $I_1 \approx 5.45 \times 10^{-19} \text{ J/mol} \approx 328 \text{ kJ/mol}$  (c) The estimated value of  $328 \text{ kJ/mol}$  is less than the Table 7.4 value of  $520 \text{ kJ/mol}$ . Our estimate for  $Z_{\text{eff}}$  was a lower limit; the [He] core electrons do not perfectly shield the 2s electron from the nuclear charge. (d) Based on the experimental ionization energy,  $Z_{\text{eff}} = 1.26$ . This value is greater than the estimate from part (a), but agrees well with the "Slater" value of 1.3 and is consistent with the explanation in part (c). 7.109 (a)  $\text{Mg}_3\text{N}_2$  (b)  $\text{Mg}_3\text{N}_2(\text{s}) + 3\text{H}_2\text{O}(\text{l}) \rightarrow 3\text{MgO}(\text{s}) + 2\text{NH}_3(\text{g})$ ; the driving force is the production of  $\text{NH}_3(\text{g})$  (c) 17%  $\text{Mg}_3\text{N}_2$  (d)  $3\text{Mg}(\text{s}) + 2\text{NH}_3(\text{g}) \rightarrow \text{Mg}_3\text{N}_2(\text{s}) + 3\text{H}_2(\text{g})$ ;  $\text{NH}_3$  is the limiting reactant and  $0.46 \text{ g H}_2$  are formed. (e)  $\Delta H_{\text{rxn}}^\circ = -368.70 \text{ kJ}$

### Chapter 8

8.2 (a)  $\text{A}^{2+}$  combines with  $\text{Y}^{2-}$  and  $\text{B}^+$  combines with  $\text{X}^-$  to form compounds with a 1:1 ratio of cations and anions. (b) AY. Lattice energy increases as ionic charge increases and decreases as inter-ionic distance increases. A and Y have the greater charges, while the A—Y and B—X separations are nearly equal. (c) BX has the smaller lattice energy. 8.5 (a) Moving from left to right along the molecule, the first C needs 2 H atoms, the second needs 1, the third needs none and the fourth needs 1. (b) In order of increasing bond length:  $3 < 1 < 2$  (c) In order of increasing bond enthalpy:  $2 < 1 < 3$  8.7 (a) Valence electrons are those that take part in chemical bonding. This usually means the electrons beyond the core noble-gas configuration of the atom, although it is sometimes only the outer-shell electrons. (b) A nitrogen atom has 5 valence electrons. (c) The atom (Si) has 4 valence electrons. 8.9 P,  $1s^2 2s^2 2p^6 3s^2 3p^3$ . The  $n = 3$  electrons are valence electrons; the others are nonvalence electrons. Valence electrons participate in chemical bonding, the others do not.

(c)  $\text{Y}_2\text{O}_3$  (d)  $\text{Mg}_3\text{N}_2$  8.17 (a)  $\text{Sr}^{2+}$ ,  $[\text{Ar}]4s^2 3d^{10} 4p^6 = [\text{Kr}]$ , noble-gas configuration (b)  $\text{Ti}^{2+}$ ,  $[\text{Ar}]3d^2$  (c)  $\text{Se}^{2-}$ ,

$[\text{Ar}]4s^2 3d^{10} 4p^6 = [\text{Kr}]$ , noble-gas configuration (d)  $\text{Ni}^{2+}$ ,  $[\text{Ar}]3d^8$  (e)  $\text{Br}^-$ ,  $[\text{Ar}]4s^2 3d^{10} 4p^6 = [\text{Kr}]$ , noble-gas configuration (f)  $\text{Mn}^{3+}$ ,  $[\text{Ar}]3d^4$  8.19 (a) Lattice energy is the energy required to totally separate one mole of solid ionic compound into its gaseous ions. (b) The magnitude of the lattice energy depends on the magnitudes of the charges of the two ions, their radii and the arrangement of ions in the lattice. 8.21 KF,  $808 \text{ kJ/mol}$ ; CaO,  $3414 \text{ kJ/mol}$ ; ScN,  $7547 \text{ kJ/mol}$ . The interionic distances in the three compounds are similar. For compounds with similar ionic separations, the lattice energies should be related as the product of the charges of the ions. The lattice energies above are approximately related as 1:4:9. Slight variations are due to the small differences in ionic separations. 8.23 Since the ionic charges are the same in the two compounds, the KBr and CsCl separations must be approximately equal. 8.25 The large attractive energy between oppositely charged  $\text{Ca}^{2+}$  and  $\text{O}^{2-}$  more than compensates for the energy required to form  $\text{Ca}^{2+}$  and  $\text{O}^{2-}$  from the neutral atoms. 8.27 The lattice energy of  $\text{RbCl}(\text{s})$  is  $+692 \text{ kJ/mol}$ . This value is smaller than the lattice energy for  $\text{NaCl}$  because  $\text{Rb}^+$  has a larger ionic radius than  $\text{Na}^+$  and therefore cannot approach  $\text{Cl}^-$  as closely as  $\text{Na}^+$  can. 8.29 (a) A covalent bond is the bond formed when two atoms share one or more pairs of electrons. (b) Any simple compound whose component atoms are nonmetals, such as  $\text{H}_2$ ,  $\text{SO}_2$ , and  $\text{CCl}_4$ , are molecular and have covalent bonds between atoms. (c) Covalent, because it is a gas at room temperature and below.

8.33 (a)  $\ddot{\text{O}}=\ddot{\text{O}}$  (b) A double bond is required because there are not enough electrons to satisfy the octet rule with single bonds and unshared pairs. (c) The greater the number of shared electron pairs between two atoms, the shorter the distance between the atoms. An  $\text{O}=\text{O}$  double bond is shorter than an  $\text{O}-\text{O}$  single bond. 8.35 (a) Electronegativity is the ability of an atom in a molecule to attract electrons to itself. (b) The range of electronegativities on the Pauling scale is 0.7–4.0. (c) Fluorine is the most electronegative element. (d) Cesium is the least electronegative element that is not radioactive. 8.37 (a) O (b) C (c) P (d) Be 8.39 The bonds in (a), (c), and (d) are polar. The more electronegative element in each polar bond is: (a) F (c) O (d) I 8.41 (a) The calculated charge on H and O is 0.38e. (b) From Sample Exercise 8.5, the calculated charge on H and Cl in  $\text{HCl}$  is 0.178e. The O—H bond in OH is more polar than the H—Cl bond in  $\text{HCl}$ . (c) Yes. The electronegativity of O is greater than that of Cl, so the electronegativity difference between O and H is greater than that between Cl and H. Based on electronegativity, we expect OH to be more polar than  $\text{HCl}$ . 8.43 (a)  $\text{SiCl}_4$ , molecular, silicon tetrachloride;  $\text{LaF}_3$ , ionic, lanthanum(III) fluoride (b)  $\text{FeCl}_2$ , ionic, iron(II) chloride;  $\text{ReCl}_6$ , molecular (metal in high oxidation state), rhenium hexachloride. (c)  $\text{PbCl}_4$ , molecular (by contrast to the distinctly ionic  $\text{RbCl}$ ), lead tetrachloride;  $\text{RbCl}$ , ionic, rubidium chloride

(b) Each terminal O=N—O group has two possible placements for the N=O; this leads to 8 resonance structures with the carbon–nitrogen framework shown in (a). Structures with N=N can be drawn, but these do not minimize formal charge. There are 7 resonance structures with one or more N=N, for a total of 15 resonance structures.  
 (c)  $C_3H_6N_6O_6(s) \rightarrow 3 CO(g) + 3 N_2(g) + 3 H_2O(g)$  (d) According to Table 8.4, N—N single bonds have the smallest bond enthalpy and are weakest. (e) The enthalpy of decomposition for the resonance structure in (a) is  $-1668 \text{ kJ/mol}$   $C_3H_6N_6O_6$ . For the resonance structure with 3 N=N and 6 N—O bonds,  $\Delta H = -2121 \text{ kJ/mol}$ . The actual value is somewhere between these two values. The enthalpy change for 5.0 g of RDX is then in the range 38–48 kJ. 8.96 (a) 1.77 Å (b) 1.75–1.76 Å (c) The resonance structures for  $SO_2$  indicate that the sulfur–oxygen bond is intermediate between a double and single bond, so the bond length of 1.43 Å should be significantly shorter than the single bond distance of 1.75 Å.

In order to rationalize the sulfur–oxygen bond distance of 1.48 Å, a resonance structure with S=O must contribute to the true structure. The sulfur atom attached to oxygen in this resonance structure has more than an octet of electrons and violates the octet rule. 8.97 (a)  $Ti^{2+}$ ,  $[Ar]3d^2$ ; Ca,  $[Ar]4s^2$ . The 2 valence electrons in  $Ti^{2+}$  and Ca are in different principal quantum levels and different subshells. (b) In Ca the 4s is lower in energy than the 3d, while in  $Ti^{2+}$  the 3d is lower in energy than the 4s. (c) There is only one 4s orbital, so the 2 valence electrons in Ca are paired; there are 5 degenerate 3d orbitals, so the 2 valence electrons in  $Ti^{2+}$  are unpaired. 8.100 (a) A,  $In_2S$ ; B,  $InS$ ; C,  $In_2S_3$  (b) A,  $In(I)$ ; B,  $In(II)$ ; C,  $In(III)$  (c)  $In(I)$ ,  $[Kr]5s^24d^{10}$ ,  $In(II)$ ,  $[Kr]5s^24d^{10}$ ,  $In(III)$ ,  $[Kr]4d^{10}$ . None of these are noble-gas configurations. (d)  $In(III)$  in compound C has the smallest ionic radius. Removing successive electrons from an atom reduces electron repulsion, increases the effective nuclear charge experienced by the valence electrons and decreases the ionic radius. (e) Lattice energy increases as ionic charge increases and as inter-ionic distance decreases. Only the charge and size of In changes in the three compounds.  $In(I)$  in compound A has the lowest charge and largest ionic radius, so compound A has the smallest lattice energy and lowest melting point. Compound C has the largest lattice energy and highest melting point. 8.103 (a) Azide ion is  $N_3^-$ . (b) Resonance structures with formal charges are shown.

(c) The left structure minimizes formal charges and is probably the main contributor. (d) The N—N distances will be equal, and have the approximate length of a N=N double bond, 1.24 Å.

## Chapter 9

9.1 Removing an atom from the equatorial plane of the trigonal bipyramid in Figure 9.3 creates a see-saw shape. 9.3 (a) Square pyramidal (b) Yes, there is one nonbonding electron

domain on A. If there were only the 5 bonding domains, the shape would be trigonal bipyramidal. (c) Yes. If the B atoms are halogens, A is also a halogen. 9.5 (a) Zero energy corresponds to two separate, non-interacting Cl atoms. This infinite Cl—Cl distance is beyond the right extreme of the horizontal axis on the diagram. (b) According to the valence bond model, valence orbitals on the approaching atoms overlap, allowing two electrons to mutually occupy space between the two nuclei and be stabilized by two nuclei rather than one. (c) The Cl—Cl distance at the energy minimum on the plot is the Cl—Cl bond length. (d) At interatomic separations shorter than the bond distance, the two nuclei begin to repel each other, increasing the overall energy of the system. (e) The y-coordinate of the minimum point on the plot is a good estimate of the Cl—Cl bond energy or bond strength. 9.7  $sp^3$  hybrid orbitals

9.9 (a) i, Formed by two s atomic orbitals; ii,  $\sigma$ -type MO; iii, antibonding MO (b) i, formed by two p atomic orbitals overlapping end-to-end; ii,  $\sigma$ -type MO; iii, bonding MO (c) i, formed by two p atomic orbitals overlapping side-to-side; ii,  $\pi$ -type MO; iii, antibonding MO 9.11 (a) Yes. The stated shape defines the bond angle and the bond length tells the size.

(b) No. Atom A could have 2, 3 or 4 nonbonding electron pairs.

9.13 (a) An *electron domain* is a region in a molecule where electrons are most likely to be found. (b) Like the balloons in

Figure 9.5, each electron domain occupies a finite volume of space, so they also adopt an arrangement where repulsions are minimized. 9.15 (a) 2 (b) 1 (c) none (d) 3 9.17 The electron-domain geometry indicated by VSEPR describes the arrangement of all bonding and nonbonding electron domains. The molecular geometry describes just the atomic positions. In  $H_2O$  there are 4 electron domains around oxygen, so the electron-domain geometry is tetrahedral. Because there are 2 bonding and 2 nonbonding domains, the molecular geometry is bent.

9.19 (a) Tetrahedral, tetrahedral (b) trigonal bipyramidal, T-shaped (c) octahedral, square pyramidal (d) octahedral, square planar 9.21 (a) Tetrahedral, trigonal pyramidal (b) trigonal planar, trigonal planar (c) trigonal bipyramidal, T-shaped (d) tetrahedral, tetrahedral (e) trigonal bipyramidal, linear (f) tetrahedral, bent 9.23 (a) i, trigonal planar; ii, tetrahedral; iii, trigonal bipyramidal (b) i, 0; ii, 1; iii, 2 (c) N and P (d) Cl (or Br or I). This T-shaped molecular geometry arises from a trigonal bipyramidal electron-domain geometry with 2 nonbonding domains. Assuming each F atom has 3 nonbonding domains and forms only single bonds with A, A must have 7 valence electrons and be in or below the third row of the periodic table to produce these electron-domain and molecular geometries. 9.25 (a)  $1-109^\circ$ ,  $2-109^\circ$  (b)  $3-109^\circ$ ,  $4-109^\circ$  (c)  $5-180^\circ$  (d)  $6-120^\circ$ ,  $7-109^\circ$ ,  $8-109^\circ$  9.27  $PF_5 > SF_4 > ClF_3$ .

As the number of nonbonding domains in the equatorial plane increases, they push back the axial A—F bonds, decreasing the F(axial)—A—F(equatorial) bond angles. 9.29 (a) Although both ions have 4 bonding electron domains, the 6 total domains around Br require octahedral domain geometry and square-planar molecular geometry, while the 4 total domains about B lead to tetrahedral domain and molecular geometry.

(b) The shape of the  $(H_2O)^{4+}$  ion is linear. 9.31 (a) Yes. The net dipole moment vector points along the Cl—S—Cl angle bisector. (b) No,  $BeCl_2$  does not have a dipole moment.

9.33 (a) In Exercise 9.23, molecules (ii) and (iii) will have non-zero dipole moments. Molecule (i) has no nonbonding electron pairs on A, and the 3 A—F bond dipoles are oriented so that they cancel. Molecules (ii) and (iii) have nonbonding electron pairs on A and their bond dipoles do not cancel. (b) In Exercise 9.24, molecules (i) and (ii) have a zero dipole moment.

9.35 (a) IF (d)  $PCl_3$  and (f)  $IF_5$  are polar.

## 9.37 (a) Lewis structures

Molecular geometries

(b) The middle isomer has a zero net dipole moment.

(c)  $\text{C}_2\text{H}_3\text{Cl}$  has only one isomer, and it has a dipole moment.

9.39 (a) *Orbital overlap* occurs when valence atomic orbitals on two adjacent atoms share the same region of space. (b) A chemical bond is a concentration of electron density between the nuclei of two atoms. This concentration can take place because orbitals on the two atoms overlap. 9.41 (a)  $\text{H}-\text{Mg}-\text{H}$ , linear electron domain and molecular geometry (b) The linear electron domain geometry in  $\text{MgH}_2$  requires  $sp$  hybridization.

9.43 Molecule	Molecular Structures	Electron Domain Geometry	Hybridization of Central Atom	Dipole Moment? Yes or No.
$\text{CO}_2$	$\text{O}=\text{C}=\text{O}$	Linear	$sp$	no
$\text{NH}_3$		Tetrahedral	$sp^3$	yes
$\text{CH}_4$		Tetrahedral	$sp^3$	no
$\text{BH}_3$		Trigonal planar	$sp^2$	no
$\text{SF}_4$		Trigonal bipyramidal	$dsp^3$	yes
$\text{SF}_6$		Octahedral	$d^2sp^3$	no
$\text{H}_2\text{CO}$		Trigonal planar	$sp^2$	yes
$\text{PF}_5$		Trigonal bipyramidal	$dsp^3$	no
$\text{XeF}_2$		Octahedral	$d^2sp^3$	no

9.45 (a) B, [He] $2s^2 2p^1$ . One  $2s$  electron is "promoted" to an empty  $2p$  orbital. The  $2s$  and two  $2p$  orbitals that each contain one electron are hybridized to form three equivalent hybrid orbitals in a trigonal planar arrangement. (b)  $sp^2$  (d) A single  $2p$  orbital is unhybridized. It lies perpendicular to the trigonal plane of the  $sp^2$  hybrid orbitals. 9.47 (a)  $sp^2$  (b)  $sp^3$  (c)  $sp$  (d)  $sp^3 d^2$  (e)  $sp^3 d^2$

(c) A  $\sigma$  bond is generally stronger than a  $\pi$  bond because there is more extensive orbital overlap. (d) No. Overlap of two  $s$  orbitals results in electron density along the internuclear axis, while a  $\pi$  bond has none. 9.51 (a)

(b)  $sp^3, sp^2, sp$  (c) nonplanar, planar, planar (d) 7  $\sigma$ , 0  $\pi$ ; 5  $\sigma$ , 1  $\pi$ ; 3  $\sigma$ , 2  $\pi$  (e) The Si analogs would have the same hybridization as the C compounds given in part (b). That Si is in the row below C means it has a larger bonding atomic radius and atomic orbitals than C. The close approach of Si atoms required for  $\pi$  bond formation is unlikely;  $Si_2H_4$  and  $Si_2H_2$  probably do not exist under standard conditions. 9.53 (a) 18 valence electrons (b) 16 valence electrons form  $\sigma$  bonds (c) 2 valence electrons form  $\pi$  bonds (d) no valence electrons are nonbonding (e) The left and central C atoms are  $sp^2$  hybridized; the right C atom is  $sp^3$  hybridized. 9.55 (a)  $\sim 109^\circ$  about the leftmost C,  $sp^3$ ,  $\sim 120^\circ$  about the right-hand C,  $sp^2$  (b) The doubly bonded O can be viewed as  $sp^2$ , and the other as  $sp^3$ ; the nitrogen is  $sp^3$  with approximately  $109^\circ$  bond angles. (c) nine  $\sigma$  bonds, one  $\pi$  bond 9.57 (a) In a localized  $\pi$  bond, the electron density is concentrated between the two atoms forming the bond. In a delocalized  $\pi$  bond, the electron density is spread over all the atoms that contribute  $p$  orbitals to the network. (b) The existence of more than one resonance form is a good indication that a molecule will have delocalized  $\pi$  bonding. (c) delocalized 9.59 (a) Hybrid orbitals are mixtures of atomic orbitals from a single atom and remain localized on that atom. Molecular orbitals are combinations of atomic orbitals from two or more atoms and are delocalized over at least two atoms. (b) Each MO can hold a maximum of two electrons. (c) Anti-bonding molecular orbitals can have electrons in them.

(b) There is one electron in  $H_2^+$ . (c)  $\sigma_{1s}^1$  (d)  $BO = \frac{1}{2}$  (e) Fall apart. If the single electron in  $H_2^+$  is excited to the  $\sigma_{1s}^*$  orbital, its energy is higher than the energy of an H  $1s$  atomic orbital and  $H_2^+$  will decompose into a hydrogen atom and a hydrogen ion. 9.63

(a) 1  $\sigma$  bond (b) 2  $\pi$  bonds (c) 1  $\sigma^*$  and 2  $\pi^*$  9.65 (a) When comparing the same two bonded atoms, bond order and bond energy are directly related, while bond order and bond length

are inversely related. When comparing different bonded nuclei, there are no simple relationships. (b)  $Be_2$  is not expected to exist; it has a bond order of zero and is not energetically favored over isolated Be atoms.  $Be_2^+$  has a bond order of 0.5 and is slightly lower in energy than isolated Be atoms. It will probably exist under special experimental conditions.

9.67 (a, b) Substances with no unpaired electrons are weakly repelled by a magnetic field. This property is called *diamagnetism*. (c)  $O_2^{2-}$ ,  $Be_2^{2+}$  9.69 (a)  $Be_2^+$ ,  $\sigma_{2s}^2 \sigma_{2s}^* \pi_{2p}^2$ , increase (b)  $Li_2^+$ ,  $\sigma_{1s}^2 \sigma_{1s}^* \sigma_{2s}^1$ , increase (c)  $N_2^+$ ,  $\sigma_{2s}^2 \sigma_{2s}^* \pi_{2p}^4 \sigma_{2p}^1$ , increase (d)  $Ne_2^{2+}$ ,  $\sigma_{2s}^2 \sigma_{2s}^* \sigma_{2p}^2 \pi_{2p}^4 \pi_{2p}^4$ , decrease 9.71 CN,  $\sigma_{2s}^2 \sigma_{2s}^* \pi_{2p}^2 \pi_{2p}^3$ , bond order = 2.5;  $CN^+$ ,  $\sigma_{2s}^2 \sigma_{2s}^* \sigma_{2p}^2 \pi_{2p}^2$ , bond order = 2.0;  $CN^-$ ,  $\sigma_{2s}^2 \sigma_{2s}^* \sigma_{2p}^2 \pi_{2p}^4$ , bond order = 3.0. (a)  $CN^-$  (b) CN,  $CN^+$  9.73 (a)  $3s, 3p_x, 3p_y, 3p_z$  (b)  $\pi_{3p}$  (c) 2 (d)

If the MO diagram for  $P_2$  is similar to that of  $N_2$ ,  $P_2$  will have no unpaired electrons and be diamagnetic. 9.76  $SiF_4$  is tetrahedral,  $SF_4$  is seesaw,  $XeF_4$  is square planar. The shapes are different because the number of nonbonding electron domains is different in each molecule, even though all have four bonding electron domains. Bond angles and thus molecular shape are determined by the total number of electron domains.

9.79 (a) 2  $\sigma$  bonds, 2  $\pi$  bonds (b) 2  $\sigma$  bonds, 2  $\pi$  bonds (c) 3  $\sigma$  bonds, 1  $\pi$  bond (d) 4  $\sigma$  bonds, 1  $\pi$  bond 9.81  $BF_3$  is trigonal planar, the B—F bond dipoles cancel and the molecule is nonpolar.  $PF_3$  has a tetrahedral electron domain geometry with one position occupied by a nonbonding electron pair. The nonbonding electron pair ensures an asymmetrical electron distribution and the molecule is polar.

(a) The molecule is nonplanar. (b) Allene has no dipole moment. (c) The bonding in allene would not be described as delocalized. The  $\pi$  electron clouds of the two adjacent  $C=C$  are mutually perpendicular, so there is no overlap and no delocalization of  $\pi$  electrons. 9.87 (a) All O atoms have  $sp^2$  hybridization. (b) The two  $\sigma$  bonds are formed by overlap of  $sp^2$  hybrid orbitals, the  $\pi$  bond is formed by overlap of atomic  $p$  orbitals, one nonbonded pair is in a  $p$  atomic orbital and the other five nonbonded pairs are in  $sp^2$  hybrid orbitals. (c) unhybridized  $p$  atomic orbitals (d) four, two from the  $\pi$  bond and two from the nonbonded pair in the  $p$  atomic orbital 9.91  $\sigma_{2s}^2 \sigma_{2s}^* \pi_{2p}^4 \sigma_{2p}^1 \pi_{2p}^1$  (a) Paramagnetic (b) The bond order of  $N_2$  in the ground state is 3; in the first excited state it has a bond order of 2. Owing to the reduction in bond order,  $N_2$  in the first excited state has a weaker N—N bond. 9.97 (a)  $2 SF_4(g) + O_2(g) \rightarrow 2 OSF_4(g)$

(c)  $\Delta H = -551$  kJ, exothermic (d) The electron domain geometry is trigonal bipyramidal. The O atom can be either equatorial or axial. (e) Since F is more electronegative than O, the structure that minimizes  $90^\circ$  F—S—F angles, the one with O axial, is preferred. 9.99 (a)  $sp^2$  hybridization at the two central C atoms (b) Isomerization requires  $180^\circ$  rotation around the  $C=C$  double bond. A  $90^\circ$  rotation eliminates all overlap of the  $p$  orbitals that form the  $\pi$  bond and it is broken. (c)  $4.42 \times 10^{-19}$  J/molecule (d)  $\lambda = 450$  nm (e) Yes, 450 nm light is in the visible portion of the spectrum. A cis-trans isomerization in the retinal portion of the large molecule rhodopsin is the first step in a sequence of molecular transformations in the eye that leads to vision. The sequence of events enables the eye to detect visible photons, in other words, to see. 9.101 From bond enthalpies,  $\Delta H = 5364$  kJ;

according to Hess's law,  $\Delta H^\circ = 5535 \text{ kJ}$ . The difference in the two results, 171 kJ, is due to the resonance stabilization in benzene. The amount of energy actually required to decompose 1 mol of  $\text{C}_6\text{H}_6(\text{g})$  is greater than the sum of the localized bond enthalpies. 9.103 (a)  $3d_{z^2}$

The "donuts" of the  $3d_{z^2}$  orbitals have been omitted from the diagram for clarity. (c) A node is generated in  $\sigma^*_{3d}$  because antibonding MOs are formed when atomic orbital lobes with opposite phases interact. Electron density is excluded from the internuclear region and a node is formed in the MO.

(e) The bond order of  $\text{Sc}_2$  is 1.0.

## Chapter 10

### 10.2

(a)  $V_2 = \frac{5}{3} V_1$

(b)  $V_2 = \frac{1}{2} V_1$

10.5 Over time, the gases will mix perfectly. Each bulb will contain 4 blue and 3 red atoms. The "blue" gas has the greater partial pressure after mixing, because it has the greater number of particles at the same  $T$  and  $V$  as the "red" gas. 10.8 (a) Curve A is  $\text{O}_2(\text{g})$  and curve B is  $\text{He}(\text{g})$ . (b) For the same gas at different temperatures, curve A represents the lower temperature and curve B the higher temperature. 10.11 (a) A gas is much less dense than a liquid. (b) A gas is much more compressible than a liquid. (c) All mixtures of gases are homogeneous. Similar liquid molecules form homogeneous mixtures, while very dissimilar molecules form heterogeneous mixtures. 10.13  $1.8 \times 10^3 \text{ kPa}$  10.15 (a) 10.3 m (b) 2.1 atm 10.17 (a) The tube can have any cross-sectional area. (b) At equilibrium the force of gravity per unit area acting on the mercury column at the level of the outside mercury is not equal to the force of gravity per unit area acting on the atmosphere. (c) The column of mercury is held up by the pressure of the atmosphere applied to the exterior pool of mercury. 10.19 (a) 0.349 atm (b) 265 mm Hg (c)  $3.53 \times 10^4 \text{ Pa}$  (d) 0.353 bar 10.21 (a)  $P = 773.4 \text{ torr}$  (b) The pressure in Chicago is greater than standard atmospheric pressure, and so it makes sense to classify this weather system as a "high-pressure system."

10.23 (i) 0.30 atm (ii) 1.073 atm (iii) 0.136 atm 10.23 (a) If  $V$  decreases by a factor of 4,  $P$  increases by a factor of 4.

(b) If  $T$  decreases by a factor of 2,  $P$  decreases by a factor of 2.

(c) If  $n$  decreases by a factor of 2,  $P$  decreases by a factor of 2.

10.27 (a) If equal volumes of gases at the same temperature and pressure contain equal numbers of molecules and molecules react in the ratios of small whole numbers, it follows that the volumes of reacting gases are in the ratios of small whole numbers. (b) Since the two gases are at the same temperature and pressure, the ratio of the numbers of atoms is the same as the ratio of volumes. There are 1.5 times as many Xe atoms as Ne atoms. 10.29 (a)  $PV = nRT$ ;  $P$  in atmospheres,  $V$  in liters,  $n$  in moles,  $T$  in kelvins. (b) An ideal gas exhibits pressure, volume, and temperature relationships described by the equation  $PV = nRT$ . 10.31 Flask A contains the gas with  $\mathcal{M} = 30 \text{ g/mol}$ , and flask B contains the gas with  $\mathcal{M} = 60 \text{ g/mol}$ .

### 10.33

$P$	$V$	$n$	$T$
2.00 atm	1.00 L	0.500 mol	48.7 K
0.300 atm	0.250 L	$3.05 \times 10^{-3} \text{ mol}$	27 °C
650 torr	11.2 L	0.333 mol	350 K
10.3 atm	585 mL	0.250 mol	295 K

10.35  $8.2 \times 10^{22} \text{ kg He}$  10.37  $5.15 \times 10^{22}$  molecules

10.39 (a) 91 atm (b)  $2.3 \times 10^2 \text{ L}$  10.41 (a) 29.8 g  $\text{Cl}_2$

(b) 9.42 L (c) 501 K (d) 1.90 atm 10.43 (a)  $n = 2 \times 10^{-4} \text{ mol O}_2$

(b) The roach needs  $8 \times 10^{-3} \text{ mol O}_2$  in 48 h, more than 100% of the  $\text{O}_2$  in the jar. 10.45 For gas samples at the same conditions,

molar mass determines density. Of the three gases listed,

(c)  $\text{Cl}_2$  has the largest molar mass. 10.47 (c) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The balloon thus weighs less

than the air displaced by its volume. 10.49 (a)  $d = 1.77 \text{ g/L}$

(b)  $\mathcal{M} = 80.1 \text{ g/mol}$  10.51  $\mathcal{M} = 89.4 \text{ g/mol}$

10.53  $3.5 \times 10^{-9} \text{ g Mg}$  10.55 21.4 L  $\text{CO}_2$  10.57 0.402 g Zn

10.59 (a) When the stopcock is opened, the volume occupied by  $\text{N}_2(\text{g})$  increases from 2.0 L to 5.0 L.  $P_{\text{N}_2} = 0.40 \text{ atm}$  (b) When the gases mix, the volume of  $\text{O}_2(\text{g})$  increases from 3.0 L to 5.0 L.

$P_{\text{O}_2} = 1.2 \text{ atm}$  (c)  $P_t = 1.6 \text{ atm}$  10.61 (a)  $P_{\text{He}} = 1.67 \text{ atm}$ ,

$P_{\text{Ne}} = 0.978 \text{ atm}$ ,  $P_{\text{Ar}} = 0.384 \text{ atm}$ , (b)  $P_t = 3.03 \text{ atm}$

10.63  $P_{\text{CO}_2} = 0.305 \text{ atm}$ ,  $P_t = 1.232 \text{ atm}$  10.65  $P_{\text{N}_2} = 0.98 \text{ atm}$ ,

$P_{\text{O}_2} = 0.39 \text{ atm}$ ,  $P_{\text{CO}_2} = 0.20 \text{ atm}$  10.67 2.5 mole %  $\text{O}_2$

10.69  $P_t = 3.04 \text{ atm}$  10.71 (a) Increase in temperature at constant volume or decrease in volume or increase in pressure

(b) decrease in temperature (c) increase in volume, decrease in pressure (d) increase in temperature 10.73 The fact that

gases are readily compressible supports the assumption that most of the volume of a gas sample is empty space. 10.75 (a)

Average kinetic energy of the molecules increases.

(b) Average speed of the molecules increases. (c) Strength of an average impact with the container walls increases. (d) Total collisions of molecules with walls per second increases.

10.77 (a) In order of increasing speed and decreasing molar mass:  $\text{HBr} < \text{NF}_3 < \text{SO}_2 < \text{CO} < \text{Ne}$  (b)  $u_{\text{NF}_3} = 324 \text{ m/s}$

10.79 The order of increasing rate of effusion is  $^2\text{H}^{37}\text{Cl} < ^1\text{H}^{37}\text{Cl} < ^2\text{H}^{35}\text{Cl} < ^1\text{H}^{35}\text{Cl}$ . 10.81  $\text{As}_4\text{S}_6$  10.83 (a)

Non-ideal-gas behavior is observed at very high pressures and low temperatures. (b) The real volumes of gas molecules and attractive intermolecular forces between molecules cause gases to behave nonideally. (c) According to the ideal-gas law, the ratio  $PV/RT$  should be constant for a given gas sample at all combinations of pressure, volume, and temperature. If this ratio changes with increasing pressure, the gas sample is not behaving ideally. 10.85 Ar ( $a = 1.34$ ,  $b = 0.0322$ ) will behave more like an ideal gas than  $\text{CO}_2$  ( $a = 3.59$ ,  $b = 0.427$ ) at high pressures. 10.87 (a)  $P = 4.89 \text{ atm}$  (b)  $P = 4.69 \text{ atm}$

(c) Qualitatively, molecular attractions are more important as the amount of free space decreases and the number of molecular collisions increases. Molecular volume is a larger part of the total volume as the container volume decreases. **10.89** A mercury barometer with water trapped in its tip will not read the correct pressure. Water at the top of the Hg column establishes a vapor pressure that exerts downward pressure in addition to gravity and partially counterbalances the pressure of the atmosphere. **10.92** 742 balloons can be filled completely, with a bit of H<sub>2</sub> left over. **10.95** (a) 13.4 mol C<sub>3</sub>H<sub>8</sub>(g) (b)  $1.47 \times 10^3$  mol C<sub>3</sub>H<sub>8</sub>(l) (c) The ratio of moles liquid to moles gas is 110. Many more molecules and moles of liquid fit in a container of fixed volume because there is much less space between molecules in the liquid phase. **10.98**  $P_1 = 5.3 \times 10^2$  torr **10.101** 42.2 g O<sub>2</sub> **10.104**  $X_{\text{Ne}} = 0.6482$  **10.107** (a) As a gas is compressed at constant temperature, the number of intermolecular collisions increases. Intermolecular attraction causes some of these collisions to be inelastic, which amplifies the deviation from ideal behavior. (b) As the temperature of a gas is increased at constant volume, a larger fraction of the molecules has sufficient kinetic energy to overcome intermolecular attractions and the effect of intermolecular attraction becomes less significant. **10.110** (a) 0.036% of the total volume is occupied by Ar atoms. (b) 3.6% of the total volume is occupied by Ar atoms. **10.112** (a) The molecular formula is C<sub>3</sub>H<sub>6</sub>. (b) Ar and C<sub>3</sub>H<sub>6</sub> are nonpolar, have similar molar masses, and experience London dispersion forces. We expect the effect of both volume and intermolecular attractions to be more significant for the structurally more complex C<sub>3</sub>H<sub>6</sub>. Cyclopropane will deviate more from ideal behavior at the specified conditions. **10.114** (a) 44.58% C, 6.596% H, 16.44% Cl, 32.38% N (b) C<sub>6</sub>H<sub>14</sub>N<sub>5</sub>Cl **10.117**  $\Delta H = -1.1 \times 10^{14}$  kJ (assuming H<sub>2</sub>O(l) is a product) **10.120** (a)  $5.02 \times 10^8$  L CH<sub>3</sub>OH(l) (b)  $\text{CH}_4(\text{g}) + 2 \text{O}_2(\text{g}) \rightarrow \text{CO}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l}), \Delta H^\circ = -890.4 \text{ kJ}$ ;  $\Delta H$  for combustion of the methane is  $-1.10 \times 10^{13}$  kJ.  $\text{CH}_3\text{OH}(\text{l}) + 3/2 \text{O}_2(\text{g}) \rightarrow \text{CO}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l}), \Delta H^\circ = -726.6 \text{ kJ}$ ;  $\Delta H$  for combustion of the methanol is  $-9.00 \times 10^{12}$  kJ.

### Chapter 11

**11.1** The diagram best describes a liquid. The particles are close together, mostly touching, but there is no regular arrangement or order. This rules out a gaseous sample, where the particles are far apart, and a crystalline solid, which has a regular repeating structure in all three directions. **11.4** (a) 385 mm Hg (b) 22 °C (c) 47 °C **11.7** (a) 3 Nb atoms, 3 O atoms (b) NbO (c) This is primarily an ionic solid, because Nb is a metal and O is a nonmetal. There may be some covalent character to the Nb...O bonds. **11.9** (a) Solid < liquid < gas (b) gas < liquid < solid (c) Matter in the gaseous state is most easily compressed, because particles are far apart and there is much empty space. **11.11** (a) The density of olive oil is less than 1.00 g/cm<sup>3</sup>. (b) At higher temperature, greater molecular motion and collisions cause the volume of the liquid to increase and the density to decrease. Olive oil is less dense at higher temperature. **11.13** (a) London dispersion forces (b) dipole-dipole and London dispersion forces (c) dipole-dipole forces and in certain cases hydrogen bonding **11.15** (a) Nonpolar covalent molecule; London dispersion forces only (b) polar covalent molecule with O—H bonds; hydrogen bonding, dipole-dipole forces and London dispersion forces (c) polar covalent molecule; dipole-dipole and London dispersion forces (but not hydrogen bonding) **11.17** (a) Polarizability is the ease with which the charge distribution in a molecule can be distorted to produce a transient dipole. (b) Sb is most polarizable because its valence electrons are farthest from the nucleus and least tightly held. (c) In order of increasing polarizability: CH<sub>4</sub> < SiH<sub>4</sub> < SiCl<sub>4</sub> < GeCl<sub>4</sub> < GeBr<sub>4</sub> (d) The magnitudes of London dispersion forces and thus the boiling points of molecules increase as polarizability increases.

The order of increasing boiling points is the order of increasing polarizability given in (c). **11.19** (a) H<sub>2</sub>S (b) CO<sub>2</sub> (c) GeH<sub>4</sub> **11.21** Both rodlike butane molecules and spherical 2-methylpropane molecules experience dispersion forces. The larger contact surface between butane molecules facilitates stronger forces and produces a higher boiling point. **11.23** (a) A molecule must contain H atoms, bound to either N, O or F atoms, in order to participate in hydrogen bonding with like molecules. (b) CH<sub>3</sub>NH<sub>2</sub> and CH<sub>3</sub>OH. **11.25** (a) Replacing a hydroxyl hydrogen with a CH<sub>3</sub> group eliminates hydrogen bonding in that part of the molecule. This reduces the strength of intermolecular forces and leads to a lower boiling point. (b) CH<sub>3</sub>OCH<sub>2</sub>CH<sub>2</sub>OCH<sub>3</sub> is a larger, more polarizable molecule with stronger London dispersion forces and thus a higher boiling point. **11.27**

Physical Property	H <sub>2</sub> O	H <sub>2</sub> S
Normal boiling point, °C	100.00	-60.7
Normal melting point, °C	0.00	-85.5

(a) Based on its much higher normal melting point and boiling point, H<sub>2</sub>O has much stronger intermolecular forces. H<sub>2</sub>O has hydrogen bonding, while H<sub>2</sub>S has dipole-dipole forces. (b) H<sub>2</sub>S is probably a typical compound with less empty space in the ordered solid than the liquid, so that the solid is denser than the liquid. For H<sub>2</sub>O, maximizing the number of hydrogen bonds to each molecule in the solid requires more empty space than in the liquid, and the solid is less dense. (c) Specific heat is the energy required to raise the temperature of one gram of the substance one degree celsius. Hydrogen bonding in water is such a strong attractive interaction that the energy required to disrupt it and increase molecular motion is large. **11.29** (a) As temperature increases, the number of molecules with sufficient kinetic energy to overcome intermolecular attractive forces increases, and viscosity and surface tension decrease. (b) The same attractive forces that cause surface molecules to be difficult to separate (high surface tension) cause molecules elsewhere in the sample to resist movement relative to each other (high viscosity). **11.31** (a) CHBr<sub>3</sub> has a higher molar mass, is more polarizable, and has stronger dispersion forces, so the surface tension is greater. (b) As temperature increases, the viscosity of the oil decreases because the average kinetic energy of the molecules increases. (c) Adhesive forces between polar water and nonpolar car wax are weak, so the large surface tension of water draws the liquid into the shape with the smallest surface area, a sphere. (d) Adhesive forces between nonpolar oil and nonpolar car wax are similar to cohesive forces in oil, so the oil drops spread out on the waxed car hood. **11.33** (a) Melting, endothermic (b) evaporation, endothermic (c) deposition, exothermic (d) condensation, exothermic **11.35** Melting does not require separation of molecules, so the energy requirement is smaller than for vaporization, where molecules must be separated. **11.37**  $2.3 \times 10^3$  g H<sub>2</sub>O **11.39** (a) 240 kJ (b)  $5.57 \times 10^3$  kJ **11.41** (a) The critical pressure is the pressure required to cause liquefaction at the critical temperature. (b) As the force of attraction between molecules increases, the critical temperature of the compound increases. (c) All the gases in Table 11.5 can be liquefied at the temperature of liquid nitrogen, given sufficient pressure. **11.43** (a) No effect (b) no effect (c) Vapor pressure decreases with increasing intermolecular attractive forces because fewer molecules have sufficient kinetic energy to overcome attractive forces and escape to the vapor phase. (d) Vapor pressure increases with increasing temperature because average kinetic energies of molecules increase. (e) Vapor pressure decreases with increasing density because attractive intermolecular forces increase. **11.45** (a) CBr<sub>4</sub> < CHBr<sub>3</sub> < CH<sub>2</sub>Br<sub>2</sub> < CH<sub>2</sub>Cl<sub>2</sub> < CH<sub>3</sub>Cl < CH<sub>4</sub>. The trend is dominated by dispersion forces even though four of the molecules are polar. The order of increasing volatility is the

order of increasing vapor pressure, decreasing molar mass, and decreasing strength of dispersion forces. (b) Boiling point increases as the strength of intermolecular forces increases; this is the order of decreasing volatility and the reverse of the order in part (a).

**11.47** (a) The temperature of the water in the two pans is the same. (b) Vapor pressure does not depend on either volume or surface area of the liquid. At the same temperature, the vapor pressures of water in the two containers are the same.

**11.49** (a) Approximately 48 °C (b) approximately 340 torr (c) approximately 16 °C (d) approximately 1000 torr **11.51** (a)

The critical point is the temperature and pressure beyond which the gas and liquid phases are indistinguishable. (b) The line that separates the gas and liquid phases ends at the critical point because at conditions beyond the critical temperature and pressure, there is no distinction between gas and liquid. In experimental terms a gas cannot be liquefied at temperatures higher than the critical temperature, regardless of pressure.

**11.53** (a)  $\text{H}_2\text{O}(\text{g})$  will condense to  $\text{H}_2\text{O}(\text{s})$  at approximately 4 torr; at a higher pressure, perhaps 5 atm or so,  $\text{H}_2\text{O}(\text{s})$  will melt to form  $\text{H}_2\text{O}(\text{l})$ . (b) At 100 °C and 0.50 atm, water is in the vapor phase. As it cools, water vapor condenses to the liquid at approximately 82 °C, the temperature where the vapor pressure of liquid water is 0.50 atm. Further cooling results in freezing at approximately 0 °C. The freezing point of water increases with decreasing pressure, so at 0.50 atm the freezing temperature is very slightly above 0 °C.

**11.55**

**11.57**

Crystalline      Amorphous

**11.59** (a)  $\text{SrTiO}_3$  (b) Each Sr atom is coordinated to six O atoms, three in this unit cell and three in adjacent unit cells. **11.61** (a)  $r = 1.355 \text{ \AA}$  (b) density =  $22.67 \text{ g/cm}^3$

**11.63** Atomic weight = 55.8 g/mol **11.65** (a)  $a = 4.70 \text{ \AA}$

(b)  $2.69 \text{ g/cm}^3$  **11.67**  $a = 6.13 \text{ \AA}$  **11.69** (a) Intermolecular (really interparticle) forces among Ar atoms are dispersion forces. (b) Solid Ar is not a covalent network solid. Atoms in a covalent network solid are joined by strong covalent bonds, whereas atoms in Ar(s) are held in place by weak dispersion forces.

**11.71** (a) Hydrogen bonding, dipole-dipole forces, London dispersion forces (b) covalent chemical bonds (c) ionic bonds (d) metallic bonds **11.73** In molecular solids relatively weak intermolecular forces bind the molecules in the lattice, so relatively little energy is required to disrupt these forces. In covalent-network solids, covalent bonds join atoms into an extended network. Melting or deforming a covalent-network solid means breaking covalent bonds, which requires a large amount of energy. **11.75** Because of its relatively high melting point and properties as a conducting solution, the solid must be ionic. **11.77** (a) Xe, greater atomic weight,

stronger dispersion forces (b)  $\text{SiO}_2$ , covalent-network lattice versus weak dispersion forces (c) KBr, strong ionic versus weak dispersion forces (d)  $\text{C}_6\text{Cl}_6$ , both are influenced by dispersion forces,  $\text{C}_6\text{Cl}_6$  has the higher molar mass **11.79** (a)

Decrease (b) increase (c) increase (d) increase (e) increase (f) increase (g) increase **11.83** When a halogen is substituted for H in benzene, molar mass, polarizability and strength of dispersion forces increase; the order of increasing molar mass is the order of increasing boiling points for the first three compounds.  $\text{C}_6\text{H}_5\text{OH}$  experiences hydrogen bonding, the strongest force between neutral molecules, so it has the highest boiling point.

**11.88** (a) Evaporation is an endothermic process. The heat required to vaporize sweat is absorbed from your body, helping to keep it cool. (b) The vacuum pump reduces the pressure of the atmosphere above the water until atmospheric pressure equals the vapor pressure of water and the water boils. Boiling is an endothermic process, and the temperature drops if the system is not able to absorb heat from the surroundings fast enough. As the temperature of the water decreases, the water freezes. **11.92** The large difference in melting points is due to the very different forces imposing atomic order in the solid state. Much more kinetic energy is required to disrupt the delocalized metallic bonding in gold than to overcome the relatively weak London dispersion forces in Xe. **11.95** Diffraction, the phenomenon that enables us to measure interatomic distances in crystals, is most efficient when the wavelength of light is similar to or smaller than the size of the object doing the diffracting. Atom sizes are on the order of 1–10 Å, and the wavelengths of x-rays are also in this range. Visible light, 400–700 nm or 4000–7000 Å, is too long to be diffracted effectively by atoms (electrons) in crystals.

**11.98** 16 Al atoms, 8 Mg atoms, 32 O atoms

**11.101**

(i)  $M = 44$

(ii)  $M = 72$

(iii)  $M = 123$

(iv)  $M = 58$

(v)  $M = 123$

(vi)  $M = 60$

(a) Molar mass: Compounds (i) and (ii) have similar rodlike structures. The longer chain in (ii) leads to greater molar mass, stronger London-dispersion forces, and higher heat of vaporization. (b) Molecular shape: Compounds (iii) and (v) have the same chemical formula and molar mass but different molecular shapes. The more rodlike shape of (v) leads to more contact between molecules, stronger dispersion forces, and higher heat of vaporization. (c) Molecular polarity: Compound (iv) has a smaller molar mass than (ii) but a larger heat of vaporization, which must be due to the presence of dipole-dipole forces. (d) Hydrogen bonding interactions: Molecules (v) and (vi) have similar structures. Even though (v) has larger molar mass and dispersion forces, hydrogen bonding causes (vi) to have the higher heat of vaporization.

**11.105**  $P(\text{benzene vapor}) = 98.6 \text{ torr}$ .

## Chapter 12

**12.1** The band structure of material A is that of a metal.

**12.3** Polymer (a), with ordered regions, is denser than branched polymer (b). The ordered regions in polymer (a) also indicate that it has stronger intermolecular forces and higher melting point than polymer (b). **12.5** (a) Molecule (i), with a terminal  $\text{C}=\text{C}$ , is the only monomer shown that is capable of

addition polymerization. (b) Molecule (iii) contains both a carboxyl group and an amine group; it can "condense" with like monomers to form a polymer and  $\text{NH}_3$ . (c) Molecule (ii), with a  $-\text{CN}$  group, a rodlike 5 C chain and a planar benzenelike (phenyl) ring, has both dipole-dipole and dispersion forces that are likely to encourage the long range order required to form a liquid crystal 12.7 (a) Semiconductor (b) insulator (c) semiconductor (d) metal

12.9

(a) Six AOs require six MOs (b) Zero nodes in the lowest energy orbital (c) Five nodes in highest energy orbital (d) Two nodes in the HOMO (e) Three nodes in the LUMO. 12.11 (a) False. Semiconductors have a smaller band gap; they conduct some electricity, while insulators do not. (b) True. Dopants create either more electrons or more "holes," both of which increase the conductivity of the semiconductor. (c) True. Metals conduct electricity because delocalized electrons in the lattice provide a mechanism for charge mobility. (d) True. Metal oxides are ionic substances with essentially localized electrons. This barrier to charge mobility renders them insulators.

12.13 (a) CdS (b) GaN (c) GaAs 12.15 Ge or Si (Ge is closer to Ga in bonding atomic radius.) 12.17 As a semiconductor material for integrated circuits, silicon has the advantages that it is abundant, cheap, nontoxic; can be highly purified; and grows nearly perfect enormous crystals. 12.19 Traditionally, the insulator silicon dioxide,  $\text{SiO}_2$ , is the material in a MOSFET gate. The next-generation material is silicon nitride,  $\text{Si}_3\text{N}_4$ , or a mixture of  $\text{SiO}_2$  and  $\text{Si}_3\text{N}_4$ . 12.21 (a) A 1.1 eV photon corresponds to a wavelength of  $1.1 \times 10^{-6}$  m. (b) According to the figure, Si can absorb a portion of the visible light that comes from the sun. 12.23  $\lambda = 560$  nm 12.25 The band gap is approximately 1.85 eV, which corresponds to a wavelength of 672 nm.

12.27 Ceramics are not readily recyclable because of their extremely high melting points and rigid ionic or covalent-network structures. 12.29 Very small, uniformly sized and shaped particles are required for the production of a strong ceramic object by sintering. Upon heating to initiate condensation reactions, the more uniform the particle size and the greater the total surface area of the solid, the more chemical bonds are formed and the stronger the ceramic object.

12.31 The ceramics are  $\text{MgO}$ , soda-lime glass,  $\text{ZrB}_2$ ,  $\text{Al}_2\text{O}_3$ , and TaC. The criteria are a combination of chemical formula (with corresponding bonding characteristics) and Knoop values. Ceramics are ionic or covalent-network solids with fairly large hardness values. Hardness alone is not a sufficient criterion for classification as a ceramic. A metal, Cr, lies in the middle of the hardness range for ceramics. Bonding characteristics as well as hardness must be taken into account when classifying materials as ceramics. 12.33 A superconducting material offers no resistance to the flow of electrical current. Superconductive materials could transmit electricity with much greater efficiency than current carriers. 12.35 The sharp drop in resistivity of  $\text{MgB}_2$  near 39 K is the superconducting transition temperature,

$T_c$ . 12.37 The phenomenon that superconductors exclude all magnetic fields from their volume is the Meissner effect. It can be used to levitate trains by having either the tracks or the train wheels made from a magnetic material, and the other from a superconductor, with the superconductor cooled below its transition temperature. It is more practical, and therefore more likely, that the train wheels are made of the superconductor and cooled. 12.39 Monomers are small molecules with low molecular mass that are joined together to form polymers. Three monomers mentioned in this chapter are

Propylene  
(propene)Styrene  
(phenyl ethene)Isoprene  
(2-methyl-1,3-butadiene)

If a dicarboxylic acid and a dialcohol are combined, there is the potential for propagation of the polymer chain at both ends of both monomers.

12.47 Flexibility of molecular chains causes flexibility of the bulk polymer. Flexibility is enhanced by molecular features that inhibit order, such as branching, and diminished by features that encourage order, such as cross-linking or delocalized  $\pi$  electron density. Cross-linking, the formation of chemical bonds between polymer chains, reduces flexibility of the molecular chains, increases the hardness of the material, and decreases the chemical reactivity of the polymer. 12.49 The function of the polymer determines whether high molecular mass and high degree of crystallinity are desirable properties. If the polymer will be used as a flexible wrapping or fiber, rigidity that is due to high molecular mass is an undesirable property. 12.51 Is the neoprene biocompatible? Does it provoke inflammatory reactions? Does neoprene meet the physical

requirements of a flexible lead? Will it remain resistant to degradation and maintain elasticity? Can neoprene be prepared in sufficiently pure form so that it can be classified as medical grade? **12.53** Current vascular graft materials cannot be lined with cells similar to those in the native artery. The body detects that the graft is "foreign," and platelets attach to the inside surfaces, causing blood clots. The inside surfaces of future vascular implants need to accommodate a lining of cells that do not attract or attach to platelets. **12.55** In order for skin cells in a culture medium to develop into synthetic skin, a mechanical matrix that holds the cells in contact with one another must be present. The matrix must be strong, biocompatible, and biodegradable. It probably has polar functional groups that form hydrogen bonds with biomolecules in the tissue cells. **12.57** Both an ordinary liquid and a nematic liquid crystal phase are fluids; they are converted directly to the solid phase upon cooling. The nematic phase is cloudy and more viscous than an ordinary liquid. Upon heating, the nematic phase is converted to an ordinary liquid. **12.59** In the solid state the relative orientation of molecules is fixed and repeating in all three dimensions. When a substance changes to the nematic liquid crystalline phase, the molecules remain aligned in one dimension; translational motion is allowed, but rotational motion is restricted. Transformation to the isotropic liquid phase destroys the one-dimensional order, resulting in free translational and rotational motion. **12.61** The presence of polar groups or nonbonded electron pairs leads to relatively strong dipole-dipole interactions between molecules. These are a significant part of the orienting forces necessary for liquid crystal formation. **12.63** In the nematic phase there is one-dimensional order, while in a smectic phase there is two-dimensional order. In a smectic phase the long directions of the molecules and the ends of the molecules are aligned. **12.65** A nematic phase is composed of sheets of molecules aligned along their lengths, with no additional order within the sheet or between sheets. A cholesteric phase also contains this kind of sheet, but with some ordering between sheets. **12.67** If a solid has nanoscale dimensions of 1–10 nm, there may not be enough atoms contributing atomic orbitals to produce continuous energy bands of molecular orbitals. **12.69** (a) False. As particle size decreases, the band gap increases. (b) False. As particle size decreases, wavelength decreases. **12.71**  $2.47 \times 10^5$  Au atoms **12.73** Semiconductors have a difference in energy, the band gap, between a filled valence band and an empty conduction band. When a semiconductor is heated, more electrons have sufficient energy to jump the band gap, and conductivity increases. Metals have a partially-filled continuous energy band. Heating a metal increases the average kinetic energy, including vibrational energy, of the metal atoms. The greater vibrational energy of the atoms leads to imperfections in the lattice and discontinuities in the energy band. This creates barriers to electron delocalization and reduces the conductivity of the metal.

Teflon™ is formed by addition polymerization. **12.79** At the temperature where a substance changes from the solid to the liquid crystalline phase, kinetic energy sufficient to overcome

most of the long-range order in the solid has been supplied. A relatively small increase in temperature is required to overcome the remaining aligning forces and produce an isotropic liquid. **12.83**  $\text{TiCl}_4(\text{g}) + 2 \text{SiH}_4(\text{g}) \longrightarrow \text{TiSi}_2(\text{s}) + 4 \text{HCl}(\text{g}) + 2 \text{H}_2(\text{g})$ . As a ceramic,  $\text{TiSi}_2$  will have a three-dimensional network structure similar to that of Si. At the surface of the thin film, there will be Ti and Si atoms with incomplete valences that will chemically bond with Si atoms on the surface of the substrate. This kind of bonding would not be possible with a Cu thin film. **12.84** (a)  $\Delta H = -82 \text{ kJ/mol}$  (b)  $\Delta H = -14 \text{ kJ/mol}$  (of either reactant) (c)  $\Delta H = 0 \text{ kJ}$  **12.87** (a)  $x = 0.22$  (b) Hg and Cu both have more than one stable oxidation state. If different ions in the solid lattice have different charges, the average charge is a noninteger value. Ca and Ba are stable only in the +2 oxidation state and are unlikely to have a noninteger average charge. (c)  $\text{Ba}^{2+}$  is largest;  $\text{Cu}^{2+}$  is smallest.

### Chapter 13

**13.1** The ion-solvent interaction should be greater for  $\text{Li}^+$ . The smaller ionic radius of  $\text{Li}^+$  means that the ion-dipole interactions with polar water molecules are stronger. **13.5** Diagram (b) is the best representation of a saturated solution. There is some undissolved solid with particles that are close together and ordered, in contact with a solution containing mobile, separated solute particles. As much solute has dissolved as can dissolve, leaving some undissolved solid in contact with the saturated solution. **13.9** (a) Yes, the molarity changes with a change in temperature. Molarity is defined as moles solute per unit volume of solution. A change of temperature changes solution volume and molarity. (b) No, molality does not change with change in temperature. Molality is defined as moles solute per kilogram of solvent. Temperature affects neither mass nor moles. **13.13** If the magnitude of  $\Delta H_3$  is small relative to the magnitude of  $\Delta H_1$ ,  $\Delta H_{\text{soln}}$  will be large and endothermic (energetically unfavorable) and not much solute will dissolve. **13.15** (a) Dispersion (b) hydrogen bonding (c) ion-dipole (d) dipole-dipole **13.17** (a)  $\Delta H_1$  (b)  $\Delta H_3$  **13.19** (a) Since the solute and solvent experience very similar London dispersion forces, the energy required to separate them individually and the energy released when they are mixed are approximately equal.  $\Delta H_1 + \Delta H_2 \approx -\Delta H_3$ . Thus,  $\Delta H_{\text{soln}}$  is nearly zero. (b) Since no strong intermolecular forces prevent the molecules from mixing, they do so spontaneously because of the increase in randomness. **13.21** (a) Supersaturated (b) Add a seed crystal. A seed crystal provides a nucleus of prealigned molecules, so that ordering of the dissolved particles (crystallization) is more facile. **13.23** (a) Unsaturated (b) saturated (c) saturated (d) unsaturated **13.25** The liquids water and glycerol form homogeneous mixtures (solutions) regardless of the relative amounts of the two components. The —OH groups of glycerol facilitate strong hydrogen bonding similar to that in water; like dissolves like. **13.27** (a) Dispersion interactions among nonpolar  $\text{CH}_3(\text{CH}_2)_{16}$ — chains dominate the properties of stearic acid, causing it to be more soluble in nonpolar  $\text{CCl}_4$ . (b) Dioxane can act as a hydrogen bond acceptor, so it will be more soluble than cyclohexane in water. **13.29** (a)  $\text{CCl}_4$  is more soluble because dispersion forces among nonpolar  $\text{CCl}_4$  molecules are similar to dispersion forces in hexane. (b)  $\text{C}_6\text{H}_6$  is a nonpolar hydrocarbon and will be more soluble in the similarly nonpolar hexane. (c) The long, rodlike hydrocarbon chain of octanoic acid forms strong dispersion interactions and causes it to be more soluble in hexane. **13.31** (a) A sealed container is required to maintain a partial pressure of  $\text{CO}_2(\text{g})$  greater than 1 atm above the beverage. (b) Since the solubility of gases increases with decreasing temperature, some  $\text{CO}_2(\text{g})$  will remain dissolved in the beverage if it is kept cool. **13.33**  $S_{\text{He}} = 5.6 \times 10^{-4} \text{ M}$ ,  $S_{\text{N}_2} = 9.0 \times 10^{-4} \text{ M}$  **13.35** (a) 2.15%  $\text{Na}_2\text{SO}_4$

by mass (b) 3.15 ppm Ag **13.37** (a)  $X_{\text{CH}_3\text{OH}} = 0.0427$  (b) 7.35%  $\text{CH}_3\text{OH}$  by mass (c) 2.48  $m$   $\text{CH}_3\text{OH}$  **13.39** (a)  $1.46 \times 10^{-2} M$   $\text{Mg}(\text{NO}_3)_2$  (b) 1.12  $M$   $\text{LiClO}_4 \cdot 3 \text{H}_2\text{O}$  (c) 0.350  $M$   $\text{HNO}_3$   
**13.41** (a) 4.70  $m$   $\text{C}_6\text{H}_6$  (b) 0.235  $m$   $\text{NaCl}$  **13.43** (a) 43.01%  $\text{H}_2\text{SO}_4$  by mass (b)  $X_{\text{H}_2\text{SO}_4} = 0.122$  (c) 7.69  $m$   $\text{H}_2\text{SO}_4$  (d) 5.827  $M$   $\text{H}_2\text{SO}_4$   
**13.45** (a)  $X_{\text{CH}_3\text{OH}} = 0.227$  (b) 7.16  $m$   $\text{CH}_3\text{OH}$  (c) 4.58  $M$   $\text{CH}_3\text{OH}$   
**13.47** (a) 0.150 mol  $\text{SrBr}_2$  (b)  $1.56 \times 10^{-2}$  mol  $\text{KCl}$   
 (c)  $4.44 \times 10^{-2}$  mol  $\text{C}_6\text{H}_{12}\text{O}_6$  **13.49** (a) Weigh out 1.3 g  $\text{KBr}$ , dissolve in water, dilute with stirring to 0.75 L. (b) Weigh out 2.62 g  $\text{KBr}$ , dissolve it in 122.38 g  $\text{H}_2\text{O}$  to make exactly 125 g of 0.180  $m$  solution. (c) Weigh 244 g  $\text{KBr}$  and dissolve in enough  $\text{H}_2\text{O}$  to make 185 L solution. (d) Weigh 10.1 g  $\text{KBr}$ , dissolve it in a small amount of water, and dilute to 0.568 L. **13.51** 71%  $\text{HNO}_3$  by mass **13.53** (a) 3.82  $m$   $\text{Zn}$  (b) 26.8  $M$   $\text{Zn}$   
**13.55**  $1.8 \times 10^{-3} M$   $\text{CO}_2$  **13.57** Freezing point depression,  $\Delta T_f = K_f(m)$ ; boiling point elevation,  $\Delta T_b = K_b(m)$ ; osmotic pressure,  $\pi = MRT$ ; vapor pressure lowering,  $P_A = X_A P_A^\circ$   
**13.59** (a) Sucrose has a greater molar mass than glucose, so the sucrose solution will contain fewer particles and have a higher vapor pressure. **13.61** (a)  $P_{\text{H}_2\text{O}} = 186.4$  torr (b) 78.9 g  $\text{C}_3\text{H}_8\text{O}_2$  **13.61** (a)  $X_{\text{Eth}} = 0.2812$  (b)  $P_{\text{soln}} = 238$  torr (c)  $X_{\text{Eth}}$  in vapor = 0.472 **13.65** (a) Because  $\text{NaCl}$  is a strong electrolyte, one mole of  $\text{NaCl}$  produces twice as many dissolved particles as one mole of the molecular solute  $\text{C}_6\text{H}_{12}\text{O}_6$ . Boiling-point elevation is directly related to total moles of dissolved particles, so 0.10  $m$   $\text{NaCl}$  has the higher boiling point. (b) 0.10  $m$   $\text{NaCl}$ :  $\Delta T_b = 0.101$   $^\circ\text{C}$ ,  $T_b = 100.1$   $^\circ\text{C}$ ; 0.10  $m$   $\text{C}_6\text{H}_{12}\text{O}_6$ :  $\Delta T_b = 0.051$   $^\circ\text{C}$ ,  $T_b = 100.1$   $^\circ\text{C}$  (c) Interactions between ions in solution result in non-ideal behavior. **13.67** 0.050  $m$   $\text{LiBr}$  < 0.120  $m$  glucose < 0.050  $m$   $\text{Zn}(\text{NO}_3)_2$  **13.69** (a)  $T_f = -115.0$   $^\circ\text{C}$ ,  $T_b = 78.7$   $^\circ\text{C}$  (b)  $T_f = -3.84$   $^\circ\text{C}$ ,  $T_b = 64.2$   $^\circ\text{C}$  (c)  $T_f = -0.604$   $^\circ\text{C}$ ,  $T_b = 100.2$   $^\circ\text{C}$  **13.71** 167 g  $\text{C}_2\text{H}_6\text{O}_2$  **13.73**  $\pi = 0.0168$  atm = 12.7 torr **13.75** Experimental molar mass of adrenaline is  $1.8 \times 10^2$  g. The structure shows a molecular formula of  $\text{C}_9\text{H}_{13}\text{NO}_3$ , with a molar mass of 183 g. The two values agree to two significant figures, the precision of the experiment.  
**13.77** Molar mass of lysozyme =  $1.39 \times 10^4$  g  
**13.79** (a)  $i = 2.76$  (b) The more concentrated the solution, the greater the ion-pairing and the smaller the measured value of  $i$ .  
**13.81** (a) In the gaseous state, particles are far apart and intermolecular attractive forces are small. When two gases combine, all terms in Equation 13.1 are essentially zero and the mixture is always homogeneous. (b) To determine whether Faraday's dispersion is a true solution or a colloid, shine a beam of light on it. If light is scattered, the dispersion is a colloid. **13.83** (a) Hydrophobic (b) hydrophilic (c) hydrophobic (d) hydrophobic (but stabilized by adsorbed charges). **13.85** When electrolytes are added to a suspension of proteins, dissolved ions form ion pairs with the protein surface charges, effectively neutralizing them. The protein's capacity for ion-dipole interactions with water is diminished and the colloid separates into a protein layer and a water layer. **13.87** The periphery of the BHT molecule is mostly hydrocarbon-like groups, such as  $-\text{CH}_3$ . The one  $-\text{OH}$  group is rather buried inside and probably does little to enhance solubility in water. Thus, BHT is more likely to be soluble in the nonpolar hydrocarbon hexane,  $\text{C}_6\text{H}_{14}$ , than in polar water. **13.90** (a)  $k_{\text{Rn}} = 7.27 \times 10^{-3}$  mol/L-atm (b)  $P_{\text{Rn}} = 1.1 \times 10^{-4}$  atm;  $S_{\text{Rn}} = 8.1 \times 10^{-7}$  M  
**13.93** (a) 2.69  $m$   $\text{LiBr}$  (b)  $X_{\text{LiBr}} = 0.0994$  (c) 81.1%  $\text{LiBr}$  by mass **13.96**  $X_{\text{H}_2\text{O}} = 0.808$ ; 0.273 mol ions; 0.136 mol  $\text{NaCl}$   
**13.99** (a)  $-0.6$   $^\circ\text{C}$  (b)  $-0.4$   $^\circ\text{C}$  **13.102** (a)  $X_{\text{KSCN}} = 0.110$ ; 6.86  $m$   $\text{KSCN}$ ; 5.02  $M$   $\text{KSCN}$  (b) In this solution, there are 4.12 mol  $\text{KSCN}$ , 824 mol of ions and 333 mol  $\text{H}_2\text{O}$ , or approximately 4 water molecules for each ion. This is too few water molecules to completely hydrate the anions and cations in the solution. For a solution this concentrated, we expect significant ion-pairing, because the ions are not completely surrounded and separated by  $\text{H}_2\text{O}$  molecules. The effective number of

particles will be less than that indicated by  $m$  and  $M$ , so the observed colligative properties will be significantly different from those predicted by formulas for ideal solutions. **13.104** (a)  $\text{CF}_4$ ,  $1.7 \times 10^{-4} m$ ;  $\text{CClF}_3$ ,  $9 \times 10^{-4} m$ ;  $\text{CCl}_2\text{F}_2$ ,  $2.3 \times 10^{-2} m$ ;  $\text{CHClF}_2$ ,  $3.5 \times 10^{-2} m$  (b) Molality and molarity are numerically similar when kilograms solvent and liters solution are nearly equal. This is true when solutions are dilute and when the density of the solvent is nearly 1 g/mL, as in this exercise. (c) Water is a polar solvent; the solubility of solutes increases as their polarity increases. Nonpolar  $\text{CF}_4$  has the lowest solubility and the most polar fluorocarbon,  $\text{CHClF}_2$ , has the greatest solubility in  $\text{H}_2\text{O}$  (d) The Henry's law constant for  $\text{CHClF}_2$  is  $3.5 \times 10^{-2}$  mol/L-atm. This value is greater than the Henry's law constant for  $\text{N}_2(\text{g})$  because  $\text{N}_2(\text{g})$  is nonpolar and of lower molecular mass than  $\text{CHClF}_2$ .

**13.108**

(a) cation (g) + anion (g) + solvent

(b) Lattice energy ( $U$ ) is inversely related to the distance between ions, so salts with large cations like  $(\text{CH}_3)_4\text{N}^+$  have smaller lattice energies than salts with simple cations like  $\text{Na}^+$ . Also, the  $-\text{CH}_3$  groups in the large cation are capable of dispersion interactions with nonpolar groups of the solvent molecules, resulting in a more negative solvation energy of the gaseous ions. Overall, for salts with larger cations, lattice energy is smaller (less positive), the solvation energy of the gaseous ions is more negative, and  $\Delta H_{\text{soln}}$  is less endothermic. These salts are more soluble in polar nonaqueous solvents.  
**13.111** The process is spontaneous with no significant change in enthalpy, so we suspect that there is an increase in entropy. In general, dilute solutions of the same solute have greater entropy than concentrated ones, because the solute particles are more free to move about the solution. In the limiting case that the more dilute solution is pure solvent, there is a definite increase in entropy as the concentrated solution is diluted. In Figure 13.23, there may be some entropy decrease as the dilute solution loses solvent, but this is more than offset by the entropy increase that accompanies dilution. There is a net increase in entropy.

**Chapter 14**

**14.1** (a) Product (b) The average rate of reaction is greater between points 1 and 2 because they are earlier in the reaction when the concentrations of reactants are greater. **14.4** Container (1) has the fastest initial rate, only slightly faster than container (2). **14.6** (a) The half-life is 15 min. (b) After four half-life periods, 1/16 of the reactant remains. **14.10** There is one intermediate, B, and two transition states,  $\text{A} \rightarrow \text{B}$  and  $\text{B} \rightarrow \text{C}$ . The  $\text{B} \rightarrow \text{C}$  step is faster, and the overall reaction is exothermic. **14.13** (a) Reaction rate is the change in the amount of products or reactants in a given amount of time. (b) Rates depend on concentration of reactants, surface area of reactants, temperature, and presence of catalyst. (c) The stoichiometry of the reaction (mole ratios of reactants and products) must be known to relate rate of disappearance of reactants to rate of appearance of products.

## 14.15

Time (min)	Mol A	(a) Mol B	[A] (mol/L)	$\Delta[A]$ (mol/L)	(b) Rate (M/s)
0	0.065	0.000	0.65		
10	0.051	0.014	0.51	-0.14	$2.3 \times 10^{-4}$
20	0.042	0.023	0.42	-0.09	$1.5 \times 10^{-4}$
30	0.036	0.029	0.36	-0.06	$1.0 \times 10^{-4}$
40	0.031	0.034	0.31	-0.05	$0.8 \times 10^{-4}$

$$(c) \Delta[B]_{\text{avg}}/\Delta t = 1.3 \times 10^{-4} \text{ M/s}$$

## 14.17 (a)

Time (s)	Time Interval (s)	Concentration (M)	$\Delta M$	Rate (M/s)
0		0.0165		
2,000	2,000	0.0110	-0.0055	$28 \times 10^{-7}$
5,000	3,000	0.00591	-0.0051	$17 \times 10^{-7}$
8,000	3,000	0.00314	-0.00277	$9.23 \times 10^{-7}$
12,000	4,000	0.00137	-0.00177	$4.43 \times 10^{-7}$
15,000	3,000	0.00074	-0.00063	$2.1 \times 10^{-7}$

(b) From the slopes of the tangents to the graph, the rates are  $12 \times 10^{-7} \text{ M/s}$  at 5000 s,  $5.8 \times 10^{-7} \text{ M/s}$  at 8000 s.

$$14.19 (a) -\Delta[\text{H}_2\text{O}_2]/\Delta t = \Delta[\text{H}_2]/\Delta t = \Delta[\text{O}_2]/\Delta t$$

$$(b) -\frac{1}{2}\Delta[\text{N}_2\text{O}]/\Delta t = \frac{1}{2}\Delta[\text{N}_2]/\Delta t = \Delta[\text{O}_2]/\Delta t$$

$$(c) -\Delta[\text{N}_2]/\Delta t = -\frac{1}{3}\Delta[\text{H}_2]/\Delta t = \frac{1}{2}\Delta[\text{NH}_3]/\Delta t$$

$$14.21 (a) -\Delta[\text{O}_2]/\Delta t = 0.43 \text{ mol/s}; \Delta[\text{H}_2\text{O}]/\Delta t = 0.85 \text{ mol/s}$$

(b)  $P_{\text{total}}$  decreases by 12 torr/min. 14.23 (a) If [A] doubles, there is no change in the rate or the rate constant. The overall rate is unchanged because [A] does not appear in the rate law; the rate constant changes only with a change in temperature.

(b) The reaction is zero order in A, second order in B, and second order overall. (c) units of  $k = \text{M}^{-1} \text{s}^{-1}$ . 14.25 (a) Rate =  $k[\text{N}_2\text{O}_5]$  (b) Rate =  $1.16 \times 10^{-4} \text{ M/s}$  (c) When the concentration of  $\text{N}_2\text{O}_5$  doubles, the rate of the reaction doubles.

14.27 (a, b)  $k = 1.7 \times 10^2 \text{ M}^{-1} \text{s}^{-1}$  (c) If  $[\text{OH}^-]$  is tripled, the rate triples. 14.29 (a) Rate =  $k[\text{OCl}^-][\text{I}^-]$  (b)  $k = 60 \text{ M}^{-1} \text{s}^{-1}$

(c) Rate =  $6.0 \times 10^{-5} \text{ M/s}$  14.31 (a) Rate =  $k[\text{BF}_3][\text{NH}_3]$

(b) The reaction is second order overall. (c)  $k_{\text{avg}} = 3.41 \text{ M}^{-1} \text{s}^{-1}$

(d) 0.170 M/s 14.33 (a) Rate =  $k[\text{NO}]^2[\text{Br}_2]$

(b)  $k_{\text{avg}} = 1.2 \times 10^4 \text{ M}^{-2} \text{s}^{-1}$  (c)  $\frac{1}{2}\Delta[\text{NOBr}]/\Delta t = -\Delta[\text{Br}_2]/\Delta t$

(d)  $-\Delta[\text{Br}_2]/\Delta t = 8.4 \text{ M/s}$  14.35 (a)  $[\text{A}]_0$  is the molar concentration of reactant A at time 0.  $[\text{A}]_t$  is the molar concentration of reactant A at time  $t$ .  $t_{1/2}$  is the time required to reduce  $[\text{A}]_0$  by a factor of 2.  $k$  is the rate constant for a particular reaction. (b) A graph of  $\ln[\text{A}]$  versus time yields a straight line for a first-order reaction. 14.37 (a)  $k = 3.0 \times 10^{-6} \text{ s}^{-1}$  (b)  $t_{1/2} = 3.2 \times 10^4 \text{ s}$

14.39 (a)  $P = 20 \text{ torr}$  (b)  $t = 51 \text{ s}$  14.41 Plot  $\ln P_{\text{SO}_2\text{Cl}_2}$  versus time,  $k = -\text{slope} = 2.19 \times 10^{-5} \text{ s}^{-1}$  14.43 (a) The plot of  $1/[\text{A}]$  versus time is linear, so the reaction is second order in [A]. (b)  $k = 0.040 \text{ M}^{-1} \text{min}^{-1}$  (c)  $t_{1/2} = 38 \text{ min}$  14.45 (a) The plot of  $1/[\text{NO}_2]$  versus time is linear, so the reaction is second order in  $\text{NO}_2$ . (b)  $k = \text{slope} = 10 \text{ M}^{-1} \text{s}^{-1}$  14.47 (a) The energy of the collision and the orientation of the molecules when they collide determine whether a reaction will occur. (b) At a higher temperature, there are more total collisions and each collision is more energetic. 14.49  $f = 4.94 \times 10^{-2}$ . At 400 K approximately 1 out of 20 molecules has this kinetic energy.

## 14.51 (a)

(b)  $E_a$  (reverse) = 73 kJ. 14.53 Reaction (b) is fastest and reaction (c) is slowest. 14.55 (a)  $k = 1.1 \text{ s}^{-1}$  (b)  $k = 13 \text{ s}^{-1}$

14.57 A plot of  $\ln k$  versus  $1/T$  has a slope of  $-5.71 \times 10^3$ ;

$E_a = -R(\text{slope}) = 47.5 \text{ kJ/mol}$ . 14.59 The reaction will occur 88 times faster at 50 °C, assuming equal initial concentrations.

14.61 (a) An elementary reaction is a process that occurs in a single event; the order is given by the coefficients in the balanced equation for the reaction. (b) A unimolecular elementary reaction involves only one reactant molecule; a bimolecular elementary reaction involves two reactant molecules. (c) A reaction mechanism is a series of elementary reactions that describe how an overall reaction occurs and explain the experimentally determined rate law. 14.63 (a) Unimolecular, rate =  $k[\text{Cl}_2]$  (b) bimolecular, rate =  $k[\text{OCl}^-][\text{H}_2\text{O}]$  (c) bimolecular, rate =  $k[\text{NO}][\text{Cl}_2]$  14.65 (a) Two intermediates, B and C. (b) three transition states (c)  $\text{C} \rightarrow \text{D}$  is fastest. (d) endothermic

14.67 (a)  $\text{H}_2(\text{g}) + 2\text{ICl}(\text{g}) \rightarrow \text{I}_2(\text{g}) + 2\text{HCl}(\text{g})$  HI is the intermediate. (c) first step: rate =  $k_1[\text{H}_2][\text{ICl}]$ , second step: rate =  $k_2[\text{HI}][\text{ICl}]$  (d) If the first step is slow, the observed rate law is rate =  $k[\text{H}_2][\text{ICl}]$  14.69 (a) Rate =  $k[\text{NO}][\text{Cl}_2]$  (b) The second step must be slow relative to the first step. 14.71 (a) A catalyst increases the rate of reaction by decreasing the activation energy,  $E_a$ , or increasing the frequency factor, A. (b) A homogeneous catalyst is in the same phase as the reactants, while a heterogeneous catalyst is in a different phase. 14.73 (a) Multiply the coefficients in the first reaction by 2 and sum.

(b)  $\text{NO}_2(\text{g})$  is a catalyst because it is consumed and then reproduced in the reaction sequence. (c) This is a homogeneous catalysis. 14.75 (a) Use of chemically stable supports makes it possible to obtain very large surface areas per unit mass of the precious metal catalyst because the metal can be deposited in a very thin, even monomolecular, layer on the surface of the support. (b) The greater the surface area of the catalyst, the more reaction sites, the greater the rate of the catalyzed reaction. 14.77 To put two D atoms on a single carbon, it is necessary that one of the already existing C—H bonds in ethylene be broken while the molecule is adsorbed, so that the H atom moves off as an adsorbed atom and is replaced by a D atom. This requires a larger activation energy than simply adsorbing  $\text{C}_2\text{H}_4$  and adding one D atom to each carbon. 14.79 (a) Living organisms operate efficiently in a very narrow temperature range; the role of enzymes as homogeneous catalysts that speed up desirable reactions, without heating and undesirable side effects, is crucial for biological systems. (b) catalase:  $2\text{H}_2\text{O}_2 \rightarrow 2\text{H}_2\text{O} + \text{O}_2$ ; nitrogenase:  $\text{N}_2 \rightarrow 2\text{NH}_3$  (nitrogen fixation) 14.81 (a) The catalyzed reaction is approximately 10,000,000 times faster at 25 °C. (b) The catalyzed reaction is 180,000 times faster at 125 °C. 14.83 A balanced equation shows the overall, net change of a chemical reaction. Most reactions occur as a series of steps. The rate law contains only those reactants that form the activated complex (transition state) of the rate-determining step. If a reaction occurs in a single elementary step, the rate law can be written directly from the balanced equation for the step. 14.86 (a) Rate =  $k[\text{HgCl}_2][\text{C}_2\text{O}_4^{2-}]^2$  (b)  $k = 8.7 \times 10^{-3} \text{ M}^{-2} \text{s}^{-1}$

(c) rate =  $5.4 \times 10^{-5}$  M/s **14.89** (a)  $t_{1/2} = 9.9 \times 10^2$  s  
 (b)  $k = 2.05 \times 10^{-4}$  s $^{-1}$  **14.92** (a)  $1.08 \times 10^{-4}$  M  
 (b)  $k = 4.91 \times 10^{-4}$  s $^{-1}$  (c)  $t_{1/2} = 1.41 \times 10^3$  s = 23.5 min  
 (d)  $t = 3.67 \times 10^3$  s = 61.1 min **14.95** A plot of  $\ln k$  versus  $1/T$  is linear with slope =  $-1.751 \times 10^4$ ,  $E_a = -(\text{slope})R = 1.5 \times 10^2$  kJ/mol. **14.99** (a)  $\text{Cl}_2(\text{g}) + \text{CHCl}_3(\text{g}) \longrightarrow \text{HCl}(\text{g}) + \text{CCl}_4(\text{g})$  (b)  $\text{Cl}(\text{g})$ ,  $\text{CCl}_3(\text{g})$  (c) reaction 1, unimolecular; reaction 2, bimolecular; reaction 3, bimolecular (d) Reaction 2, the slow step, is rate determining. (e) Rate =  $k[\text{CHCl}_3][\text{Cl}_2]^{1/2}$   
**14.101** Enzyme: carbonic anhydrase; substrate: carbonic acid ( $\text{H}_2\text{CO}_3$ ); turnover number:  $1 \times 10^7$  molecules/s. **14.104** partial pressure of  $\text{O}_2 = 0.402$  atm **14.106** (a) Use an open-end manometer, a clock, a ruler, and a constant-temperature bath. Load the flask with  $\text{HCl}(\text{aq})$ , and read the height of the Hg in both arms of the manometer. Quickly add  $\text{Zn}(\text{s})$  to the flask, and record time = 0 when the  $\text{Zn}(\text{s})$  contacts the acid. Record the height of the Hg in one arm of the manometer at convenient time intervals such as 5 s. Calculate the pressure of  $\text{H}_2(\text{g})$  at each time. Since  $P = (n/V)RT$ ,  $\Delta P/\Delta t$  at constant temperature is an acceptable measure of reaction rate. (b) Keep the amount of  $\text{Zn}(\text{s})$  constant, and vary the concentration of  $\text{HCl}(\text{aq})$  to determine the reaction order for  $\text{H}^+$  and  $\text{Cl}^-$ . Keep the concentration of  $\text{HCl}(\text{aq})$  constant, and vary the amount of  $\text{Zn}(\text{s})$  to determine the order for  $\text{Zn}(\text{s})$ . Combine this information to write the rate law. (c)  $-\Delta[\text{H}^+]/\Delta t = 2\Delta[\text{H}_2]/\Delta t$ ; the rate of disappearance of  $\text{H}^+$  is twice the rate of appearance of  $\text{H}_2(\text{g})$ .  $[\text{H}_2] = P/RT$  (d) By changing the temperature of the constant-temperature bath, measure the rate data at several temperatures and calculate the rate constant  $k$  at these temperatures. Plot  $\ln k$  versus  $1/T$ ; the slope of the line is  $-E_a/R$ . (e) Measure rate data at constant temperature,  $\text{HCl}$  concentration, and mass of  $\text{Zn}(\text{s})$ , varying only the form of the  $\text{Zn}(\text{s})$ . Compare the rate of reaction for metal strips and granules. **14.109** Changes in temperature change the kinetic energy of the various groups on the enzyme and their tendency to form intermolecular associations or break free from them. At temperatures above the temperature of maximum activity, sufficient kinetic energy has been imparted so that the three-dimensional structure of the enzyme is destroyed. This is the process of denaturation. In the lock-and-key model of enzyme action, the active site is the specific location in the enzyme where the reaction takes place. The precise geometry of the active site both accommodates and activates the substrate. When an enzyme is denatured, its activity is destroyed because the active site has collapsed.

## Chapter 15

**15.1**  $k_f > k_r$  (b) The equilibrium constant is greater than 1.  
**15.4** (a)  $\text{A}_2 + \text{B} \longrightarrow \text{A}_2\text{B}$  (b)  $K_c = [\text{A}_2\text{B}]/[\text{A}_2][\text{B}]$  (c)  $\Delta n = -1$  (d)  $K_p = K_c(RT)^{\Delta n}$  **15.6** (a) Mixture (ii) is at equilibrium.  
 (b) Mixture (i) proceeds toward reactants; mixture (iii) proceeds toward products. **15.9**  $K_c$  decreases as  $T$  increases, so the reaction is exothermic. **15.11** (a)  $K_p = K_c = 2.8 \times 10^{-2}$   
 (b) Since  $k_f < k_r$ , in order for the two rates to be equal,  $[\text{A}]$  must be greater than  $[\text{B}]$ , and the partial pressure of A is greater than the partial pressure of B. **15.13** (a)  $K_c = [\text{N}_2\text{O}][\text{NO}_2]/[\text{NO}]^2$ ; homogeneous (b)  $K_c = [\text{CS}_2][\text{H}_2]^4/[\text{CH}_4][\text{H}_2\text{S}]^2$ ; homogeneous (c)  $K_c = [\text{CO}]^4/[\text{Ni}(\text{CO})_4]$ ; heterogeneous (d)  $K_c = [\text{H}^+][\text{F}^-]/[\text{HF}]$ ; homogeneous (e)  $K_c = [\text{Ag}^+]^2/[\text{Zn}^{2+}]$ ; heterogeneous **15.15** (a) Mostly reactants (b) mostly products  
**15.17**  $K_p = 1.0 \times 10^{-3}$  **15.19** (a)  $K_c = 1.3 \times 10^{-3}$  (b) The equilibrium favors NO and  $\text{Br}_2$  at this temperature. **15.21** (a)  $K_p = 0.541$  (b)  $K_p = 3.42$  (c)  $K_c = 128$  **15.23**  $K_c = 0.14$   
**15.25** (a)  $K_p = P_{\text{O}_2}$  (b) The molar concentration, the ratio of moles of a substance to volume occupied by the substance, is a constant for pure solids and liquids. **15.27**  $K_c = 0.0204$   
**15.29**  $K_p = 51$  **15.31** (a)  $[\text{H}_2] = 0.012$  M,  $[\text{N}_2] = 0.019$  M,  $[\text{H}_2\text{O}] = 0.138$  M (b)  $K_c = 653.7 = 7 \times 10^2$  **15.33** (a)  $P_{\text{CO}_2} = 4.10$  atm,  $P_{\text{H}_2} = 2.05$  atm,  $P_{\text{H}_2\text{O}} = 3.28$  atm

(b)  $P_{\text{CO}_2} = 3.87$  atm,  $P_{\text{H}_2} = 1.82$  atm,  $P_{\text{H}_2\text{O}} = 3.51$  atm  
 (c)  $K_p = 0.11$  **15.35** (a) A reaction quotient is the result of a general set of concentrations whereas the equilibrium constant requires equilibrium concentrations. (b) to the right (c) The concentrations used to calculate  $Q$  must be equilibrium concentrations. **15.37** (a)  $Q = 1.1 \times 10^{-8}$ , the reaction will proceed to the left. (b)  $Q = 5.5 \times 10^{-12}$ , the reaction will proceed to the right. (c)  $Q = 2.2 \times 10^{-10}$ , the mixture is at equilibrium.  
**15.39**  $P_{\text{Cl}_2} = 4.96$  atm **15.41** (a)  $[\text{Br}_2] = 0.00767$  M,  $[\text{Br}] = 0.00282$  M,  $0.0451$  g  $\text{Br}(\text{g})$  (b)  $[\text{H}_2] = 0.014$  M,  $[\text{I}_2] = 0.00859$  M,  $[\text{HI}] = 0.081$  M, 21 g HI  
**15.43**  $[\text{NO}] = 0.002$  M,  $[\text{N}_2] = [\text{O}_2] = 0.099$  M **15.45** The equilibrium pressure of  $\text{Br}_2(\text{g})$  is  $0.416$  atm. **15.47** (a)  $[\text{Ca}^{2+}] = [\text{SO}_4^{2-}] = 4.9 \times 10^{-3}$  M (b) A bit more than 2.0 g  $\text{CaSO}_4$  is needed in order to have some undissolved  $\text{CaSO}_4(\text{s})$  in equilibrium with 3.0 L of saturated solution.  
**15.49**  $[\text{Br}] = 0.447$  M,  $[\text{I}_2] = [\text{Br}_2] = 0.0267$  M **15.51** (a) Shift equilibrium to the right (b) decrease the value of  $K$  (c) shift equilibrium to the left (d) no effect (e) no effect (f) shift equilibrium to the right **15.53** (a) No effect (b) no effect (c) increase equilibrium constant (d) no effect **15.55** (a)  $\Delta H^\circ = -155.7$  kJ (b) The reaction is exothermic, so the equilibrium constant will decrease with increasing temperature. (c)  $\Delta n$  does not equal zero, so a change in volume at constant temperature will affect the fraction of products in the equilibrium mixture. **15.57** (a)  $K_c = K_p = 1.5 \times 10^{-39}$  (b) Reactants are much more plentiful than products at equilibrium. **15.60**  $K_c = 0.71$  **15.63** (a)  $P_t = 1.14$  atm (b)  $K_p = 1.7$  **15.66** (a)  $K_c = 7.0 \times 10^{-5}$   
 (b)  $[\text{PH}_3] = 2.5 \times 10^{-3}$  M **15.69** (a)  $Q = 1.7$ ;  $Q > K_p$ ; the reaction will shift to the left (b)  $Q = 1.7$ ;  $Q > K_p$ ; the reaction will shift to the left. (c)  $Q = 5.8 \times 10^{-3}$ ;  $Q < K_p$ ; the reaction will shift to the right. **15.73** The maximum value of  $Q$  is 4.1, which is less than  $K_p$ ; reduction will occur. **15.76**  $P_{\text{H}_2} = P_{\text{I}_2} = 1.48$  atm;  $P_{\text{HI}} = 10.22$  atm **15.79** The patent claim is false. A catalyst does not alter the position of equilibrium in a system, only the rate of approach to the equilibrium condition.  
**15.80** At equilibrium,  $[\text{H}_6\text{IO}_4^-] = 0.0024$  M **15.83** (a) At equilibrium, the forward and reverse reactions occur at equal rates. (b) Reactants are favored at equilibrium. (c) A catalyst lowers the activation energy for both the forward and reverse reactions. (d) The ratio of the rate constants remains unchanged. (e) The value of  $K$  will increase with increasing temperature. **15.86** At  $850^\circ\text{C}$ ,  $K_p = 14.1$ ; at  $950^\circ\text{C}$ ,  $K_p = 73.8$ ; at  $1050^\circ\text{C}$ ,  $K_p = 2.7 \times 10^2$ ; at  $1200^\circ\text{C}$ ,  $K_p = 1.7 \times 10^3$ . Because  $K$  increases with increasing temperature, the reaction is endothermic.

## Chapter 16

**16.1** (a) HX, the  $\text{H}^+$  donor, is the Brønsted-Lowry acid.  $\text{NH}_3$ , the  $\text{H}^+$  acceptor, is the Brønsted-Lowry base. (b) HX, the electron pair acceptor, is the Lewis acid.  $\text{NH}_3$ , the electron pair donor, is the Lewis base. **16.3** (a) HY is a strong acid. There are no neutral HY molecules in solution, only  $\text{H}^+$  cations and  $\text{Y}^-$  anions. (b) HX has the smallest  $K_a$  value. It has most neutral acid molecules and fewest ions. (c) HX has fewest  $\text{H}^+$  and highest pH. **16.6** (a) The order of base strength is the reverse of the order of acid strength; the diagram of the acid with the most free  $\text{H}^+$  has the weakest conjugate base  $\text{Y}^-$ . The order of increasing basicity is:  $\text{Y}^- < \text{Z}^- < \text{X}^-$ . (b) The strongest base,  $\text{X}^-$ , has the largest  $K_b$  value. **16.9** (a) Both molecules are oxyacids; the ionizable H atom is attached to O. The right molecule is a carboxylic acid; the ionizable H is part of a carboxyl group. (b) Increasing the electronegativity of X increases the strength of both acids. As X becomes more electronegative and attracts more electron density, the O—H bond becomes weaker, more polar, and more likely to be ionized. An electronegative X group also stabilizes the anionic conjugate base, causing

the ionization equilibrium to favor products and the value of  $K_a$  to increase. **16.13** Solutions of HCl and  $H_2SO_4$  conduct electricity, taste sour, turn litmus paper red (are acidic), neutralize solutions of bases, and react with active metals to form  $H_2(g)$ . HCl and  $H_2SO_4$  solutions have these properties in common because both compounds are strong acids. That is, they both ionize completely in  $H_2O$  to form  $H^+(aq)$  and an anion. ( $HSO_4^-$  is not completely ionized, but the first ionization step for  $H_2SO_4$  is complete.) The presence of ions enables the solutions to conduct electricity; the presence of  $H^+(aq)$  in excess of  $1 \times 10^{-7} M$  accounts for all other properties listed. **16.15** (a) The Arrhenius definition of an acid is confined to aqueous solution; the Brønsted-Lowry definition applies to any physical state. (b) HCl is the Brønsted-Lowry acid;  $NH_3$  is the Brønsted-Lowry base. **16.17** (a) (i)  $IO_3^-$  (ii)  $NH_3$  (b) (i)  $OH^-$  (ii)  $H_3PO_4$

16.19

Acid	+	Base	$\rightleftharpoons$	Conjugate Acid	+	Conjugate Base
(a) $NH_4^+(aq)$		$CN^-(aq)$		$HCN(aq)$		$NH_3(aq)$
(b) $H_2O(l)$		$(CH_3)_3N(aq)$		$(CH_3)_3NH^+(aq)$		$OH^-(aq)$
(c) $HCOOH(aq)$		$PO_4^{3-}(aq)$		$HPO_4^{2-}(aq)$		$HCOO^-(aq)$

16.21 (a)

Acid:  $HC_2O_4^-(aq) + H_2O(l) \rightleftharpoons C_2O_4^{2-}(aq) + H_3O^+(aq)$ ;  
 Base:  $HC_2O_4^-(aq) + H_2O(l) \rightleftharpoons H_2C_2O_4(aq) + OH^-(aq)$   
 (b)  $H_2C_2O_4$  is the conjugate acid of  $HC_2O_4^-$ .  $C_2O_4^{2-}$  is the conjugate base of  $HC_2O_4^-$ . **16.23** (a)  $CH_3COO^-$ , weak base;  $CH_3COOH$ , weak acid (b)  $HCO_3^-$ , weak base;  $H_2CO_3$ , weak acid (c)  $O_2^{2-}$ , strong base;  $OH^-$ , strong base (d)  $Cl^-$ , negligible base; HCl, strong acid (e)  $NH_3$ , weak base;  $NH_4^+$ , weak acid **16.25** (a) HBr. It is one of the seven strong acids. (b)  $F^-$ . HCl is a stronger acid than HF, so  $F^-$  is the stronger conjugate base. **16.27** (a)  $OH^-(aq) + OH^-(aq)$ , the equilibrium lies to the right. (b)  $H_2S(aq) + CH_3COO^-(aq)$ , the equilibrium lies to the right. (c)  $HNO_3(aq) + OH^-(aq)$ , the equilibrium lies to the left. **16.29** (a) Autoionization is the ionization of a neutral molecule into an anion and a cation. The equilibrium expression for the autoionization of water is  $H_2O(l) \rightleftharpoons H^+(aq) + OH^-(aq)$ . (b) Pure water is a poor conductor of electricity because it contains very few ions. (c) If a solution is acidic, it contains more  $H^+$  than  $OH^-$ . **16.31** (a)  $[H^+] = 2.2 \times 10^{-11} M$ , basic (b)  $[H^+] = 1.1 \times 10^{-6} M$ , acidic (c)  $[H^+] = 1.0 \times 10^{-8} M$ , basic **16.33**  $[H^+] = [OH^-] = 3.5 \times 10^{-8} M$  **16.35** (a)  $[H^+]$  changes by a factor of 100. (b)  $[H^+]$  changes by a factor of 3.2 **16.37** (a)  $[H^+]$  decreases, pH increases (b) The pH is between 3 and 4. By calculation, pH = 3.2; the solution is acidic. (c) pH = 5.2 is between pH 5 and pH 6, closer to pH = 5. A good estimate is  $7 \times 10^{-6} M H^+$  and  $3 \times 10^{-9} M OH^-$ . By calculation,  $[H^+] = 6 \times 10^{-6} M$  and  $[OH^-] = 2 \times 10^{-9} M$ . **16.39**

$[H^+]$	$[OH^-]$	pH	pOH	Acidic or Basic
$7.5 \times 10^{-3} M$	$1.3 \times 10^{-12} M$	2.12	11.88	acidic
$2.8 \times 10^{-5} M$	$3.6 \times 10^{-10} M$	4.56	9.44	acidic
$5.6 \times 10^{-9} M$	$1.8 \times 10^{-6} M$	8.25	5.75	basic
$5.0 \times 10^{-9} M$	$2.0 \times 10^{-6} M$	8.30	5.70	basic

**16.41**  $[H^+] = 4.0 \times 10^{-8} M$ ,  $[OH^-] = 6.0 \times 10^{-7} M$ , pOH = 6.22 **16.43** (a) A strong acid is completely ionized in aqueous solution. (b)  $[H^+] = 0.500 M$  (c) HCl, HBr, HI **16.45** (a)  $[H^+] = 8.5 \times 10^{-3} M$ , pH = 2.07 (b)  $[H^+] = 0.0419 M$ , pH = 1.377 (c)  $[H^+] = 0.0250 M$ , pH = 1.602 (d)  $[H^+] = 0.167 M$ , pH = 0.778

**16.47** (a)  $[OH^-] = 3.0 \times 10^{-3} M$ , pH = 11.48 (b)  $[OH^-] = 0.3758 M$ , pH = 13.5750 (c)  $[OH^-] = 8.75 \times 10^{-5} M$ , pH = 9.942 (d)  $[OH^-] = 0.17 M$ , pH = 13.23 **16.49**  $3.2 \times 10^{-3} M NaOH$  **16.51** (a)  $HBrO_2(aq) \rightleftharpoons H^+(aq) + BrO_2^-(aq)$ ,  $K_a = [H^+][BrO_2^-]/[HBrO_2]$ ;  $HBrO_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + BrO_2^-(aq)$ ,  $K_a = [H_3O^+][BrO_2^-]/[HBrO_2]$  (b)  $C_2H_5COOH(aq) \rightleftharpoons H^+ + C_2H_5COO^-(aq)$ ,  $K_a = [H^+][C_2H_5COO^-]/[C_2H_5COOH]$ ;  $C_2H_5COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+ + C_2H_5COO^-(aq)$ ,  $K_a = [H_3O^+][C_2H_5COO^-]/[C_2H_5COOH]$  **16.53**  $K_a = 1.4 \times 10^{-4}$  **16.55**  $[H^+] = [ClCH_2COO^-] = 0.0110 M$ ,  $[ClCH_2COOH] = 0.089 M$ ,  $K_a = 1.4 \times 10^{-3}$  **16.57**  $0.089 M CH_3COOH$  **16.59**  $[H^+] = [C_6H_5COO^-] = 1.8 \times 10^{-3} M$ ,  $[C_6H_5COOH] = 0.048 M$  **16.61** (a)  $[H^+] = 1.1 \times 10^{-3} M$ , pH = 2.95 (b)  $[H^+] = 1.7 \times 10^{-4} M$ , pH = 3.76 (c)  $[OH^-] = 1.4 \times 10^{-5} M$ , pH = 9.15 **16.63**  $[H^+] = 2.0 \times 10^{-2} M$ , pH = 1.71 **16.65** (a)  $[H^+] = 2.8 \times 10^{-3} M$ , 0.69% ionization (b)  $[H^+] = 1.4 \times 10^{-3} M$ , 1.4% ionization (c)  $[H^+] = 8.7 \times 10^{-4} M$ , 2.2% ionization **16.67**  $HX(aq) \rightleftharpoons H^+(aq) + X^-(aq)$ ;  $K_a = [H^+][X^-]/[HX]$ . Assume that the percent of acid that ionizes is small. Let  $[H^+] = [X^-] = y$ ,  $K_a = y^2/[HX]$ ;  $y = K_a^{1/2}[HX]^{1/2}$ . Percent ionization =  $y/[HX] \times 100$ . Substituting for  $y$ , percent ionization =  $100 K_a^{1/2}[HX]^{1/2}/[HX]$  or  $100 K_a^{1/2}/[HX]^{1/2}$ . That is, percent ionization varies inversely as the square root of the concentration of HX. **16.69**  $[H^+] = 5.72 \times 10^{-3} M$ , pH = 2.24,  $[C_6H_5O_7^{3-}] = 1.2 \times 10^{-9} M$ . The approximation that the first ionization is less than 5% of the total acid concentration is not valid; the quadratic equation must be solved. The  $[H^+]$  produced from the second and third ionizations is small with respect to that present from the first step; the second and third ionizations can be neglected when calculating the  $[H^+]$  and pH. **16.71** All Brønsted-Lowry bases contain at least one unshared (lone) pair of electrons to attract  $H^+$ . **16.73** (a)  $(CH_3)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3)_2NH_2^+(aq) + OH^-(aq)$ ;  $K_b = [(CH_3)_2NH_2^+][OH^-]/[(CH_3)_2NH]$  (b)  $CO_3^{2-}(aq) + H_2O(l) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$ ;  $K_b = [HCO_3^-][OH^-]/[CO_3^{2-}]$  (c)  $HCOO^-(aq) + H_2O(l) \rightleftharpoons HCOOH(aq) + OH^-(aq)$   $K_b = [HCOOH][OH^-]/[HCOO^-]$  **16.75** From the quadratic formula,  $[OH^-] = 6.6 \times 10^{-3} M$ , pH = 11.82. **16.77** (a)  $[C_{10}H_{15}ON] = 0.033 M$ ,  $[C_{10}H_{15}ONH^+] = [OH^-] = 2.1 \times 10^{-3} M$  (b)  $K_b = 1.4 \times 10^{-4}$  **16.79** (a) For a conjugate acid/conjugate base pair such as  $C_6H_5OH/C_6H_5O^-$ ,  $K_b$  for the conjugate base can always be calculated from  $K_a$  for the conjugate acid, so a separate list of  $K_b$  values is not necessary. (b)  $K_b = 7.7 \times 10^{-5}$  (c) Phenolate is a stronger base than  $NH_3$ . **16.81** (a) Acetic acid is stronger. (b) Hypochlorite ion is the stronger base. **16.83** (a)  $[OH^-] = 1.4 \times 10^{-3} M$ , pH = 11.15 (b)  $[OH^-] = 3.8 \times 10^{-3} M$ , pH = 11.58 (c)  $[OH^-] = 3.3 \times 10^{-6} M$ , pH = 8.52 **16.85** (a) Acidic (b) acidic (c) basic (d) neutral (e) acidic **16.87**  $K_b$  for the anion of the unknown salt is  $1.4 \times 10^{-11}$ ;  $K_a$  for the conjugate acid is  $7.1 \times 10^{-4}$ . The conjugate acid is HF and the salt is NaF. **16.89**  $[OH^-] = 5.0 \times 10^{-6} M$ , pH = 8.70 **16.91** (a) As the electronegativity of the central atom (X) increases, the strength of the oxyacid increases. (b) As the number of nonprotonated oxygen atoms in the molecule increases, the strength of the oxyacid increases. **16.93** (a)  $HNO_3$  is a stronger acid because it has one more nonprotonated oxygen atom and thus a higher oxidation number on N. (b) For binary hydrides, acid strength increases going down a family, so  $H_2S$  is a stronger acid than  $H_2O$ . (c)  $H_2SO_4$  is a stronger acid because  $H^+$  is much more tightly held by the anion  $HSO_4^-$ . (d) For oxyacids, the greater the electronegativity of the central atom, the stronger the acid, so  $H_2SO_4$  is the stronger acid. (e)  $CCl_3COOH$  is stronger because the electronegative Cl atoms withdraw electron density from other parts of the molecule, which weakens the O—H bond and stabilizes the anionic conjugate base. Both effects favor increased ionization and acid strength. **16.95** (a)  $BrO^-$  (b)  $BrO^-$  (c)  $HPO_4^{2-}$  **16.97** (a) True (b) False. In a series of

acids that have the same central atom, acid strength increases with the number of nonprotonated oxygen atoms bonded to the central atom. (c) False.  $\text{H}_2\text{Te}$  is a stronger acid than  $\text{H}_2\text{S}$  because the  $\text{H}-\text{Te}$  bond is longer, weaker, and more easily ionized than the  $\text{H}-\text{S}$  bond. 16.99 Yes. The Arrhenius definition of a base, an  $\text{OH}^-$  donor, is most restrictive; the Brønsted definition, an  $\text{H}^+$  acceptor, is more general; and the Lewis definition, an electron-pair donor, is most general. Any substance that fits the narrow Arrhenius definition will fit the broader Brønsted and Lewis definitions. 16.101 (a) Acid,  $\text{Fe}(\text{ClO}_4)_3$  or  $\text{Fe}^{3+}$ ; base,  $\text{H}_2\text{O}$  (b) Acid,  $\text{H}_2\text{O}_2$ ; base,  $\text{CN}^-$  (c) Acid,  $\text{BF}_3$ ; base,  $(\text{CH}_3)_3\text{N}$  (d) Acid,  $\text{HIO}_3$ ; base,  $\text{NH}_2^-$  16.103 (a)  $\text{Cu}^{2+}$ , higher cation charge (b)  $\text{Fe}^{3+}$ , higher cation charge (c)  $\text{Al}^{3+}$ , smaller cation radius, same charge 16.105 (a)  $K_w$  is the equilibrium constant for the reaction of two water molecules to form hydronium ion and hydroxide ion. (b)  $K_a$  is the equilibrium constant for the reaction of any acid, neutral or ionic, with water to form hydronium ion and the conjugate base of the acid. (c)  $\text{pOH}$  is the negative log of hydroxide ion concentration;  $\text{pOH}$  decreases as hydroxide ion concentration increases. (d)  $\text{p}K_b$  is the negative log of  $K_b$ ;  $\text{p}K_b$  increases as base strength decreases. 16.108  $K = 3.3 \times 10^7$  16.111 (a) For solutions with equal concentrations, the weaker acid will have a lower  $[\text{H}^+]$  and higher pH. (b) The acid with  $K_a = 8 \times 10^{-5}$  is the weaker acid, so it has the higher pH. (c) The base with  $\text{p}K_b = 4.5$  is the stronger base, has the greater  $[\text{OH}^-]$  and smaller  $[\text{H}^+]$ , so higher pH. 16.113  $K_a = 1.4 \times 10^{-5}$  16.117  $[\text{H}^+] = 0.010 \text{ M}$ ,  $[\text{H}_2\text{PO}_4^-] = 0.010 \text{ M}$ ,  $[\text{HPO}_4^{2-}] = 6.2 \times 10^{-8} \text{ M}$ ,  $[\text{PO}_4^{3-}] = 2.6 \times 10^{-18} \text{ M}$  16.121  $6.0 \times 10^{13} \text{ H}^+$  ions 16.124 (a) To the precision of the reported data, the pH of rainwater 40 years ago was 5.4, no different from the pH today. With extra significant figures,  $[\text{H}^+] = 3.61 \times 10^{-6} \text{ M}$ ,  $\text{pH} = 5.443$  (b) A 20.0-L bucket of today's rainwater contains 0.02 L (with extra significant figures, 0.0200 L) of dissolved  $\text{CO}_2$ . 16.127 [cocaine] =  $2.93 \times 10^{-3} \text{ M}$ ,  $[\text{OH}^-] = 3.4 \times 10^{-6} \text{ M}$ ,  $K_b = 3.9 \times 10^{-9}$  16.129 (a)  $K(i) = 5.6 \times 10^3$ ,  $K(ii) = 10$  (b) Both (i) and (ii) have  $K > 1$ , so both could be written with a single arrow.

## Chapter 17

17.1 The middle box has the highest pH. For equal amounts of acid  $\text{HX}$ , the greater the amount of conjugate base  $\text{X}^-$ , the smaller the amount of  $\text{H}^+$  and the higher the pH. 17.4 (a) Drawing 3 (b) Drawing 1 (c) Drawing 2 17.7 (a) The red curve corresponds to the more concentrated acid solution. (b) On the titration curve of a weak acid,  $\text{pH} = \text{p}K_a$  at the volume half-way to the equivalence point. At this volume, the red curve has the smaller  $\text{p}K_a$  and the larger  $K_a$ . 17.10 (a) The right diagram (b) the left diagram (c) the center diagram 17.13 (a) The extent of ionization of a weak electrolyte is decreased when a strong electrolyte containing an ion in common with the weak electrolyte is added to it (b)  $\text{NaNO}_2$  17.15 (a)  $[\text{H}^+] = 1.8 \times 10^{-5} \text{ M}$ ,  $\text{pH} = 4.73$  (b)  $[\text{OH}^-] = 4.8 \times 10^{-5} \text{ M}$ ,  $\text{pH} = 9.68$  (c)  $[\text{H}^+] = 1.4 \times 10^{-5} \text{ M}$ ,  $\text{pH} = 4.87$  17.17 (a) 4.5% ionization (b) 0.018% ionization 17.19 In a mixture of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COONa}$ ,  $\text{CH}_3\text{COOH}$  reacts with added base and  $\text{CH}_3\text{COO}^-$  combines with added acid, leaving  $[\text{H}^+]$  relatively unchanged. Although  $\text{HCl}$  and  $\text{Cl}^-$  are a conjugate acid-base pair,  $\text{Cl}^-$  has no tendency to combine with added acid to form undissociated  $\text{HCl}$ . Any added acid simply increases  $[\text{H}^+]$  in an  $\text{HCl}-\text{NaCl}$  mixture. 17.21 (a)  $\text{pH} = 3.82$  (b)  $\text{pH} = 3.96$  17.23 (a)  $\text{pH} = 4.60$  (b)  $\text{Na}^+(\text{aq}) + \text{CH}_3\text{COO}^-(\text{aq}) + \text{H}^+(\text{aq}) + \text{Cl}^-(\text{aq}) \rightarrow \text{CH}_3\text{COOH}(\text{aq}) + \text{Na}^+(\text{aq}) + \text{Cl}^-(\text{aq})$  (c)  $\text{CH}_3\text{COOH}(\text{aq}) + \text{Na}^+(\text{aq}) + \text{OH}^-(\text{aq}) \rightarrow \text{CH}_3\text{COO}^-(\text{aq}) + \text{H}_2\text{O}(\text{l}) + \text{Na}^+(\text{aq})$  17.25 0.18 mol  $\text{NaBrO}$  17.27 (a)  $\text{pH} = 4.86$  (b)  $\text{pH} = 5.0$  (c)  $\text{pH} = 4.71$  17.29 (a)  $[\text{HCO}_3^-]/[\text{H}_2\text{CO}_3] = 11$  (b)  $[\text{HCO}_3^-]/[\text{H}_2\text{CO}_3] = 5.4$  17.31 360 mL of 0.10 M  $\text{HCOONa}$ , 640 mL of 0.10 M  $\text{HCOOH}$  17.33 (a) Curve B (b)  $\text{pH}$  at the approximate equivalence point of curve A = 8.0,  $\text{pH}$  at the approximate equivalence point of curve B = 7.0 (c) For equal

volumes of A and B, the concentration of acid B is greater, since it requires a larger volume of base to reach the equivalence point. 17.35 (a) Above pH 7 (b) below pH 7 (c) at pH 7 17.37 (a)  $\text{HX}$  is weaker. The higher the pH at the equivalence point, the stronger the conjugate base ( $\text{X}^-$ ) and the weaker the conjugate acid  $\text{HX}$ . (b) Phenolphthalein, which changes color in the pH 8–10 range, is perfect for  $\text{HX}$  and probably appropriate for  $\text{HY}$ . 17.39 (a) 42.4 mL  $\text{NaOH}$  soln (b) 35.0 mL  $\text{NaOH}$  soln (c) 29.8 mL  $\text{NaOH}$  soln 17.41 (a)  $\text{pH} = 1.54$  (b)  $\text{pH} = 3.30$  (c)  $\text{pH} = 7.00$  (d)  $\text{pH} = 10.69$  (e)  $\text{pH} = 12.74$  17.43 (a)  $\text{pH} = 2.78$  (b)  $\text{pH} = 4.74$  (c)  $\text{pH} = 6.58$  (d)  $\text{pH} = 8.81$  (e)  $\text{pH} = 11.03$  (f)  $\text{pH} = 12.42$  17.45 (a)  $\text{pH} = 7.00$  (b)  $[\text{HONH}_3^+] = 0.100 \text{ M}$ ,  $\text{pH} = 3.52$  (c)  $[\text{C}_6\text{H}_5\text{NH}_3^+] = 0.100 \text{ M}$ ,  $\text{pH} = 2.82$  17.47 (a) The concentration of undissolved solid does not appear in the solubility product expression because it is constant. (b)  $K_{sp} = [\text{Ag}^+][\text{I}^-]$ ;  $K_{sp} = [\text{Sr}^{2+}][\text{SO}_4^{2-}]$ ;  $K_{sp} = [\text{Fe}^{2+}][\text{OH}^-]^2$ ;  $K_{sp} = [\text{Hg}_2^{2+}][\text{Br}^-]^2$ ; 17.49 (a)  $K_{sp} = 7.63 \times 10^{-9}$  (b)  $K_{sp} = 2.7 \times 10^{-9}$  (c)  $5.3 \times 10^{-4} \text{ mol Ba}(\text{IO}_3)_2/\text{L}$  17.51  $K_{sp} = 2.3 \times 10^{-9}$  17.53 (a)  $7.1 \times 10^{-7} \text{ mol AgBr/L}$  (b)  $1.7 \times 10^{-11} \text{ mol AgBr/L}$  (c)  $5.0 \times 10^{-12} \text{ mol AgBr/L}$  17.55 (a)  $1.4 \times 10^3 \text{ g Mn}(\text{OH})_2/\text{L}$  (b) 0.014 g/L (c)  $3.6 \times 10^{-7} \text{ g/L}$  17.57 More soluble in acid: (a)  $\text{ZnCO}_3$  (b)  $\text{ZnS}$  (d)  $\text{AgCN}$  (e)  $\text{Ba}_3(\text{PO}_4)_2$  17.59  $[\text{Cu}^{2+}] = 2 \times 10^{-12} \text{ M}$  17.61  $K = K_{sp} \times K_f = 8 \times 10^4$  17.63 (a)  $Q < K_{sp}$ ; no  $\text{Ca}(\text{OH})_2$  precipitates (b)  $Q < K_{sp}$ ; no  $\text{Ag}_2\text{SO}_4$  precipitates 17.65  $\text{pH} = 11.5$  17.67  $\text{AgI}$  will precipitate first, at  $[\text{I}^-] = 4.2 \times 10^{-13} \text{ M}$ . 17.69 The first two experiments eliminate group 1 and 2 ions (Figure 17.22). The absence of insoluble carbonate precipitates in the filtrate from the third experiment rules out group 4 ions. The ions that might be in the sample are those from group 3,  $\text{Al}^{3+}$ ,  $\text{Fe}^{3+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Co}^{2+}$ , or  $\text{Mn}^{2+}$ , and from group 5,  $\text{NH}_4^+$ ,  $\text{Na}^+$ , or  $\text{K}^+$ . 17.71 (a) Make the solution acidic with 0.5 M  $\text{HCl}$ ; saturate with  $\text{H}_2\text{S}$ .  $\text{CdS}$  will precipitate;  $\text{ZnS}$  will not. (b) Add excess base;  $\text{Fe}(\text{OH})_3(\text{s})$  precipitates, but  $\text{Cr}^{3+}$  forms the soluble complex  $\text{Cr}(\text{OH})_4^-$ . (c) Add  $(\text{NH}_4)_2\text{HPO}_4$ ;  $\text{Mg}^{2+}$  precipitates as  $\text{MgNH}_4\text{PO}_4$ ;  $\text{K}^+$  remains soluble. (d) Add 6 M  $\text{HCl}$ ; precipitate  $\text{Ag}^+$  as  $\text{AgCl}(\text{s})$ ;  $\text{Mn}^{2+}$  remains soluble. 17.73 (a) Base is required to increase  $[\text{PO}_4^{3-}]$  so that the solubility product of the metal phosphates of interest is exceeded and the phosphate salts precipitate. (b)  $K_{sp}$  for the cations in group 3 is much larger, and so to exceed  $K_{sp}$ , a higher  $[\text{S}^{2-}]$  is required. (c) They should all redissolve in strongly acidic solution. 17.75  $\text{pOH} = \text{p}K_b + \log\{[\text{BH}^+]/[\text{B}]\}$  17.77 (a)  $\text{pH} = 3.025$  (b)  $\text{pH} = 2.938$  (c)  $\text{pH} = 12.862$  17.80 (a)  $\text{pH}$  of buffer A =  $\text{pH}$  of buffer B = 3.74. For buffers containing the same conjugate acid and base components, the pH is determined by the ratio of concentrations of conjugate acid and base. Buffers A and B have the same ratio of concentrations, so their pH values are equal. (b) Buffer capacity is determined by the absolute amount of buffer components available to absorb strong acid or strong base. Buffer A has the greater capacity because it contains the greater absolute concentrations of  $\text{HCOOH}$  and  $\text{HCOO}^-$ . (c) Buffer A:  $\text{pH} = 3.74$ ,  $\Delta\text{pH} = 0.00$ ; buffer B:  $\text{pH} = 3.66$ ,  $\Delta\text{pH} = -0.12$  (d) Buffer A:  $\text{pH} = 3.74$ ,  $\Delta\text{pH} = 0.00$ ; buffer B:  $\text{pH} = 2.74$ ,  $\Delta\text{pH} = -1.00$  (e) The results of parts (c) and (d) are quantitative confirmation that buffer A has a significantly greater capacity than buffer B. 17.82 (a) molar mass = 82.2 g/mol (b)  $K_a = 3.8 \times 10^{-7}$  17.85 (a)  $[\text{OH}^-] = 4.23 \times 10^{-3} \text{ M}$ ,  $\text{pH} = 11.63$  (b) It will require 40.00 mL of 0.100 M  $\text{HCl}$  to reach the first equivalence point;  $\text{HCO}_3^-$  is the predominant species at this point. (c) An additional 40.00 mL are required to form  $\text{H}_2\text{CO}_3$ , the predominant species at the second equivalence point (d)  $[\text{H}^+] = 1.2 \times 10^{-4} \text{ M}$ ,  $\text{pH} = 3.92$  17.88 1.6 L of 1.0 M  $\text{NaOH}$  17.91 (a)  $\text{CdS}$  (b)  $\text{BaCrO}_4$  (c)  $\text{NiCO}_3$  (d)  $\text{Ag}_2\text{SO}_4$  17.94 The solubility of  $\text{Mg}(\text{OH})_2$  in 0.50 M  $\text{NH}_4\text{Cl}$  is 0.057 mol/L. 17.96  $[\text{KMnO}_4] = [\text{MnO}_4^-] = 0.11 \text{ M}$  17.99  $[\text{OH}^-] = 1.7 \times 10^{-11} \text{ M}$ ,  $\text{pH}$  of the buffer = 3.22 17.102 (a)  $\text{H}^+(\text{aq}) + \text{HCOO}^-(\text{aq}) \rightarrow \text{HCOOH}(\text{aq})$  (b)  $K = 5.6 \times 10^3$  (c)  $[\text{Na}^+] = [\text{Cl}^-] = 0.075 \text{ M}$ ,

$[H^+] = [HCOO^-] = 3.7 \times 10^{-3} M$ ,  $[HCOOH] = 0.071 M$   
**17.105** At these conditions, the concentration of the anion is  $1 \times 10^{-5} M$ , the extent of ionization is 0.3%, and 99.7% of the aspirin is in the form of neutral molecules. **17.108**  $[Sr^{2+}] = [SO_4^{2-}] = 5.7 \times 10^{-4} M$ ,  $K_{sp} = 3.2 \times 10^{-7}$

### Chapter 18

**18.1** A greater volume than 22.4 L (b) The gas will occupy more volume at 85 km than at 50 km. **18.3** Ozone concentration varies with altitude because conditions favorable to ozone formation and unfavorable to its decomposition vary with altitude. Above 60 km, there are too few  $O_2$  molecules. Below 30 km, there are too few O atoms. Between 30 km and 60 km,  $O_3$  concentration varies depending on the concentrations of  $O$ ,  $O_2$  and  $M^*$ . **18.5**  $CO_2(g)$  dissolves in seawater to form  $H_2CO_3(aq)$ . Carbon is removed from the ocean as  $CaCO_3(s)$  in the form of sea shells, coral, and other carbonates. As carbon is removed, more  $CO_2(g)$  dissolves to maintain the balance of complex and interacting acid-base and precipitation equilibria. **18.7** The guiding principle of green chemistry is that processes should be designed to minimize or eliminate solvents and waste, generate nontoxic waste, be energy efficient, employ renewable starting materials, and take advantage of catalysts that enable the use of safe and common reagents. **18.9** (a) Its temperature profile (b) troposphere, 0 to 12 km; stratosphere, 12 to 50 km; mesosphere, 50 to 85 km; thermosphere, 85 to 110 km **18.11** The partial pressure of  $O_3$  is  $3.0 \times 10^{-7}$  atm ( $2.2 \times 10^{-4}$  torr). **18.13**  $8.4 \times 10^{16}$  CO molecules **18.15** 570 nm **18.17** (a) *Photodissociation* is cleavage of a bond such that two neutral species are produced. *Photoionization* is absorption of a photon with sufficient energy to eject an electron, producing an ion and the ejected electron. (b) Photoionization of  $O_2$  requires 1205 kJ/mol. Photodissociation requires only 495 kJ/mol. At lower elevations, high-energy short-wavelength solar radiation has already been absorbed. Below 90 km, the increased concentration of  $O_2$  and the availability of longer wavelength radiation cause the photodissociation process to dominate. **18.19** A hydrofluorocarbon is a compound that contains hydrogen, fluorine, and carbon; it contains hydrogen in place of chlorine. HFCs are potentially less harmful than CFCs because photodissociation does not produce Cl atoms, which catalyze the destruction of ozone. **18.21** (a) The C—F bond requires more energy for dissociation than the C—Cl bond and is not readily cleaved by the available wavelengths of UV light. (b) Chlorine is present as chlorine atoms and chlorine oxide molecules, Cl and ClO, respectively. **18.23** (a) Methane,  $CH_4$ , arises from decomposition of organic matter by certain microorganisms; it also escapes from underground gas deposits. (b)  $SO_2$  is released in volcanic gases and also is produced by bacterial action on decomposing vegetable and animal matter. (c) Nitric oxide, NO, results from oxidation of decomposing organic matter and is formed in lightning flashes. (d) CO is a possible product of some vegetable matter decay. **18.25** (a)  $H_2SO_4(aq) + CaCO_3(s) \rightarrow CaSO_4(s) + H_2O(l) + CO_2(g)$  (b) The  $CaSO_4(s)$  would be much less reactive with acidic solution, since it would require a strongly acidic solution to shift the relevant equilibrium to the right.  $CaSO_4(s) + 2H^+(aq) \rightleftharpoons Ca^{2+}(aq) + 2HSO_4^-(aq)$  **18.27** (a) Ultraviolet (b) 357 kJ/mol (c) The average C—H bond energy from Table 8.4 is 413 kJ/mol. The C—H bond energy in  $CH_2O$ , 357 kJ/mol, is less than the “average” C—H bond energy.

**18.29** Incoming and outgoing energies are in different regions of the electromagnetic spectrum.  $CO_2$  is transparent to incoming visible radiation but absorbs outgoing infrared radiation. **18.31** 0.099 M  $Na^+$  **18.33**  $4.361 \times 10^5$  g CaO **18.35** The minimum pressure required to initiate reverse osmosis is greater than 5.1 atm. **18.37** (a)  $CO_2(g)$ ,  $HCO_3^-$ ,  $H_2O(l)$ ,  $SO_4^{2-}$ ,  $NO_3^-$ ,  $HPO_4^{2-}$ ,  $H_2PO_4^-$  (b)  $CH_4(g)$ ,  $H_2S(g)$ ,  $NH_3(g)$ ,  $PH_3(g)$  **18.39** 2.5 g  $O_2$  **18.41**  $Mg^{2+}(aq) + Ca(OH)_2(s) \rightarrow Mg(OH)_2(s) + Ca^{2+}(aq)$  **18.43** 0.42 mol  $Ca(OH)_2$ , 0.18 mol  $Na_2CO_3$  **18.45**  $4 FeSO_4(aq) + O_2(aq) + 2 H_2O(l) \rightarrow 4 Fe^{3+}(aq) + 4 OH^- + 4 SO_4^{2-}(aq)$ ;  $Fe^{3+}(aq) + 3 HCO_3^-(aq) \rightarrow Fe(OH)_3(s) + 3 CO_2(g)$  **18.47** The fewer steps in a process, the less waste is generated. Processes with fewer steps require less energy at the site of the process, and for subsequent cleanup or disposal of waste. **18.49** (a)  $H_2O$  (b) It is better to prevent waste than to treat it. Produce as little nontoxic waste as possible. Chemical processes should be efficient. Raw materials should be renewable. **18.51** (a) Acid rain is rain with a larger  $[H^+]$  and a lower pH than expected. The additional  $H^+$  is produced by the dissolution of sulfur and nitrogen oxides in rain droplets to form sulfuric and nitric acid. (b) A greenhouse gas such as  $CO_2$  or  $H_2O$  absorbs infrared or “heat” radiation emitted from Earth’s surface and helps to maintain a relatively constant temperature at the surface. A significant build-up of greenhouse gases in the atmosphere could cause a corresponding increase in the average surface temperature and stimulate global climate change. (c) Photochemical smog is an unpleasant collection of atmospheric pollutants initiated by photochemical dissociation of  $NO_2$  to form NO and O atoms. The major components are NO(g),  $NO_2(g)$ , CO(g),  $O_3(g)$ , and unburned hydrocarbons from gasoline. (d) Ozone depletion is the loss of stratospheric ozone due to reactions between  $O_3$  and Cl. Insufficient stratospheric ozone allows damaging ultraviolet radiation to reach our ecosystem. **18.56** (a) Photodissociation of  $CBrF_3$  to form Br atoms requires less energy than the production of Cl atoms and should occur readily in the stratosphere. (b)  $CBrF_3(g) \xrightarrow{h\nu} CF_3(g) + Br(g)$ ;  $Br(g) + O_3(g) \rightarrow BrO(g) + O_2(g)$  **18.59** The formation of NO(g) is endothermic, so  $K$  increases with increasing temperature. The oxidation of NO(g) to  $NO_2(g)$  is exothermic, so the value of  $K$  decreases with increasing temperature. **18.61** (a)  $CH_4(g) + 2 O_2(g) \rightarrow CO_2(g) + 2 H_2O(g)$  (b)  $2 CH_4(g) + 3 O_2(g) \rightarrow 2 CO(g) + 4 H_2O(g)$  (c) 9.5 L dry air **18.63** Most of the 390 watts/ $m^2$  radiated from Earth’s surface is in the infrared region of the spectrum. Greenhouse gases absorb much of this radiation, which warms the atmosphere close to Earth’s surface and makes the planet liveable. **18.64**  $7.1 \times 10^8$   $m^2$  **18.67** Because NO has an odd electron, like Cl(g), it could act as a catalyst for decomposition of stratospheric ozone. This would lead to an increase in the amount of damaging ultraviolet radiation that reaches the troposphere. In the troposphere NO is oxidized to  $NO_2$  by  $O_2$ . On dissolving in water,  $NO_2$  disproportionates into  $NO_3^-(aq)$  and NO(g). Over time the NO in the troposphere will be converted into  $NO_3^-$ , which is in turn incorporated into soils. **18.69** (a)  $P_{NO_2} = 1.4 \times 10^{-5}$  torr (b)  $2 \times 10^{15}$   $NO_2$  molecules **18.72** (a)  $\text{H}-\ddot{\text{O}}-\text{H} \rightarrow \text{H}\cdot + \cdot\ddot{\text{O}}-\text{H}$  (b) 258 nm (c) The overall reaction is  $O_3(g) + O(g) \rightarrow 2 O_2(g)$ . OH(g) is the catalyst in the overall reaction, because it is consumed and then reproduced. **18.75** (a) The energy required is  $9.8 \times 10^3$  kJ/gal  $H_2O$ . (b) The energy cost is \$0.23/gal  $H_2O$ . (c) 18% of the total cost is energy. **18.78** (a) rate =  $k[O_3][H]$  (b)  $k_{avg} = 1.13 \times 10^{44} M^{-1} s^{-1}$  **18.81**  $2 \times 10^6$  kg  $H_2SO_4$

## Chapter 19

19.1 (a)

(b)  $\Delta H = 0$  for mixing ideal gases.  $\Delta S$  is positive, because the disorder of the system increases. (c) The process is spontaneous and therefore irreversible. (d) Since  $\Delta H = 0$ , the process does not affect the entropy of the surroundings. 19.4 (a) phase changes: 1 = melting (fusion), 2 = vaporization. (b) The larger volume and greater motional freedom of the gas phase causes  $\Delta S$  for vaporization (2) to be larger than  $\Delta S$  for fusion (1).

19.6 (a) At 250 K,  $\Delta G = 0$  and the system is at equilibrium. (b) The reaction is spontaneous at temperatures above 250 K. (c)  $\Delta H$  is the  $y$ -intercept of the graph, and is positive. (d)  $\Delta G$  decreases as  $T$  increases, so  $\Delta S$  is positive. 19.9 Spontaneous: a, b, c, d; nonspontaneous: e 19.11 (a)  $\text{NH}_4\text{NO}_3(\text{s})$  dissolves in water, as in a chemical cold pack. Naphthalene (moth balls) sublimates at room temperature. (b) Melting of a solid is spontaneous above its melting point but nonspontaneous below its melting point. 19.13 (a) Endothermic (b) at or above 100 °C (c) below 100 °C (d) at 100 °C 19.15 (a) For a reversible process, the forward and reverse changes occur by the same path. In a reversible process, both the system and the surroundings are restored to their original condition by exactly reversing the change. A reversible change produces the maximum amount of work. (b) There is no net change in the surroundings. (c) The vaporization of water to steam is reversible if it occurs at the boiling temperature of water for a specified external (atmospheric) pressure, and only if the heat is heat needed is added infinitely slowly. (d) No. Natural processes are spontaneous in the direction they occur and nonspontaneous in the opposite direction. By definition they are irreversible. 19.17 (a) If the ideal gas is contained in a closed system at constant volume, a decrease in external temperature leads to a decrease in both temperature and pressure of the gas. (b) If the ideal gas is contained in a closed system at constant pressure, a decrease in external temperature leads to a decrease in both temperature and volume of the gas. (c) No.  $\Delta E$  is a state function.  $\Delta E = q + w$ ;  $q$  and  $w$  are not state functions. Their values do depend on path, but their sum,  $\Delta E$ , does not. 19.19 (a) An ice cube can melt reversibly at the conditions of temperature and pressure where the solid and liquid are in equilibrium. (b) We know that melting is a process that increases the energy of the system even though there is no change in temperature.  $\Delta E$  is not zero for the process. 19.21 (a) At constant temperature,  $\Delta S = q_{\text{rev}}/T$ , where  $q_{\text{rev}}$  is the heat that would be transferred if the process were reversible. (b) No.  $\Delta S$  is a state function, so it is independent of path. 19.23 (a) Entropy increases (b) 213 J/K

19.25 (a) For a spontaneous process, the entropy of the universe increases; for a reversible process, the entropy of the universe does not change. (b) For a reversible process, if the entropy of the system increases, the entropy of the surroundings must decrease by the same amount. (c) For a spontaneous process, the entropy of the universe must increase, so the entropy of the surroundings must decrease by less than 42 J/K. 19.27  $\Delta S = 0.762 \text{ J/K}$  19.29 (a) An increase in temperature produces more available microstates for a system. (b) A decrease in volume produces fewer available microstates for a system. (c) Going from liquid to gas, the number of available microstates increases. 19.31 (a)  $\Delta S$  is positive. (b)  $S$  of the system clearly increases in 19.9 (b) and (d). 19.33  $S$  increases in (a) and (c);  $S$  decreases in (b) 19.35 (a) The entropy of a pure crystalline substance at absolute zero is zero. (b) In translational motion the entire molecule moves in a single direction; in rotational motion the molecule rotates or spins around a fixed axis. In vibrational

motion the bonds within a molecule stretch and bend, but the average position of the atoms does not change.

19.37

19.39 (a) Ar(g) (b) He(g) at 1.5 atm (c) 1 mol of Ne(g) in 15.0 L (d)  $\text{CO}_2(\text{g})$  19.41 (a)  $\Delta S < 0$  (b)  $\Delta S > 0$  (c)  $\Delta S < 0$  (d)  $\Delta S > 0$  19.43 (a)  $\text{C}_2\text{H}_6(\text{g})$  (b)  $\text{CO}_2(\text{g})$  19.45 (a) Sc(s), 34.6 J/mol-K; Sc(g), 174.7 J/mol-K. In general, the gas phase of a substance has a larger  $S^\circ$  than the solid phase because of the greater volume and motional freedom of the molecules. (b)  $\text{NH}_3(\text{g})$ , 192.5 J/mol-K;  $\text{NH}_3(\text{aq})$ , 111.3 J/mol-K. Molecules in the gas phase have more motional freedom than molecules in solution. (c) 1 mol of  $\text{P}_4(\text{g})$ , 280 J/K; 2 mol of  $\text{P}_2(\text{g})$ , 2(218.1) = 436.2 J/K. More particles have a greater motional energy (more available microstates). (d) C (diamond), 2.43 J/mol-K; C (graphite), 5.69 J/mol-K. The internal entropy in graphite is greater because there is translational freedom among planar sheets of C atoms, while there is very little freedom within the covalent-network diamond lattice. 19.47 For elements with similar structures, the heavier the atoms, the lower the vibrational frequencies at a given temperature. This means that more vibrations can be accessed at a particular temperature, resulting in greater absolute entropy for the heavier elements. 19.49 (a)  $\Delta S^\circ = -120.5 \text{ J/K}$ .  $\Delta S^\circ$  is negative because there are fewer moles of gas in the products. (b)  $\Delta S^\circ = +176.6 \text{ J/K}$ .  $\Delta S^\circ$  is positive because there are more moles of gas in the products. (c)  $\Delta S^\circ = +152.39 \text{ J/K}$ .  $\Delta S^\circ$  is positive because the product contains more total particles and more moles of gas. (d)  $\Delta S^\circ = +92.3 \text{ J/K}$ .  $\Delta S^\circ$  is positive because there are more moles of gas in the products. 19.51 (a)  $\Delta G = \Delta H - T\Delta S$  (b) If  $\Delta G$  is positive, the process is nonspontaneous, but the reverse process is spontaneous. (c) There is no relationship between  $\Delta G$  and rate of reaction. 19.53 (a) Exothermic (b)  $\Delta S^\circ$  is negative; the reaction leads to a decrease in disorder. (c)  $\Delta G^\circ = -99 \text{ kJ}$  (d) If all reactants and products are present in their standard states, the reaction is spontaneous in the forward direction at this temperature. 19.55 (a)  $\Delta H^\circ = -537.22 \text{ kJ}$ ,  $\Delta S^\circ = 13.7 \text{ J/K}$ ,  $\Delta G^\circ = -541.40 \text{ kJ}$ ,  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -541.31 \text{ kJ}$  (b)  $\Delta H^\circ = -106.7 \text{ kJ}$ ,  $\Delta S^\circ = -142.2 \text{ J/K}$ ,  $\Delta G^\circ = -64.0 \text{ kJ}$ ,  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -64.3 \text{ kJ}$  (c)  $\Delta H^\circ = -508.3 \text{ kJ}$ ,  $\Delta S^\circ = -178 \text{ J/K}$ ,  $\Delta G^\circ = -465.8 \text{ kJ}$ ,  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -455.1 \text{ kJ}$ . The discrepancy in  $\Delta G^\circ$  values is due to experimental uncertainties in the tabulated thermodynamic data. (d)  $\Delta H^\circ = -165.9 \text{ kJ}$ ,  $\Delta S^\circ = 1.4 \text{ J/K}$ ,  $\Delta G^\circ = -166.2 \text{ kJ}$ ,  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -166.3 \text{ kJ}$

19.57 (a)  $\Delta G^\circ = -140.0 \text{ kJ}$ , spontaneous (b)  $\Delta G^\circ = +104.70 \text{ kJ}$ , nonspontaneous (c)  $\Delta G^\circ = +146 \text{ kJ}$ , nonspontaneous

(d)  $\Delta G^\circ = -156.7 \text{ kJ}$ , spontaneous **19.59** (a)  $\text{C}_6\text{H}_{12}(\text{l}) + 9 \text{O}_2(\text{g}) \longrightarrow 6 \text{CO}_2(\text{g}) + 6 \text{H}_2\text{O}(\text{l})$  (b) Because  $\Delta S^\circ$  is negative,  $\Delta G^\circ$  is less negative than  $\Delta H^\circ$ . **19.61** (a) The forward reaction is spontaneous at low temperatures, but becomes nonspontaneous at higher temperatures. (b) The reaction is nonspontaneous in the forward direction at all temperatures. (c) The forward reaction is nonspontaneous at low temperatures, but becomes spontaneous at higher temperatures. **19.63**  $\Delta S > +76.7 \text{ J/K}$  **19.65** (a)  $T = 330 \text{ K}$  (b) nonspontaneous **19.67** (a)  $\Delta H^\circ = 155.7 \text{ kJ}$ ,  $\Delta S^\circ = 171.4 \text{ J/K}$ . Since  $\Delta S^\circ$  is positive,  $\Delta G^\circ$  becomes more negative with increasing temperature. (b)  $\Delta G^\circ = 19 \text{ kJ}$ . The reaction is not spontaneous under standard conditions at  $800 \text{ K}$  (c)  $\Delta G^\circ = -15.7 \text{ kJ}$ . The reaction is spontaneous under standard conditions at  $1000 \text{ K}$ . **19.69** (a)  $T_b = 79^\circ \text{C}$  (b) From the *Handbook of Chemistry and Physics*, 74th Edition,  $T_b = 80.1^\circ \text{C}$ . The values are remarkably close; the small difference is due to deviation from ideal behavior by  $\text{C}_6\text{H}_6(\text{g})$  and experimental uncertainty in the boiling point measurement and the thermodynamic data. **19.71** (a)  $\text{C}_2\text{H}_2(\text{g}) + \frac{5}{2}\text{O}_2(\text{g}) \longrightarrow 2 \text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{l})$  (b)  $-1299.5 \text{ kJ}$  of heat produced/mol  $\text{C}_2\text{H}_2$  burned (c)  $w_{\text{max}} = -1235.1 \text{ kJ/mol}$   $\text{C}_2\text{H}_2$  **19.73** (a)  $\Delta G$  becomes more negative. (b)  $\Delta G$  becomes more positive. (c)  $\Delta G$  becomes more positive. **19.75** (a)  $\Delta G^\circ = -5.40 \text{ kJ}$  (b)  $\Delta G = 0.30 \text{ kJ}$  **19.77** (a)  $\Delta G^\circ = -16.77 \text{ kJ}$ ,  $K = 870$  (b)  $\Delta G^\circ = 8.0 \text{ kJ}$ ,  $K = 0.04$  (c)  $\Delta G^\circ = -497.9 \text{ kJ}$ ,  $K = 2 \times 10^{87}$  **19.79**  $\Delta H^\circ = 269.3 \text{ kJ}$ ,  $\Delta S^\circ = 0.1719 \text{ kJ/K}$  (a)  $P_{\text{CO}_2} = 6.0 \times 10^{-39} \text{ atm}$  (b)  $P_{\text{CO}_2} = 1.6 \times 10^{-4} \text{ atm}$  **19.81** (a)  $\text{HN}_2(\text{aq}) \rightleftharpoons \text{H}^+(\text{aq}) + \text{NO}_2^-(\text{aq})$  (b)  $\Delta G^\circ = 19.1 \text{ kJ}$  (c)  $G = 0$  at equilibrium (d)  $\Delta G = -2.72 \text{ kJ}$  **19.84** (a)  $\Delta H > 0$ ,  $\Delta S > 0$  (b)  $\Delta H < 0$ ,  $\Delta S < 0$  (c)  $\Delta H > 0$ ,  $\Delta S > 0$  (d)  $\Delta H > 0$ ,  $\Delta S > 0$  (e)  $\Delta H < 0$ ,  $\Delta S > 0$  **19.88** (a) For all three compounds listed, there are fewer moles of gaseous products than reactants in the formation reaction, so we expect  $\Delta S_f^\circ$  to be negative. If  $\Delta G_f^\circ = \Delta H_f^\circ - T\Delta S_f^\circ$  and  $\Delta S_f^\circ$  is negative,  $-T\Delta S_f^\circ$  is positive and  $\Delta G_f^\circ$  is more positive than  $\Delta H_f^\circ$ . **19.92** (a)  $K = 4 \times 10^{15}$  (b) An increase in temperature will decrease the mole fraction of  $\text{CH}_3\text{COOH}$  at equilibrium. Elevated temperatures must be used to increase the speed of the reaction. (c)  $K = 1$  at  $836 \text{ K}$  or  $563^\circ \text{C}$ . **19.96** (a)  $\Delta G = 8.77 \text{ kJ}$  (b)  $w_{\text{min}} = 8.77 \text{ kJ}$ . In practice, a larger than minimum amount of work is required. **19.100** (a) Acetone,  $\Delta S_{\text{vap}}^\circ = 88.4 \text{ J/mol}\cdot\text{K}$ ; dimethyl ether,  $\Delta S_{\text{vap}}^\circ = 86.6 \text{ J/mol}\cdot\text{K}$ ; ethanol,  $\Delta S_{\text{vap}}^\circ = 110 \text{ J/mol}\cdot\text{K}$ ; octane,  $\Delta S_{\text{vap}}^\circ = 86.3 \text{ J/mol}\cdot\text{K}$ ; pyridine,  $\Delta S_{\text{vap}}^\circ = 90.4 \text{ J/mol}\cdot\text{K}$ . Ethanol does not obey Trouton's rule. (b) Hydrogen bonding (in ethanol and other liquids) leads to more ordering in the liquid state and a greater than usual increase in entropy upon vaporization. Liquids that experience hydrogen bonding are probably exceptions to Trouton's rule. (c) Owing to strong hydrogen bonding interactions, water probably does not obey Trouton's rule.  $\Delta S_{\text{vap}}^\circ = 109.0 \text{ J/mol}\cdot\text{K}$ . (d)  $\Delta H_{\text{vap}}$  for  $\text{C}_6\text{H}_5\text{Cl} \approx 36 \text{ kJ/mol}$  **19.103** (a)  $S$  increases (b)  $S$  decreases (c)  $S$  increases (d)  $S$  decreases **19.106** (a) For any given total pressure, the condition of equal moles of the two gases can be achieved at some temperature. For individual gas pressures of  $1 \text{ atm}$  and a total pressure of  $2 \text{ atm}$ , the mixture is at equilibrium at  $328.5 \text{ K}$  or  $55.5^\circ \text{C}$ . (b)  $333.0 \text{ K}$  or  $60^\circ \text{C}$  (c)  $374.2 \text{ K}$  or  $101.2^\circ \text{C}$  (d) The reaction is endothermic, so an increase in the value of  $K$  as calculated in parts (a)–(c) should be accompanied by an increase in  $T$ .

## Chapter 20

**20.1** In a Bronsted–Lowry acid–base reaction,  $\text{H}^+$  is transferred from the acid to the base. In a redox reaction, one or more electrons are transferred from the reductant to the oxidant. The greater the tendency of an acid to donate  $\text{H}^+$ , the lesser the tendency of its conjugate base to accept  $\text{H}^+$ . The stronger the acid, the weaker its conjugate base. Similarly, the greater the tendency of a reduced species to donate electrons, the lesser the tendency of the corresponding oxidized species to accept electrons.

The stronger the reducing agent, the weaker the corresponding oxidizing agent. **20.4** (a) Add  $1 \text{ M A}^{2+}(\text{aq})$  to the beaker with the A(s) electrode. Add  $1 \text{ M B}^{2+}(\text{aq})$  to the beaker with the B(s) electrode. Add a salt bridge to enable the flow of ions from one compartment to the other. (b) The A electrode functions as the cathode. (c) Electrons flow through the external circuit from the anode to the cathode, from B to A in this cell. (d)  $E_{\text{cell}}^\circ = 1.00 \text{ V}$  **20.7** (a) Line 3 (b)  $E_{\text{red}} = E_{\text{ox}}^\circ = 0.80 \text{ V}$  **20.11** (a) Oxidation is the loss of electrons. (b) Electrons appear on the products' side (right side). (c) The oxidant is the reactant that is reduced. (d) An oxidizing agent is the substance that promotes oxidation; it is the oxidant. **20.13** (a) True (b) false (c) true **20.15** (a) I, +5 to 0; C, +2 to +4 (b) Hg, +2 to 0; N, -2 to 0 (c) N, +5 to +2; S, -2 to 0 (d) Cl, +4 to +3; O, -1 to 0 **20.17** (a)  $\text{TiCl}_4(\text{g}) + 2 \text{Mg}(\text{l}) \longrightarrow \text{Ti}(\text{s}) + 2 \text{MgCl}_2(\text{l})$  (b)  $\text{Mg}(\text{l})$  is oxidized;  $\text{TiCl}_4(\text{g})$  is reduced. (c)  $\text{Mg}(\text{l})$  is the reductant;  $\text{TiCl}_4(\text{g})$  is the oxidant. **20.19** (a)  $\text{Sn}^{2+}(\text{aq}) \longrightarrow \text{Sn}^{4+}(\text{aq}) + 2\text{e}^-$ , oxidation (b)  $\text{TiO}_2(\text{s}) + 4 \text{H}^+(\text{aq}) + 2\text{e}^- \longrightarrow \text{Ti}^{2+}(\text{aq}) + 2 \text{H}_2\text{O}(\text{l})$ , reduction (c)  $\text{ClO}_3^-(\text{aq}) + 6 \text{H}^+(\text{aq}) + 6\text{e}^- \longrightarrow \text{Cl}^-(\text{aq}) + 3 \text{H}_2\text{O}(\text{l})$ , reduction (d)  $\text{N}_2(\text{g}) + 8 \text{H}^+(\text{aq}) + 6\text{e}^- \longrightarrow 2 \text{NH}_4^+(\text{aq})$ , reduction (e)  $4 \text{OH}^-(\text{aq}) \longrightarrow \text{O}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l}) + 4\text{e}^-$ , oxidation (f)  $\text{SO}_3^{2-}(\text{aq}) + 2 \text{OH}^-(\text{aq}) \longrightarrow \text{SO}_4^{2-}(\text{aq}) + \text{H}_2\text{O}(\text{l}) + 2\text{e}^-$ , oxidation (g)  $\text{N}_2(\text{g}) + 6 \text{H}_2\text{O}(\text{l}) + 2\text{e}^- \longrightarrow 2 \text{NH}_3(\text{g}) + 6 \text{OH}^-(\text{aq})$ , reduction **20.21** (a)  $\text{Cr}_2\text{O}_7^{2-}(\text{aq}) + \text{I}^-(\text{aq}) \longrightarrow 2 \text{Cr}^{3+}(\text{aq}) + \text{IO}_3^-(\text{aq}) + 4 \text{H}_2\text{O}(\text{l})$ ; oxidizing agent,  $\text{Cr}_2\text{O}_7^{2-}$ ; reducing agent,  $\text{I}^-$  (b)  $4 \text{MnO}_4^-(\text{aq}) + 5 \text{CH}_3\text{OH}(\text{l}) + 12 \text{H}^+(\text{aq}) \longrightarrow 4 \text{Mn}^{2+}(\text{aq}) + 5 \text{HCO}_2\text{H}(\text{aq}) + 11 \text{H}_2\text{O}(\text{l})$ ; oxidizing agent,  $\text{MnO}_4^-$ ; reducing agent,  $\text{CH}_3\text{OH}$  (c)  $\text{I}_2(\text{s}) + 5 \text{OCl}^-(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{IO}_3^-(\text{aq}) + 5 \text{Cl}^-(\text{aq}) + 2 \text{H}^+(\text{aq})$ ; oxidizing agent,  $\text{OCl}^-$ ; reducing agent,  $\text{I}_2$  (d)  $\text{As}_2\text{O}_3(\text{s}) + 2 \text{NO}_3^-(\text{aq}) + 2 \text{H}_2\text{O}(\text{l}) + 2 \text{H}^+(\text{aq}) \longrightarrow 2 \text{H}_3\text{AsO}_4(\text{aq}) + \text{N}_2\text{O}_3(\text{aq})$ ; oxidizing agent,  $\text{NO}_3^-$ ; reducing agent,  $\text{As}_2\text{O}_3$  (e)  $2 \text{MnO}_4^-(\text{aq}) + \text{Br}^-(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{MnO}_2(\text{s}) + \text{BrO}_3^-(\text{aq}) + 2 \text{OH}^-(\text{aq})$ ; oxidizing agent,  $\text{MnO}_4^-$ ; reducing agent,  $\text{Br}^-$  (f)  $\text{Pb}(\text{OH})_4^{2-}(\text{aq}) + \text{ClO}^-(\text{aq}) \longrightarrow \text{PbO}_2(\text{s}) + \text{Cl}^-(\text{aq}) + 2 \text{OH}^-(\text{aq}) + \text{H}_2\text{O}(\text{l})$ ; oxidizing agent,  $\text{ClO}^-$ ; reducing agent,  $\text{Pb}(\text{OH})_4^{2-}$  **20.23** (a) The reaction  $\text{Cu}^{2+}(\text{aq}) + \text{Zn}(\text{s}) \longrightarrow \text{Cu}(\text{s}) + \text{Zn}^{2+}(\text{aq})$  is occurring in both figures. In Figure 20.3 the reactants are in contact, while in Figure 20.4 the oxidation half-reaction and reduction half-reaction are occurring in separate compartments. In Figure 20.3 the flow of electrons cannot be isolated or utilized; in Figure 20.4 electrical current is isolated and flows through the voltmeter. (b)  $\text{Na}^+$  cations are drawn into the cathode compartment to maintain charge balance as  $\text{Cu}^{2+}$  ions are removed. **20.25** (a) Fe(s) is oxidized,  $\text{Ag}^+(\text{aq})$  is reduced. (b)  $\text{Ag}^+(\text{aq}) + \text{Ie}^- \longrightarrow \text{Ag}(\text{s})$ ; Fe(s)  $\longrightarrow \text{Fe}^{2+}(\text{aq}) + 2\text{e}^-$  (c) Fe(s) is the anode, Ag(s) is the cathode. (d) Fe(s) is negative; Ag(s) is positive. (e) Electrons flow from the Fe electrode (–) toward the Ag electrode (+). (f) Cations migrate toward the Ag(s) cathode; anions migrate toward the Fe(s) anode. **20.27** Electromotive force, emf, is the potential energy difference between an electron at the anode and an electron at the cathode of a voltaic cell. (b) One volt is the potential energy difference required to impart 1 J of energy to a charge of 1 coulomb. (c) Cell potential,  $E_{\text{cell}}$ , is the emf of an electrochemical cell. **20.29** (a)  $2 \text{H}^+(\text{aq}) + 2\text{e}^- \longrightarrow \text{H}_2(\text{g})$  (b) A standard hydrogen electrode, SHE, has components that are at standard conditions,  $1 \text{ M H}^+(\text{aq})$  and  $\text{H}_2(\text{g})$  at  $1 \text{ atm}$ . (c) The platinum foil in a SHE serves as an inert electron carrier and a solid reaction surface. **20.31** (a) A standard reduction potential is the relative potential of a reduction half-reaction measured at standard conditions. (b)  $E_{\text{red}}^\circ = 0$  **20.33** (a)  $\text{Cr}^{2+}(\text{aq}) \longrightarrow \text{Cr}^{3+}(\text{aq}) + \text{e}^-$ ;  $\text{Ti}^{3+}(\text{aq}) + 2\text{e}^- \longrightarrow \text{Ti}^+(\text{aq})$  (b)  $E_{\text{red}}^\circ = 0.78 \text{ V}$

20.35 (a)  $E^\circ = 0.823 \text{ V}$  (b)  $E^\circ = 1.89 \text{ V}$  (c)  $E^\circ = 1.211 \text{ V}$   
 (d)  $E^\circ = 1.21 \text{ V}$  20.37 (a)  $3 \text{ Ag}^+(aq) + \text{Cr}(s) \longrightarrow 3 \text{ Ag}(s) + \text{Cr}^{3+}(aq)$ ,  $E^\circ = 1.54 \text{ V}$  (b) Two of the combinations have essentially equal  $E^\circ$  values:  $2 \text{ Ag}^+(aq) + \text{Cu}(s) \longrightarrow 2 \text{ Ag}(s) + \text{Cu}^{2+}(aq)$ ,  $E^\circ = 0.462 \text{ V}$ ;  $3 \text{ Ni}^{2+}(aq) + 2 \text{ Cr}(s) \longrightarrow 3 \text{ Ni}(s) + 2 \text{ Cr}^{3+}(aq)$ ,  $E^\circ = 0.46 \text{ V}$  20.39 (a) Anode, Sn(s); cathode, Cu(s). (b) The copper electrode gains mass as Cu is plated out, and the tin electrode loses mass as Sn is oxidized. (c)  $\text{Cu}^{2+}(aq) + \text{Sn}(s) \longrightarrow \text{Cu}(s) + \text{Sn}^{2+}(aq)$ . (d)  $E^\circ = 0.473 \text{ V}$ . 20.41 (a)  $\text{Cl}_2(g)$  (b)  $\text{Ni}^{2+}(aq)$  (c)  $\text{BrO}_3^-(aq)$  (d)  $\text{O}_3(g)$  20.43 (a)  $\text{Cl}_2(aq)$ , strong oxidant (b)  $\text{MnO}_4^-(aq)$ , acidic, strong oxidant (c) Ba(s) strong reductant (d) Zn(s), reductant 20.45 (a)  $\text{Cu}^{2+}(aq) < \text{O}_2(g) < \text{Cr}_2\text{O}_7^{2-}(aq) < \text{Cl}_2(g) < \text{H}_2\text{O}_2(aq)$  (b)  $\text{H}_2\text{O}_2(aq) < \text{I}^-(aq) < \text{Sn}^{2+}(aq) < \text{Zn}(s) < \text{Al}(s)$  20.47 Al and  $\text{H}_2\text{C}_2\text{O}_4$  20.49 (a)  $2 \text{ Fe}^{2+}(aq) + \text{S}_2\text{O}_6^{2-}(aq) + 4 \text{ H}^+(aq) \longrightarrow 2 \text{ Fe}^{3+}(aq) + 2 \text{ H}_2\text{SO}_3(aq)$ ;  $2 \text{ Fe}^{2+}(aq) + \text{N}_2\text{O}(aq) + 2 \text{ H}^+(aq) \longrightarrow 2 \text{ Fe}^{3+}(aq) + \text{N}_2(g) + \text{H}_2\text{O}(l)$ ;  $\text{Fe}^{2+}(aq) + \text{VO}_2^+(aq) + 2 \text{ H}^+(aq) \longrightarrow \text{Fe}^{3+}(aq) + \text{VO}_2^+(aq) + \text{H}_2\text{O}(l)$  (b)  $E^\circ = -0.17 \text{ V}$ ,  $\Delta G^\circ = 33 \text{ kJ}$ ;  $E^\circ = -2.54 \text{ V}$ ,  $\Delta G^\circ = 4.90 \times 10^2 \text{ kJ}$ ;  $E^\circ = 0.23 \text{ V}$ ,  $\Delta G^\circ = -22 \text{ kJ}$  (c)  $K = 1.8 \times 10^{-6}$ ,  $K = 1.2 \times 10^{-86} = 10^{-86}$ ,  $K = 7.8 \times 10^3 = 8 \times 10^3$  20.51  $\Delta G^\circ = 21.8 \text{ kJ}$ ,  $E_{\text{cell}}^\circ = -0.113 \text{ V}$  20.53 (a)  $E^\circ = 0.16 \text{ V}$ ,  $K = 2.54 \times 10^5 = 3 \times 10^5$  (b)  $E^\circ = 0.277 \text{ V}$ ,  $K = 2.3 \times 10^9$  (c)  $E^\circ = 0.45 \text{ V}$ ,  $K = 1.5 \times 10^{75} = 10^{75}$  20.55 (a)  $K = 9.8 \times 10^2$  (b)  $K = 9.5 \times 10^5$  (c)  $K = 9.3 \times 10^8$  20.57 (a) The Nernst equation is applicable when the components of an electrochemical cell are at non-standard conditions. (b)  $Q = 1$  (c)  $Q$  decreases and  $E$  increases 20.59 (a)  $E$  decreases (b)  $E$  decreases (c)  $E$  decreases (d) no effect 20.61 (a)  $E^\circ = 0.48 \text{ V}$  (b)  $E = 0.53 \text{ V}$  (c)  $E = 0.46 \text{ V}$  20.63 (a)  $E^\circ = 0.46 \text{ V}$  (b)  $E = 0.37 \text{ V}$  20.65 (a) The compartment with  $[\text{Zn}^{2+}] = 1.00 \times 10^{-2} \text{ M}$  is the anode. (b)  $E^\circ = 0$  (c)  $E = 0.0668 \text{ V}$  (d) In the anode compartment  $[\text{Zn}^{2+}]$  increases; in the cathode compartment  $[\text{Zn}^{2+}]$  decreases 20.67  $E^\circ = 0.763 \text{ V}$ , pH = 1.6 20.69 (a) The emf of a battery decreases as it is used. The concentrations of products increase and the concentrations of reactants decrease, causing  $Q$  to increase and  $E_{\text{cell}}$  to decrease. (b) A D-size battery contains more reactants than a AA, enabling the D to provide power for a longer time. 20.71 464 g  $\text{PbO}_2$  20.73 (a) The anode (b)  $E^\circ = 3.50 \text{ V}$  (c) The emf of the battery, 3.5 V, is exactly the standard cell potential calculated in part (b). (d) At ambient conditions,  $E \approx E^\circ$ , so  $\log Q \approx 1$ . Assuming that the value of  $E^\circ$  is relatively constant with temperature, the value of the second term in the Nernst equation is approximately zero at 37 °C, and  $E \approx 3.5 \text{ V}$ . 20.75 (a) The cell emf will have a smaller value. (b) NiMH batteries use an alloy such as  $\text{ZrNi}_2$  as the anode material. This eliminates the use and disposal problems associated with Cd,

a toxic heavy metal. 20.77 The main advantage of a fuel cell is that fuel is continuously supplied, so that it can produce electrical current for a time limited only by the amount of available fuel. For the hydrogen-oxygen fuel cell, this is also a disadvantage because volatile and explosive hydrogen must be acquired and stored. Alkaline batteries are convenient, but they have a short lifetime, and the disposal of their zinc and manganese solids is more problematic than disposal of water produced by the hydrogen-oxygen fuel cell. 20.79 (a) anode:  $\text{Fe}(s) \longrightarrow \text{Fe}^{2+}(aq) + 2e^-$ ; cathode:  $\text{O}_2(g) + 4 \text{ H}^+(aq) + 4e^- \longrightarrow 2 \text{ H}_2\text{O}(l)$  (b)  $2 \text{ Fe}^{2+}(aq) + 3 \text{ H}_2\text{O}(l) + 3 \text{ H}_2\text{O}(l) \longrightarrow \text{Fe}_2\text{O}_3 \cdot 3 \text{ H}_2\text{O}(s) + 6 \text{ H}^+(aq) + 2e^-$ ;  $\text{O}_2(g) + 4 \text{ H}^+(aq) + 4e^- \longrightarrow 2 \text{ H}_2\text{O}(l)$  20.81 (a) Mg is called a "sacrificial anode" because it has a more negative  $E_{\text{red}}^\circ$  than the pipe metal and is preferentially oxidized when the two are coupled. It is sacrificed to preserve the pipe. (b)  $E_{\text{red}}^\circ$  for  $\text{Mg}^{2+}$  is  $-2.37 \text{ V}$ , more negative than most metals present in pipes, including Fe and Zn. 20.83 Under acidic conditions, air ( $\text{O}_2$ ) oxidation of Zn(s), 1.99 V, Fe(s), 1.67 V, and Cu(s), 0.893 V, are all spontaneous. When the three metals are in contact, Zn will act as a sacrificial anode for both Fe and Cu, but after the Zn is depleted, Fe will be oxidized (corroded). 20.85 (a) Electrolysis is an electrochemical process driven by an outside energy source. (b) By definition, electrolysis reactions are nonspontaneous. (c)  $2 \text{ Cl}^-(l) \longrightarrow \text{Cl}_2(g) + 2e^-$  20.87 (a) 236 g Cr(s) (b) 2.51 A 20.89  $w_{\text{max}} = -8.19 \times 10^4 \text{ J}$  20.91 (a)  $4.0 \times 10^5 \text{ g Li}$  (b) 0.24 kWh/mol Li 20.93 (a)  $2 \text{ Ni}^+(aq) \longrightarrow \text{Ni}(s) + \text{Ni}^{2+}(aq)$  (b)  $3 \text{ MnO}_4^{2-}(aq) + 4 \text{ H}^+(aq) \longrightarrow 2 \text{ MnO}_4^-(aq) + \text{MnO}_2(s) + 3 \text{ H}_2\text{O}(l)$  (c)  $3 \text{ H}_2\text{SO}_3(aq) \longrightarrow \text{S}(s) + 2 \text{ HSO}_4^-(aq) + 2 \text{ H}^+(aq) + \text{H}_2\text{O}(l)$  (d)  $\text{Cl}_2(aq) + 2 \text{ OH}^-(aq) \longrightarrow \text{Cl}^-(aq) + \text{ClO}^-(aq) + \text{H}_2\text{O}(l)$  20.96 (a)  $E^\circ = 0.672 \text{ V}$ , spontaneous (b)  $E^\circ = -0.82 \text{ V}$ , nonspontaneous (c)  $E^\circ = 0.93 \text{ V}$ , spontaneous (d)  $E^\circ = 0.183 \text{ V}$ , spontaneous 20.99 (a)  $E^\circ = 1.08 \text{ V}$  (b)  $[\text{Ni}^{2+}]$  increases as the cell operates. (c) Initial  $[\text{Ag}^+] = 0.474 = 0.5 \text{ M}$  20.102  $K = 1.6 \times 10^6$  20.105 The ship's hull should be made negative. The ship, as a negatively charged "electrode," becomes the site of reduction, rather than oxidation, in an electrolytic process. 20.107 (a)  $6.4 \times 10^6 \text{ C}$  (b)  $6.4 \times 10^5 \text{ amp}$  (c) 16 kWh 20.110 A battery is a voltaic cell in which the cathode compartment contains the positive terminal of the battery. In alkaline batteries,  $\text{OH}^-(aq)$  is produced at the cathode. The wire that turns the indicator pink is in contact with  $\text{OH}^-(aq)$ , so the rightmost wire is connected to the positive terminal of the battery. 20.113 (a) The oxidation potential of A is equal in magnitude but opposite in sign to the reduction potential of  $\text{A}^+$ . (b) Li(s) has the highest oxidation potential, Au(s) the lowest. (c) The relationship is reasonable because both oxidation potential and ionization energy describe removing electrons from a substance. Ionization energy is a property of gas phase atoms or ions, while oxidation potential is a property of the bulk material. 20.115 (a)  $E^\circ = 0.028 \text{ V}$  (b) anode:  $\text{Fe}^{2+}(aq) \longrightarrow \text{Fe}^{3+}(aq) + e^-$ ; cathode:  $\text{Ag}^+(aq) + e^- \longrightarrow \text{Ag}(s)$  (c)  $\Delta S^\circ = 148.5 \text{ J}$ . Since  $\Delta S^\circ$  is positive,  $\Delta G^\circ$  will become more negative and  $E^\circ$  will become more positive as temperature is increased. 20.118  $K_{\text{sp}}$  for  $\text{AgSCN}$  is  $1 \times 10^{12}$ .

## Chapter 21

21.1 (a)  $^{24}\text{Ne}$ ; outside; reduce neutron-to-proton ratio via  $\beta$  decay (b)  $^{32}\text{Cl}$ ; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (c)  $^{108}\text{Sn}$ ; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (d)  $^{216}\text{Po}$ ; outside; nuclei with  $Z \geq 84$  usually decay via  $\alpha$  emission. 21.4 (a) 7 min (b)  $0.1 \text{ min}^{-1}$  (c) 30% (3/10) of the sample remains after 12 min. (d)  $^{88}\text{Nb}$  21.7 (a) 25 protons, 30 neutrons (b) 80 protons, 121 neutrons (c) 19 protons, 20 neutrons 21.9 (a)  $\frac{1}{2}$  (b)  $\frac{1}{2}$  He or  $\frac{1}{2}$   $\alpha$  (c)  $\frac{0}{0}$  21.11 (a)  $^{90}\text{Rb} \longrightarrow ^{90}\text{Sr} + \text{}_{-1}^0\text{e}$  (b)  $^{74}\text{Se} + \text{}_{-1}^0\text{e}$  (orbital electron)  $\longrightarrow ^{73}\text{As}$  (c)  $^{76}\text{Kr} \longrightarrow ^{76}\text{Br} + \text{}_{-1}^0\text{e}$

(d)  ${}^{226}_{88}\text{Ra} \rightarrow {}^{222}_{86}\text{Rn} + {}^4_2\text{He}$  21.13 (a)  ${}^{211}_{82}\text{Pb} \rightarrow {}^{211}_{83}\text{Bi} + {}^0_{-1}\text{e}$   
 (b)  ${}^{50}_{25}\text{Mn} \rightarrow {}^{50}_{26}\text{Cr} + {}^0_{-1}\text{e}$  (c)  ${}^{179}_{74}\text{W} + {}^0_{-1}\text{e} \rightarrow {}^{179}_{73}\text{Ta}$   
 (d)  ${}^{230}_{90}\text{Th} \rightarrow {}^{226}_{88}\text{Ra} + {}^4_2\text{He}$  21.15 7 alpha emissions, 4 beta emissions 21.17 (a) Positron emission (for low atomic numbers, positron emission is more common than electron capture) (b) beta emission (c) beta emission (d) beta emission 21.19 (a) Stable:  ${}^{39}_{19}\text{K}$ , 20 neutrons is a magic number (b) stable:  ${}^{209}_{83}\text{Bi}$ , 126 neutrons is a magic number (c) stable:  ${}^{58}_{28}\text{Ni}$  even proton, even neutron more likely to be stable;  ${}^{58}_{28}\text{Ni}$  has high neutron/proton ratio 21.21 (a)  ${}^4_2\text{He}$  (c)  ${}^{40}_{20}\text{Ca}$  (e)  ${}^{126}_{82}\text{Pb}$  21.23 The alpha particle,  ${}^4_2\text{He}$ , has a magic number of both protons and neutrons, while the proton is an odd proton, even neutron particle. Alpha is a very stable emitted particle, which makes alpha emission a favorable process. The proton is not a stable emitted particle, and its formation does not encourage proton emission as a process. 21.25 Protons and alpha particles are positively charged and must be moving very fast to overcome electrostatic forces which would repel them from the target nucleus. Neutrons are electrically neutral and not repelled by the nucleus. 21.27 (a)  ${}^{252}_{98}\text{Cf} + {}^{10}_0\text{B} \rightarrow 3\text{}^1_0\text{n} + {}^{259}_{103}\text{Lr}$  (b)  ${}^1_1\text{H} + {}^3_2\text{He} \rightarrow {}^4_2\text{He} + {}^1_1\text{H}$  (c)  ${}^1_1\text{H} + {}^1_1\text{H} \rightarrow {}^2_2\text{He}$  (d)  ${}^{123}_{51}\text{I} \rightarrow {}^{123}_{54}\text{Xe} + {}^0_{-1}\text{e}$  (e)  ${}^{59}_{26}\text{Fe} \rightarrow {}^0_{-1}\text{e} + {}^{59}_{27}\text{Co}$  21.29 (a)  ${}^{238}_{92}\text{U} \rightarrow {}^4_2\text{He} + {}^{234}_{90}\text{Th}$  (b)  ${}^{19}_{9}\text{F} + {}^4_2\text{He} \rightarrow {}^{23}_{11}\text{Na} + {}^1_0\text{n}$  (c)  ${}^{238}_{92}\text{U} \rightarrow {}^4_2\text{He} + {}^{234}_{90}\text{Th}$  21.31 (a) True. The decay rate constant and half-life are inversely related. (b) False. If X is not radioactive, its half-life is essentially infinity. (c) True. Changes in the amount of A would be substantial and measurable over the 40-year time frame, while changes in the amount of X would be very small and difficult to detect. 21.33 28.1 mg tritium remain after 12.3 yr, 0.201 mg after 100 yr 21.35 (a) The source must be replaced after 2.18 yr or 26.2 months; this corresponds to August of 2008. (b) Partially decayed cobalt-60 can be encased in a gamma-absorbing material such as lead and stored in a safe, remote facility until it is no longer active. 21.37 (a)  $4.1 \times 10^{-11}$  g  ${}^{226}_{88}\text{Ra}$  decays in 5.0 min,  $1.1 \times 10^{11}$  alpha particles emitted (b) 10 mCi 21.39  $k = 1.21 \times 10^{-4} \text{ yr}^{-1}$ ;  $t = 4.3 \times 10^3$  yr 21.41  $k = 5.46 \times 10^{-10} \text{ yr}^{-1}$ ;  $t = 3.0 \times 10^9$  yr 21.43  $\Delta m = 9.474 \times 10^{-9}$  g per mole of  $\text{Fe}_2\text{O}_3$  21.45  $\Delta m = 0.2414960$  amu,  $\Delta E = 3.604129 \times 10^{-11}$  J/ ${}^{27}\text{Al}$  nucleus required,  $8.044234 \times 10^{13}$  J/100 g  ${}^{27}\text{Al}$  21.47 (a) mass defect = 0.098940 amu, binding energy/nucleon =  $1.2305 \times 10^{-12}$  J (b) mass defect = 0.340423 amu, binding energy/nucleon =  $1.37312 \times 10^{-12}$  J (c) mass defect = 0.949189 amu, binding energy/nucleon =  $1.37533 \times 10^{-12}$  J 21.49 (a)  $1.71 \times 10^3$  kg/d (b)  $2.1 \times 10^8$  g  ${}^{235}\text{U}$  21.51 (a)  ${}^{59}\text{Co}$ ; it has the largest binding energy per nucleon, and binding energy gives rise to mass defect. 21.53 (a) NaI is a good source of iodine because iodine is a large percentage of its mass, it is completely dissociated into ions in aqueous solution and iodine in the form of  $\text{I}^-$  (aq) is mobile and immediately available for bio-uptake. (b) A Geiger counter placed near the thyroid immediately after injection will register background, then gradually increase in signal until the concentration of iodine in the thyroid reaches a maximum. Over time, iodine-131 decays, and the signal decreases. (c) The radioactive iodine will decay to 0.01% of the original amount in approximately 82 days. 21.55 (a) In a fission chain reaction, one neutron initiates a nuclear transformation that produces more than one neutron. The product neutrons initiate more transformations, so that the reaction is self-sustaining. (b) Critical mass is the mass of fissionable material required to sustain a chain reaction so that only one product neutron is effective at initiating a new transformation. 21.57 (a)  ${}^1_1\text{H} + {}^1_1\text{H} \rightarrow {}^3_2\text{He} + {}^1_0\text{n}$  (b)  ${}^{233}_{92}\text{U} + {}^1_0\text{n} \rightarrow {}^{135}_{51}\text{Sb} + {}^{90}_{41}\text{Nb} + 3{}^1_0\text{n}$  21.59 (a) The extremely high temperature is required to overcome electrostatic charge repulsions between the nuclei so that they can come together to react.

(b) The sun is not solid. No element or compound is solid at temperatures of 1,000,000 to 10,000,000 K. 21.61 Hydrogen abstraction:  $\text{RCOOH} + \cdot\text{OH} \rightarrow \text{RCOO}\cdot + \text{H}_2\text{O}$ ; deprotonation:  $\text{RCOOH} + \text{OH}^- \rightarrow \text{RCOO}^- + \text{H}_2\text{O}$ . Hydroxyl radical is more toxic to living systems, because it produces other radicals when it reacts with molecules in the organism. Hydroxide ion,  $\text{OH}^-$ , on the other hand, will be readily neutralized in the buffered cell environment. The acid-base reactions of  $\text{OH}^-$  are usually much less disruptive to the organism than the chain of redox reactions initiated by  $\cdot\text{OH}$  radical. 21.63 (a)  $5.3 \times 10^8$  dis/s,  $5.3 \times 10^8$  Bq (b)  $6.1 \times 10^2$  mrad,  $6.1 \times 10^{-3}$  Gy (c)  $5.8 \times 10^3$  mrem,  $5.8 \times 10^{-2}$  Sv 21.65  ${}^{210}_{82}\text{Pb}$  21.69 (a)  ${}^6_3\text{Li} \rightarrow {}^4_2\text{He} + {}^2_1\text{H}$  (b)  ${}^{40}_{20}\text{Ca} + {}^{248}_{96}\text{Cm} \rightarrow {}^{142}_{54}\text{Sm} + {}^{141}_{54}\text{Xe}$  (c)  ${}^{88}_{38}\text{Sr} + {}^{84}_{36}\text{Kr} \rightarrow {}^{116}_{36}\text{Pd} + {}^{56}_{28}\text{Ni}$  (d)  ${}^{40}_{20}\text{Ca} + {}^{238}_{92}\text{U} \rightarrow {}^{70}_{30}\text{Zn} + 4{}^1_0\text{n} + 2{}^{140}_{41}\text{Nb}$  21.73 The C—OH bond of the acid and the O—H bond of the alcohol break in this reaction. Initially,  ${}^{18}\text{O}$  is present in the C— ${}^{18}\text{OH}$  group of the alcohol. In order for  ${}^{18}\text{O}$  to end up in the ester, the  ${}^{18}\text{O}$ —H bond of the alcohol must break. This requires that the C—OH bond in the acid also breaks. The unlabeled O from the acid ends up in the  $\text{H}_2\text{O}$  product. 21.75  ${}^9\text{Be}$ ,  $8.612 \times 10^{-13}$  J/nucleon;  ${}^9\text{Be}$ ,  $1.035 \times 10^{-12}$  J/nucleon;  ${}^{10}\text{Be}$ ,  $1.042 \times 10^{-12}$  J/nucleon. The binding energies/nucleon for  ${}^9\text{Be}$  and  ${}^{10}\text{Be}$  are very similar; that for  ${}^{10}\text{Be}$  is slightly higher. 21.81  $1.4 \times 10^4$  kg  $\text{C}_8\text{H}_{18}$

## Chapter 22

22.2 (a) Acid-base (Brønsted) (b) From left to right in the reaction, the charges are: 0, 0, 1+, 1- (c)  $\text{NH}_3(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{NH}_4^+(\text{aq}) + \text{OH}^-(\text{aq})$  22.5 (a)  $\text{N}_2\text{O}_5$ . Resonance structures other than the ones shown are possible. Those with double bonds to the central oxygen do not minimize formal charge and make a smaller contribution to the net bonding model.

(b)  $\text{N}_2\text{O}_4$ . Resonance structures other than the ones shown are possible.

(c)  $\text{NO}_2$ . We place the odd electron on N because of electronegativity arguments.

(d)  $\text{N}_2\text{O}_3$ .

(e)  $\text{NO}$ . We place the odd electron on N because of electronegativity arguments.

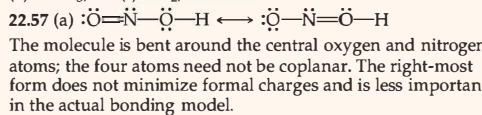

(f)  $\text{N}_2\text{O}$ . The rightmost structure does not minimize formal charge and makes a smaller contribution to the net bonding model.

22.8 Only ionization energy fits the trend. Electronegativity varies smoothly, and there is no value for Ar. Both atomic radius and melting point vary in the direction opposite that shown in the diagram. X—X single bond enthalpies show no consistent trend and there should be no value for Ar.

- 22.11** Metals: (b) Sr, (c) Mn, (e) Rh; nonmetals: (a) P, (d) Se, (f) Kr; metalloids: none. **22.13** (a) O (b) Br (c) Ba (d) O (e) Co
- 22.15** (a) N is too small a central atom to fit five fluorine atoms, and it does not have available *d* orbitals, which can help accommodate more than eight electrons. (b) Si does not readily form  $\pi$  bonds, which are necessary to satisfy the octet rule for both atoms in the molecule. (c) As has a lower electronegativity than N; that is, it more readily gives up electrons to an acceptor and is more easily oxidized.
- 22.17** (a)  $\text{Mg}_3\text{N}_2(\text{s}) + 6 \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{NH}_3(\text{aq}) + 3 \text{Mg}(\text{OH})_2(\text{s})$   
 (b)  $2 \text{C}_3\text{H}_7\text{OH}(\text{l}) + 9 \text{O}_2(\text{g}) \longrightarrow 6 \text{CO}_2(\text{g}) + 8 \text{H}_2\text{O}(\text{l})$   
 (c)  $\text{MnO}_2(\text{s}) + \text{C}(\text{s}) \xrightarrow{\Delta} \text{CO}(\text{g}) + \text{MnO}(\text{s})$  or  $\text{MnO}_2(\text{s}) + 2 \text{C}(\text{s}) \xrightarrow{\Delta} 2 \text{CO}(\text{g}) + \text{Mn}(\text{s})$  or  $\text{MnO}_2(\text{s}) + \text{C}(\text{s}) \xrightarrow{\Delta} \text{CO}_2(\text{g}) + \text{Mn}(\text{s})$  (d)  $\text{AlP}(\text{s}) + 3 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{PH}_3(\text{g}) + \text{Al}(\text{OH})_3(\text{s})$  (e)  $\text{Na}_2\text{S}(\text{s}) + 2 \text{HCl}(\text{aq}) \longrightarrow \text{H}_2\text{S}(\text{g}) + 2 \text{NaCl}(\text{aq})$
- 22.19** (a)  $^1\text{H}$ , protium;  $^2\text{H}$ , deuterium;  $^3\text{H}$ , tritium (b) in order of decreasing natural abundance: protium > deuterium > tritium
- 22.21** Like other elements in group 1A, hydrogen has only one valence electron and its most common oxidation number is +1.
- 22.23** (a)  $\text{Mg}(\text{s}) + 2 \text{H}^+(\text{aq}) \longrightarrow \text{Mg}^{2+}(\text{aq}) + \text{H}_2(\text{g})$   
 (b)  $\text{C}(\text{s}) + \text{H}_2\text{O}(\text{g}) \xrightarrow{1000^\circ\text{C}} \text{CO}(\text{g}) + \text{H}_2(\text{g})$   
 (c)  $\text{CH}_4(\text{g}) + \text{H}_2\text{O}(\text{g}) \xrightarrow{1100^\circ\text{C}} \text{CO}(\text{g}) + 3 \text{H}_2(\text{g})$
- 22.25** (a)  $\text{NaH}(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{NaOH}(\text{aq}) + \text{H}_2(\text{g})$   
 (b)  $\text{Fe}(\text{s}) + \text{H}_2\text{SO}_4(\text{aq}) \longrightarrow \text{Fe}^{2+}(\text{aq}) + \text{H}_2(\text{g}) + \text{SO}_4^{2-}(\text{aq})$   
 (c)  $\text{H}_2(\text{g}) + \text{Br}_2(\text{g}) \longrightarrow 2 \text{HBr}(\text{g})$   
 (d)  $2 \text{Na}(\text{l}) + \text{H}_2(\text{g}) \longrightarrow 2 \text{NaH}(\text{s})$   
 (e)  $\text{PbO}(\text{s}) + \text{H}_2(\text{g}) \xrightarrow{\Delta} \text{Pb}(\text{s}) + \text{H}_2\text{O}(\text{g})$
- 22.27** (a) Ionic (b) molecular (c) metallic **22.29** Vehicle fuels produce energy via combustion reactions. The combustion of hydrogen is very exothermic and its only product,  $\text{H}_2\text{O}$ , is a nonpollutant. **22.31** Xenon has a lower ionization energy than argon; because the valence electrons are not as strongly attracted to the nucleus, they are more readily promoted to a state in which the atom can form bonds with fluorine. Also, Xe is larger and can more easily accommodate an expanded octet of electrons. **22.33** (a)  $\text{ClO}_3^-$ , +5 (b) HI, -1 (c)  $\text{ICl}_3$ ; I, +3, Cl, -1 (d) NaOCl, +1 (e)  $\text{HClO}_4$ , +7 (f)  $\text{XeF}_4$ ; Xe, +4, F, -1 **22.35** (a) iron(III) chlorate (b) chlorous acid (c) xenon hexafluoride (d) bromine pentafluoride (e) xenon oxide tetrafluoride (f) iodic acid **22.37** (a) van der Waals intermolecular attractive forces increase with increasing number of electrons in the atoms. (b)  $\text{F}_2$  reacts with water.  $\text{F}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{HF}(\text{g}) + \text{O}_2(\text{g})$ . That is, fluorine is too strong an oxidizing agent to exist in water. (c) HF has extensive hydrogen bonding. (d) Oxidizing power is related to electronegativity. Electronegativity and oxidizing power decrease in the order given. **22.39** Perchlorate anion,  $\text{ClO}_4^-$ , must be extremely unreactive in aqueous solutions and aerobic environments. Although chlorine is in a very high oxidation state, it is not readily reduced, because the ion has a stable, symmetric structure that protects it against reactions.
- 22.41** (a) As an oxidizing agent in steelmaking; to bleach pulp and paper; in oxyacetylene torches; in medicine to assist in breathing (b) synthesis of pharmaceuticals, lubricants, and other organic compounds where  $\text{C}=\text{C}$  bonds are cleaved; in water treatment.
- 22.43** (a)  $2 \text{HgO}(\text{s}) \xrightarrow{\Delta} 2 \text{Hg}(\text{l}) + \text{O}_2(\text{g})$   
 (b)  $2 \text{Cu}(\text{NO}_3)_2(\text{s}) \xrightarrow{\Delta} 2 \text{CuO}(\text{s}) + 4 \text{NO}_2(\text{g}) + \text{O}_2(\text{g})$   
 (c)  $\text{PbS}(\text{s}) + 4 \text{O}_3(\text{g}) \longrightarrow \text{PbSO}_4(\text{s}) + 4 \text{O}_2(\text{g})$   
 (d)  $2 \text{ZnS}(\text{s}) + 3 \text{O}_2(\text{g}) \longrightarrow 2 \text{ZnO}(\text{s}) + 2 \text{SO}_2(\text{g})$   
 (e)  $2 \text{K}_2\text{O}_2(\text{s}) + 2 \text{CO}_2(\text{g}) \longrightarrow 2 \text{K}_2\text{CO}_3(\text{s}) + \text{O}_2(\text{g})$
- 22.45** (a) acidic (b) acidic (c) amphoteric (d) basic **22.47** (a)  $\text{H}_2\text{SeO}_3$ , +4 (b)  $\text{KHSO}_3$ , +4 (c)  $\text{H}_2\text{Te}$ , -2 (d)  $\text{CS}_2$ , -2 (e)  $\text{CaSO}_4$ , +6 **22.49** (a)  $2 \text{Fe}^{3+}(\text{aq}) + \text{H}_2\text{S}(\text{aq}) \longrightarrow 2 \text{Fe}^{2+}(\text{aq}) + \text{S}(\text{s}) + 2 \text{H}^+(\text{aq})$   
 (b)  $\text{Br}_2(\text{l}) + \text{H}_2\text{S}(\text{aq}) \longrightarrow 2 \text{Br}^-(\text{aq}) + \text{S}(\text{s}) + 2 \text{H}^+(\text{aq})$

The molecule is linear.

The geometry is tetrahedral around the left nitrogen, trigonal pyramidal around the right.

The ion is trigonal planar; it has three equivalent resonance forms.

- 22.59** (a)  $\text{Mg}_3\text{N}_2(\text{s}) + 6 \text{H}_2\text{O}(\text{l}) \longrightarrow 3 \text{Mg}(\text{OH})_2(\text{s}) + 2 \text{NH}_3(\text{aq})$   
 (b)  $2 \text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{NO}_2(\text{g})$   
 (c)  $\text{N}_2\text{O}_5(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{H}^+(\text{aq}) + 2 \text{NO}_3^-(\text{aq})$   
 (d)  $\text{NH}_3(\text{aq}) + \text{H}^+(\text{aq}) \longrightarrow \text{NH}_4^+(\text{aq})$   
 (e)  $\text{N}_2\text{H}_4(\text{l}) + \text{O}_2(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{g})$
- 22.61** (a)  $\text{HNO}_2(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{NO}_3^-(\text{aq}) + 2\text{e}^-$   
 (b)  $\text{N}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{N}_2\text{O}(\text{aq}) + 2 \text{H}^+(\text{aq}) + 2\text{e}^-$
- 22.63** (a)  $\text{H}_3\text{PO}_3$ , +3 (b)  $\text{H}_4\text{P}_2\text{O}_7$ , +5 (c)  $\text{SbCl}_3$ , +3 (d)  $\text{Mg}_3\text{As}_2$ , +5 (e)  $\text{P}_2\text{O}_5$ , +5 **22.65** (a) Phosphorus is a larger atom than nitrogen, and P has energetically available *3d* orbitals, which participate in the bonding, but nitrogen does not. (b) Only one of the three hydrogens in  $\text{H}_3\text{PO}_2$  is bonded to oxygen. The other two are bonded directly to phosphorus and are not easily ionized. (c)  $\text{PH}_3$  is a weaker base than  $\text{H}_2\text{O}$  so any attempt to add  $\text{H}^+$  to  $\text{PH}_3$  in the presence of  $\text{H}_2\text{O}$  causes protonation of  $\text{H}_2\text{O}$ . (d) Because of the severely strained bond angles in  $\text{P}_4$  molecules, white phosphorus is highly reactive.

- 22.67 (a)  $2 \text{Ca}_3\text{PO}_4(\text{s}) + 6 \text{SiO}_2(\text{s}) + 10 \text{C}(\text{s}) \longrightarrow \text{P}_4(\text{g}) + 6 \text{CaSiO}_3(\text{l}) + 10 \text{CO}(\text{g})$   
 (b)  $\text{PBr}_3(\text{l}) + 3 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_3\text{PO}_3(\text{aq}) + 3 \text{HBr}(\text{aq})$   
 (c)  $4 \text{PBr}_3(\text{g}) + 6 \text{H}_2(\text{g}) \longrightarrow \text{P}_4 + 12 \text{HBr}(\text{g})$   
 22.69 (a) HCN (b) Ni(CO)<sub>4</sub> (c) Ba(HCO<sub>3</sub>)<sub>2</sub> (d) CaC<sub>2</sub>  
 22.71 (a)  $\text{ZnCO}_3(\text{s}) \xrightarrow{\Delta} \text{ZnO}(\text{s}) + \text{CO}_2(\text{g})$   
 (b)  $\text{BaC}_2(\text{s}) + 2 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{Ba}^{2+}(\text{aq}) + 2 \text{OH}^-(\text{aq}) + \text{C}_2\text{H}_2(\text{g})$   
 (c)  $2 \text{C}_2\text{H}_2(\text{g}) + 5 \text{O}_2(\text{g}) \longrightarrow 4 \text{CO}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{g})$   
 (d)  $\text{CS}_2(\text{g}) + 3 \text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + 2 \text{SO}_2(\text{g})$   
 (e)  $\text{Ca}(\text{CN})_2(\text{s}) + 2 \text{HBr}(\text{aq}) \longrightarrow \text{CaBr}_2(\text{aq}) + 2 \text{HCN}(\text{aq})$   
 22.73 (a)  $2 \text{CH}_4(\text{g}) + 2 \text{NH}_3(\text{g}) + 3 \text{O}_2(\text{g}) \xrightarrow{800^\circ\text{C}} 2 \text{HCN}(\text{g}) + 6 \text{H}_2\text{O}(\text{g})$   
 (b)  $\text{NaHCO}_3(\text{s}) + \text{H}^+(\text{aq}) \longrightarrow \text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) + \text{Na}^+(\text{aq})$   
 (c)  $2 \text{BaCO}_3(\text{s}) + \text{O}_2(\text{g}) + 2 \text{SO}_2(\text{g}) \longrightarrow 2 \text{BaSO}_4(\text{s}) + 2 \text{CO}_2(\text{g})$   
 22.75 (a) H<sub>3</sub>BO<sub>3</sub>, +3 (b) SiBr<sub>4</sub>, +4 (c) PbCl<sub>2</sub>, +2  
 (d) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> · 10 H<sub>2</sub>O, +3 (e) B<sub>2</sub>O<sub>3</sub>, +3 22.77 (a) Lead (b) carbon, silicon, and germanium (c) silicon 22.79 (a) Tetrahedral (b) Metasilicic acid will probably adopt the single-strand silicate chain structure shown in Figure 22.46 (a). The Si to O ratio is correct and there are two terminal O atoms per Si that can accommodate the two H atoms associated with each Si atom of the acid. 22.81 (a) Diborane has bridging H atoms linking the two B atoms. The structure of ethane has the C atoms bound directly, with no bridging atoms. (b) B<sub>2</sub>H<sub>6</sub> is an electron-deficient molecule. The 6 valence electron pairs are all involved in B—H sigma bonding, so the only way to satisfy the octet rule at B is to have the bridging H atoms shown in Figure 22.48. (c) The term 'hydridic' indicates that the H atoms in B<sub>2</sub>H<sub>6</sub> have more than the usual amount of electron density for a covalently bound H atom. 22.85 BrO<sub>3</sub><sup>-</sup>(aq) + XeF<sub>2</sub>(aq) + H<sub>2</sub>O(l) → Xe(g) + 2 HF(aq) + BrO<sub>4</sub><sup>-</sup>(aq)  
 22.87 (a) SO<sub>3</sub> (b) Cl<sub>2</sub>O<sub>5</sub> (c) N<sub>2</sub>O<sub>3</sub> (d) CO<sub>2</sub> (e) P<sub>2</sub>O<sub>5</sub> 22.90 (a) PO<sub>4</sub><sup>3-</sup>, +5; NO<sub>3</sub><sup>-</sup>, +5. (b) The Lewis structure for NO<sub>4</sub><sup>3-</sup> would be:
- $$\left[ \begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\ | \\ \text{:}\ddot{\text{O}}\text{---N---}\ddot{\text{O}}\text{:} \\ | \\ \text{:}\ddot{\text{O}}\text{:} \end{array} \right]^{3-}$$
- The formal charge on N is +1 and on each O atom is -1. The four electronegative oxygen atoms each withdraw electron density, leaving the nitrogen deficient. Since N can form a maximum of four bonds, it cannot form a π bond with one or more of the O atoms to regain electron density, as the P atom in PO<sub>4</sub><sup>3-</sup> does. Also, the short N—O distance would lead to a tight tetrahedron of O atoms subject to steric repulsion.
- 22.93  $\text{GeO}_2(\text{s}) + \text{C}(\text{s}) \xrightarrow{\Delta} \text{Ge}(\text{l}) + \text{CO}_2(\text{g})$

 (e)  $2 \text{Fe}^{2+}(\text{aq}) + \text{H}_2\text{O}_2(\text{aq}) + 2 \text{H}^+(\text{aq}) \longrightarrow 2 \text{Fe}^{3+}(\text{aq}) + 2 \text{H}_2\text{O}(\text{l})$   
 22.97 (a) 88.2 g H<sub>2</sub> (b) 980 L 22.100 [HClO] = 0.036 M  
 22.103 (a)  $\text{SO}_2(\text{g}) + 2 \text{H}_2\text{S}(\text{aq}) \longrightarrow 3 \text{S}(\text{s}) + 2 \text{H}_2\text{O}(\text{l})$  or  $8 \text{SO}_2(\text{g}) + 16 \text{H}_2\text{S}(\text{aq}) \longrightarrow 3 \text{S}_8(\text{s}) + 16 \text{H}_2\text{O}(\text{l})$  (b)  $2.0 \times 10^3 \text{ mol} = 5.01 \times 10^4 \text{ L H}_2\text{S}(\text{g})$  (c)  $9.5 \times 10^4 \text{ g S} = 210 \text{ lb S}$  per ton of coal combusted. 22.106 (a) covalent network (b)  $\text{MnSi}(\text{s}) + \text{HF}(\text{aq}) \longrightarrow \text{SiH}_4(\text{g}) + \text{MnF}_4(\text{s})$ . Reduction of Mn(IV) to Mn(II) is unlikely, because F<sup>-</sup> is an extremely weak reducing agent. 22.109 (a)  $\text{HOOC---CH}_2\text{---COOH} \xrightarrow{\text{P}_2\text{O}_5} \text{C}_3\text{O}_2 + 2 \text{H}_2\text{O}$  (b) 24 valence e<sup>-</sup>, 12 e<sup>-</sup> pair  $\ddot{\text{O}}=\text{C}=\text{C}=\text{C}=\ddot{\text{O}}$

(c) C=O; about 1.23 Å; C=C, 1.34 Å or less. Consecutive C=C bonds require sp hybrid orbitals on C, so we expect the orbital overlap requirements of this bonding arrangement to require smaller than usual C=C distances.  
 (d) Two possible products are:

## Chapter 23

- 23.1 The diagram indicates that the roasting of ZnS is exothermic. The roasting reaction, once under way, will increase the temperature of the oven. The thermodynamic characteristics of the reaction do not affect its rate. Although the reaction produces heat when underway, heating is probably required so that the roasting reaction occurs at a practical rate. 23.3 The stronger the metal-metal bonding of the element, the greater the magnitude of  $\Delta H_f^\circ(\text{g})$ . Molybdenum, with valence orbitals that are exactly half-full, has a full bonding band and an empty valence band. It has stronger metal-metal bonding than zirconium and a larger  $\Delta H_f^\circ(\text{g})$ . Cadmium atoms have filled valence orbitals, filled bonding and valence bands and weaker metal-metal bonding than zirconium. It has a smaller  $\Delta H_f^\circ(\text{g})$  than zirconium. 23.5 Moving from left to right in a period,  $Z_{\text{eff}}$  increases. Increasing  $Z_{\text{eff}}$  leads to increasing ionization energy and electronegativity, but decreasing atomic radius. The chart shows a general decrease in magnitude of the property from K to Ge, so the property must be atomic radius. 23.7 Iron: hematite, Fe<sub>2</sub>O<sub>3</sub>; magnetite, Fe<sub>3</sub>O<sub>4</sub>. Aluminum: bauxite, Al<sub>2</sub>O<sub>3</sub> · xH<sub>2</sub>O. In ores, iron is present as the 3+ ion or as both the 2+ and 3+ ions as in magnetite. Aluminum is always present in the +3 oxidation state. 23.9 An ore consists of a little bit of the stuff we want (chalcopyrite, CuFeS<sub>2</sub>) and lots of other junk (gangue).  
 23.11 (a)  $\text{Cr}_2\text{O}_3(\text{s}) + 6 \text{Na}(\text{l}) \longrightarrow 2 \text{Cr}(\text{s}) + 3 \text{Na}_2\text{O}(\text{s})$   
 (b)  $\text{PbCO}_3(\text{s}) \xrightarrow{\Delta} \text{PbO}(\text{s}) + \text{CO}_2(\text{g})$   
 (c)  $2 \text{CdS}(\text{s}) + 3 \text{O}_2(\text{g}) \xrightarrow{\Delta} 2 \text{CdO}(\text{s}) + 2 \text{SO}_2(\text{g})$   
 (d)  $\text{ZnO}(\text{s}) + \text{CO}(\text{g}) \xrightarrow{\Delta} \text{Zn}(\text{l}) + \text{CO}_2(\text{g})$   
 23.13 (a) SO<sub>3</sub>(g) (b) CO(g) provides a reducing environment for the transformation of Pb<sup>2+</sup> to Pb. (c)  $\text{PbSO}_4(\text{s}) \longrightarrow \text{PbO}(\text{s}) + \text{SO}_3(\text{g})$ ;  $\text{PbO}(\text{s}) + \text{CO}(\text{g}) \longrightarrow \text{Pb}(\text{s}) + \text{CO}_2(\text{g})$   
 23.15  $\Delta H^\circ = -65.7 \text{ kJ}$ ;  $\Delta G^\circ = -325.9 \text{ kJ}$ ;  $\Delta S^\circ = 15.9 \text{ J/K}$ . Both  $\Delta H^\circ$  and  $\Delta G^\circ$  are negative; the reaction is exothermic and spontaneous under standard conditions at 25 °C.  
 23.17 The major reducing agent is CO, formed by partial oxidation of the coke (C) with which the furnace is charged.  $\text{Fe}_2\text{O}_3(\text{s}) + 3 \text{CO}(\text{g}) \longrightarrow 2 \text{Fe}(\text{l}) + 3 \text{CO}_2(\text{g})$ ;  $\text{Fe}_3\text{O}_4(\text{s}) + 4 \text{CO}(\text{g}) \longrightarrow 3 \text{Fe}(\text{l}) + \text{CO}_2(\text{g})$  23.19 (a) Air serves mainly to oxidize coke to CO; this exothermic reaction also provides heat for the furnace:  $2 \text{C}(\text{s}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{CO}(\text{g})$ ,  $\Delta H = -221 \text{ kJ}$ . (b) Limestone, CaCO<sub>3</sub>, is the source of basic oxide for slag formation:  $\text{CaCO}_3(\text{s}) \xrightarrow{\Delta} \text{CaO}(\text{s}) + \text{CO}_2(\text{g})$ ;  $\text{CaO}(\text{l}) + \text{SiO}_2(\text{l}) \longrightarrow \text{CaSiO}_3(\text{l})$ . (c) Coke is the fuel for the blast furnace and the source of CO, the major reducing agent in the furnace.  $2 \text{C}(\text{s}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{CO}(\text{g})$ ;  $4 \text{CO}(\text{g}) + \text{Fe}_3\text{O}_4(\text{s}) \longrightarrow 4 \text{CO}_2(\text{g}) + 3 \text{Fe}(\text{l})$  (d) Water acts as a source of hydrogen and as a means of controlling temperature.  $\text{C}(\text{s}) + \text{H}_2\text{O}(\text{g}) \longrightarrow \text{CO}(\text{g}) + \text{H}_2(\text{g})$ ,  $\Delta H = +131 \text{ kJ}$  23.21 To purify crude cobalt electrochemically, use an electrolysis cell in which the crude metal is the anode, a thin sheet of pure cobalt is the cathode, and the electrolyte is an aqueous solution of a soluble cobalt salt such as CoSO<sub>4</sub> · 7 H<sub>2</sub>O. Reduction of water doesn't occur, because of kinetic effects. Anode reaction:  $\text{Co}(\text{s}) \longrightarrow \text{Co}^{2+}(\text{aq}) + 2 \text{e}^-$ ; cathode reaction:  $\text{Co}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Co}(\text{s})$ .

**23.23** Sodium is metallic; each atom is bonded to many others. When the metal lattice is distorted, many bonds remain intact. In NaCl the ionic forces are strong, and the ions are arranged in very regular arrays. The ionic forces tend to be broken along certain cleavage planes in the solid, and the substance does not tolerate much distortion before cleaving. **23.25** In the electron-sea model, valence electrons move about the metallic lattice, while metal atoms remain more or less fixed in position. Under the influence of an applied potential, the electrons are free to move throughout the structure, giving rise to thermal and electrical conductivity. **23.27** Moving left to right in the period, atomic mass and  $Z_{\text{eff}}$  increase. The increase in  $Z_{\text{eff}}$  leads to smaller bonding atomic radii and shorter metal-metal bond distances. It seems that the extent of metal-metal bonding increases in the series, which is consistent with greater occupancy of the bonding band as the number of valence electrons increases up to 6. The increasing metal-metal bond strength in the series is probably the most important factor influencing the increase in density. **23.29** (a) Ag (b) Zn. Ductility decreases as the strength of metal-metal bonding increases, producing a stiffer lattice, less susceptible to distortion. **23.31** White tin has a structure characteristic of a metal, while gray tin has the diamond structure characteristic of group 4A semiconductors. Metallic white tin has the longer bond distance because the valence electrons are shared with twelve nearest neighbors rather than being localized in four bonds as in gray tin. **23.33** An alloy contains atoms of more than one element and has the properties of a metal. In a solution alloy the components are randomly dispersed. In a heterogeneous alloy the components are not evenly dispersed and can be distinguished at a macroscopic level. In an intermetallic compound the components have interacted to form a compound substance, as in  $\text{Cu}_3\text{As}$ . **23.35** (a) Interstitial alloy (b) solution alloy (c) intermetallic compound **23.37** Isolated atoms: (b) and (f); bulk metal: (a), (c), (d), and (e). Although it seems that atomic radius is a property of isolated atoms, it can only be measured on a bulk sample. **23.39** Hf has a completed  $4f$  subshell, while Zr does not. The build-up in  $Z$  that accompanies the filling of the  $4f$  orbitals, along with additional shielding of valence electrons, offsets the typical effect of the larger  $n$  value for the valence electrons of Hf. Thus, the atomic radius of Hf is about the same as that of Zr, the element above it in group 4B. **23.41** (a)  $5\text{CF}_3$  (b)  $\text{CoF}_3$  (c)  $\text{ZnF}_2$  (d)  $\text{MoF}_6$  **23.43** Chromium,  $[\text{Ar}]4s^13d^5$ , has six valence electrons, some or all of which can be involved in bonding, leading to multiple stable oxidation states. Al,  $[\text{Ne}]3s^23p^1$ , has only three valence electrons, which are all lost or shared during bonding, producing the +3 state exclusively. **23.45** (a)  $\text{Cr}^{3+}$ ,  $[\text{Ar}]3d^3$  (b)  $\text{Au}^{3+}$ ,  $[\text{Xe}]4f^{14}5d^8$  (c)  $\text{Ru}^{2+}$ ,  $[\text{Kr}]4d^6$  (d)  $\text{Cu}^+$ ,  $[\text{Ar}]3d^{10}$  (e)  $\text{Mn}^{4+}$ ,  $[\text{Ar}]3d^3$  (f)  $\text{Ir}^+$ ,  $[\text{Xe}]4f^{14}5d^8$  **23.47**  $\text{Ti}^{2+}$  **23.49**  $\text{Fe}^{2+}$  is a reducing agent that is readily oxidized to  $\text{Fe}^{3+}$  in the presence of  $\text{O}_2$  from air. **23.51** (a)  $\text{Fe}(s) + 2\text{HCl}(aq) \longrightarrow \text{FeCl}_2(aq) + \text{H}_2(g)$  (b)  $\text{Fe}(s) + 4\text{HNO}_3(g) \longrightarrow \text{Fe}(\text{NO}_3)_3(aq) + \text{NO}(g) + 2\text{H}_2\text{O}(l)$  **23.53** The unpaired electrons in a paramagnetic material cause it to be weakly attracted into a magnetic field. A diamagnetic material, where all electrons are paired, is very weakly repelled by a magnetic field. **23.55** (a) In ferromagnetic materials, coupled electron spins are aligned in the same direction. In antiferromagnetic materials, coupled spins are aligned in opposite directions and the opposing spins exactly cancel. In ferrimagnetic materials coupled spins are aligned in opposite directions but the opposing spins do not cancel. (b) Antiferromagnetic materials have no net electron spin and cannot be used to make permanent magnets. **23.57**  $\text{PbS}(s) + \text{O}_2(g) \longrightarrow \text{Pb}(l) + \text{SO}_2(g)$ .  $\text{SO}_2(g)$  is a product of roasting sulfide ores. In an oxygen-rich environment,  $\text{SO}_2(g)$  is oxidized to  $\text{SO}_3(g)$ , which dissolves in  $\text{H}_2\text{O}(l)$  to form sulfuric acid,  $\text{H}_2\text{SO}_4(aq)$ . A sulfuric acid plant near a roasting plant would provide a means for disposing of hazardous  $\text{SO}_2(g)$  that would also generate a profit. **23.59**  $\text{CO}(g)$ ;  $\text{Pb}(s)$ ;  $\text{H}_2(g)$ ;  $\text{Fe}(s)$ ;

$\text{Zn}(s)$ ;  $\text{Au}(s)$  **23.62** Based on its reduction potential, Te is less active and more difficult to oxidize than Cu. While Cu is oxidized from the crude anode during electrorefining, Te will not be oxidized. It is likely to accumulate, along with other impurities less active than Cu, in the so-called anode sludge. **23.67**  $E^\circ$  will become more negative as the stability ( $K_f$  value) of the complex increases. **23.71** (a)  $\text{Mn}(s) + 2\text{HNO}_3(aq) \longrightarrow \text{Mn}(\text{NO}_3)_2(aq) + \text{H}_2(g)$  (b)  $\text{Mn}(\text{NO}_3)_2(s) \xrightarrow{\Delta} \text{MnO}_2(s) + 2\text{NO}_2(g)$  (c)  $\text{MnO}_2(s) \xrightarrow{\Delta} \text{Mn}_3\text{O}_4(s) + \text{O}_2(g)$  (d)  $2\text{MnCl}_2(s) + 9\text{F}_2(g) \longrightarrow 2\text{MnF}_3(s) + 4\text{ClF}_3(g)$  **23.73** (a) Insulator (b) semiconductor (c) metallic conductor (d) metallic conductor (e) insulator (f) metallic conductor **23.74** (a)  $6.7 \times 10^8$  g  $\text{SO}_2$  (b) 2.3 mol Cu/mol Fe (c) CuO and  $\text{Fe}_2\text{O}_3$  (d)  $\text{Cu}_2\text{S}(s) + 2\text{O}_2(g) \longrightarrow 2\text{CuO}(s) + \text{SO}_2(g)$ ;  $4\text{FeS}(s) + 7\text{O}_2(g) \longrightarrow 2\text{Fe}_2\text{O}_3(s) + 4\text{SO}_2(g)$  **23.76**  $7.3 \times 10^2$  g  $\text{Ni}^{2+}(aq)$  **23.79**  $K = 1.6 \times 10^6$  **23.82** (a) The standard reduction potential for  $\text{H}_2\text{O}(l)$  is much greater than that of  $\text{Mg}^{2+}(aq)$  ( $-0.83$  V vs.  $-2.37$  V). In aqueous solution  $\text{H}_2\text{O}(l)$  would be preferentially reduced and no Mg(s) would be obtained. (b)  $1.0 \times 10^3$  kg Mg **23.85** The density of pure Ni is  $8.86$  g/cm<sup>3</sup>; the density of  $\text{Ni}_3\text{Al}$  is  $7.47$  g/cm<sup>3</sup>. In  $\text{Ni}_3\text{Al}$ , one of every four Ni atoms is replaced with a lighter Al atom. The mass of the unit cell contents of  $\text{Ni}_3\text{Al}$  is  $\approx 85\%$  of that of pure Ni, and the densities show the same relationship.

## Chapter 24

(b) coordination number = 4, coordination geometry = square planar (c) oxidation number = +2 **24.4** Structures (3) and (4) are identical to (1); (2) and (5) are geometric isomers of (1). **24.6** The yellow-orange solution absorbs blue-violet; the blue-green solution absorbs orange-red. **24.9** (a) In Werner's theory, *primary valence* is the charge of the metal cation at the center of the complex. *Secondary valence* is the number of atoms bound or coordinated to the central metal ion. The modern terms for these concepts are oxidation state and coordination number, respectively. (b) Ligands are the Lewis base in metal-ligand interactions. As such, they must possess at least one unshared electron pair.  $\text{NH}_3$  has an unshared electron pair but  $\text{BH}_3$ , with less than 8 electrons about B, has no unshared electron pair and cannot act as a ligand. **24.11** (a) +2 (b) 6 (c) 2 mol  $\text{AgBr}(s)$  will precipitate per mole of complex. **24.13** (a) Coordination number = 4, oxidation number = +2 (b) 5, +4 (c) 6, +3 (d) 5, +2 (e) 6, +3 (f) 4, +2 **24.15** (a)  $4\text{Cl}^-$  (b)  $4\text{Cl}^-$ ,  $1\text{O}^{2-}$  (c) 4 N,  $2\text{Cl}^-$  (d) 5 C (e) 6 O (f) 4 N **24.17** (a) A monodentate ligand binds to a metal via one atom, a bidentate ligand binds through two atoms. (b) Three bidentate ligands fill the coordination sphere of a six-coordinate complex. (c) A tridentate ligand has at least three atoms with unshared electron pairs in the correct orientation to simultaneously bind one or more metal ions. **24.19** (a) *Ortho*-phenanthroline, *o*-phen, is bidentate (b) oxalate,  $\text{C}_2\text{O}_4^{2-}$ , is bidentate (c) ethylenediaminetetraacetate, EDTA, is pentadentate (d) ethylenediamine, en, is bidentate. **24.21** (a) The term *chelate effect* refers to the special stability associated with formation of a metal complex containing a polydentate (chelate) ligand relative to a complex containing only monodentate ligands. (b) The increase in entropy,  $+\Delta S$ , associated with the substitution of a chelating ligand for two or more monodentate ligands generally gives rise to the *chelate effect*. Chemical reactions with  $+\Delta S$  tend to be spontaneous, have negative  $\Delta G$  and large values of  $K$ . (c) Polydentate ligands are used as *sequestering agents* to bind metal ions and prevent them from undergoing unwanted chemical reactions without removing them from solution. **24.23** (a)  $[\text{Cr}(\text{NH}_3)_6][\text{NO}_3]_3$  (b)  $[\text{Co}(\text{NH}_3)_4\text{CO}_3]\text{SO}_4$

- (c)  $[\text{Pt}(\text{en})_2\text{Cl}_2]\text{Br}_2$  (d)  $\text{K}[\text{V}(\text{H}_2\text{O})_2\text{Br}_4]$  (e)  $[\text{Zn}(\text{en})_2][\text{HgI}_4]$   
 24.25 (a) tetraamminedichlororhodium(III) chloride (b) potassium hexachlorotitanate(IV) (c) tetrachlorooxomolybdenum(VI) (d) tetraaqua(oxalato)platinum(IV) bromide

- (d)  $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{Cl}$ ,  $[\text{Co}(\text{NH}_3)_4\text{BrCl}]\text{Br}$  24.29 Yes. No structural or stereoisomers are possible for a tetrahedral complex of the form  $\text{MA}_2\text{B}_2$ . The complex must be square planar with cis and trans geometric isomers. 24.31 (a) One isomer (b) trans and cis isomers with  $180^\circ$  and  $90^\circ$  Cl—Ir—Cl angles, respectively (c) trans and cis isomers with  $180^\circ$  and  $90^\circ$  Cl—Fe—Cl angles, respectively. The cis isomer is optically active.

24.33 (a) Visible light has wavelengths between 400 and 700 nm. (b) Complementary colors are opposite each other on an artist's color wheel. (c) A colored metal complex absorbs visible light of its complementary color. (d) 196 kJ/mol

24.35 Most of the attraction between a metal ion and a ligand is electrostatic. Whether the interaction is ion-ion or ion-dipole, the ligand is strongly attracted to the metal center and can be modeled as a point negative charge.

(b) The magnitude of  $\Delta$  and the energy of the  $d-d$  transition for a  $d^1$  complex are equal. (c)  $\Delta = 203$  kJ/mol 24.39 A yellow color is due to absorption of light around 400 to 430 nm, a blue color to absorption near 620 nm. The shorter wavelength corresponds to a higher-energy electron transition and larger  $\Delta$  value. Cyanide is a stronger-field ligand, and its complexes are expected to have larger  $\Delta$  values than aqua complexes.

- 24.41 (a)  $\text{Ti}^{3+}$ ,  $d^1$  (b)  $\text{Co}^{3+}$ ,  $d^6$  (c)  $\text{Ru}^{3+}$ ,  $d^5$  (d)  $\text{Mo}^{5+}$ ,  $d^1$ , (e)  $\text{Re}^{3+}$ ,  $d^4$  24.43 (a) Mn,  $[\text{Ar}]4s^23d^5$ ;  $\text{Mn}^{2+}$ ,  $[\text{Ar}]3d^5$ ; 1 unpaired electron (b) Ru,  $[\text{Kr}]5s^14d^7$ ;  $\text{Ru}^{2+}$ ,  $[\text{Kr}]4d^6$ ; 0 unpaired electrons (c) Rh,  $[\text{Kr}]5s^14d^8$ ;  $\text{Rh}^{2+}$ ,  $[\text{Kr}]4d^7$ ; 1 unpaired electron 24.45 All complexes in this exercise are six-coordinate octahedral.

- 24.49  $[\text{Pt}(\text{NH}_3)_6]\text{Cl}_4$ ;  $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}_2$ ;  $[\text{Pt}(\text{NH}_3)_3\text{Cl}_3]\text{Cl}$ ;  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_4]$ ;  $\text{K}[\text{Pt}(\text{NH}_3)_3\text{Cl}_5]$  24.52 (a)  $[\text{Zn}(\text{en})_2]$  cis-tetraamminediaquacobalt(II) nitrate;  $[\text{Zn}(\text{en})_2]$  sodium aquapentachlororuthenate(III);  $[\text{Zn}(\text{en})_2]$  ammonium trans-diaquabisoxalato cobaltate(III);  $[\text{Zn}(\text{en})_2]$  cis-dichlorobisethylenediamineruthenium(II) (b) Only the complex in 24.51(d) is optically active. The mirror images of (a)–(c) can be superimposed on the original structure. The

chelating ligands in (d) prevent its enantiomers from being superimposable. 24.54 (a) In a square-planar complex, if one pair of ligands is trans, the remaining two coordination sites are also trans to each other. The bidentate ethylenediamine ligand is too short to occupy trans coordination sites, so the trans isomer of  $[\text{Pt}(\text{en})\text{Cl}_2]$  is unknown. (b) The minimum steric requirement for a trans-bidentate ligand is a medium-length chain between the two coordinating atoms that will occupy the trans positions. A polydentate ligand such as EDTA is much more likely to occupy trans positions because it locks the metal ion in place with multiple coordination sites and shields the metal ion from competing ligands present in the solution.

(b) Visible light with  $\lambda = hc/\Delta$  is absorbed by the complex, promoting one of the  $d$  electrons into a higher energy  $d$  orbital. The remaining wavelengths are reflected or transmitted; the combination of these wavelengths is the color we see. (c)  $[\text{V}(\text{H}_2\text{O})_6]^{3+}$  will absorb light with higher energy because it has a larger  $\Delta$  than  $[\text{Vf}_6]^{3-}$ .  $\text{H}_2\text{O}$  is in the middle of the spectrochemical series and causes a larger  $\Delta$  than  $\text{F}^-$ , a weak-field ligand.

24.62  $[\text{Co}(\text{NH}_3)_6]^{3+}$ , yellow;  $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$ , pink;  $[\text{CoCl}_4]^{2-}$ , blue

24.64 (a) The term isoelectronic means that the three ions have the same number of valence electrons and the same electron configuration. (b) The three metal atoms are in their maximum oxidation states and have no  $d$ -electrons, so there should be no  $d-d$  transitions. (c) A ligand-to-metal charge transfer transition occurs when an electron in a filled ligand orbital is excited to an empty  $d$ -orbital of the metal. (d) Compounds appear the complementary color of the light they absorb. Permanganate appears purple because it is absorbing 565 nm yellow light. Chromate appears yellow because it is absorbing violet light of approximately 420 nm. The wavelength of the LMCT transition for chromate is smaller than that in permanganate. (e) Yes. A white compound indicates that no visible light is absorbed. Moving left on the periodic chart from Mn to Cr, the wavelength of the LMCT decreases. It is consistent that the ion containing V, further left on the chart, has a LMCT at an even shorter wavelength in the ultraviolet region of the spectrum.

- (b) sodium dicarbonyltetracyanoferrate(II) (c) +2, 6d electrons (d) We expect the complex to be low spin. Cyanide (and carbonyl) are high on the spectrochemical series, which means the complex will have a large  $\Delta$  splitting, characteristic of low-spin complexes. 24.71 In carbonic anhydrase,  $\text{Zn}^{2+}$  is the Lewis acid, withdrawing electron density from  $\text{H}_2\text{O}$ , the Lewis base. The O—H bond is polarized and H becomes more ionizable, more acidic than the bulk solvent. 24.73  $\text{K}_4[\text{Mn}(\text{ox})_2\text{Br}_2]$  24.75 The chemical formula is  $[\text{Pd}(\text{NC}_5\text{H}_5)_2\text{Br}_2]$ . This is an

electrically neutral square-planar complex of Pd(II), a nonelectrolyte whose solutions do not conduct electricity. Because the dipole moment is zero, it must be the trans isomer.  $24.77 \text{ } 47.3 \text{ mg Mg}^{2+}/\text{L}$ ,  $53.4 \text{ mg Ca}^{2+}/\text{L}$   
 $24.80 \Delta E = 3.02 \times 10^{-19} \text{ J/photon}$ ,  $\lambda = 657 \text{ nm}$ . The complex will absorb in the visible around  $660 \text{ nm}$  and appear blue-green.

### Chapter 25

**25.1** Molecules (c) and (d) are unsaturated. **25.3** Compound (b), which has hydrogen bonding, has the highest boiling point. **25.5** (a) Molecule (i), disaccharide (b) molecule (iv), amino acid (c) molecule (iii), organic base (d) molecule (v), alcohol (e) molecule (ii), fatty acid **25.7** Numbering from the right on the condensed structural formula, C1 has trigonal planar electron domain geometry,  $120^\circ$  bond angles and  $sp^2$  hybridization; C2 and C5 have tetrahedral electron-domain geometry,  $109^\circ$  bond angles, and  $sp^3$  hybridization; C3 and C4 have linear electron domain geometry,  $180^\circ$  bond angles and  $sp$  hybridization. **25.9** Neither  $\text{NH}_3$  nor  $\text{CO}$  are typical organic molecules.  $\text{NH}_3$  contains no carbon atoms. Carbon monoxide contains a C atom that does not form four bonds. **25.11** (a) A straight-chain hydrocarbon has all carbon atoms connected in a continuous chain. A branched-chain hydrocarbon has a branch; at least one carbon atom is bound to three or more carbon atoms. (b) An alkane is a complete molecule composed of carbon and hydrogen in which all bonds are  $\sigma$  bonds. An alkyl group is a substituent formed by removing a hydrogen atom from an alkane. (c) Alkanes are said to be saturated because they cannot undergo addition reactions, such as those characteristic of carbon-carbon double bonds. (d) Ethylene (or ethene),  $\text{CH}_2=\text{CH}_2$ , is unsaturated. **25.13** (a)  $\text{C}_5\text{H}_{12}$  (b)  $\text{C}_5\text{H}_{10}$  (c)  $\text{C}_5\text{H}_{10}$  (d)  $\text{C}_5\text{H}_8$ ; saturated: (a), (b); unsaturated: (c), (d)

**25.15** One possible structure is

**25.17** There are at least 46 structural isomers with the formula  $\text{C}_6\text{H}_{10}$ . A few of them are

**25.19** (a)  $sp^3$  (b)  $sp^2$  (c)  $sp^2$  (d)  $sp$  **25.21** (a) 2-methylhexane

(b) 4-ethyl-2,4-dimethyldecane

**25.23** (a) 2,3-dimethylheptane (b) *cis*-6-methyl-3-octene (c) *para*-dibromobenzene (d) 4,4-dimethyl-1-hexyne (e) methylcyclobutane **25.25** Geometric isomerism in alkenes is the result of restricted rotation about the double bond. In alkanes bonding sites are interchangeable by free rotation about the C—C single bonds. In alkynes there is only one additional bonding site on a triply bound carbon, so no isomerism results. **25.27** (a) No

(c) no (d) no **25.29** 65 **25.31** (a) An addition reaction is the addition of some reagent to the two atoms that form a multiple bond. In a substitution reaction one atom or group of atoms replaces another atom. Alkenes typically undergo addition, while aromatic hydrocarbons usually undergo substitution.

**25.33** (a) The  $60^\circ$  C—C—C angles in the cyclopropane ring cause strain that provides a driving force for reactions that result in ring opening. There is no comparable strain in the five- or six-membered rings. (b)  $\text{C}_2\text{H}_4(\text{g}) + \text{HBr}(\text{g}) \longrightarrow \text{CH}_3\text{CH}_2\text{Br}(\text{l}); \text{C}_6\text{H}_6(\text{l}) + \text{CH}_3\text{CH}_2\text{Br}(\text{l}) \xrightarrow{\text{AlCl}_3} \text{C}_6\text{H}_5\text{CH}_2\text{CH}_3(\text{l}) + \text{HBr}(\text{g})$  **25.35** Not necessarily. That the two rate laws are first order in both reactants and second order overall indicates that the activated complex in the rate-determining step in each mechanism is bimolecular and contains one molecule of each reactant. This is usually an indication that the mechanisms are the same, but it does not rule out the possibility of different fast steps, or a different order of elementary steps. **25.37**  $\Delta H_{\text{comb}}/\text{mol CH}_2$  for cyclopropane =  $696.3 \text{ kJ}$ , for cyclopentane =  $663.4 \text{ kJ}$ .  $\Delta H_{\text{comb}}/\text{CH}_2$  group for cyclopropane is greater because  $\text{C}_3\text{H}_6$  contains a strained ring. When combustion occurs, the strain is relieved and the stored energy is released. **25.39** (a) Alcohol (b) amine, alkene (c) ether (d) ketone, alkene (e) aldehyde (f) carboxylic acid, alkyne **25.41** (a) Propionaldehyde (or propanal):

(b) ethylmethyl ether:

or

25.45

Ethylbenzoate

25.47

25.49 The presence of both  $-\text{OH}$  and  $-\text{C}=\text{O}$  groups in pure acetic acid leads us to conclude that it will be a strongly hydrogen-bonded substance. That the melting and boiling points of pure acetic acid are both higher than those of water, a substance we know to be strongly hydrogen-bonded, supports this conclusion. 25.51 (a)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}(\text{OH})\text{CH}_3$

25.55 (a) An  $\alpha$ -amino acid contains an  $\text{NH}_2$  group attached to the carbon adjacent to the carboxylic acid function. (b) In protein formation, amino acids undergo a condensation reaction between the amino group of one molecule and the carboxylic

acid group of another to form the amide linkage. (c) The bond that links amino acids in proteins is called the peptide bond.

(b) Three tripeptides are possible: Gly-Gly-His, GGH; Gly-His-Gly, GHG; His-Gly-Gly, HGG. 25.61 The primary structure of a protein refers to the sequence of amino acids in the chain. The secondary structure is the configuration (helical, folded, open) of the protein chain. The tertiary structure is the overall shape of the protein determined by the way the segments fold together. (b) X-ray crystallography is the primary and preferred technique for determining protein structure. 25.63 (a) Carbohydrates, or sugars, are polyhydroxyaldehydes or ketones composed of carbon, hydrogen, and oxygen. They are derived primarily from plants and are a major food source for animals. (b) A monosaccharide is a simple sugar molecule that cannot be decomposed into smaller sugar molecules by hydrolysis. (c) A disaccharide is a carbohydrate composed of two simple sugar units. Hydrolysis breaks a disaccharide into two monosaccharides. (d) A polysaccharide is a polymer composed of many simple sugar units. 25.65 The empirical formula of cellulose is  $\text{C}_6\text{H}_{10}\text{O}_5$ . As in glycogen, the six-membered ring form of glucose forms the monomer unit that is the basis of the polymer cellulose. In cellulose, glucose monomer units are joined by  $\beta$  linkages. 25.67 (a) In the linear form of mannose, the aldehydic carbon is C1. Carbon atoms 2, 3, 4, and 5 are chiral because they each carry four different groups. (b) Both the  $\alpha$  (left) and  $\beta$  (right) forms are possible.

# Answers to Give It Some Thought

## Chapter 1

page 3 (a) about 100 elements, (b) atoms and molecules

page 6 oxygen, O

page 8 The water molecule contains atoms of two different elements, hydrogen and oxygen. A compound consists of two or more different elements.

page 11 (a) is a chemical change because a new substance is being formed. (b) is a physical change because the water merely changes its physical state and not its composition.

page 14 1 pg, which equals  $10^{-12}$  g.

page 17  $2.5 \times 10^2 \text{ m}^3$ . The volume of a rectangular object is length  $\times$  width  $\times$  height. The units for volume, based on the SI unit of length, m, are  $\text{m}^3$ . 5.77 L/s is a different derived unit because it contains time in the denominator.

page 20 (b) is inexact because it is a measured quantity. Both (a) and (c) are exact; (a) involves counting; and (c) is a defined value.

page 26 Whenever possible, we must avoid using a conversion factor that has fewer significant figures than the data whose units are being converted. It is best to use at least one more significant figure in the conversion factor than in the data, which is what was done in Sample Exercise 1.9.

## Chapter 2

page 39 (a) the law of multiple proportions. (b) The second compound must contain two oxygen atoms for each carbon atom (that is, twice as many carbon atoms as the first compound).

page 43 (top) Most  $\alpha$  particles pass through the foil without being deflected because most of the volume of the atoms that comprise the foil is empty space.

page 43 (bottom) (a) The atom has 15 electrons because atoms have equal numbers of electrons and protons. (b) The protons reside in the nucleus of the atom.

page 47 Any single atom of chromium must be one of the isotopes of that element. The isotope mentioned has a mass of 52.94 amu and is probably  $^{53}\text{Cr}$ . The atomic weight differs from the mass of any particular atom because it is the average atomic mass of the naturally occurring isotopes of the element.

page 51 (a) Cl, (b) third period and group 7A, (c) 17, (d) non-metal

page 54 (a)  $\text{C}_2\text{H}_6$ , (b)  $\text{CH}_3$ , (c) probably the ball-and-stick model because the angles between the sticks indicate the angles between the atoms.

page 58 We write the empirical formulas for ionic compounds. Thus, the formula is CaO.

page 60 The transition metals can form more than one type of cation, and the charges of these ions are therefore indicated explicitly with Roman numerals: Chromium(II) ion is  $\text{Cr}^{2+}$ . Calcium, on the other hand, always forms the  $\text{Ca}^{2+}$  ion, so there is no need to distinguish it from other calcium ions with different charges.

page 61 An *-ide* ending usually means a monatomic anion, although there are some anions with two atoms that are also named this way. An *-ate* ending indicates an oxyanion. The most common oxyanions have the *-ate* ending. An *-ite* end-

ing also indicates an oxyanion, but one having less O than the anion whose name ends in *-ate*.

page 62  $\text{BO}_3^{3-}$  and  $\text{SiO}_4^{4-}$ . The borate has three O atoms, like the other oxyanions of the second period in Figure 2.27, and its charge is  $3-$ , following the trend of increasing negative charge as you move to the left in the period. The silicate has four O atoms, as do the other oxyanions in the third period in Figure 2.27, and its charge is  $4-$ , also following the trend of increasing charge moving to the left.

## Chapter 3

page 80 Each  $\text{Mg}(\text{OH})_2$  has 1 Mg, 2 O, and 2 H; thus,  $3 \text{Mg}(\text{OH})_2$  represents 3 Mg, 6 O, and 6 H.

page 84 The product is an ionic compound involving  $\text{Na}^+$  and  $\text{S}^{2-}$ , and its chemical formula is therefore  $\text{Na}_2\text{S}$ .

page 91 (a) A mole of glucose. By inspection of their chemical formulas we find that glucose has more atoms of hydrogen and oxygen than water and in addition it also has carbon atoms; thus, a molecule of glucose has a greater mass than a molecule of water. (b) They both contain the same number of molecules because a mole of each substance contains  $6.02 \times 10^{23}$  molecules.

page 98 There are experimental uncertainties in the measurements.

page 99 3.14 mol because 2 mol  $\text{H}_2 \approx 1$  mol  $\text{O}_2$  based on the stoichiometry of the chemical reaction.

page 100 The number of grams of product formed is the sum of the masses of the two reactants, 50 g. When two substances react in a combination reaction only one substance is formed as a product. According to the law of conservation of mass, the mass of the product must equal the masses of the two reactants.

## Chapter 4

page 122 (a)  $\text{K}^+(\text{aq})$  and  $\text{CN}^-(\text{aq})$ , (b)  $\text{Na}^+(\text{aq})$  and  $\text{ClO}_4^-(\text{aq})$

page 123  $\text{MgBr}_2$ , because it leads to ions in solution.

page 127 Yes, the  $\text{Na}^+$  ion. It appears both a reactant and a product in the same state and does change to form a new substance.

page 129 Three. Each COOH group will partially ionize in water to form  $\text{H}^+(\text{aq})$ .

page 130 HBr

page 135  $\text{SO}_2(\text{g})$

page 137 (a) Ne, (b) 0

page 142  $\text{Ni}^{2+}(\text{aq})$ . In Table 4.5 the ease of reduction of ions increases down the table.

page 144  $1.00 \times 10^{-2} \text{ M}$  solution of sucrose is more concentrated; that is, it has the larger value of molarity. The smaller the value of  $x$  in  $10^{-x}$ , the larger the value of  $10^{-x}$ .

page 148 The molarity decreases to 0.25 M. Molarity is directly proportional to the number of moles of solute (not changed) and inversely proportional to the volume of the solution in liters. Doubling the volume changes moles/V to moles/2V and the molarity is reduced by one half.

page 150 12.50 mL. The stoichiometry of the reaction between HBr and NaOH shows a 1 : 1 mole ratio. The given concentration of NaOH is twice that of HBr and, thus, a given volume of NaOH contains twice as many moles of solute than an equivalent volume of HBr. Therefore, the volume of NaOH required to reach the equivalence point is half of the original volume of HBr.

## Chapter 5

page 167 (a) kinetic energy, (b) potential energy, (c) heat, (d) work

page 168 Open system. Humans exchange matter and energy with their surroundings.

page 171

page 172 Endothermic. In Figure 5.5, the final state has a higher internal energy than the initial state and this is a characteristic of an endothermic process. Also, the figure shows  $\Delta E > 0$  which means energy flows into the system from the surroundings.

page 173 The balance (current state) does not depend on the ways the money may have been transferred into the account or on the particular expenditures made in withdrawing money from the account. It depends only on the net total of all the transactions.

page 175 (top) No. If  $\Delta V$  is zero then the expression  $w = -P\Delta V$  is also zero.

page 175 (bottom) It provides us with a state function that allows us to focus on heat flow, which is easier to measure than the work that accompanies a process.

page 178 The coefficients indicate the numbers of moles of reactants and products that give rise to the stated enthalpy change.

page 181  $\text{Hg}(l)$ . Rearranging equation 5.22 gives  $\Delta T = \frac{q}{C_s \times m}$ .

When  $q$  and  $m$  are constant for a series of substances then  $\Delta T = \frac{\text{constant}}{C_s}$ . Therefore, the element with the smallest  $C_s$  in Table 5.2 has the largest  $\Delta T$ ,  $\text{Hg}(l)$ .

page 182 (a) The energy lost by a system is gained by its surroundings. (b)  $q_{\text{system}} = -q_{\text{surroundings}}$

page 186 (a) The sign of  $\Delta H$  changes. (b) The magnitude of  $\Delta H$  doubles.

page 189  $2\text{C}(s) + \text{H}_2(g) \longrightarrow \text{C}_2\text{H}_2(g) \quad \Delta H_f^\circ = 226.7 \text{ kJ}$

page 194 Fats, because they have the largest fuel value of the three.

## Chapter 6

page 215 No. Both visible light and X-rays are forms of electromagnetic radiation. They therefore both travel at the speed of light,  $c$ . The differing ability to penetrate skin is due to the different energies of visible light and X-rays, which we will discuss in the next section.

page 216 As temperature increases, the average energy of the emitted radiation increases. Blue-white light is at the short end of the visible spectrum (at about 400 nm), whereas red light is closer to the other end of the visible spectrum (about 700 nm). Thus, the blue-white light has a higher

frequency, is more energetic, and is consistent with higher temperatures.

page 218 Ultraviolet. Figure 6.4 shows that a photon in the ultraviolet region of electromagnetic radiation has a higher frequency and greater energy than a photon in the infrared.

page 220 According to the third postulate, photons of only certain allowed frequencies can be absorbed or emitted as the electron changes energy state. The lines in the spectrum correspond to the allowed frequencies.

page 221 Absorb, because it is moving from a lower-energy state ( $n = 3$ ) to a higher-energy state ( $n = 7$ ).

page 223 Yes, all moving objects produce matter waves, but the wavelengths associated with macroscopic objects, such as the baseball, are too small to allow for any way of observing them.

page 224 The small size and mass of a subatomic particle. The term  $h/4\pi$  in the uncertainty principle is a very small number that becomes important only when considering extremely small objects, such as electrons.

page 226 Yes, there is a difference. The first statement says that the electron's position is known exactly, which violates the uncertainty principle. The second statement says that there is a high probability of where the electron is, but there is still uncertainty in its position.

page 227 Bohr proposed that the electron in the hydrogen atom moves in a well-defined circular orbit about the nucleus, which violates the uncertainty principle. An orbital is a wave function that gives the probability of finding the electron at any point in space, in accord with the uncertainty principle.

page 228 The energy of an orbital is proportional to  $-1/n^2$ . The difference between  $-1/(2)^2$  and  $-1/(1)^2$  is much greater than the difference between  $-1/(3)^2$  and  $-1/(2)^2$ .

page 230 The radial probability function for the  $4s$  orbital will have four maxima and three nodes.

page 232 The probability of finding the electron when it is in this  $p$  orbital is greater in the interior of the lobe than on the edges, which corresponds to changes in intensity of the pink color.

page 233 No. We know that the  $4s$  orbital is higher in energy than the  $3s$  orbital. Likewise, we know that the  $3d$  orbitals are higher in energy than the  $3s$  orbital. But, without more information, we do not know whether the  $4s$  orbital is higher or lower in energy than the  $3d$  orbitals.

page 239 The  $6s$  orbital, which starts to hold electrons at element 55, Cs.

page 243 We can't conclude anything! Each of the three elements has a different valence electron configuration for its  $nd$  and  $(n + 1)s$  subshells: For Ni,  $3d^8 4s^2$ ; for Pd,  $4d^{10}$ ; and for Pt,  $5d^9 6s^1$ .

## Chapter 7

page 257 The atomic number of an element depends on the number of protons in the nucleus, whereas the atomic weight depends (mainly) on the number of protons and the number of neutrons in the nucleus. Another example: Co has a lower atomic number (27) than that of Ni (28) but Co has a larger atomic weight (58.933 amu) than that of Ni (58.693 amu).

page 259 The  $2p$  electron of an Ne atom experiences a greater  $Z_{\text{eff}}$ . The atomic number of Na is greater than that of Ne, but an electron in the  $3s$  orbital of Na is farther from the nucleus and therefore more screened than is an electron in the  $2p$  orbital of Ne.

**page 262** The trends work against each other. Atomic radii tend to increase down a column in the periodic table. Atomic radius is determined by the distribution of the electrons in an atom and the volume they occupy in space. The effective nuclear charge experienced by outer electrons increases slightly down a column and this would tend to reduce orbital "size" and determines the trend in atomic radii of atoms in a column.

**page 266 (top)** The process in [7.4] requires energy with a shorter wavelength. The second ionization energy is associated with the process in [7.4] and it is a greater endothermic quantity than the first ionization energy associated with the process in [7.3]. An inverse relationship exists between energy of electromagnetic radiation and wavelength: the larger the energy, the smaller the wavelength.

**page 266 (bottom)**  $I_2$  for a carbon atom. In each process an electron is being removed from an atom or ion with five electrons, either  $B(g)$  or  $C^+(g)$ . The higher nuclear charge of the carbon nucleus makes  $I_2$  for carbon greater than  $I_1$  for boron.

**page 269** The same:  $[Ar]3d^3$ . The  $4s$  electrons are removed before the  $3d$  electrons in forming transition metal ions.

**page 271** The first ionization energy of  $Cl^-(g)$  is the energy needed to remove an electron from  $Cl^-$ , forming  $Cl(g) + e^-$ . That is the reverse process of Equation 7.6, so the first ionization energy of  $Cl^-(g)$  is  $+349$  kJ/mol.

**page 273** In general, increasing ionization energy correlates with decreasing metallic character.

**page 275** Molecular, because it has a relatively low melting point.  $P$ , because it is a nonmetallic element.

**page 278**  $Cs$  has the lowest ionization energy among the alkali metals.

**page 281** Gastric fluids in the stomach are very acidic (see the "Chemistry at Work" box on antacids in Section 4.3). Metal carbonates are soluble in acidic solution, where they react with the acid to form  $CO_2(g)$  and soluble salts, as in Equations 4.19 and 4.20.

**page 284** We can extrapolate the data in the table to make intelligent guesses for these numbers. Notice that the atomic radii increase by  $0.15$  Å and  $0.19$  Å, respectively, from  $Cl$  to  $Br$  and from  $Br$  to  $I$ . We might therefore expect an increase of  $0.15$ – $0.2$  Å from  $I$  to  $At$ , leading to an estimate of roughly  $1.5$  Å for the atomic radius of  $At$ . Similarly, we might expect  $I_1$  for  $At$  to be about  $900$  kJ/mol.

## Chapter 8

**page 299** No.  $Cl$  has seven valence electrons. The first and second Lewis symbols are both correct—they both show seven valence electrons, and it doesn't matter which of the four sides has the single electron. The third symbol shows only five electrons and is incorrect.

**page 301 (top)**  $CaO$  is an ionic compound consisting of  $Ca^{2+}$  and  $O^{2-}$  ions. When  $Ca$  and  $O_2$  react to form  $CaO$ , two  $Ca$  atoms lose two electrons each to form two  $Ca^{2+}$  ions and each oxygen atom in  $O_2$  takes up two electrons to form two  $O^{2-}$  ions. Thus, we can say that each  $Ca$  atom transfers two electrons to each oxygen atom.

**page 301 (bottom)** No. Figure 7.11 shows that the alkali metal with the smallest first ionization energy is  $Cs$  with a value of  $+376$  kJ/mol. Figure 7.12 shows that the halogen with the largest electron affinity is  $Cl$  with a value of  $-349$  kJ/mol. The sum of the two energies gives a positive energy (endothermic). Therefore, all other combinations of alkali metals with halogens will also have positive values.

**page 305 (top)** Palladium,  $Pd$

**page 305 (bottom)** Weaker. In both  $H_2$  and  $H_2^+$  the two  $H$  atoms are principally held together by the electrostatic attractions between the nuclei and the electron(s) concentrated between them.  $H_2^+$  has only one electron between the nuclei whereas  $H_2$  has two and this results in the  $H-H$  bond in  $H_2$  being stronger.

**page 307** Triple bond.  $CO_2$  has two  $C=O$  double bonds. Because the  $C=O$  bond in carbon monoxide is shorter, it is likely to be a triple bond.

**page 308** Electron affinity measures the energy released when an isolated atom gains an electron to form a  $1-$  ion. The electronegativity measures the ability of the atom to hold on to its own electrons and attract electrons from other atoms in compounds.

**page 309** Polar covalent. The difference in electronegativity between  $N$  and  $Si$  is  $3.0 - 1.8 = 1.2$ . Based on the examples of  $F_2$ ,  $HF$ , and  $LiF$ , the difference in electronegativity is great enough to introduce some polarity to the bond, but not sufficient to cause a complete electron transfer from one atom to the other.

**page 311**  $IF$ . Because the difference in electronegativity between  $I$  and  $F$  is greater than that between  $Cl$  and  $F$ , the magnitude of  $Q$  should be greater for  $IF$ . In addition, because  $I$  has a larger atomic radius than  $Cl$ , the bond length in  $IF$  is longer than that in  $ClF$ . Thus, both  $Q$  and  $r$  are larger for  $IF$ , and therefore  $\mu = Qr$  will be larger for  $IF$ .

**page 312** Smaller dipole moment for  $C-H$ . The magnitude of  $Q$  should be similar for  $C-H$  and  $H-I$  bonds because the difference in electronegativity for each bond is  $0.4$ . The  $C-H$  bond length is  $1.1$  Å and the  $H-I$  bond length is  $1.6$  Å. Therefore  $\mu = Qr$  will be greater for  $H-I$  because it has a larger bond length (larger  $r$ ).

**page 314**  $OsO_4$ . The data suggests that the yellow substance is a molecular species with its low melting and boiling points.  $Os$  in  $OsO_4$  has an oxidation number of  $+8$  and  $Cr$  in  $Cr_2O_3$  has an oxidation number of  $+3$ . In Section 8.4, we learn that a compound with a metal in a high oxidation state should show a high degree of covalence and  $OsO_4$  fits this situation.

**page 317** There is probably a better choice of Lewis structure than the one chosen. Because the formal charges must add up to  $0$  and the formal charge on the  $F$  atom is  $+1$ , there must be an atom that has a formal charge of  $-1$ . Because  $F$  is the most electronegative element, we don't expect it to carry a positive formal charge.

**page 319** Yes. There are two resonance structures for ozone that each contribute equally to the overall description of the molecule. Each  $O-O$  bond is therefore an average of a single bond and a double bond, which is a "one-and-a-half" bond.

**page 320** As "one-and-a-third" bonds. There are three resonance structures, and each of the three  $N-O$  bonds is single in two of those structures and double in the third. Each bond in the actual ion is an average of these:  $(1 + 1 + 2)/3 = 1\frac{1}{3}$ .

**page 321** No, it will not have multiple resonance structures. We can't "move" the double bonds, as we did in benzene, because the positions of the hydrogen atoms dictate specific positions for the double bonds. We can't write any other reasonable Lewis structures for the molecule.

page 322 The formal charge of each atom is shown below:

The first structure shows each atom with a zero formal charge and therefore it is the preferred Lewis structure. The second one shows a positive formal charge for an oxygen atom, which is a highly electronegative atom, and this is not a favorable situation.

page 325 The atomization of ethane produces  $2\text{C}(\text{g}) + 6\text{H}(\text{g})$ . In this process, six C—H bonds and one C—C bond are broken. We can use  $6D(\text{C—H})$  to estimate the amount of enthalpy needed to break the six C—H bonds. The difference between that number and the enthalpy of atomization is an estimate of the bond enthalpy of the C—C bond,  $D(\text{C—C})$ .

## Chapter 9

page 344 (top) Octahedral. Removing two atoms that are opposite each other leads to a square planar geometry.

page 344 (bottom) The molecule does not follow the octet rule because it has ten electrons around the central A atom. There are four electron domains around A: two single bonds, one double bond, and one nonbonding pair.

page 349 Yes. Based on one resonance structure, we might expect the electron domain that is due to the double bond to “push” the domains that are due to the single bonds, leading to angles slightly different from  $120^\circ$ . However, we must remember that there are two other equivalent resonance structures—each of the three O atoms has a double bond to N in one of the three resonance structures (Section 8.6). Because of resonance, all three O atoms are equivalent, and they will experience the same amount of repulsion, which leads to bond angles equal to  $120^\circ$ .

page 351 A tetrahedral arrangement of electron domains is preferred because the bond angles are  $109.5^\circ$  compared to  $90^\circ$  bond angles in a square planar arrangement of electron domains. The larger bond angles result in smaller repulsions among electron domains and a more stable structure.

page 354 No. The C—O and C—S bond dipoles exactly oppose each other, like in  $\text{CO}_2$ , but because O and S have different electronegativities, the magnitudes of the bond dipoles will be different. As a consequence, the bond dipoles will not cancel each other and the OCS molecule has a nonzero dipole moment.

page 357 Decrease. Figure 9.15 shows the potential energy of the system increasing when the H—H bond length is shorter than the equilibrium H—H bond position. The equilibrium H—H bond length corresponds to the system in its lowest energy state and any other H—H bond lengths correspond to weaker H—H bond strengths.

page 358 (top) The three  $2p$  orbitals are equivalent to one another; they differ only in their orientation. Thus, the two Be—F bonds would be equivalent to each other. Because  $p$  orbitals are perpendicular to one another, we would expect an F—Be—F bond angle of  $90^\circ$ . Experimentally, the bond angle is  $180^\circ$ .

page 358 (bottom) The unhybridized  $p$  orbital is oriented perpendicular to the plane defined by the three  $sp^2$  hybrids (trigonal planar array of lobes), with one lobe on each side of the plane.

page 363 The molecule should not be linear. Because there are three electron domains around each N atom, we expect  $sp^2$  hybridization and H—N—N angles of approximately  $120^\circ$ .

The molecule is expected to be planar; the unhybridized  $2p$  orbitals on the N atoms can form a  $\pi$  bond only if all four atoms lie in the same plane. You might notice that there are two ways in which the H atoms can be arranged: They can be both on the same side of the N=N bond or on opposite sides of the N=N bond.

page 370 The molecule would fall apart. With one electron in the bonding MO and one in the antibonding MO, there is no net stabilization of the electrons relative to two separate H atoms.

page 372 Yes. In  $\text{Be}_2^+$  there would be two electrons in the  $\sigma_{2s}$  MO but only one electron in the  $\sigma_{2s}^*$  MO, and therefore the ion is predicted to have a bond order of  $\frac{1}{2}$ . It should (and does) exist.

page 377 No. If the  $\sigma_{2p}$  MO were lower in energy than the  $\pi_{2p}$  MOs, we would expect the  $\sigma_{2p}$  MO to hold two electrons and the  $\pi_{2p}$  MOs to hold one electron each, with the same spin. The molecule would therefore be paramagnetic.

## Chapter 10

page 395 The major reason is the relatively large distance between molecules of gases. Each molecule is acting almost independently from the other molecules.

page 396 The height of the column decreases because atmospheric pressure decreases with increasing altitude.

page 400 (top) As the pressure increases, the volume decreases. Doubling the pressure causes the volume to decrease to half its original value.

page 400 (bottom) The volume decreases, but it doesn't decrease to half because the volume is proportional to the temperature on the Kelvin scale but not on the Celsius scale.

page 403 Because 22.41 L is the volume of one mole of the gas at STP, it contains Avogadro's number of molecules,  $6.022 \times 10^{23}$ .

page 407 Because water has a lower molar mass (18.0 g/mol) than  $\text{N}_2$  (28.0 g/mol), the water vapor is less dense. Note that density is proportional to the molar mass of a gas as shown in Equation 10.10.

page 410 According to Dalton's law of partial pressures, the pressure that is due to  $\text{N}_2$  (its partial pressure) does not change. However, the total pressure that is due to the partial pressures of both  $\text{N}_2$  and  $\text{O}_2$  increases.

page 414 The average kinetic energies depend only on temperature and not on the identity of the gas. Thus, the trend in average kinetic energies is  $\text{HCl}$  (298 K) =  $\text{H}_2$  (298 K) <  $\text{O}_2$  (350 K).

page 415 Average speed:  $\text{HCl} < \text{O}_2 < \text{H}_2$ . The average kinetic energy ( $\epsilon$ ) of gas molecules in a sample is  $\epsilon = \frac{1}{2}m\mu^2$ , where  $\mu$  is the root mean square speed (rms) and  $m$  is the mass of a molecule. Rms is not the same as average speed, but it is very close. Thus, the rms of a sample of a gas is inversely proportional to the square root of  $m$ ,  $\mu = \sqrt{\frac{2}{m}\epsilon}$ .

The greater the mass of a gas particle, the smaller the rms, and average speed. At the same temperature, all gases have the same average kinetic energy and  $\epsilon$  is a constant for the three gases. The gases are listed in order of increasing average speed (decreasing  $m$ ).

page 420 (a) Mean free path decreases because the molecules are crowded closer together. (b) There is no effect. Although the molecules are moving faster at the higher temperature, they are not crowded any closer together.

**page 421** (b) Gases deviate from ideality most at low temperatures and high pressures. Thus, the helium gas would deviate most from ideal behavior at 100 K (the lowest temperature listed) and 5 atm (the highest pressure listed).

**page 422** The fact that real gases deviate from ideal behavior can be attributed to the finite sizes of the molecules and to the attractions that exist between molecules.

### Chapter 11

**page 439** (a) In a gas the energy of attraction is less than the average kinetic energy. (b) In a solid, the energy of attraction is greater than the average kinetic energy.

**page 440**  $\text{Ca}(\text{NO}_3)_2$  in water.  $\text{CH}_3\text{OH}$  is a molecular substance and a nonelectrolyte. When it dissolves in water, no ions are present.  $\text{Ca}(\text{NO}_3)_2$  is an ionic compound and a strong electrolyte. When it dissolves in water, the  $\text{Ca}^{2+}$  ions and the  $\text{NO}_3^-$  ions interact with the polar water molecules by ion-dipole attractive forces.

**page 441** The magnitude of the dipole-dipole force depends on both the magnitude of the dipoles and the distance between the dipoles. We cannot judge the distance from Table 11.2, but we see that acetonitrile has the largest dipole moment and the highest boiling point, suggesting that the dipole-dipole attractions are greatest for that substance.

**page 442** (a) Polarizability increases in order of increasing molecular size and molecular weight:  $\text{CH}_4 < \text{CCl}_4 < \text{CBr}_4$ . (b) The strength of the dispersion forces follows the same order:  $\text{CH}_4 < \text{CCl}_4 < \text{CBr}_4$ .

**page 446** For nearly all substances, the solid phase is more dense than the liquid phase. For water, however, the solid is less dense than the liquid.

**page 448 (top)** (a) Both viscosity and surface tension decrease with increasing temperature because of the increased molecular motion. (b) Both properties increase as the strength of intermolecular forces increases.

**page 448 (bottom)** The strengths of the cohesive and adhesive forces are equal.

**page 450** Melting (or fusion), endothermic

**page 455**  $\text{CCl}_4$ . Both compounds are nonpolar. Consequently, only dispersion forces exist between the molecules. Because dispersion forces are stronger for the larger, heavier  $\text{CBr}_4$  than for  $\text{CCl}_4$ ,  $\text{CBr}_4$  has a lower vapor pressure than  $\text{CCl}_4$ . The substance with the larger vapor pressure at a given temperature is more volatile. Thus,  $\text{CCl}_4$  is more volatile than  $\text{CBr}_4$ .

**page 457** The line slopes to the right with increasing pressure because a liquid is more dense than a gas.

**page 460** Crystalline solids melt at a specific temperature, whereas amorphous ones tend to melt over a temperature range.

**page 461** Density is the mass of the unit cell in grams divided by the volume of the unit cell in  $\text{cm}^3$ . Calculate the total mass of the unit cell by summing the atomic masses (amu) of the net number of atoms contained within the unit cell. This mass is converted to grams using the equivalence of 1 gram equals  $6.02 \times 10^{23}$  amu. The volume of the unit cell is the length  $\times$  width  $\times$  height. Assuming a cubic unit cell, the length of an edge is cubed. Volume is converted to units of  $\text{cm}^3$ . Density is then calculated.

**page 464** The higher the coordination number of the particles in a crystal, the greater the packing efficiency.

**page 466**  $\text{C}_6\text{H}_6$ . Molecular solids are composed of molecules or nonmetal atoms. Because Co is a metal and  $\text{K}_2\text{O}$  is an ionic

substance, they do not form molecular solids.  $\text{C}_6\text{H}_6$ , however, is a molecular substance and forms a molecular solid.

### Chapter 12

**page 502** Yes, the molecule has both the  $-\text{NH}_2$  and  $-\text{COOH}$  groups in it, which can react as in nylon to make a polymer.

**page 503** Vinyl acetate interferes with intermolecular interactions between adjacent ethylene chains, and so reduces crystallinity and melting point.

### Chapter 13

**page 529** The lattice energy of  $\text{NaCl}(\text{s})$  must be overcome to separate  $\text{Na}^+$  and  $\text{Cl}^-$  ions and disperse them into a solvent.  $\text{C}_6\text{H}_{14}$  is a nonpolar hydrocarbon and  $\text{C}_6\text{H}_{14}$  molecules are held together by London dispersion forces. An ion is normally not attracted to a nonpolar molecule. (In some situations a weak ion-induced dipole interaction can exist.) Thus, the energy required to separate the ions in  $\text{NaCl}$  is not recovered in the form of ion- $\text{C}_6\text{H}_{14}$  interactions and prevents  $\text{NaCl}$  from dissolving in  $\text{C}_6\text{H}_{14}$ .

**page 531** (a) exothermic, (b) endothermic

**page 532** No, because the  $\text{AgCl}$  is not dispersed throughout the liquid phase.

**page 535** No. The concentration of sodium acetate is higher than the stable equilibrium value, so some of the dissolved solute comes out of solution when a seed crystal initiates the process. The concentration of sodium acetate eventually reaches its equilibrium value.

**page 538** Considerably lower because there would no longer be hydrogen bonding with water.

**page 541** Dissolved gases are less soluble as temperature increases and they begin to escape below the boiling point of water. Also, adsorbed oxygen on the surface of the cooking pot begins to escape with increasing temperature.

**page 542** 230 ppm (1 ppm is 1 part in  $10^6$ ).  $2.30 \times 10^5$  ppb (1 ppb is 1 part in  $10^9$ ).

**page 544** For dilute solutions the two concentration units are approximately the same numerically. Molarity is the number of moles of solute per liter of solution. Molality is the number of moles of solute per kilogram of solvent. In a liter of solution there will generally be less than 1 kg of water because the solute takes up some of the volume. However, in dilute solutions the two ratios are essentially the same.

**page 547**  $\text{NaCl}$ . Raoult's law is  $P_A = X_A P_A^\lambda$ . From this relationship we see that as the mole fraction of solvent,  $X_A$ , decreases (increasing mole fraction of solute), the partial pressure exerted by the solvent vapor,  $P_A$ , decreases. The solute with the greater mole fraction will cause a larger reduction in  $P_A$ . When 1 mole of  $\text{NaCl}$  dissolves in water it forms one mole each of  $\text{Na}^+$  and  $\text{Cl}^-$  ions whereas 1 mole of  $\text{C}_6\text{H}_{12}\text{O}_6$  does not dissociate because it is a nonelectrolyte. Thus, the mole fraction of  $\text{NaCl}$  is twice that of  $\text{C}_6\text{H}_{12}\text{O}_6$  and the  $\text{NaCl}$  solution has a greater vapor pressure lowering. A useful relationship can be derived from Raoult's law:  $\Delta P_A = X_B P_A^\lambda$  where  $\Delta P_A$  is the vapor pressure lowering of the solvent and  $X_B$  is the mole fraction of solute.

**page 548**  $P_A^\lambda$  is the vapor pressure of pure solvent and  $P_A$  is the vapor pressure of the solvent when a solute is present.

**page 549** Not necessarily; if the solute dissociates into particles, it could have a lower molality and still cause an increase of  $0.51^\circ\text{C}$ . The total molality of all the particles in the solution is 1 *m*.

**page 553** The 0.20 *m* solution is hypotonic with respect to the 0.5 *m* solution. A hypotonic solution has the lower osmotic pressure of two solutions.

**page 555** They would have the same osmotic pressure because they would have the same total concentration of dissolved particles.

**page 558** The smaller droplets carry negative charges because of the embedded stearate ions and thus repel one another.

## Chapter 14

**page 575** Increasing the partial pressure of a gas increases the number of gas molecules in a given volume and therefore increases the concentration of the gas. Rates normally increase with increasing reactant concentrations.

**page 577** The rate of a reaction is measured by the change in concentration of a reactant in a given unit of time. As a reaction proceeds, the concentration of a reactant decreases. As the concentration of a reactant decreases, the frequency with which the reactant particles collide with one another decreases, resulting in a smaller change in reactant concentration, and thus a decreased reaction rate.

**page 578** The size of the triangle is mostly a matter of convenience. Drawing a larger triangle will give larger values of both  $\Delta[C_4H_9Cl]$  and  $\Delta t$ , but their ratio,  $\Delta[C_4H_9Cl]/\Delta t$ , remains constant. Thus, the calculated slope is independent of the size of the triangle.

**page 581** (a) The rate law for any chemical reaction is the equation that relates the concentrations of reactants to the rate of the reaction. The general form for a rate law is given in Equation 14.7. (b) The quantity *k* in any rate law is the rate constant.

**page 582** (a) The rate law is second order in NO, first order in H<sub>2</sub>, and third order overall. (b) No. Doubling [NO] will cause the rate to increase fourfold, whereas doubling [H<sub>2</sub>] will merely double the rate.

**page 587** In (a) the intercept is the initial partial pressure of the CH<sub>3</sub>NC, 150 torr. In (b) it is the natural logarithm of this pressure,  $\ln(150) = 5.01$ .

**page 590** As the reaction proceeds, the concentration of the reactant decreases. At the end of each half-life the substance loses half of its initial amount at the start of each half-life. At the end of the first half-life, the substance loses 5.0 g and 5.0 g remains. At the end of the second half-life, 2.5 g remains, and at the end of the third half-life, 1.3 g remains (rounded value). In general, the amount of a substance remaining

after *n* half-lives, is: (initial amount)  $\left(\frac{1}{2^n}\right)$ .

**page 591** According to Equation 14.17 the half-life of a second order reaction depends inversely on the concentration of the reactant at the start of each half-life reaction. At the end of each half-life the concentration of the reactant is reduced and thus the half-life is larger for the next half-life reaction. That is, the half-life of a second-order reaction increases during the course of the reaction.

**page 592** Molecules must collide in order to react.

**page 594** The molecules must not merely collide in order to react, but they must collide in the proper orientation and with an energy greater than the activation energy for the reaction.

**page 598** Because the elementary reaction involves two molecules, it is bimolecular.

**page 601** The rate law depends not on the overall reaction, but on the slowest step in the mechanism.

**page 606** Generally, a catalyst lowers the activation energy by providing a different, lower-energy pathway (different mechanism) for a reaction.

**page 608** A heterogeneous catalyst is more easily removed. A heterogeneous catalyst is in a different phase from the reactants and therefore a heterogeneous mixture exists. Typically a heterogeneous catalyst is a solid and the reactants are either in a liquid or gas phase. A heterogeneous catalyst is identifiable as a separate phase in the mixture and an experimental method, such as filtration, can be designed to remove it. In a homogenous mixture, a one phase system, the catalyst is uniformly dispersed throughout the mixture, and its identification and removal is a more complex process.

**page 610** (a) active site, (b) substrate

## Chapter 15

**page 630 (top)** (a) The rates of opposing reactions are equal. (b) If the forward step is faster than the reverse step,  $k_f > k_r$ , and the constant, which equals  $k_f/k_r$ , will be greater than 1.

**page 630 (bottom)** The fact that concentrations no longer change with time indicates that equilibrium has been reached.

**page 633 (top)** It is independent of the starting concentrations of reactants and products.

**page 633 (bottom)** They represent equilibrium constants.  $K_c$  is obtained when equilibrium concentrations expressed in molarity are substituted into the equilibrium-constant expression.  $K_p$  is obtained when equilibrium partial pressures expressed in atmospheres are substituted into the expression.

**page 635**  $0.00140 M/1 M = 0.00140$  (no units)

**page 638** Because the coefficients in the equation have been multiplied by 3, the exponents in  $K_p$  are also multiplied by 3, so that the magnitude of the equilibrium constant will be  $(K_p)^3$ .

**page 639** Because the pure H<sub>2</sub>O liquid is omitted from the equilibrium-constant expression,  $K_p = P_{H_2O}$ . Thus, at any particular temperature, the equilibrium vapor pressure is a constant.

**page 641**  $K_c = \frac{[NH_4^+][OH^-]}{[NH_3]}$ . Water is the solvent and is excluded from the equilibrium-constant expression.

**page 649** (a) The equilibrium shifts to the right, using up some of the added O<sub>2</sub> and forming NO<sub>2</sub>. (b) The equilibrium shifts to the left, forming more NO to replace some of the NO that was removed.

**page 650** Increasing the volume of the system decreases the total gas pressure. The system is no longer at equilibrium and it responds to this stress by favoring the side of the equilibrium which counteracts the effect of the change. The total gas pressure is directly related to the total number of gas molecules in the system. Because there are three gas molecules on the left in the equation and only two on the right, the equilibrium position shifts to the left. This change increases the total number of gas molecules by converting SO<sub>3</sub> into SO<sub>2</sub> and O<sub>2</sub> and also increases the total gas pressure until equilibrium is restored.

**page 652** Evaporation is an endothermic process. Increasing the temperature of an endothermic process shifts the equilibrium to the right, forming more product. Because the product of the evaporation is the vapor, the vapor pressure increases.

page 655 No; catalysts have no effect on the position of an equilibrium, although they do affect how quickly equilibrium is reached.

### Chapter 16

page 668 The  $H^+$  ion for acids and the  $OH^-$  ion for bases.

page 670  $NH_3$  is the base because it accepts a  $H^+$  from  $HSO_4^-$  as the reaction moves from the left side of the equation to the right side.

page 672  $HNO_3$  is a strong acid, which means that  $NO_3^-$  has negligible basicity. In most questions involving the conjugate base of a strong acid we assume it does affect the concentration of hydrogen or hydroxide ions of a solution.

page 676 (a) The solution is neutral,  $[H^+] = [OH^-]$ . (b) The pH increases as  $[OH^-]$  increases.

page 678 (top)  $pH = 14.00 - 3.00 = 11.00$ . The solution is basic because  $pH > 7$ .

page 678 (bottom) From Figure 16.7, we see that the pH must be above about 8, meaning that the solution is basic.

page 681 Because  $CH_3^-$  is the conjugate base of a substance that has negligible acidity,  $CH_3^-$  must be a strong base. Bases stronger than  $OH^-$  abstract  $H^+$  from water molecules:  $CH_3^- + H_2O \rightarrow CH_4 + OH^-$ .

page 685 Because weak acids typically undergo very little ionization, often less than 1%. Normally we make the assumption and then check its validity based on the concentration of conjugate base formed in the calculation. If it is  $\leq 5\%$  of the initial concentration of the weak acid, we will use the assumption. If not, we have to do an exact calculation.

page 688 This is the acid-dissociation constant for the loss of the third and final proton from  $H_3PO_4$ :  $HPO_4^{2-}(aq) \rightleftharpoons H^+(aq) + PO_4^{3-}(aq)$ .

page 696 Because the  $NO_3^-$  ion is the conjugate base of a strong acid, it will not affect pH. ( $NO_3^-$  has negligible basicity.) Because the  $CO_3^{2-}$  ion is the conjugate base of a weak acid, it will affect pH, increasing the pH.

page 697  $K^+$ , an alkali metal cation, does not affect pH. Most transition metal ions with a 2+ charge or higher form acidic solutions.

page 700 The increasing acidity down a column is due mainly to decreasing H—X bond strength. The trend across a period is due mainly to the increasing electronegativity of X, which weakens the H—X bond.

page 703 The carboxyl group,  $-COOH$ .

page 704 It must have an unshared pair of electrons which can be shared with another atom.

page 706  $Fe^{3+}$ , because it has the highest charge. The ratio  $\frac{Z_+}{r_+}$

is an indicator we can use to compare relative abilities of cations to form acidic solutions. The greater the ratio for a cation, the greater is its tendency to react with water and form an acidic solution. Note that a large radius and a small positive charge for an ion, such as for  $Na^+$ , results in a low value for the ratio.  $Na^+$  exhibits no reaction with water to form an acidic solution.  $Fe^{3+}$  has a large charge and a relatively small ion size; thus, it will have a high value for the ratio.

### Chapter 17

page 723 (top) (a)  $[NH_4^+] = 0.10 M$ ;  $[Cl^-] = 0.10 M$ ;  $[NH_3] = 0.12 M$ . (b)  $Cl^-$ , (c) Equation 17.2.

page 723 (bottom)  $HNO_3$  and  $NO_3^-$ . This is a strong acid and its conjugate base. Buffers are composed of weak acids and their conjugate bases. The  $NO_3^-$  ion is merely a spectator in any acid–base chemistry and is therefore ineffective in helping control the pH of a solution.

page 724 (a) The  $OH^-$  of  $NaOH$  (a strong base) reacts with the acid member of the buffer ( $HC_2H_3O_2$ ), abstracting a proton. Thus,  $[HC_2H_3O_2]$  decreases and  $[C_2H_3O_2^-]$  increases. (b) The  $H^+$  of  $HCl$  (a strong acid) reacts with the base member of the buffer ( $C_2H_3O_2^-$ ). Thus,  $[C_2H_3O_2^-]$  decreases and  $[HC_2H_3O_2]$  increases.

page 727 The solution will most effectively resist a change in either direction when its  $pH = pK_a$ . Thus, the optimal pH is  $pH = pK_a = -\log(1.8 \times 10^{-5}) = 4.74$ , and the pH range of the buffer is about  $4.7 \pm 1$ .

page 730 pH increases. When  $NaOH$ , the titrant, is added to the  $HCl$  solution, a strong acid–strong base neutralization reaction occurs. The amount of hydrogen ion decreases and pH increases.

page 733  $pH = 7$ . The neutralization of a strong acid and a strong base at the equivalence point gives a solution of a salt and water. The salt contains ions which do not change the pH of water.

page 737 (top) The nearly vertical part of the titration curve at the equivalence point is smaller for the weak acid–strong base titration, and fewer indicators undergo their color change within this narrow range.

page 737 (bottom) The following titration curve shows the titration of 25 mL of  $Na_2CO_3$  with  $HCl$ , both with 0.1 M concentrations. The overall reaction between the two is

The initial pH [sodium carbonate in water only] is near 11 because  $CO_3^{2-}$  is a weak base in water. The graph shows two equivalence points, A and B. The first point, A, is reached at a pH of about 9:

$HCO_3^-$  is weakly basic in water, and is a weaker base than the carbonate ion.

The second point, B, is reached at a pH of about 4:

$H_2CO_3$ , a weak acid, forms and decomposes to carbon dioxide and water.

page 739 Because all three compounds produce the same number of ions, their relative solubilities correspond directly to their  $K_{sp}$  values, with the compound with the largest  $K_{sp}$  value being most soluble,  $AgCl$ .

page 750 They are insoluble in water but dissolve in the presence of either an acid or a base.

page 753 A high concentration of  $\text{H}_2\text{S}$  and a low concentration of  $\text{H}^+$  (that is, high pH) will shift the equilibrium to the right, reducing  $[\text{Cu}^{2+}]$ .

page 754 The solution must contain one or more of the cations in group 1 of the qualitative analysis scheme shown in Figure 17.22:  $\text{Ag}^+$ ,  $\text{Pb}^{2+}$ , or  $\text{Hg}_2^{2+}$ .

## Chapter 18

page 773 It looks like the area of the upper curve to the left of the visible portion is about twice as large as the area of the lower curve. The upper curve corresponds to radiation at the "top" of the atmosphere, and the bottom curve corresponds to radiation at sea level; therefore, we estimate about half of the ultraviolet light that arrives at Earth from the Sun gets absorbed by the upper atmosphere and does not make it to the ground.

page 775 Atomic Cl is the catalyst. In Equation 18.6, atomic Cl is produced by the reaction of CFCs with solar radiation with wavelengths in the range of 190 to 225 nm. Atomic Cl is a catalyst for the overall reaction shown in Equation 18.10. The sequence of reactions above Equation 18.10 shows atomic Cl reacting and reforming, which is characteristic of a catalyst.

page 778  $\text{SO}_2$  in the atmosphere reacts with oxygen to form  $\text{SO}_3$ .  $\text{SO}_3$  reacts with water in the atmosphere to form  $\text{H}_2\text{SO}_4$ . Air containing sulfuric acid is referred to as "acid rain" because the presence of sulfuric acid lowers the pH to about 4.

page 780 Equation 18.13

page 783 The higher the humidity of air, the higher the quantity of water vapor in the atmosphere. Water vapor absorbs infrared radiation and at night it radiates part of the absorbed infrared energy back to the surface of the Earth. This warms the surface and helps to reduce cooling at night.

page 786 Biodegradable organic materials consume oxygen in water. A decrease in oxygen concentration in water stored in a closed container over five days shows a significant presence of these materials.

page 790 As with so many other things, there are trade-offs in selecting processes for green chemistry. Yes, increasing  $\text{CO}_2$  is expected to lead to global warming; however, the main source of  $\text{CO}_2$  is from combustion of fossil fuels. If we can reduce the amount of  $\text{CO}_2$  entering the atmosphere from that source, perhaps we can afford to use supercritical or liquid  $\text{CO}_2$  in industrial processes, which are safer for workers than other chemicals and form less harmful by-products. Supercritical (or just liquid) water would be a better choice environmentally if the industrial process you want to change still works with water as a solvent.

## Chapter 19

page 804 No, nonspontaneous processes can occur so long as they receive some continuous outside assistance. Examples of nonspontaneous processes with which we may be familiar include the building of a brick wall and the electrolysis of water to form hydrogen gas and oxygen gas.

page 805 No. Just because the system is restored to its original condition doesn't mean that the surroundings have likewise been restored to their original condition.

page 807  $\Delta S$  depends not merely on  $q$  but on  $q_{\text{rev}}$ . Although there are many possible paths that could take a system from its initial to final state, there is always only one reversible isothermal path between two states. Thus,  $\Delta S$  has only one particular value regardless of the path taken between states.

page 809 Because rusting is a spontaneous process,  $\Delta S_{\text{univ}}$  must be positive. Therefore the entropy of the surroundings must increase, and that increase must be larger than the entropy decrease of the system.

page 810 A molecule can vibrate (atoms moving relative to one another) and rotate (tumble), whereas a single atom cannot undergo these motions.

page 811  $S = 0$ , based on Equation 19.5 and the fact that  $\ln 1 = 0$ .

page 817 It must be a perfect crystal at 0 K (third law of thermodynamics), which means it has only a single accessible microstate.

page 819 Depends on whether the system is open, closed, or isolated. For an open or closed system,  $\Delta S_{\text{surr}}$  always increases. The change in entropy of the surroundings in an isothermal

process is  $\Delta S_{\text{surr}} = -\frac{q_{\text{sys}}}{T}$ . The energy evolved by an open or

closed system is transferred to the surroundings and  $-q_{\text{sys}}$  is a positive number. Thus  $\Delta S_{\text{surr}}$  is a positive number and the entropy of the surroundings increases. If it is an isolated system, then energy is not transferred to the surroundings and the entropy of the surroundings does not change.

page 820 In any spontaneous process the entropy of the universe increases. In any spontaneous process operating at constant temperature, the free energy of the system decreases.

page 822 It indicates that the process to which the thermodynamic quantity refers has taken place under standard conditions, as summarized in Table 19.3.

page 825 Above the boiling point, vaporization is spontaneous, and  $\Delta G < 0$ . Therefore,  $\Delta H - T\Delta S < 0$ , and  $\Delta H < T\Delta S$ .

## Chapter 20

page 845 Oxygen is first assigned a  $-2$  oxidation number. Nitrogen must have a  $+3$  oxidation number for the sum of oxidation numbers to equal  $-1$ , the charge of the ion.

page 848 No. Electrons should appear in the two half-reactions but cancel when the half-reactions are added properly. That is, the oxidation half-reaction and the reduction half-reaction must show the same number of electrons, but on different sides of the arrow. The electrons cancel when the two half-reactions are added. So, when you are balancing a redox equation and find yourself with  $e^-$ 's on either side of the reaction arrow when you are done, you know you should go back and check your work.

page 853 The anode is where oxidation takes place. Because electrons are being removed from the anode, negatively charged anions must migrate to the anode to maintain charge balance.

page 854 The zinc atoms on the surface lose two electrons, forming  $\text{Zn}^{2+}$  ions, which leave and go into the solution. The surface of the electrode becomes pitted and the size of the electrode diminishes as the reaction proceeds.

page 855 Yes. A redox reaction in a cell with a positive potential is spontaneous.

page 858 1 atm pressure of  $\text{Cl}_2(\text{g})$  and 1 M solution of  $\text{Cl}^-(\text{aq})$ .

page 859 True.  $E_{\text{cell}}^\circ = E_{\text{red}}^\circ(\text{cathode}) - E_{\text{red}}^\circ(\text{anode})$  for a cell at standard-state conditions.  $E_{\text{cell}}^\circ$  is a measure of the net

driving force for the overall redox reaction; thus, the smaller the number, the smaller is the net driving force for the overall redox reaction.

**page 863** Pb(s) is stronger because it lies above Hg(l) in the activity series, which means that it more readily loses electrons.

**page 876** Al, Zn. Both are easier to oxidize than Fe.

## Chapter 21

**page 895** The mass number decreases by 4.

**page 897** Only the neutron, as it is the only neutral particle listed.

**page 898** From Figure 21.2, we see that the center of the belt of stability for a nucleus containing 70 protons lies at about 102 neutrons.

**page 903** Particle accelerators are designed to accelerate particles with a charge. Normal particle accelerators cannot accelerate neutrons, which are not charged particles. Fast-moving neutrons are typically formed by high-energy protons crashing into a nucleus, resulting in the emission of a number of fast-moving particles, including neutrons.

**page 906 (top)** Spontaneous radioactive decay is a unimolecular process:  $A \longrightarrow \text{Products}$ . The rate law that fits this observation is a first-order kinetic rate law,  $\text{rate} = k[A]$ . A second-order kinetic process has  $\text{rate} = k[A]^2$  and the elementary reaction is bimolecular:  $A + A \longrightarrow \text{Products}$ . A zero-order kinetic process has  $\text{rate} = k$ , and the rate does not change until the limiting reactant is entirely consumed. The latter two rate laws do not fit a unimolecular process.

**page 906 (bottom)** (a) Yes; doubling the mass would double the amount of radioactivity of the sample as shown in equation 21.18. (b) No; changing the mass would not change the half-life as shown in equation 21.20.

**page 909** No. Alpha particles are more readily absorbed by matter than beta or gamma rays. Geiger counters must be calibrated for the radiation they are being used to detect.

**page 913** No. Stable nuclei having mass numbers around 100 are the most stable nuclei. They could not form a still more stable nucleus with an accompanying release of energy.

## Chapter 22

**page 933** No. Phosphorus, being a third-row element, does not have a capacity for forming strong  $\pi$  bonds. Instead, it exists as a solid in which the phosphorus atoms are singly bonded to one another.

**page 938** No. As shown in Figure 22.7, the free energy of formation of  $\text{H}_2\text{Se}(\text{g})$  is positive, indicating that the equilibrium constant for the reaction will be small. (Section 19.7)

**page 943**  $\text{NaBrO}_3$  and  $\text{NaClO}_3$  should be strong oxidizing agents because the halogen in each is in the +5 oxidation state and readily reducible to a lower oxidation state such as 0 or -1. In the Appendix, we find the standard reduction potential in acid solution for  $\text{BrO}_3^-$  is +1.52 V and for  $\text{ClO}_3^-$  it is +1.47 V. At standard state conditions, the bromate ion is a slightly better oxidizing agent than the chlorate ion.

**page 946**  $\text{HIO}_3$ . Note that the iodine remains in the +5 oxidation state.

**page 951** No; the oxidation number of sulfur is the same in both reactants and products.

**page 956** The nitrogen atom in nitric acid has an oxidation number of +5 and that in nitrous acid has an oxidation number of +3.

**page 963**  $\text{MgCO}_3(\text{s})$ . The bicarbonate ion of washing soda ionizes to form a proton and  $\text{CO}_3^{2-}$  ion.  $\text{Mg}^{2+}$  reacts with  $\text{CO}_3^{2-}$  to precipitate  $\text{MgCO}_3$ .

## Chapter 23

**page 984** No. CaO contains a metal which is too active to be reduced with CO. Yes.  $\text{Ag}_2\text{O}$  should reduce readily with CO because Ag is not an active metal.

**page 987** Gold is the reducing agent, oxidized from 0 to +1 oxidation state. Dissolved oxygen is the oxidizing agent, reduced from 0 to -2 oxidation state.

**page 988**  $\text{Al}_2\text{O}_3$

**page 989**  $\text{Na}^+$  and  $\text{Cl}^-$

**page 990** Ionic conductivity. Charles Hall needed an ionic salt that melted to form a conducting medium, dissolved aluminum oxide and did not interfere with electrolysis. Ions move toward the anode and cathode in the molten salt solution and electrons in the outer circuit of the cell.

**page 991**  $\text{Cu}^{2+}$  and  $\text{H}^+$  as cations, and  $\text{SO}_4^{2-}$  as the anion

**page 995** Hg. Hg has more valence electron per atom than W and also lies to the right of the elements in the middle of the transition columns. Thus, Hg has more antibonding orbitals occupied. W is to the left of the elements in middle and has no antibonding orbitals occupied. Hg, with antibonding orbitals occupied, should have weaker bonding between atoms compared to the bonding structure in W. Hg is a liquid at room temperature and has a melting point of  $-38.8^\circ\text{C}$  and W is a solid at room temperature and has a melting point of  $3422^\circ\text{C}$ .

**page 997** Interstitial, because B is so much smaller than Pd.

**page 999** Cr has a smaller bonding atomic radius than Mn as shown in Table 23.4. From Figure 23.19, we see in the group 7B metals that the elements of the third series have greater bonding atomic radii than those of the first series. Therefore, Re, which is in the third series, is larger than either Cr or Mn. Cr has the smallest bonding atomic radius.

**page 1002** Yes. From Section 6.9 we expect Cr to have an outer  $4s^2 3d^4$  valence electron configuration and  $\text{Cr}^{3+}$  to have a  $3d^3$  configuration.  $\text{Cr}^{3+}$  would possess three unpaired electrons. Note: even if we wrote  $4s^2 3d^1$  instead of  $3d^3$  it would still have one unpaired electron.

## Chapter 24

**page 1016**  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}(\text{aq}) + \text{SCN}^-(\text{aq}) \longrightarrow [\text{Fe}(\text{H}_2\text{O})_5\text{NCS}]^{2+}(\text{aq}) + \text{H}_2\text{O}(\text{l})$

**page 1018** (a) tetrahedral and square planar; (b) octahedral

**page 1021** Each  $\text{NH}_3$  has one donor atom. Consequently, the  $\text{CO}_3^{2-}$  ion must have two donor atoms to give the cobalt atom a coordination number of 6. Thus,  $\text{CO}_3^{2-}$  is acting as a bidentate ligand.

**page 1023** The porphine ligand has conjugated double bonds which permit it to strongly absorb light in the visible region.

**page 1031** The two compounds have the same composition and bonds, but they are optical isomers of each other (nonsuperimposable mirror images). The *d* isomer rotates plane-polarized light to the right (dextrorotatory), whereas the *l* isomer rotates plane-polarized light to the left (levorotatory).

**page 1033** (a)  $[\text{Ar}]4s^2 3d^7$ , three unpaired electrons; (b)  $[\text{Ar}]3d^6$ , four unpaired electrons

**page 1035** The  $d_{x^2}$  and  $d_{x^2-y^2}$  orbitals

*page 1036* The Ti(IV) ion has no  $d$  electrons, so there can be no  $d-d$  transitions, which are the ones usually responsible for the color of transition-metal compounds.

*page 1039* The  $d_{xy}$  orbital, which has electron density in the  $xy$  plane, strongly interacts with the four ligands which are along the  $x$  and  $y$  axes. The  $d_{xz}$  and  $d_{yz}$  orbitals interact less strongly with the ligands in a tetrahedral complex compared to an octahedral complex because the two ligands along the vertical  $z$ -axis are removed. (Note that the two orbitals have a significant  $z$ -component of electron density.) These differences result in the  $d_{xy}$  orbital having a higher energy than that of the  $d_{xz}$  or  $d_{yz}$  orbitals.

## Chapter 25

*page 1053*  $C=N$ , because it is a polar double bond.  $C-H$  and  $C-C$  bonds are relatively unreactive.

*page 1056* Two  $C-H$  bonds and two  $C-C$  bonds

*page 1059*  $C_3H_7$ . The propyl group is formed by removing one hydrogen atom from propane,  $C_3H_8$ .

*page 1063* Only two of the four possible  $C=C$  bond sites are distinctly different in a linear chain of five carbon atoms with one double bond.

*page 1069*

*page 1074*

*page 1079* All four groups must be different from one another.

*page 1085* No. Breaking the hydrogen bonds between  $N-H$  and  $O=C$  groups in a protein by heating causes the  $\alpha$ -helix structure to unwind and the  $\beta$ -sheet structure to separate.

*page 1089* The  $\alpha$  form of the  $C-O-C$  linkage. Glycogen serves as a source of energy in the body, which means that the body's enzymes must be able to hydrolyze it to sugars. The enzymes work only on polysaccharides having the  $\alpha$  linkage.

## A

# Mathematical Operations

## A.1 EXPONENTIAL NOTATION

The numbers used in chemistry are often either extremely large or extremely small. Such numbers are conveniently expressed in the form

$$N \times 10^n$$

where  $N$  is a number between 1 and 10, and  $n$  is the exponent. Some examples of this *exponential notation*, which is also called *scientific notation*, follow.

1,200,000 is  $1.2 \times 10^6$  (read “one point two times ten to the sixth power”)

0.000604 is  $6.04 \times 10^{-4}$  (read “six point zero four times ten to the negative fourth power”)

A positive exponent, as in the first example, tells us how many times a number must be multiplied by 10 to give the long form of the number:

$$\begin{aligned} 1.2 \times 10^6 &= 1.2 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \quad (\text{six tens}) \\ &= 1,200,000 \end{aligned}$$

It is also convenient to think of the *positive exponent* as the number of places the decimal point must be moved to the *left* to obtain a number greater than 1 and less than 10: If we begin with 3450 and move the decimal point three places to the left, we end up with  $3.45 \times 10^3$ .

In a related fashion, a negative exponent tells us how many times we must divide a number by 10 to give the long form of the number.

$$6.04 \times 10^{-4} = \frac{6.04}{10 \times 10 \times 10 \times 10} = 0.000604$$

It is convenient to think of the *negative exponent* as the number of places the decimal point must be moved to the *right* to obtain a number greater than 1 but less than 10: If we begin with 0.0048 and move the decimal point three places to the right, we end up with  $4.8 \times 10^{-3}$ .

In the system of exponential notation, with each shift of the decimal point one place to the right, the exponent *decreases* by 1:

$$4.8 \times 10^{-3} = 48 \times 10^{-4}$$

Similarly, with each shift of the decimal point one place to the left, the exponent *increases* by 1:

$$4.8 \times 10^{-3} = 0.48 \times 10^{-2}$$

Many scientific calculators have a key labeled EXP or EE, which is used to enter numbers in exponential notation. To enter the number  $5.8 \times 10^3$  on such a calculator, the key sequence is

$$\boxed{5} \cdot \boxed{8} \boxed{\text{EXP}} \text{ (or } \boxed{\text{EE}} \text{) } \boxed{3}$$

On some calculators the display will show 5.8, then a space, followed by 03, the exponent. On other calculators, a small 10 is shown with an exponent 3.

To enter a negative exponent, use the key labeled  $+/-$ . For example, to enter the number  $8.6 \times 10^{-5}$ , the key sequence is

$$\boxed{8} \boxed{\cdot} \boxed{6} \boxed{\text{EXP}} \boxed{+/-} \boxed{5}$$

When entering a number in exponential notation, do not key in the 10 if you use the EXP or EE button.

In working with exponents, it is important to recall that  $10^0 = 1$ . The following rules are useful for carrying exponents through calculations.

1. **Addition and Subtraction** In order to add or subtract numbers expressed in exponential notation, the powers of 10 must be the same.

$$\begin{aligned}(5.22 \times 10^4) + (3.21 \times 10^2) &= (522 \times 10^2) + (3.21 \times 10^2) \\ &= 525 \times 10^2 \quad (3 \text{ significant figures}) \\ &= 5.25 \times 10^4 \\ (6.25 \times 10^{-2}) - (5.77 \times 10^{-3}) &= (6.25 \times 10^{-2}) - (0.577 \times 10^{-2}) \\ &= 5.67 \times 10^{-2} \quad (3 \text{ significant figures})\end{aligned}$$

When you use a calculator to add or subtract, you need not be concerned with having numbers with the same exponents, because the calculator automatically takes care of this matter.

2. **Multiplication and Division** When numbers expressed in exponential notation are multiplied, the exponents are added; when numbers expressed in exponential notation are divided, the exponent of the denominator is subtracted from the exponent of the numerator.

$$\begin{aligned}(5.4 \times 10^2)(2.1 \times 10^3) &= (5.4)(2.1) \times 10^{2+3} \\ &= 11 \times 10^5 \\ &= 1.1 \times 10^6 \\ (1.2 \times 10^5)(3.22 \times 10^{-3}) &= (1.2)(3.22) \times 10^{5+(-3)} = 3.9 \times 10^2 \\ \frac{3.2 \times 10^5}{6.5 \times 10^2} &= \frac{3.2}{6.5} \times 10^{5-2} = 0.49 \times 10^3 = 4.9 \times 10^2 \\ \frac{5.7 \times 10^7}{8.5 \times 10^{-2}} &= \frac{5.7}{8.5} \times 10^{7-(-2)} = 0.67 \times 10^9 = 6.7 \times 10^8\end{aligned}$$

3. **Powers and Roots** When numbers expressed in exponential notation are raised to a power, the exponents are multiplied by the power. When the roots of numbers expressed in exponential notation are taken, the exponents are divided by the root.

$$\begin{aligned}(1.2 \times 10^5)^3 &= (1.2)^3 \times 10^{5 \times 3} \\ &= 1.7 \times 10^{15} \\ \sqrt[3]{2.5 \times 10^6} &= \sqrt[3]{2.5 \times 10^{6/3}} \\ &= 1.3 \times 10^2\end{aligned}$$

Scientific calculators usually have keys labeled  $x^2$  and  $\sqrt{x}$  for squaring and taking the square root of a number, respectively. To take higher powers or roots, many calculators have  $y^x$  and  $\sqrt[y]{y}$  (or INV  $y^x$ ) keys. For example, to perform the operation  $\sqrt[3]{7.5 \times 10^{-4}}$  on such a calculator, you would key in  $7.5 \times 10^{-4}$ , press the  $\sqrt[y]{y}$  key (or the INV and then the  $y^x$  keys), enter the root, 3, and finally press =. The result is  $9.1 \times 10^{-2}$ .

**SAMPLE EXERCISE 1** | Using Exponential Notation

Perform each of the following operations, using your calculator where possible:

(a) Write the number 0.0054 in standard exponential notation

(b)  $(5.0 \times 10^{-2}) + (4.7 \times 10^{-3})$

(c)  $(5.98 \times 10^{12})(2.77 \times 10^{-5})$

(d)  $\sqrt[4]{1.75 \times 10^{-12}}$

**SOLUTION**

(a) Because we move the decimal point three places to the right to convert 0.0054 to 5.4, the exponent is  $-3$ :

$$5.4 \times 10^{-3}$$

Scientific calculators are generally able to convert numbers to exponential notation using one or two keystrokes. Consult your instruction manual to see how this operation is accomplished on your calculator.

(b) To add these numbers longhand, we must convert them to the same exponent.

$$(5.0 \times 10^{-2}) + (0.47 \times 10^{-2}) = (5.0 + 0.47) \times 10^{-2} = 5.5 \times 10^{-2}$$

(Note that the result has only two significant figures.) To perform this operation on a calculator, we enter the first number, strike the  $+$  key, then enter the second number and strike the  $=$  key.

(c) Performing this operation longhand, we have

$$(5.98 \times 2.77) \times 10^{12-5} = 16.6 \times 10^7 = 1.66 \times 10^8$$

On a scientific calculator, we enter  $5.98 \times 10^{12}$ , press the  $\times$  key, enter  $2.77 \times 10^{-5}$ , and press the  $=$  key.

(d) To perform this operation on a calculator, we enter the number, press the  $\sqrt[4]{y}$  key (or the  $\text{INV}$  and  $y^x$  keys), enter 4, and press the  $=$  key. The result is  $1.15 \times 10^{-3}$ .

**PRACTICE EXERCISE**

Perform the following operations:

(a) Write 67,000 in exponential notation, showing two significant figures

(b)  $(3.378 \times 10^{-3}) - (4.97 \times 10^{-5})$

(c)  $(1.84 \times 10^{15})(7.45 \times 10^{-2})$

(d)  $(6.67 \times 10^{-8})^3$

*Answers:* (a)  $6.7 \times 10^4$ , (b)  $3.328 \times 10^{-3}$ , (c)  $2.47 \times 10^{16}$ , (d)  $2.97 \times 10^{-22}$

**A.2 LOGARITHMS****Common Logarithms**

The common, or base-10, logarithm (abbreviated  $\log$ ) of any number is the power to which 10 must be raised to equal the number. For example, the common logarithm of 1000 (written  $\log 1000$ ) is 3 because raising 10 to the third power gives 1000.

$$10^3 = 1000, \text{ therefore, } \log 1000 = 3$$

Further examples are

$$\log 10^5 = 5$$

$$\log 1 = 0 \quad (\text{Remember that } 10^0 = 1)$$

$$\log 10^{-2} = -2$$

In these examples the common logarithm can be obtained by inspection. However, it is not possible to obtain the logarithm of a number such as 31.25 by inspection. The logarithm of 31.25 is the number  $x$  that satisfies the following relationship:

$$10^x = 31.25$$

Most electronic calculators have a key labeled LOG that can be used to obtain logarithms. For example, on many calculators we obtain the value of  $\log 31.25$  by entering 31.25 and pressing the LOG key. We obtain the following result:

$$\log 31.25 = 1.4949$$

Notice that 31.25 is greater than 10 ( $10^1$ ) and less than 100 ( $10^2$ ). The value for  $\log 31.25$  is accordingly between  $\log 10$  and  $\log 100$ , that is, between 1 and 2.

## Significant Figures and Common Logarithms

For the common logarithm of a measured quantity, the number of digits after the decimal point equals the number of significant figures in the original number. For example, if 23.5 is a measured quantity (three significant figures), then  $\log 23.5 = 1.371$  (three significant figures after the decimal point).

## Antilogarithms

The process of determining the number that corresponds to a certain logarithm is known as obtaining an *antilogarithm*. It is the reverse of taking a logarithm. For example, we saw above that  $\log 23.5 = 1.371$ . This means that the antilogarithm of 1.371 equals 23.5.

$$\begin{aligned}\log 23.5 &= 1.371 \\ \text{antilog } 1.371 &= 23.5\end{aligned}$$

The process of taking the antilog of a number is the same as raising 10 to a power equal to that number.

$$\text{antilog } 1.371 = 10^{1.371} = 23.5$$

Many calculators have a key labeled  $10^x$  that allows you to obtain antilogs directly. On others, it will be necessary to press a key labeled INV (for *inverse*), followed by the LOG key.

## Natural Logarithms

Logarithms based on the number  $e$  are called natural, or base  $e$ , logarithms (abbreviated  $\ln$ ). The natural log of a number is the power to which  $e$  (which has the value 2.71828...) must be raised to equal the number. For example, the natural log of 10 equals 2.303.

$$e^{2.303} = 10, \text{ therefore } \ln 10 = 2.303$$

Your calculator probably has a key labeled LN that allows you to obtain natural logarithms. For example, to obtain the natural log of 46.8, you enter 46.8 and press the LN key.

$$\ln 46.8 = 3.846$$

The natural antilog of a number is  $e$  raised to a power equal to that number. If your calculator can calculate natural logs, it will also be able to calculate natural antilogs. On some calculators there is a key labeled  $e^x$  that allows you to calculate natural antilogs directly; on others, it will be necessary to first press the INV key followed by the LN key. For example, the natural antilog of 1.679 is given by

$$\text{Natural antilog } 1.679 = e^{1.679} = 5.36$$

The relation between common and natural logarithms is as follows:

$$\ln a = 2.303 \log a$$

Notice that the factor relating the two, 2.303, is the natural log of 10, which we calculated above.

## Mathematical Operations Using Logarithms

Because logarithms are exponents, mathematical operations involving logarithms follow the rules for the use of exponents. For example, the product of  $z^a$  and  $z^b$  (where  $z$  is any number) is given by

$$z^a \cdot z^b = z^{(a+b)}$$

Similarly, the logarithm (either common or natural) of a product equals the *sum* of the logs of the individual numbers.

$$\log ab = \log a + \log b \quad \ln ab = \ln a + \ln b$$

For the log of a quotient,

$$\log(a/b) = \log a - \log b \quad \ln(a/b) = \ln a - \ln b$$

Using the properties of exponents, we can also derive the rules for the logarithm of a number raised to a certain power.

$$\begin{aligned} \log a^n &= n \log a & \ln a^n &= n \ln a \\ \log a^{1/n} &= (1/n) \log a & \ln a^{1/n} &= (1/n) \ln a \end{aligned}$$

### pH Problems

One of the most frequent uses for common logarithms in general chemistry is in working pH problems. The pH is defined as  $-\log[\text{H}^+]$ , where  $[\text{H}^+]$  is the hydrogen ion concentration of a solution (Section 16.4). The following sample exercise illustrates this application.

#### **SAMPLE EXERCISE 2** | Using Logarithms

- (a) What is the pH of a solution whose hydrogen ion concentration is 0.015 *M*?  
 (b) If the pH of a solution is 3.80, what is its hydrogen ion concentration?

#### **SOLUTION**

1. We are given the value of  $[\text{H}^+]$ . We use the LOG key of our calculator to calculate the value of  $\log[\text{H}^+]$ . The pH is obtained by changing the sign of the value obtained. (Be sure to change the sign *after* taking the logarithm.)

$$[\text{H}^+] = 0.015$$

$$\log[\text{H}^+] = -1.82 \quad (2 \text{ significant figures})$$

$$\text{pH} = -(-1.82) = 1.82$$

2. To obtain the hydrogen ion concentration when given the pH, we must take the antilog of  $-\text{pH}$ .

$$\text{pH} = -\log[\text{H}^+] = 3.80$$

$$\log[\text{H}^+] = -3.80$$

$$[\text{H}^+] = \text{antilog}(-3.80) = 10^{-3.80} = 1.6 \times 10^{-4} \text{ M}$$

#### **PRACTICE EXERCISE**

Perform the following operations: (a)  $\log(2.5 \times 10^{-5})$ , (b)  $\ln 32.7$ , (c) antilog  $-3.47$ , (d)  $e^{-1.89}$ .

**Answers:** (a)  $-4.60$ , (b)  $3.487$ , (c)  $3.4 \times 10^{-4}$ , (d)  $1.5 \times 10^{-1}$

## A.3 QUADRATIC EQUATIONS

An algebraic equation of the form  $ax^2 + bx + c = 0$  is called a *quadratic equation*. The two solutions to such an equation are given by the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

**SAMPLE EXERCISE 3** | Using the Quadratic Formula

Find the values of  $x$  that satisfy the equation  $2x^2 + 4x = 1$ .

**SOLUTION**

To solve the given equation for  $x$ , we must first put it in the form

$$ax^2 + bx + c = 0$$

and then use the quadratic formula. If

$$2x^2 + 4x = 1$$

then

$$2x^2 + 4x - 1 = 0$$

Using the quadratic formula, where  $a = 2$ ,  $b = 4$ , and  $c = -1$ , we have

$$\begin{aligned} x &= \frac{-4 \pm \sqrt{(4)(4) - 4(2)(-1)}}{2(2)} \\ &= \frac{-4 \pm \sqrt{16 + 8}}{4} = \frac{-4 \pm \sqrt{24}}{4} = \frac{-4 \pm 4.899}{4} \end{aligned}$$

The two solutions are

$$x = \frac{0.899}{4} = 0.225 \quad \text{and} \quad x = \frac{-8.899}{4} = -2.225$$

Often in chemical problems the negative solution has no physical meaning, and only the positive answer is used.

**A.4 GRAPHS**

Often the clearest way to represent the interrelationship between two variables is to graph them. Usually, the variable that is being experimentally varied, called the *independent variable*, is shown along the horizontal axis ( $x$ -axis). The variable that responds to the change in the independent variable, called the *dependent variable*, is then shown along the vertical axis ( $y$ -axis). For example, consider an experiment in which we vary the temperature of an enclosed gas and measure its pressure. The independent variable is temperature, and the dependent variable is pressure. The data shown in Table A-1 can be obtained by means of this experiment. These data are shown graphically in Figure A.1. The relationship between temperature and pressure is linear. The equation for any straight-line graph has the form

$$y = mx + b$$

where  $m$  is the slope of the line and  $b$  is the intercept with the  $y$ -axis. In the case of Figure 1, we could say that the relationship between temperature and pressure takes the form

$$P = mT + b$$

where  $P$  is pressure in atm and  $T$  is temperature in  $^{\circ}\text{C}$ . As shown in Figure 1, the slope is  $4.10 \times 10^{-4} \text{ atm}/^{\circ}\text{C}$ , and the intercept—the point where the line crosses the  $y$ -axis—is 0.112 atm. Therefore, the equation for the line is

$$P = \left(4.10 \times 10^{-4} \frac{\text{atm}}{^{\circ}\text{C}}\right)T + 0.112 \text{ atm}$$

**TABLE A-1** | Interrelation between Pressure and Temperature

Temperature ( $^{\circ}\text{C}$ )	Pressure (atm)
20.0	0.120
30.0	0.124
40.0	0.128
50.0	0.132

**▲ Figure A.1**

## A.5 STANDARD DEVIATION

The standard deviation from the mean,  $s$ , is a common method from describing precision. We define the standard deviation as follows:

$$s = \sqrt{\frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N - 1}}$$

where  $N$  is the number of measurements,  $\bar{x}$  is the average (also called the mean), and  $x_i$  represents the individual measurements. Electronic calculators with built-in statistical functions can calculate  $s$  directly by inputting the individual measurements.

A smaller value of  $s$  indicates a higher precision, meaning that the data is more closely clustered around the average. The standard deviation has a statistical significance. Thus, if a large number of measurements is made, 68% of the measured values is expected to be within one standard deviation of the average, assuming only random errors are associated with the measurements.

### SAMPLE EXERCISE 4 | Calculating an Average and Standard Deviation

The percent carbon in a sugar is measured four times: 42.01%, 42.28%, 41.79%, and 42.25%. Calculate (a) the average and (b) the standard deviation for these measurements.

#### SOLUTION

(a) The average is found by adding the quantities and dividing by the number of measurements:

$$\bar{x} = \frac{42.01 + 42.28 + 41.79 + 42.25}{4} = \frac{168.33}{4} = 42.08$$

(b) The standard deviation is found using the equation above:

$$s = \sqrt{\frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N - 1}}$$

Let's tabulate the data so the calculation of  $\sum_{i=1}^N (x_i - \bar{x})^2$  can be seen clearly.

Percent C	Difference between Measurement and Average, $(x_i - \bar{x})$	Square of Difference, $(x_i - \bar{x})^2$
42.01	$42.01 - 42.08 = -0.07$	$(-0.07)^2 = 0.005$
42.28	$42.28 - 42.08 = 0.20$	$(0.20)^2 = 0.040$
41.79	$41.79 - 42.08 = -0.29$	$(-0.29)^2 = 0.084$
42.25	$42.25 - 42.08 = 0.17$	$(0.17)^2 = 0.029$

The sum of the quantities in the last column is

$$\sum_{i=1}^N (x_i - \bar{x})^2 = 0.005 + 0.040 + 0.084 + 0.029 = 0.16$$

Thus, the standard deviation is

$$s = \sqrt{\frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N - 1}} = \sqrt{\frac{0.16}{4 - 1}} = \sqrt{\frac{0.16}{3}} = \sqrt{0.053} = 0.23$$

Based on these measurements, it would be appropriate to represent the measured percent carbon as  $42.08 \pm 0.23$ .

## Properties of Water

---

Density:	0.99987 g/mL at 0 °C 1.00000 g/mL at 4 °C 0.99707 g/mL at 25 °C 0.95838 g/mL at 100 °C

## D

## Aqueous Equilibrium Constants

TABLE D-1 ■ Dissociation Constants for Acids at 25 °C

Name	Formula	$K_{a1}$	$K_{a2}$	$K_{a3}$
Acetic	CH <sub>3</sub> COOH (or HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub> )	$1.8 \times 10^{-5}$		
Arsenic	H <sub>3</sub> AsO <sub>4</sub>	$5.6 \times 10^{-3}$	$1.0 \times 10^{-7}$	$3.0 \times 10^{-12}$
Arsenous	H <sub>3</sub> AsO <sub>3</sub>	$5.1 \times 10^{-10}$		
Ascorbic	H <sub>2</sub> C <sub>6</sub> H <sub>6</sub> O <sub>6</sub>	$8.0 \times 10^{-5}$	$1.6 \times 10^{-12}$	
Benzoic	C <sub>6</sub> H <sub>5</sub> COOH (or HC <sub>7</sub> H <sub>5</sub> O <sub>2</sub> )	$6.3 \times 10^{-5}$		
Boric	H <sub>3</sub> BO <sub>3</sub>	$5.8 \times 10^{-10}$		
Butanoic	C <sub>3</sub> H <sub>7</sub> COOH (or HC <sub>4</sub> H <sub>7</sub> O <sub>2</sub> )	$1.5 \times 10^{-5}$		
Carbonic	H <sub>2</sub> CO <sub>3</sub>	$4.3 \times 10^{-7}$	$5.6 \times 10^{-11}$	
Chloroacetic	CH <sub>2</sub> ClCOOH (or HC <sub>2</sub> H <sub>2</sub> O <sub>2</sub> Cl)	$1.4 \times 10^{-3}$		
Chlorous	HClO <sub>2</sub>	$1.1 \times 10^{-2}$		
Citric	HOOC(OH)(CH <sub>2</sub> COOH) <sub>2</sub> (or H <sub>3</sub> C <sub>6</sub> H <sub>5</sub> O <sub>7</sub> )	$7.4 \times 10^{-4}$	$1.7 \times 10^{-5}$	$4.0 \times 10^{-7}$
Cyanic	HCNO	$3.5 \times 10^{-4}$		
Formic	HCOOH (or HCHO <sub>2</sub> )	$1.8 \times 10^{-4}$		
Hydroazoic	HN <sub>3</sub>	$1.9 \times 10^{-5}$		
Hydrocyanic	HCN	$4.9 \times 10^{-10}$		
Hydrofluoric	HF	$6.8 \times 10^{-4}$		
Hydrogen chromate ion	HCrO <sub>4</sub> <sup>-</sup>	$3.0 \times 10^{-7}$		
Hydrogen peroxide	H <sub>2</sub> O <sub>2</sub>	$2.4 \times 10^{-12}$		
Hydrogen selenate ion	HSeO <sub>4</sub> <sup>-</sup>	$2.2 \times 10^{-2}$		
Hydrosulfuric	H <sub>2</sub> S	$9.5 \times 10^{-8}$	$1 \times 10^{-19}$	
Hypobromous	HBrO	$2.5 \times 10^{-9}$		
Hypochlorous	HClO	$3.0 \times 10^{-8}$		
Hypoiodous	HIO	$2.3 \times 10^{-11}$		
Iodic	HIO <sub>3</sub>	$1.7 \times 10^{-1}$		
Lactic	CH <sub>3</sub> CH(OH)COOH (or HC <sub>3</sub> H <sub>5</sub> O <sub>3</sub> )	$1.4 \times 10^{-4}$		
Malonic	CH <sub>2</sub> (COOH) <sub>2</sub> (or H <sub>2</sub> C <sub>3</sub> H <sub>2</sub> O <sub>4</sub> )	$1.5 \times 10^{-3}$	$2.0 \times 10^{-6}$	
Nitrous	HNO <sub>2</sub>	$4.5 \times 10^{-4}$		
Oxalic	(COOH) <sub>2</sub> (or H <sub>2</sub> C <sub>2</sub> O <sub>4</sub> )	$5.9 \times 10^{-2}$	$6.4 \times 10^{-5}$	
Paraperiodic	H <sub>5</sub> IO <sub>6</sub>	$2.8 \times 10^{-2}$	$5.3 \times 10^{-9}$	
Phenol	C <sub>6</sub> H <sub>5</sub> OH (or HC <sub>6</sub> H <sub>5</sub> O)	$1.3 \times 10^{-10}$		
Phosphoric	H <sub>3</sub> PO <sub>4</sub>	$7.5 \times 10^{-3}$	$6.2 \times 10^{-8}$	$4.2 \times 10^{-13}$
Propionic	C <sub>2</sub> H <sub>5</sub> COOH (or HC <sub>3</sub> H <sub>5</sub> O <sub>2</sub> )	$1.3 \times 10^{-5}$		
Pyrophosphoric	H <sub>4</sub> P <sub>2</sub> O <sub>7</sub>	$3.0 \times 10^{-2}$	$4.4 \times 10^{-3}$	$2.1 \times 10^{-7}$
Selenous	H <sub>2</sub> SeO <sub>3</sub>	$2.3 \times 10^{-3}$	$5.3 \times 10^{-9}$	
Sulfuric	H <sub>2</sub> SO <sub>4</sub>	Strong acid	$1.2 \times 10^{-2}$	
Sulfurous	H <sub>2</sub> SO <sub>3</sub>	$1.7 \times 10^{-2}$	$6.4 \times 10^{-8}$	
Tartaric	HOOC(CHOH) <sub>2</sub> COOH (or H <sub>2</sub> C <sub>4</sub> H <sub>4</sub> O <sub>6</sub> )	$1.0 \times 10^{-3}$	$4.6 \times 10^{-5}$	

TABLE D-2 ■ Dissociation Constants for Bases at 25 °C

Name	Formula	$K_b$
Ammonia	NH <sub>3</sub>	$1.8 \times 10^{-5}$
Aniline	C <sub>6</sub> H <sub>5</sub> NH <sub>2</sub>	$4.3 \times 10^{-10}$
Dimethylamine	(CH <sub>3</sub> ) <sub>2</sub> NH	$5.4 \times 10^{-4}$
Ethylamine	C <sub>2</sub> H <sub>5</sub> NH <sub>2</sub>	$6.4 \times 10^{-4}$
Hydrazine	H <sub>2</sub> NNH <sub>2</sub>	$1.3 \times 10^{-6}$
Hydroxylamine	HONH <sub>2</sub>	$1.1 \times 10^{-8}$
Methylamine	CH <sub>3</sub> NH <sub>2</sub>	$4.4 \times 10^{-4}$
Pyridine	C <sub>5</sub> H <sub>5</sub> N	$1.7 \times 10^{-9}$
Trimethylamine	(CH <sub>3</sub> ) <sub>3</sub> N	$6.4 \times 10^{-5}$

TABLE D-3 ■ Solubility-Product Constants for Compounds at 25 °C

Name	Formula	$K_{sp}$	Name	Formula	$K_{sp}$
Barium carbonate	BaCO <sub>3</sub>	$5.0 \times 10^{-9}$	Lead(II) fluoride	PbF <sub>2</sub>	$3.6 \times 10^{-8}$
Barium chromate	BaCrO <sub>4</sub>	$2.1 \times 10^{-10}$	Lead(II) sulfate	PbSO <sub>4</sub>	$6.3 \times 10^{-7}$
Barium fluoride	BaF <sub>2</sub>	$1.7 \times 10^{-6}$	Lead(II) sulfide*	PbS	$3 \times 10^{-28}$
Barium oxalate	BaC <sub>2</sub> O <sub>4</sub>	$1.6 \times 10^{-6}$	Magnesium hydroxide	Mg(OH) <sub>2</sub>	$1.8 \times 10^{-11}$
Barium sulfate	BaSO <sub>4</sub>	$1.1 \times 10^{-10}$	Magnesium carbonate	MgCO <sub>3</sub>	$3.5 \times 10^{-8}$
Cadmium carbonate	CdCO <sub>3</sub>	$1.8 \times 10^{-14}$	Magnesium oxalate	MgC <sub>2</sub> O <sub>4</sub>	$8.6 \times 10^{-5}$
Cadmium hydroxide	Cd(OH) <sub>2</sub>	$2.5 \times 10^{-14}$	Manganese(II) carbonate	MnCO <sub>3</sub>	$5.0 \times 10^{-10}$
Cadmium sulfide*	CdS	$8 \times 10^{-28}$	Manganese(II) hydroxide	Mn(OH) <sub>2</sub>	$1.6 \times 10^{-13}$
Calcium carbonate (calcite)	CaCO <sub>3</sub>	$4.5 \times 10^{-9}$	Manganese(II) sulfide*	MnS	$2 \times 10^{-53}$
Calcium chromate	CaCrO <sub>4</sub>	$7.1 \times 10^{-4}$	Mercury(I) chloride	Hg <sub>2</sub> Cl <sub>2</sub>	$1.2 \times 10^{-18}$
Calcium fluoride	CaF <sub>2</sub>	$3.9 \times 10^{-11}$	Mercury(I) iodide	Hg <sub>2</sub> I <sub>2</sub>	$1.1 \times 10^{-28}$
Calcium hydroxide	Ca(OH) <sub>2</sub>	$6.5 \times 10^{-6}$	Mercury(II) sulfide*	HgS	$2 \times 10^{-53}$
Calcium phosphate	Ca <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>	$2.0 \times 10^{-29}$	Nickel(II) carbonate	NiCO <sub>3</sub>	$1.3 \times 10^{-7}$
Calcium sulfate	CaSO <sub>4</sub>	$2.4 \times 10^{-5}$	Nickel(II) hydroxide	Ni(OH) <sub>2</sub>	$6.0 \times 10^{-16}$
Chromium(III) hydroxide	Cr(OH) <sub>3</sub>	$1.6 \times 10^{-30}$	Nickel(II) sulfide*	NiS	$3 \times 10^{-20}$
Cobalt(II) carbonate	CoCO <sub>3</sub>	$1.0 \times 10^{-10}$	Silver bromate	AgBrO <sub>3</sub>	$5.5 \times 10^{-5}$
Cobalt(II) hydroxide	Co(OH) <sub>2</sub>	$1.3 \times 10^{-15}$	Silver bromide	AgBr	$5.0 \times 10^{-13}$
Cobalt(II) sulfide*	CoS	$5 \times 10^{-22}$	Silver carbonate	Ag <sub>2</sub> CO <sub>3</sub>	$8.1 \times 10^{-12}$
Copper(I) bromide	CuBr	$5.3 \times 10^{-9}$	Silver chloride	AgCl	$1.8 \times 10^{-10}$
Copper(II) carbonate	CuCO <sub>3</sub>	$2.3 \times 10^{-10}$	Silver chromate	Ag <sub>2</sub> CrO <sub>4</sub>	$1.2 \times 10^{-12}$
Copper(II) hydroxide	Cu(OH) <sub>2</sub>	$4.8 \times 10^{-20}$	Silver iodide	AgI	$8.3 \times 10^{-17}$
Copper(II) sulfide*	CuS	$6 \times 10^{-37}$	Silver sulfate	Ag <sub>2</sub> SO <sub>4</sub>	$1.5 \times 10^{-5}$
Iron(II) carbonate	FeCO <sub>3</sub>	$2.1 \times 10^{-11}$	Silver sulfide*	Ag <sub>2</sub> S	$6 \times 10^{-51}$
Iron(II) hydroxide	Fe(OH) <sub>2</sub>	$7.9 \times 10^{-16}$	Strontium carbonate	SrCO <sub>3</sub>	$9.3 \times 10^{-10}$
Lanthanum fluoride	LaF <sub>3</sub>	$2 \times 10^{-19}$	Tin(II) sulfide*	SnS	$1 \times 10^{-26}$
Lanthanum iodate	La(IO <sub>3</sub> ) <sub>3</sub>	$6.1 \times 10^{-12}$	Zinc carbonate	ZnCO <sub>3</sub>	$1.0 \times 10^{-10}$
Lead(II) carbonate	PbCO <sub>3</sub>	$7.4 \times 10^{-14}$	Zinc hydroxide	Zn(OH) <sub>2</sub>	$3.0 \times 10^{-16}$
Lead(II) chloride	PbCl <sub>2</sub>	$1.7 \times 10^{-5}$	Zinc oxalate	ZnC <sub>2</sub> O <sub>4</sub>	$2.7 \times 10^{-8}$
Lead(II) chromate	PbCrO <sub>4</sub>	$2.8 \times 10^{-13}$	Zinc sulfide*	ZnS	$2 \times 10^{-25}$

\*For a solubility equilibrium of the type MS(s) + H<sub>2</sub>O(l) ⇌ M<sup>2+</sup>(aq) + HS<sup>-</sup>(aq) + OH<sup>-</sup>(aq)

# Glossary

**absorption spectrum** A pattern of variation in the amount of light absorbed by a sample as a function of wavelength. (Section 24.5)

**accuracy** A measure of how closely individual measurements agree with the correct value. (Section 1.5)

**acid** A substance that is able to donate a  $H^+$  ion (a proton) and hence increases the concentration of  $H^+(aq)$  when it dissolves in water. (Section 4.3)

**acid-dissociation constant ( $K_a$ )** An equilibrium constant that expresses the extent to which an acid transfers a proton to solvent water. (Section 16.6)

**acidic anhydride (acidic oxide)** An oxide that forms an acid when added to water; soluble non-metal oxides are acidic anhydrides. (Section 22.5)

**acidic oxide (acidic anhydride)** An oxide that either reacts with a base to form a salt or with water to form an acid. (Section 22.5)

**acid rain** Rainwater that has become excessively acidic because of absorption of pollutant oxides, notably  $SO_3$ , produced by human activities. (Section 18.4)

**actinide element** Element in which the 5f orbitals are only partially occupied. (Section 6.8)

**activated complex (transition state)** The particular arrangement of atoms found at the top of the potential-energy barrier as a reaction proceeds from reactants to products. (Section 14.5)

**activation energy ( $E_a$ )** The minimum energy needed for reaction; the height of the energy barrier to formation of products. (Section 14.5)

**active site** Specific site on a heterogeneous catalyst or an enzyme where catalysis occurs. (Section 14.7)

**activity** The decay rate of a radioactive material, generally expressed as the number of disintegrations per unit time. (Section 21.4)

**activity series** A list of metals in order of decreasing ease of oxidation. (Section 4.4)

**addition polymerization** Polymerization that occurs through coupling of monomers with one another, with no other products formed in the reaction. (Section 12.6)

**addition reaction** A reaction in which a reagent adds to the two carbon atoms of a carbon-carbon multiple bond. (Section 25.3)

**adsorption** The binding of molecules to a surface. (Section 14.7)

**alcohol** An organic compound obtained by substituting a hydroxyl group ( $-OH$ ) for a hydrogen on a hydrocarbon. (Sections 2.9 and 25.4)

**aldehyde** An organic compound that contains a carbonyl group ( $C=O$ ) to which at least one hydrogen atom is attached. (Section 25.4)

**alkali metals** Members of group 1A in the periodic table. (Section 7.7)

**alkaline earth metals** Members of group 2A in the periodic table. (Section 7.7)

**alkanes** Compounds of carbon and hydrogen containing only carbon-carbon single bonds. (Sections 2.9 and 25.2)

**alkenes** Hydrocarbons containing one or more carbon-carbon double bonds. (Section 25.2)

**alkyl group** A group that is formed by removing a hydrogen atom from an alkane. (Section 25.3)

**alkynes** Hydrocarbons containing one or more carbon-carbon triple bonds. (Section 25.2)

**alloy** A substance that has the characteristic properties of a metal and contains more than one element. Often there is one principal metallic component, with other elements present in smaller amounts. Alloys may be homogeneous or heterogeneous in nature. (Section 23.6)

**alpha ( $\alpha$ ) helix** A protein structure in which the protein is coiled in the form of a helix, with hydrogen bonds between  $C=O$  and  $N-H$  groups on adjacent turns. (Section 25.7)

**alpha particles** Particles that are identical to helium-4 nuclei, consisting of two protons and two neutrons, symbol  ${}^4_2He$  or  ${}^4_2\alpha$ . (Section 21.1)

**amide** An organic compound that has an  $NR_2$  group attached to a carbonyl. (Section 25.4)

**amine** A compound that has the general formula  $R_3N$ , where R may be H or a hydrocarbon group. (Section 16.7)

**amino acid** A carboxylic acid that contains an amino ( $-NH_2$ ) group attached to the carbon atom adjacent to the carboxylic acid ( $-COOH$ ) functional group. (Section 25.7)

**amorphous solid** A solid whose molecular arrangement lacks a regular, long-range pattern. (Section 11.7)

**amphiprotic** Refers to the capacity of a substance to either add or lose a proton ( $H^+$ ). (Section 16.2)

**amphoteric** Capable of behaving as either an acid or a base. (Section 17.5)

**amphoteric oxides and hydroxides** Oxides and hydroxides that are only slightly soluble in water, but which dissolve on addition of either acid or base. (Section 17.5)

**angstrom** A common non-SI unit of length, denoted  $\text{\AA}$ , that is used to measure atomic dimensions:  $1 \text{\AA} = 10^{-10} \text{ m}$ . (Section 2.3)

**anion** A negatively charged ion. (Section 2.7)

**anode** An electrode at which oxidation occurs. (Section 20.3)

**antibonding molecular orbital** A molecular orbital in which electron density is concentrated outside the region between the two nuclei of bonded atoms. Such orbitals, designated as  $\sigma^*$  or  $\pi^*$ , are less stable (of higher energy) than bonding molecular orbitals. (Section 9.7)

**antiferromagnetism** A form of magnetism in which unpaired electron spins on adjacent sites point in opposite directions and cancel each other's effects. (Section 23.8)

**aqueous solution** A solution in which water is the solvent. (Chapter 4: Introduction)

**aromatic hydrocarbons** Hydrocarbon compounds that contain a planar, cyclic arrangement of carbon atoms linked by both  $\sigma$  and delocalized  $\pi$  bonds. (Section 25.2)

**Arrhenius equation** An equation that relates the rate constant for a reaction to the frequency factor,  $A$ , the activation energy,  $E_a$ , and the temperature,  $T$ :  $k = Ae^{-E_a/RT}$ . In its logarithmic form it is written  $\ln k = -E_a/RT + \ln A$ . (Section 14.5)

**atmosphere (atm)** A unit of pressure equal to 760 torr;  $1 \text{ atm} = 101.325 \text{ kPa}$ . (Section 10.2)

**atom** The smallest representative particle of an element. (Sections 1.1 and 2.1)

**atomic mass unit (amu)** A unit based on the value of exactly 12 amu for the mass of the isotope of carbon that has six protons and six neutrons in the nucleus. (Sections 2.3 and 3.3)

**atomic number** The number of protons in the nucleus of an atom of an element. (Section 2.3)

**atomic radius** An estimate of the size of an atom. See **bonding atomic radius**. (Section 7.3)

**atomic weight** The average mass of the atoms of an element in atomic mass units (amu); it is numerically equal to the mass in grams of one mole of the element. (Section 2.4)

**autoionization** The process whereby water spontaneously forms low concentrations of  $H^+(aq)$  and  $OH^-(aq)$  ions by proton transfer from one water molecule to another. (Section 16.3)

**Avogadro's hypothesis** A statement that equal volumes of gases at the same temperature and pressure contain equal numbers of molecules. (Section 10.3)

**Avogadro's law** A statement that the volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas. (Section 10.3)

**Avogadro's number** The number of  ${}^{12}C$  atoms in exactly 12 g of  ${}^{12}C$ ; it equals  $6.022 \times 10^{23}$ . (Section 3.4)

**band** An array of closely spaced molecular orbitals occupying a discrete range of energy. (Section 12.2)

**band gap** The energy gap between an occupied valence band and a vacant band called the conduction band. (Section 12.2)

**bar** A unit of pressure equal to  $10^5 \text{ Pa}$ . (Section 10.2)

**base** A substance that is an  $H^+$  acceptor; a base produces an excess of  $OH^-(aq)$  ions when it dissolves in water. (Section 4.3)

**base-dissociation constant ( $K_b$ )** An equilibrium constant that expresses the extent to which a base reacts with solvent water, accepting a proton and forming  $OH^-(aq)$ . (Section 16.7)

**basic anhydride (basic oxide)** An oxide that forms a base when added to water; soluble metal oxides are basic anhydrides. (Section 22.5)

**basic oxide (basic anhydride)** An oxide that either reacts with water to form a base or reacts with an acid to form a salt and water. (Section 22.5)

**battery** A self-contained electrochemical power source that contains one or more voltaic cells. (Section 20.7)

**Bayer process** A hydrometallurgical procedure for purifying bauxite in the recovery of aluminum from bauxite-containing ores. (Section 23.3)

**becquerel** The SI unit of radioactivity. It corresponds to one nuclear disintegration per second. (Section 21.4)

**Beer's law** The light absorbed by a substance ( $A$ ) equals the product of its molar absorptivity constant ( $a$ ), the path length through which the light passes ( $b$ ), and the molar concentration of the substance ( $c$ ):  $A = abc$ . (Section 14.2)

**beta particles** Energetic electrons emitted from the nucleus, symbol  ${}_{-1}^0e$ . (Section 21.1)

**beta sheet** A structural form of protein in which two strands of amino acids are hydrogen-bonded together in a zipperlike configuration. (Section 25.7)

**bidentate ligand** A ligand in which two linked coordinating atoms are bound to a metal. (Section 24.2)

**bimolecular reaction** An elementary reaction that involves two molecules. (Section 14.6)

**biochemistry** The study of the chemistry of living systems. (Chapter 25: Introduction)

**biocompatible** Any substance or material that can be compatibly placed within living systems. (Section 12.7)

**biodegradable** Organic material that bacteria are able to oxidize. (Section 18.6)

**biomaterial** Any material that has a biomedical application. (Section 12.7)

**biopolymer** A polymeric molecule of high molecular weight found in living systems. The three major classes of biopolymers are proteins, carbohydrates, and nucleic acids. (Section 25.6)

**body-centered cubic cell** A cubic unit cell in which the lattice points occur at the corners and at the center. (Section 11.7)

**bomb calorimeter** A device for measuring the heat evolved in the combustion of a substance under constant-volume conditions. (Section 5.5)

**bond angles** The angles made by the lines joining the nuclei of the atoms in a molecule. (Section 9.1)

**bond dipole** The dipole moment that is due to unequal electron sharing between two atoms in a covalent bond. (Section 9.3)

**bond enthalpy** The enthalpy change,  $\Delta H$ , required to break a particular bond when the substance is in the gas phase. (Section 8.8)

**bonding atomic radius** The radius of an atom as defined by the distances separating it from other atoms to which it is chemically bonded. (Section 7.3)

**bonding molecular orbital** A molecular orbital in which the electron density is concentrated in the internuclear region. The energy of a bonding molecular orbital is lower than the energy of the separate atomic orbitals from which it forms. (Section 9.7)

**bonding pair** In a Lewis structure a pair of electrons that is shared by two atoms. (Section 9.2)

**bond length** The distance between the centers of two bonded atoms. (Section 8.8)

**bond order** The number of bonding electron pairs shared between two atoms, minus the number of antibonding electron pairs: bond order = (number of bonding electrons - number of antibonding electrons)/2. (Section 9.7)

**bond polarity** A measure of the degree to which the electrons are shared unequally between two atoms in a chemical bond. (Section 8.4)

**boranes** Covalent hydrides of boron. (Section 22.11)

**Born-Haber cycle** A thermodynamic cycle based on Hess's law that relates the lattice energy of an ionic substance to its enthalpy of formation and to other measurable quantities. (Section 8.2)

**Boyle's law** A law stating that at constant temperature, the product of the volume and pressure of a given amount of gas is a constant. (Section 10.3)

**Bronsted-Lowry acid** A substance (molecule or ion) that acts as a proton donor. (Section 16.2)

**Bronsted-Lowry base** A substance (molecule or ion) that acts as a proton acceptor. (Section 16.2)

**buffer capacity** The amount of acid or base a buffer can neutralize before the pH begins to change appreciably. (Section 17.2)

**buffered solution (buffer)** A solution that undergoes a limited change in pH upon addition of a small amount of acid or base. (Section 17.2)

**calcination** The heating of an ore to bring about its decomposition and the elimination of a volatile product. For example, a carbonate ore might be calcined to drive off  $\text{CO}_2$ . (Section 23.2)

**calorie** A unit of energy, it is the amount of energy needed to raise the temperature of 1 g of water by  $1^\circ\text{C}$  from  $14.5^\circ\text{C}$  to  $15.5^\circ\text{C}$ . A related unit is the joule:  $1\text{ cal} = 4.184\text{ J}$ . (Section 5.1)

**calorimeter** An apparatus that measures the evolution of heat. (Section 5.5)

**calorimetry** The experimental measurement of heat produced in chemical and physical processes. (Section 5.5)

**capillary action** The process by which a liquid rises in a tube because of a combination of adhesion to the walls of the tube and cohesion between liquid particles. (Section 11.3)

**carbide** A binary compound of carbon with a metal or metalloid. (Section 22.9)

**carbohydrates** A class of substances formed from polyhydroxy aldehydes or ketones. (Section 25.8)

**carbon black** A microcrystalline form of carbon. (Section 22.9)

**carbonyl group** The  $\text{C}=\text{O}$  double bond, a characteristic feature of several organic functional groups, such as ketones and aldehydes. (Section 25.4)

**carboxylic acid** A compound that contains the  $-\text{COOH}$  functional group. (Sections 16.10 and 25.4)

**catalyst** A substance that changes the speed of a chemical reaction without itself undergoing a permanent chemical change in the process. (Section 14.7)

**cathode** An electrode at which reduction occurs. (Section 20.3)

**cathode rays** Streams of electrons that are produced when a high voltage is applied to electrodes in an evacuated tube. (Section 2.2)

**cathodic protection** A means of protecting a metal against corrosion by making it the cathode in a voltaic cell. This can be achieved by attaching a more easily oxidized metal, which serves as an anode, to the metal to be protected. (Section 20.8)

**cation** A positively charged ion. (Section 2.7)

**cell potential** A measure of the driving force, or "electrical pressure," for an electrochemical reaction; it is measured in volts:  $1\text{ V} = 1\text{ J/C}$ . Also called electromotive force. (Section 20.4)

**cellulose** A polysaccharide of glucose; it is the major structural element in plant matter. (Section 25.8)

**Celsius scale** A temperature scale on which water freezes at  $0^\circ$  and boils at  $100^\circ$  at sea level. (Section 1.4)

**ceramic** A solid inorganic material, either crystalline (oxides, carbides, silicates) or amorphous (glasses). Most ceramics melt at high temperatures. (Section 12.1)

**chain reaction** A series of reactions in which one reaction initiates the next. (Section 21.7)

**changes of state** Transformations of matter from one state to a different one, for example, from a gas to a liquid. (Section 1.3)

**charcoal** A form of carbon produced when wood is heated strongly in a deficiency of air. (Section 22.9)

**Charles's law** A law stating that at constant pressure, the volume of a given quantity of gas is proportional to absolute temperature. (Section 10.3)

**chelate effect** The generally larger formation constants for polydentate ligands as compared with the corresponding *monodentate* ligands. (Section 24.2)

**chelating agent** A polydentate ligand that is capable of occupying two or more sites in the coordination sphere. (Section 24.2)

**chemical bond** A strong attractive force that exists between atoms in a molecule. (Section 8.1)

**chemical changes** Processes in which one or more substances are converted into other

substances; also called **chemical reactions**. (Section 1.3)

**chemical equation** A representation of a chemical reaction using the chemical formulas of the reactants and products; a balanced chemical equation contains equal numbers of atoms of each element on both sides of the equation. (Section 3.1)

**chemical equilibrium** A state of dynamic balance in which the rate of formation of the products of a reaction from the reactants equals the rate of formation of the reactants from the products; at equilibrium the concentrations of the reactants and products remain constant. (Section 4.1; Chapter 15: Introduction)

**chemical formula** A notation that uses chemical symbols with numerical subscripts to convey the relative proportions of atoms of the different elements in a substance. (Section 2.6)

**chemical kinetics** The area of chemistry concerned with the speeds, or rates, at which chemical reactions occur. (Chapter 14: Introduction)

**chemical nomenclature** The rules used in naming substances. (Section 2.8)

**chemical properties** Properties that describe a substance's composition and its reactivity; how the substance reacts or changes into other substances. (Section 1.3)

**chemical reactions** Processes in which one or more substances are converted into other substances; also called **chemical changes**. (Section 1.3)

**chemistry** The scientific discipline that treats the composition, properties, and transformations of matter. (Chapter 1: Introduction)

**chiral** A term describing a molecule or an ion that cannot be superimposed on its mirror image. (Sections 24.4 and 25.5)

**chlorofluorocarbons** Compounds composed entirely of chlorine, fluorine, and carbon. (Section 18.3)

**chlorophyll** A plant pigment that plays a major role in conversion of solar energy to chemical energy in photosynthesis. (Section 24.2)

**cholesteric liquid crystalline phase** A liquid crystal formed from flat, disc-shaped molecules that align through a stacking of the molecular discs. (Section 12.8)

**coal** A naturally occurring solid containing hydrocarbons of high molecular weight, as well as compounds containing sulfur, oxygen, and nitrogen. (Section 5.8)

**coke** An impure form of carbon, formed when coal is heated strongly in the absence of air. (Section 22.9)

**colligative properties** Those properties of a solvent (vapor-pressure lowering, freezing-point lowering, boiling-point elevation, osmotic pressure) that depend on the total concentration of solute particles present. (Section 13.5)

**collision model** A model of reaction rates based on the idea that molecules must collide to react; it explains the factors influencing reaction rates in terms of the frequency of collisions, the number of collisions with energies exceeding the activation energy, and the probability that the collisions occur with suitable orientations. (Section 14.5)

**colloids (colloidal dispersions)** Mixtures containing particles larger than normal solutes but small enough to remain suspended in the dispersing medium. (Section 13.6)

**combination reaction** A chemical reaction in which two or more substances combine to form a single product. (Section 3.2)

**combustion reaction** A chemical reaction that proceeds with evolution of heat and usually also a flame; most combustion involves reaction with oxygen, as in the burning of a match. (Section 3.2)

**common-ion effect** A shift of an equilibrium induced by an ion common to the equilibrium. For example, added  $\text{Na}_2\text{SO}_4$  decreases the solubility of the slightly soluble salt  $\text{BaSO}_4$ , or added  $\text{NaF}$  decreases the percent ionization of  $\text{HF}$ . (Section 17.1)

**complementary colors** Colors that, when mixed in proper proportions, appear white or colorless. (Section 24.5)

**complete ionic equation** A chemical equation in which dissolved strong electrolytes (such as dissolved ionic compounds) are written as separate ions. (Section 4.2)

**complex ion (complex)** An assembly of a metal ion and the Lewis bases (ligands) bonded to it. (Sections 17.5 and 24.1)

**compound** A substance composed of two or more elements united chemically in definite proportions. (Section 1.2)

**compound semiconductor** A semiconducting material formed from two or more elements. (Section 12.3)

**concentration** The quantity of solute present in a given quantity of solvent or solution. (Section 4.5)

**concentration cell** A voltaic cell containing the same electrolyte and the same electrode materials in both the anode and cathode compartments. The emf of the cell is derived from a difference in the concentrations of the same electrolyte solutions in the compartments. (Section 20.6)

**condensation polymerization** Polymerization in which molecules are joined together through condensation reactions. (Section 12.6)

**condensation reaction** A chemical reaction in which a small molecule (such as a molecule of water) is split out from between two reacting molecules. (Sections 12.6 and 22.8)

**conduction band** A band of molecular orbitals lying higher in energy than the occupied valence band, and distinctly separated from it. (Section 12.2)

**conjugate acid** A substance formed by addition of a proton to a Brønsted-Lowry base. (Section 16.2)

**conjugate acid-base pair** An acid and a base, such as  $\text{H}_2\text{O}$  and  $\text{OH}^-$ , that differ only in the presence or absence of a proton. (Section 16.2)

**conjugate base** A substance formed by the loss of a proton from a Brønsted-Lowry acid. (Section 16.2)

**continuous spectrum** A spectrum that contains radiation distributed over all wavelengths. (Section 6.3)

**conversion factor** A ratio relating the same quantity in two systems of units that is used to convert the units of measurement. (Section 1.6)

**coordination compound or complex** A compound containing a metal ion bonded to a group of surrounding molecules or ions that act as ligands. (Section 24.1)

**coordination number** The number of adjacent atoms to which an atom is directly bonded. In a complex the coordination number of the metal ion is the number of donor atoms to which it is bonded. (Sections 11.7 and 24.1)

**coordination sphere** The metal ion and its surrounding ligands. (Section 24.1)

**coordination-sphere isomers** Structural isomers of coordination compounds in which the ligands within the coordination sphere differ. (Section 24.4)

**copolymer** A complex polymer resulting from the polymerization of two or more chemically different monomers. (Section 12.6)

**core electrons** The electrons that are not in the outermost shell of an atom. (Section 6.8)

**corrosion** The process by which a metal is oxidized by substances in its environment. (Section 20.8)

**covalent bond** A bond formed between two or more atoms by a sharing of electrons. (Section 8.1)

**covalent-network solids** Solids in which the units that make up the three-dimensional network are joined by covalent bonds. (Section 11.8)

**critical mass** The amount of fissionable material necessary to maintain a nuclear chain reaction. (Section 21.7)

**critical pressure** The pressure at which a gas at its critical temperature is converted to a liquid state. (Section 11.4)

**critical temperature** The highest temperature at which it is possible to convert the gaseous form of a substance to a liquid. The critical temperature increases with an increase in the magnitude of intermolecular forces. (Section 11.4)

**cross-linking** The formation of bonds between polymer chains. (Section 12.6)

**crystal-field theory** A theory that accounts for the colors and the magnetic and other properties of transition-metal complexes in terms of the splitting of the energies of metal ion  $d$  orbitals by the electrostatic interaction with the ligands. (Section 24.6)

**crystal lattice** An imaginary network of points on which the repeating unit of the structure of a solid (the contents of the unit cell) may be imagined to be laid down so that the structure of the crystal is obtained. Each point represents an identical environment in the crystal. (Section 11.7)

**crystalline solid (crystal)** A solid whose internal arrangement of atoms, molecules, or ions shows a regular repetition in any direction through the solid. (Section 11.7)

**crystallinity** A measure of the extent of crystalline character (order) in a polymer. (Section 12.6)

**crystallization** The process in which a dissolved solute comes out of solution and forms a crystalline solid. (Section 13.2)

**cubic close packing** A close-packing arrangement in which the atoms of the third layer of a solid are not directly over those in the first layer. (Section 11.7)

**curie** A measure of radioactivity: 1 curie =  $3.7 \times 10^{10}$  nuclear disintegrations per second. (Section 21.4)

**cycloalkanes** Saturated hydrocarbons of general formula  $C_nH_{2n}$  in which the carbon atoms form a closed ring. (Section 25.3)

**Dalton's law of partial pressures** A law stating that the total pressure of a mixture of gases is the sum of the pressures that each gas would exert if it were present alone. (Section 10.6)

**d-d transition** The transition of an electron in a transition metal compound from a lower-energy *d* orbital to a higher-energy *d* orbital. (Section 24.6)

**decomposition reaction** A chemical reaction in which a single compound reacts to give two or more products. (Section 3.2)

**degenerate** A situation in which two or more orbitals have the same energy. (Section 6.7)

**delocalized electrons** Electrons that are spread over a number of atoms in a molecule rather than localized between a pair of atoms. (Section 9.6)

**density** The ratio of an object's mass to its volume. (Section 1.4)

**deoxyribonucleic acid (DNA)** A polynucleotide in which the sugar component is deoxyribose. (Section 25.10)

**desalination** The removal of salts from seawater, brine, or brackish water to make it fit for human consumption. (Section 18.5)

**deuterium** The isotope of hydrogen whose nucleus contains a proton and a neutron:  ${}^2\text{H}$ . (Section 22.2)

**dextrorotatory, or merely dextro or d** A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the right (clockwise). (Section 24.4)

**diamagnetism** A type of magnetism that causes a substance with no unpaired electrons to be weakly repelled from a magnetic field. (Section 9.8)

**diatomic molecule** A molecule composed of only two atoms. (Section 2.6)

**diffusion** The spreading of one substance through a space occupied by one or more other substances. (Section 10.8)

**dilution** The process of preparing a less concentrated solution from a more concentrated one by adding solvent. (Section 4.5)

**dimensional analysis** A method of problem solving in which units are carried through all calculations. Dimensional analysis ensures that the final answer of a calculation has the desired units. (Section 1.6)

**dipole** A molecule with one end having a partial negative charge and the other end having a partial positive charge; a polar molecule. (Section 8.4)

**dipole-dipole force** The force that exists because of the interactions of dipoles on polar molecules in close contact. (Section 11.2)

**dipole moment** A measure of the separation and magnitude of the positive and negative charges in polar molecules. (Section 8.4)

**displacement reaction** A reaction in which an element reacts with a compound, displacing an element from it. (Section 4.4)

**disproportionation** A reaction in which a species undergoes simultaneous oxidation and reduction [as in  $\text{N}_2\text{O}_3(\text{g}) \longrightarrow \text{NO}(\text{g}) + \text{NO}_2(\text{g})$ ]. (Section 22.5)

**donor atom** The atom of a ligand that bonds to the metal. (Section 24.1)

**doping** Incorporation of a hetero atom into a solid to change its electrical properties. For example, incorporation of P into Si. (Section 12.3)

**double bond** A covalent bond involving two electron pairs. (Section 8.3)

**double helix** The structure for DNA that involves the winding of two DNA polynucleotide chains together in a helical arrangement. The two strands of the double helix are complementary in that the organic bases on the two strands are paired for optimal hydrogen bond interaction. (Section 25.10)

**Downs cell** A cell used to obtain sodium metal by electrolysis of molten NaCl. (Section 23.4)

**dynamic equilibrium** A state of balance in which opposing processes occur at the same rate. (Section 11.5)

**effective nuclear charge** The net positive charge experienced by an electron in a many-electron atom; this charge is not the full nuclear charge because there is some shielding of the nucleus by the other electrons in the atom. (Section 7.2)

**effusion** The escape of a gas through an orifice or hole. (Section 10.8)

**elastomer** A material that can undergo a substantial change in shape via stretching, bending, or compression and return to its original shape upon release of the distorting force. (Section 12.6)

**electrochemistry** The branch of chemistry that deals with the relationships between electricity and chemical reactions. (Chapter 20: Introduction)

**electrolysis reaction** A reaction in which a nonspontaneous redox reaction is brought about by the passage of current under a sufficient external electrical potential. The devices in which electrolysis reactions occur are called electrolytic cells. (Section 20.9)

**electrolyte** A solute that produces ions in solution; an electrolytic solution conducts an electric current. (Section 4.1)

**electrolytic cell** A device in which a nonspontaneous oxidation-reduction reaction is caused to occur by passage of current under a sufficient external electrical potential. (Section 20.9)

**electromagnetic radiation (radiant energy)** A form of energy that has wave characteristics and that propagates through a vacuum at the characteristic speed of  $3.00 \times 10^8$  m/s. (Section 6.1)

**electrometallurgy** The use of electrolysis to reduce or refine metals. (Section 23.4)

**electromotive force (emf)** A measure of the driving force, or *electrical pressure*, for the completion of an electrochemical reaction. Electromotive force is measured in volts:  $1 \text{ V} = 1 \text{ J/C}$ . Also called the cell potential. (Section 20.4)

**electron** A negatively charged subatomic particle found outside the atomic nucleus; it is a part of all atoms. An electron has a mass  $1/1836$  times that of a proton. (Section 2.3)

**electron affinity** The energy change that occurs when an electron is added to a gaseous atom or ion. (Section 7.5)

**electron capture** A mode of radioactive decay in which an inner-shell orbital electron is captured by the nucleus. (Section 21.1)

**electron configuration** A particular arrangement of electrons in the orbitals of an atom. (Section 6.8)

**electron density** The probability of finding an electron at any particular point in an atom; this probability is equal to  $\psi^2$ , the square of the wave function. (Section 6.5)

**electron domain** In the VSEPR model, a region about a central atom in which an electron pair is concentrated. (Section 9.2)

**electron-domain geometry** The three-dimensional arrangement of the electron domains around an atom according to the VSEPR model. (Section 9.2)

**electronegativity** A measure of the ability of an atom that is bonded to another atom to attract electrons to itself. (Section 8.4)

**electronic charge** The negative charge carried by an electron; it has a magnitude of  $1.602 \times 10^{-19}$  C. (Section 2.3)

**electronic structure** The arrangement of electrons in an atom or molecule. (Chapter 6: Introduction)

**electron-sea model** A model for the behavior of electrons in metals. (Section 23.5)

**electron shell** A collection of orbitals that have the same value of *n*. For example, the orbitals with *n* = 3 (the 3*s*, 3*p*, and 3*d* orbitals) comprise the third shell. (Section 6.5)

**electron spin** A property of the electron that makes it behave as though it were a tiny magnet. The electron behaves as if it were spinning on its axis; electron spin is quantized. (Section 6.7)

**element** A substance that cannot be separated into simpler substances by chemical means. (Sections 1.1 and 1.2)

**elemental semiconductor** A semiconducting material composed of just one element (Section 12.3)

**elementary reaction** A process in a chemical reaction that occurs in a single event or step. An overall chemical reaction consists of one or more elementary reactions or steps. (Section 14.6)

**empirical formula (simplest formula)** A chemical formula that shows the kinds of atoms and their relative numbers in a substance in the smallest possible whole-number ratios. (Section 2.6)

**enantiomers** Two mirror-image molecules of a chiral substance. The enantiomers are non-superimposable. (Section 24.4)

**endothermic process** A process in which a system absorbs heat from its surroundings. (Section 5.2)

**energy** The capacity to do work or to transfer heat. (Section 5.1)

**energy band** A band of allowed energy states of electrons in metals and semiconductors. (Section 23.5)

**energy-level diagram** A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived. Also called a **molecular-orbital diagram**. (Section 9.7)

**enthalpy** A quantity defined by the relationship  $H = E + PV$ ; the enthalpy change,  $\Delta H$ , for a reaction that occurs at constant pressure is the heat evolved or absorbed in the reaction:  $\Delta H = q_p$ . (Section 5.3)

**enthalpy (heat) of formation** The enthalpy change that accompanies the formation of a substance from the most stable forms of its component elements. (Section 5.7)

**enthalpy of reaction** The enthalpy change associated with a chemical reaction. (Section 5.4)

**entropy** A thermodynamic function associated with the number of different equivalent energy states or spatial arrangements in which a system may be found. It is a thermodynamic state function, which means that once we specify the conditions for a system—that is, the temperature, pressure, and so on—the entropy is defined. (Sections 13.1 and 19.2)

**enzyme** A protein molecule that acts to catalyze specific biochemical reactions. (Section 14.7)

**equilibrium constant** The numerical value of the equilibrium-constant expression for a system at equilibrium. The equilibrium constant is most usually denoted by  $K_p$  for gas-phase systems or  $K_c$  for solution-phase systems. (Section 15.2)

**equilibrium-constant expression** The expression that describes the relationship among the concentrations (or partial pressures) of the substances present in a system at equilibrium. The numerator is obtained by multiplying the concentrations of the substances on the product side of the equation, each raised to a power equal to its coefficient in the chemical equation. The denominator similarly contains the concentrations of the substances on the reactant side of the equation. (Section 15.2)

**equivalence point** The point in a titration at which the added solute reacts completely with the solute present in the solution. (Section 4.6)

**ester** An organic compound that has an OR group attached to a carbonyl; it is the product of a reaction between a carboxylic acid and an alcohol. (Section 25.4)

**ether** A compound in which two hydrocarbon groups are bonded to one oxygen. (Section 25.4)

**exchange (metathesis) reaction** A reaction between compounds that when written as a molecular equation appears to involve the exchange of ions between the two reactants. (Section 4.2)

**excited state** A higher energy state than the ground state. (Section 6.3)

**exothermic process** A process in which a system releases heat to its surroundings. (Section 5.2)

**extensive property** A property that depends on the amount of material considered; for example, mass or volume. (Section 1.3)

**face-centered cubic cell** A cubic unit cell that has lattice points at each corner as well as at the center of each face. (Section 11.7)

**faraday** A unit of charge that equals the total charge of one mole of electrons:  $1 F = 96,500 C$ . (Section 20.5)

**f-block metals** Lanthanide and actinide elements in which the  $4f$  or  $5f$  orbitals are partially occupied. (Section 6.9)

**ferrimagnetism** A form of magnetism in which electron spins on different kinds of sites point in opposite directions but do not fully cancel out. (Section 23.8)

**ferromagnetism** A form of magnetism in which unpaired electron spins at lattice sites are permanently aligned. (Section 23.7)

**first law of thermodynamics** A statement of our experience that energy is conserved in any process. We can express the law in many ways. One of the more useful expressions is that the change in internal energy,  $\Delta E$ , of a system in any process is equal to the heat,  $q$ , added to the system, plus the work,  $w$ , done on the system by its surroundings:  $\Delta E = q + w$ . (Section 5.2)

**first-order reaction** A reaction in which the reaction rate is proportional to the concentration of a single reactant, raised to the first power. (Section 14.4)

**fission** The splitting of a large nucleus into two smaller ones. (Section 21.6)

**folding** The process by which a protein adopts its biologically active shape. (Section 25.7)

**force** A push or a pull. (Section 5.1)

**formal charge** The number of valence electrons in an isolated atom minus the number of electrons assigned to the atom in the Lewis structure. (Section 8.5)

**formation constant** For a metal ion complex, the equilibrium constant for formation of the complex from the metal ion and base species present in solution. It is a measure of the tendency of the complex to form. (Section 17.5)

**formula weight** The mass of the collection of atoms represented by a chemical formula. For example, the formula weight of  $\text{NO}_2$  (46.0 amu) is the sum of the masses of one nitrogen atom and two oxygen atoms. (Section 3.3)

**fossil fuels** Coal, oil, and natural gas, which are presently our major sources of energy. (Section 5.8)

**free energy (Gibbs free energy, G)** A thermodynamic state function that gives a criterion for spontaneous change in terms of enthalpy and entropy:  $G = H - TS$ . (Section 19.5)

**free radical** A substance with one or more unpaired electrons. (Section 21.9)

**frequency** The number of times per second that one complete wavelength passes a given point. (Section 6.1)

**frequency factor (A)** A term in the Arrhenius equation that is related to the frequency of collision and the probability that the collisions are favorably oriented for reaction. (Section 14.5)

**fuel cell** A voltaic cell that utilizes the oxidation of a conventional fuel, such as  $\text{H}_2$  or  $\text{CH}_4$ , in the cell reaction. (Section 20.7)

**fuel value** The energy released when 1 g of a substance is combusted. (Section 5.8)

**functional group** An atom or group of atoms that imparts characteristic chemical properties to an organic compound. (Section 25.1)

**fusion** The joining of two light nuclei to form a more massive one. (Section 21.6)

**galvanic cell** See **voltaic cell**. (Section 20.3)

**gamma radiation** Energetic electromagnetic radiation emanating from the nucleus of a radioactive atom. (Section 21.1)

**gas** Matter that has no fixed volume or shape; it conforms to the volume and shape of its container. (Section 1.2)

**gas constant (R)** The constant of proportionality in the ideal-gas equation. (Section 10.4)

**Geiger counter** A device that can detect and measure radioactivity. (Section 21.5)

**geometric isomers** Compounds with the same type and number of atoms and the same chemical bonds but different spatial arrangements of these atoms and bonds. (Sections 24.4 and 25.4)

**Gibbs free energy** A thermodynamic state function that combines enthalpy and entropy, in the form  $G = H - TS$ . For a change occurring at constant temperature and pressure, the change in free energy is  $\Delta G = \Delta H - T\Delta S$ . (Section 19.5)

**glass** An amorphous solid formed by fusion of  $\text{SiO}_2$ ,  $\text{CaO}$ , and  $\text{Na}_2\text{O}$ . Other oxides may also be used to form glasses with differing characteristics. (Section 22.10)

**glucose** A polyhydroxy aldehyde whose formula is  $\text{CH}_2\text{OH}(\text{CHOH})_4\text{CHO}$ ; it is the most important of the monosaccharides. (Section 25.8)

**glycogen** The general name given to a group of polysaccharides of glucose that are synthesized in mammals and used to store energy from carbohydrates. (Section 25.8)

**Graham's law** A law stating that the rate of effusion of a gas is inversely proportional to the square root of its molecular weight. (Section 10.8)

**gray (Gy)** The SI unit for radiation dose corresponding to the absorption of 1 J of energy per kilogram of biological material;  $1 \text{ Gy} = 100 \text{ rads}$ . (Section 21.9)

**green chemistry** Chemistry that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. (Section 18.7)

**ground state** The lowest-energy, or most stable, state. (Section 6.3)

**group** Elements that are in the same column of the periodic table; elements within the same group or family exhibit similarities in their chemical behavior. (Section 2.5)

**Haber process** The catalyst system and conditions of temperature and pressure developed by Fritz Haber and coworkers for the formation of  $\text{NH}_3$  from  $\text{H}_2$  and  $\text{N}_2$ . (Section 15.1)

**half-life** The time required for the concentration of a reactant substance to decrease to half its initial value; the time required for half of a sample of a particular radioisotope to decay. (Sections 14.4 and 21.4)

**half-reaction** An equation for either an oxidation or a reduction that explicitly shows the electrons involved, for example,  $\text{Zn}^{2+}(\text{aq}) + 2\text{e}^- \rightarrow \text{Zn}(\text{s})$ . (Section 20.2)

**Hall process** A process used to obtain aluminum by electrolysis of  $\text{Al}_2\text{O}_3$  dissolved in molten cryolite,  $\text{Na}_3\text{AlF}_6$ . (Section 23.4)

**halogens** Members of group 7A in the periodic table. (Sections 7.8 and 22.4)

**hard water** Water that contains appreciable concentrations of  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ ; these ions react with soaps to form an insoluble material. (Section 18.6)

**heat** The flow of energy from a body at higher temperature to one at lower temperature when they are placed in thermal contact. (Section 5.1)

**heat capacity** The quantity of heat required to raise the temperature of a sample of matter by  $1^\circ\text{C}$  (or 1 K). (Section 5.5)

**heat of fusion** The enthalpy change,  $\Delta H$ , for melting a solid. (Section 11.4)

**heat of sublimation** The enthalpy change,  $\Delta H$ , for vaporization of a solid. (Section 11.4)

**heat of vaporization** The enthalpy change,  $\Delta H$ , for vaporization of a liquid. (Section 11.4)

**hemoglobin** An iron-containing protein responsible for oxygen transport in the blood. (Section 18.4)

**Henderson-Hasselbalch equation** The relationship among the pH,  $\text{pK}_a$ , and the concentrations of acid and conjugate base in an aqueous solution:  $\text{pH} = \text{pK}_a + \log \frac{[\text{base}]}{[\text{acid}]}$ . (Section 17.2)

**Henry's law** A law stating that the concentration of a gas in a solution,  $C_g$ , is proportional to the pressure of gas over the solution:  $C_g = kP_g$ . (Section 13.3)

**Hess's law** The heat evolved in a given process can be expressed as the sum of the heats of several processes that, when added, yield the process of interest. (Section 5.6)

**heterogeneous alloy** An alloy in which the components are not distributed uniformly; instead, two or more distinct phases with characteristic compositions are present. (Section 23.6)

**heterogeneous catalyst** A catalyst that is in a different phase from that of the reactant substances. (Section 14.7)

**heterogeneous equilibrium** The equilibrium established between substances in two or more different phases, for example, between a gas and a solid or between a solid and a liquid. (Section 15.4)

**hexagonal close packing** A close-packing arrangement in which the atoms of the third

layer of a solid lie directly over those in the first layer. (Section 11.7)

**high-spin complex** A complex whose electrons populate the  $d$  orbitals to give the maximum number of unpaired electrons. (Section 24.6)

**high-temperature superconductivity** The "frictionless" flow of electrical current (superconductivity) at temperatures above 30 K in certain complex metal oxides. (Section 12.1)

**hole** A vacancy in the valence band of a semiconductor, created by doping. (Section 12.3)

**homogeneous catalyst** A catalyst that is in the same phase as the reactant substances. (Section 14.7)

**homogeneous equilibrium** The equilibrium established between reactant and product substances that are all in the same phase. (Section 15.4)

**Hund's rule** A rule stating that electrons occupy degenerate orbitals in such a way as to maximize the number of electrons with the same spin. In other words, each orbital has one electron placed in it before pairing of electrons in orbitals occurs. Note that this rule applies only to orbitals that are degenerate, which means that they have the same energy. (Section 6.8)

**hybridization** The mixing of different types of atomic orbitals to produce a set of equivalent hybrid orbitals. (Section 9.5)

**hybrid orbital** An orbital that results from the mixing of different kinds of atomic orbitals on the same atom. For example, an  $sp^3$  hybrid results from the mixing, or hybridizing, of one  $s$  orbital and three  $p$  orbitals. (Section 9.5)

**hydration** Solvation when the solvent is water. (Section 13.1)

**hydride ion** An ion formed by the addition of an electron to a hydrogen atom:  $\text{H}^-$ . (Section 7.7)

**hydrocarbons** Compounds composed of only carbon and hydrogen. (Section 2.9)

**hydrogen bonding** Bonding that results from intermolecular attractions between molecules containing hydrogen bonded to an electronegative element. The most important examples involve OH, NH, and HF. (Section 11.2)

**hydrolysis** A reaction with water. When a cation or anion reacts with water, it changes the pH. (Section 16.9)

**hydrometallurgy** Aqueous chemical processes for recovery of a metal from an ore. (Section 23.3)

**hydronium ion ( $\text{H}_3\text{O}^+$ )** The predominant form of the proton in aqueous solution. (Section 16.2)

**hydrophilic** Water-attracting. The term is often used to describe a type of colloid. (Section 13.6)

**hydrophobic** Water-repelling. The term is often used to describe a type of colloid. (Section 13.6)

**hypothesis** A tentative explanation of a series of observations or of a natural law. (Section 1.3)

**ideal gas** A hypothetical gas whose pressure, volume, and temperature behavior is completely described by the ideal-gas equation. (Section 10.4)

**ideal-gas equation** An equation of state for gases that embodies Boyle's law, Charles's law, and Avogadro's hypothesis in the form  $PV = nRT$ . (Section 10.4)

**ideal solution** A solution that obeys Raoult's law. (Section 13.5)

**immiscible liquids** Liquids that do not dissolve in one another to a significant extent. (Section 13.3)

**indicator** A substance added to a solution that changes color when the added solute has reacted with all the solute present in solution. (Section 4.6)

**instantaneous rate** The reaction rate at a particular time as opposed to the average rate over an interval of time. (Section 14.2)

**insulator** A solid with extremely low electrical conductivity. (Section 12.1)

**intensive property** A property that is independent of the amount of material considered, for example, density. (Section 1.3)

**interhalogens** Compounds formed between two different halogen elements. Examples include  $\text{IBr}$  and  $\text{BrF}_3$ . (Section 22.4)

**intermediate** A substance formed in one elementary step of a multistep mechanism and consumed in another; it is neither a reactant nor an ultimate product of the overall reaction. (Section 14.6)

**intermetallic compound** A homogeneous alloy with definite properties and composition. Intermetallic compounds are stoichiometric compounds, but their compositions are not readily explained in terms of ordinary chemical bonding theory. (Section 23.6)

**intermolecular forces** The short-range attractive forces operating between the particles that make up the units of a liquid or solid substance. These same forces also cause gases to liquefy or solidify at low temperatures and high pressures. (Chapter 11: Introduction)

**internal energy** The total energy possessed by a system. When a system undergoes a change, the change in internal energy,  $\Delta E$ , is defined as the heat,  $q$ , added to the system, plus the work,  $w$ , done on the system by its surroundings:  $\Delta E = q + w$ . (Section 5.2)

**ion** Electrically charged atom or group of atoms (polyatomic ion); ions can be positively or negatively charged, depending on whether electrons are lost (positive) or gained (negative) by the atoms. (Section 2.7)

**ion-dipole force** The force that exists between an ion and a neutral polar molecule that possesses a permanent dipole moment. (Section 11.2)

**ion exchange** A process by which ions in solution are exchanged for other ions held on the surface of an ion-exchange resin; the exchange of a hard-water cation such as  $\text{Ca}^{2+}$  for a soft-water cation such as  $\text{Na}^+$  is used to soften water. (Section 18.6)

**ionic bond** A bond between oppositely charged ions. The ions are formed from atoms by transfer of one or more electrons. (Section 8.1)

**ionic compound** A compound composed of cations and anions. (Section 2.7)

**ionic hydrides** Compounds formed when hydrogen reacts with alkali metals and also the heavier alkaline earths (Ca, Sr, and Ba); these compounds contain the hydride ion,  $\text{H}^-$ . (Section 22.2)

**ionic solids** Solids that are composed of ions. (Section 11.8)

**ionization energy** The energy required to remove an electron from a gaseous atom when the atom is in its ground state. (Section 7.4)

**ionizing radiation** Radiation that has sufficient energy to remove an electron from a molecule, thereby ionizing it. (Section 21.9)

**ion-product constant** For water,  $K_w$  is the product of the aquated hydrogen ion and hydroxide ion concentrations:  $[\text{H}^+][\text{OH}^-] = K_w = 1.0 \times 10^{-14}$  at 25 °C. (Section 16.3)

**irreversible process** A process that cannot be reversed to restore both the system and its surroundings to their original states. Any spontaneous process is irreversible. (Section 19.1)

**isoelectronic series** A series of atoms, ions, or molecules having the same number of electrons. (Section 7.3)

**isomers** Compounds whose molecules have the same overall composition but different structures. (Section 24.4)

**isothermal process** One that occurs at constant temperature. (Section 19.1)

**isotopes** Atoms of the same element containing different numbers of neutrons and therefore having different masses. (Section 2.3)

**joule (J)** The SI unit of energy,  $1 \text{ kg}\cdot\text{m}^2/\text{s}^2$ . A related unit is the calorie:  $4.184 \text{ J} = 1 \text{ cal}$ . (Section 5.1)

**Kelvin scale** The absolute temperature scale; the SI unit for temperature is the kelvin. Zero on the Kelvin scale corresponds to  $-273.15 \text{ }^\circ\text{C}$ ; therefore,  $\text{K} = \text{ }^\circ\text{C} + 273.15$ . (Section 1.4)

**ketone** A compound in which the carbonyl group ( $\text{C}=\text{O}$ ) occurs at the interior of a carbon chain and is therefore flanked by carbon atoms. (Section 25.4)

**kinetic energy** The energy that an object possesses by virtue of its motion. (Section 5.1)

**kinetic-molecular theory** A set of assumptions about the nature of gases. These assumptions, when translated into mathematical form, yield the ideal-gas equation. (Section 10.7)

**lanthanide contraction** The gradual decrease in atomic and ionic radii with increasing atomic number among the lanthanide elements, atomic numbers 57 through 70. The decrease arises because of a gradual increase in effective nuclear charge through the lanthanide series. (Section 23.7)

**lanthanide (rare earth) element** Element in which the  $4f$  subshell is only partially occupied. (Sections 6.8 and 6.9)

**lattice energy** The energy required to separate completely the ions in an ionic solid. (Section 8.2)

**law of conservation of mass** A scientific law stating that the total mass of the products of a chemical reaction is the same as the total mass of the reactants, so that mass remains constant during the reaction. (Section 3.1)

**law of constant composition** A law that states that the elemental composition of a pure compound is always the same, regardless of its source; also called the **law of definite proportions**. (Section 1.2)

**law of definite proportions** A law that states that the elemental composition of a pure substance is always the same, regardless of its source; also called the **law of constant composition**. (Section 1.2)

**law of mass action** The rules by which the equilibrium constant is expressed in terms of the concentrations of reactants and products, in accordance with the balanced chemical equation for the reaction. (Section 15.2)

**leaching** The selective dissolution of a desired mineral by passing an aqueous reagent solution through an ore. (Section 23.3)

**Le Châtelier's principle** A principle stating that when we disturb a system at chemical equilibrium, the relative concentrations of reactants and products shift so as to partially undo the effects of the disturbance. (Section 15.7)

**levorotatory, or merely levo or *l*** A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the left (counterclockwise). (Section 24.4)

**Lewis acid** An electron-pair acceptor. (Section 16.11)

**Lewis base** An electron-pair donor. (Section 16.11)

**Lewis structure** A representation of covalent bonding in a molecule that is drawn using Lewis symbols. Shared electron pairs are shown as lines, and unshared electron pairs are shown as pairs of dots. Only the valence-shell electrons are shown. (Section 8.3)

**Lewis symbol** (electron-dot symbol) The chemical symbol for an element, with a dot for each valence electron. (Section 8.1)

**ligand** An ion or molecule that coordinates to a metal atom or to a metal ion to form a complex. (Section 24.1)

**light-emitting diode** A semiconductor device in which electrical energy can be converted into radiant energy, usually in the form of visible light. (Section 12.3)

**lime-soda process** A method used in large-scale water treatment to reduce water hardness by removing  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$ . The substances added to the water are lime,  $\text{CaO}$  [or slaked lime,  $\text{Ca}(\text{OH})_2$ ], and soda ash,  $\text{Na}_2\text{CO}_3$ , in amounts determined by the concentrations of the undesired ions. (Section 18.6)

**limiting reactant** (limiting reagent) The reactant present in the smallest stoichiometric quantity in a mixture of reactants; the amount of product that can form is limited by the complete consumption of the limiting reactant. (Section 3.7)

**line spectrum** A spectrum that contains radiation at only certain specific wavelengths. (Section 6.3)

**linkage isomers** Structural isomers of coordination compounds in which a ligand differs in its mode of attachment to a metal ion. (Section 24.4)

**lipid** A nonpolar molecule derived from glycerol and fatty acids that is used by organisms for long-term energy storage. (Section 25.9)

**liquid** Matter that has a distinct volume but no specific shape. (Section 1.2)

**liquid crystal** A substance that exhibits one or more partially ordered liquid phases above the melting point of the solid form. By contrast, in nonliquid crystalline substances the liquid phase that forms upon melting is completely unordered. (Section 12.8)

**lithosphere** That portion of our environment consisting of the solid Earth. (Section 23.1)

**lock-and-key model** A model of enzyme action in which the substrate molecule is pictured as fitting rather specifically into the active site on the enzyme. It is assumed that in being bound to the active site, the substrate is somehow activated for reaction. (Section 14.7)

**London dispersion forces** Intermolecular forces resulting from attractions between induced dipoles. (Section 11.2)

**low-spin complex** A metal complex in which the electrons are paired in lower-energy orbitals. (Section 24.6)

**magic numbers** Numbers of protons and neutrons that result in very stable nuclei. (Section 21.2)

**main-group elements** Elements in the *s* and *p* blocks of the periodic table. (Section 6.9)

**mass** A measure of the amount of material in an object. It measures the resistance of an object to being moved. In SI units, mass is measured in kilograms. (Section 1.4)

**mass defect** The difference between the mass of a nucleus and the total masses of the individual nucleons that it contains. (Section 21.6)

**mass number** The sum of the number of protons and neutrons in the nucleus of a particular atom. (Section 2.3)

**mass percentage** The number of grams of solute in each 100 g of solution. (Section 13.4)

**mass spectrometer** An instrument used to measure the precise masses and relative amounts of atomic and molecular ions. (Section 2.4)

**matter** Anything that occupies space and has mass; the physical material of the universe. (Section 1.1)

**matter waves** The term used to describe the wave characteristics of a particle. (Section 6.4)

**mean free path** The average distance traveled by a gas molecule between collisions. (Section 10.8)

**metal complex (complex ion or complex)** An assembly of a metal ion and the Lewis bases bonded to it. (Section 24.1)

**metallic bond** Bonding, usually in solid metals, in which the bonding electrons are relatively free to move throughout the three-dimensional structure. (Section 8.1)

**metallic character** The extent to which an element exhibits the physical and chemical properties characteristic of metals, for example, luster, malleability, ductility, and good thermal and electrical conductivity. (Section 7.6)

**metallic elements (metals)** Elements that are usually solids at room temperature, exhibit high electrical and heat conductivity, and appear lustrous. Most of the elements in the periodic table are metals. (Sections 2.5 and 12.1)

**metallic hydrides** Compounds formed when hydrogen reacts with transition metals; these compounds contain the hydride ion,  $\text{H}^-$ . (Section 22.2)

**metallic solids** Solids that are composed of metal atoms. (Section 11.8)

**metalloids** Elements that lie along the diagonal line separating the metals from the nonmetals in the periodic table; the properties of metalloids are intermediate between those of metals and nonmetals. (Section 2.5)

**metallurgy** The science of extracting metals from their natural sources by a combination of chemical and physical processes. It is also concerned with the properties and structures of metals and alloys. (Section 23.1)

**metathesis (exchange) reaction** A reaction in which two substances react through an exchange of their component ions:  $\text{AX} + \text{BY} \longrightarrow \text{AY} + \text{BX}$ . Precipitation and acid-base neutralization reactions are examples of metathesis reactions. (Section 4.2)

**metric system** A system of measurement used in science and in most countries. The meter and the gram are examples of metric units. (Section 1.4)

**microstate** The state of a system at a particular instant; one of many possible energetically equivalent ways to arrange the components of a system to achieve a particular state. (Section 19.3)

**mineral** A solid, inorganic substance occurring in nature, such as calcium carbonate, which occurs as calcite. (Section 23.1)

**miscible** Liquids that mix in all proportions. (Section 13.3)

**mixture** A combination of two or more substances in which each substance retains its own chemical identity. (Section 1.2)

**molal boiling-point-elevation constant ( $K_b$ )** A constant characteristic of a particular solvent that gives the increase in boiling point as a function of solution molality:  $\Delta T_b = K_b m$ . (Section 13.5)

**molal freezing-point-depression constant ( $K_f$ )** A constant characteristic of a particular solvent that gives the decrease in freezing point as a function of solution molality:  $\Delta T_f = K_f m$ . (Section 13.5)

**molality** The concentration of a solution expressed as moles of solute per kilogram of solvent; abbreviated  $m$ . (Section 13.4)

**molar heat capacity** The heat required to raise the temperature of one mole of a substance by 1 °C. (Section 5.5)

**molarity** The concentration of a solution expressed as moles of solute per liter of solution; abbreviated  $M$ . (Section 4.5)

**molar mass** The mass of one mole of a substance in grams; it is numerically equal to the formula weight in atomic mass units. (Section 3.4)

**mole** A collection of Avogadro's number ( $6.022 \times 10^{23}$ ) of objects; for example, a mole of  $\text{H}_2\text{O}$  is  $6.022 \times 10^{23}$   $\text{H}_2\text{O}$  molecules. (Section 3.4)

**molecular compound** A compound that consists of molecules. (Section 2.6)

**molecular equation** A chemical equation in which the formula for each substance is written without regard for whether it is an electrolyte or a nonelectrolyte. (Section 4.2)

**molecular formula** A chemical formula that indicates the actual number of atoms of each element in one molecule of a substance. (Section 2.6)

**molecular geometry** The arrangement in space of the atoms of a molecule. (Section 9.2)

**molecular hydrides** Compounds formed when hydrogen reacts with nonmetals and metalloids. (Section 22.2)

**molecularity** The number of molecules that participate as reactants in an elementary reaction. (Section 14.6)

**molecular orbital (MO)** An allowed state for an electron in a molecule. According to molecular-orbital theory, a molecular orbital is entirely analogous to an atomic orbital, which is an allowed state for an electron in an atom. Most bonding molecular orbitals can be classified as  $\sigma$  or  $\pi$ , depending on the disposition of electron density with respect to the internuclear axis. (Section 9.7)

**molecular-orbital diagram** A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived; also called an **energy-level diagram**. (Section 9.7)

**molecular-orbital theory** A theory that accounts for the allowed states for electrons in molecules. (Section 9.7)

**molecular solids** Solids that are composed of molecules. (Section 11.8)

**molecular weight** The mass of the collection of atoms represented by the chemical formula for a molecule. (Section 3.3)

**molecule** A chemical combination of two or more atoms. (Sections 1.1 and 2.6)

**mole fraction** The ratio of the number of moles of one component of a mixture to the total moles of all components; abbreviated  $X$ , with a subscript to identify the component. (Section 10.6)

**momentum** The product of the mass,  $m$ , and velocity,  $v$ , of an object. (Section 6.4)

**monodentate ligand** A ligand that binds to the metal ion via a single donor atom. It occupies one position in the coordination sphere. (Section 24.2)

**monomers** Molecules with low molecular weights, which can be joined together (polymerized) to form a polymer. (Section 12.6)

**monosaccharide** A simple sugar, most commonly containing six carbon atoms. The joining together of monosaccharide units by condensation reactions results in formation of polysaccharides. (Section 25.8)

**multiple bonding** Bonding involving two or more electron pairs. (Section 8.3)

**nanomaterial** A material whose useful characteristics are the result of dimensions in the range from 1 to 100 nm. (Section 12.9)

**nanotechnology** Technology that relies on the properties of matter at the nanoscale, that is, in the range from 1 to 100 nm. (Section 12.9)

**natural gas** A naturally occurring mixture of gaseous hydrocarbon compounds composed of hydrogen and carbon. (Section 5.8)

**nematic liquid crystalline phase** A liquid crystal in which the molecules are aligned in the same general direction, along their long axes, but in which the ends of the molecules are not aligned. (Section 12.8)

**Nernst equation** An equation that relates the cell emf,  $E$ , to the standard emf,  $E^\circ$ , and the reaction quotient,  $Q$ :  $E = E^\circ - (RT/nF) \ln Q$ . (Section 20.6)

**net ionic equation** A chemical equation for a solution reaction in which soluble strong electrolytes are written as ions and spectator ions are omitted. (Section 4.2)

**neutralization reaction** A reaction in which an acid and a base react in stoichiometrically equivalent amounts; the neutralization reaction between an acid and a metal hydroxide produces water and a salt. (Section 4.3)

**neutron** An electrically neutral particle found in the nucleus of an atom; it has approximately the same mass as a proton. (Section 2.3)

**noble gases** Members of group 8A in the periodic table. (Section 7.8)

**node** A locus of points in an atom at which the electron density is zero. For example, the node in a 2s orbital is a spherical surface. (Section 6.6)

**nonbonding pair** In a Lewis structure a pair of electrons assigned completely to one atom; also called a lone pair. (Section 9.2)

**nonelectrolyte** A substance that does not ionize in water and consequently gives a nonconducting solution. (Section 4.1)

**nonionizing radiation** Radiation that does not have sufficient energy to remove an electron from a molecule. (Section 21.9)

**nonmetallic elements (nonmetals)** Elements in the upper right corner of the periodic table; nonmetals differ from metals in their physical and chemical properties. (Section 2.5)

**nonpolar covalent bond** A covalent bond in which the electrons are shared equally. (Section 8.4)

**normal boiling point** The boiling point at 1 atm pressure. (Section 11.5)

**normal melting point** The melting point at 1 atm pressure. (Section 11.6)

**nuclear binding energy** The energy required to decompose an atomic nucleus into its component protons and neutrons. (Section 21.6)

**nuclear disintegration series** A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one; also called a **radioactive series**. (Section 21.2)

**nuclear transmutation** A conversion of one kind of nucleus to another. (Section 21.3)

**nucleic acids** Polymers of high molecular weight that carry genetic information and control protein synthesis. (Section 25.10)

**nucleon** A particle found in the nucleus of an atom. (Section 21.1)

**nucleotide** Compounds formed from a molecule of phosphoric acid, a sugar molecule, and an organic nitrogen base. Nucleotides form linear polymers called DNA and RNA, which are involved in protein synthesis and cell reproduction. (Section 25.11)

**nucleus** The very small, very dense, positively charged portion of an atom; it is composed of protons and neutrons. (Section 2.2)

**nucleide** A nucleus of a specific isotope of an element. (Section 2.3)

**octet rule** A rule stating that bonded atoms tend to possess or share a total of eight valence-shell electrons. (Section 8.1)

**optical isomers** Stereoisomers in which the two forms of the compound are nonsuperimposable mirror images. (Section 24.4)

**optically active** Possessing the ability to rotate the plane of polarized light. (Section 24.4)

**orbital** An allowed energy state of an electron in the quantum mechanical model of the atom; the term orbital is also used to describe the spatial distribution of the electron. An orbital is defined by the values of three quantum numbers:  $n$ ,  $l$ , and  $m_l$ . (Section 6.5)

**ore** A source of a desired element or mineral, usually accompanied by large quantities of other materials such as sand and clay. (Section 23.1)

**organic chemistry** The study of carbon-containing compounds, typically containing carbon-carbon bonds. (Section 2.9; Chapter 25: Introduction)

**osmosis** The net movement of solvent through a semipermeable membrane toward the solution with greater solute concentration. (Section 13.5)

**osmotic pressure** The pressure that must be applied to a solution to stop osmosis from pure solvent into the solution. (Section 13.5)

**Ostwald process** An industrial process used to make nitric acid from ammonia. The  $\text{NH}_3$  is catalytically oxidized by  $\text{O}_2$  to form  $\text{NO}$ ;  $\text{NO}$  in air is oxidized to  $\text{NO}_2$ ;  $\text{HNO}_3$  is formed in a disproportionation reaction when  $\text{NO}_2$  dissolves in water. (Section 22.7)

**overall reaction order** The sum of the reaction orders of all the reactants appearing in the rate expression when the rate can be expressed as  $\text{rate} = k[\text{A}]^m[\text{B}]^n \dots$ . (Section 14.3)

**overlap** The extent to which atomic orbitals on different atoms share the same region of space. When the overlap between two orbitals is large, a strong bond may be formed. (Section 9.4)

**oxidation** A process in which a substance loses one or more electrons. (Section 4.4)

**oxidation number (oxidation state)** A positive or negative whole number assigned to an element in a molecule or ion on the basis of a set of formal rules; to some degree it reflects the positive or negative character of that atom. (Section 4.4)

**oxidation-reduction (redox) reaction** A chemical reaction in which the oxidation states of certain atoms change. (Chapter 20: Introduction)

**oxidizing agent, or oxidant** The substance that is reduced and thereby causes the oxidation of some other substance in an oxidation-reduction reaction. (Section 20.1)

**oxyacid** A compound in which one or more OH groups, and possibly additional oxygen atoms, are bonded to a central atom. (Section 16.10)

**oxyanion** A polyatomic anion that contains one or more oxygen atoms. (Section 2.8)

**ozone** The name given to  $\text{O}_3$ , an allotrope of oxygen. (Section 7.8)

**paramagnetism** A property that a substance possesses if it contains one or more unpaired electrons. A paramagnetic substance is drawn into a magnetic field. (Section 9.8)

**partial pressure** The pressure exerted by a particular gas in a mixture. (Section 10.6)

**particle accelerator** A device that uses strong magnetic and electrostatic fields to accelerate charged particles. (Section 21.3)

**parts per billion (ppb)** The concentration of a solution in grams of solute per  $10^9$  (billion) grams of solution; equals micrograms of solute per liter of solution for aqueous solutions. (Section 13.4)

**parts per million (ppm)** The concentration of a solution in grams of solute per  $10^6$  (million) grams of solution; equals milligrams of solute per liter of solution for aqueous solutions. (Section 13.4)

**pascal (Pa)** The SI unit of pressure:  $1 \text{ Pa} = 1 \text{ N/m}^2$ . (Section 10.2)

**Pauli exclusion principle** A rule stating that no two electrons in an atom may have the same four quantum numbers ( $n$ ,  $l$ ,  $m_l$ , and  $m_s$ ). As a reflection of this principle, there can be no more than two electrons in any one atomic orbital. (Section 6.7)

**peptide bond** A bond formed between two amino acids. (Section 25.7)

**percent ionization** The percent of a substance that undergoes ionization on dissolution in water. The term applies to solutions of weak acids and bases. (Section 16.6)

**percent yield** The ratio of the actual (experimental) yield of a product to its theoretical (calculated) yield, multiplied by 100. (Section 3.7)

**period** The row of elements that lie in a horizontal row in the periodic table. (Section 2.5)

**periodic table** The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns. (Section 2.5)

**petroleum** A naturally occurring combustible liquid composed of hundreds of hydrocarbons and other organic compounds. (Section 5.8)

**pH** The negative log in base 10 of the aquated hydrogen ion concentration:  $\text{pH} = -\log[\text{H}^+]$ . (Section 16.4)

**pH titration curve** See titration curve. (Section 17.3)

**phase change** The conversion of a substance from one state of matter to another. The phase changes we consider are melting and freezing (solid  $\rightleftharpoons$  liquid), sublimation and deposition (solid  $\rightleftharpoons$  gas), and vaporization and condensation (liquid  $\rightleftharpoons$  gas). (Section 11.4)

**phase diagram** A graphic representation of the equilibria among the solid, liquid, and gaseous phases of a substance as a function of temperature and pressure. (Section 11.6)

**phospholipid** A form of lipid molecule that contains charged phosphate groups. (Section 25.9)

**photochemical smog** A complex mixture of undesirable substances produced by the action of sunlight on an urban atmosphere polluted with automobile emissions. The major starting ingredients are nitrogen oxides and organic substances, notably alkenes and aldehydes. (Section 18.4)

**photodissociation** The breaking of a molecule into two or more neutral fragments as a result of absorption of light. (Section 18.2)

**photoelectric effect** The emission of electrons from a metal surface induced by light. (Section 6.2)

**photoionization** The removal of an electron from an atom or molecule by absorption of light. (Section 18.2)

**photon** The smallest increment (a quantum) of radiant energy; a photon of light with frequency  $\nu$  has an energy equal to  $h\nu$ . (Section 6.2)

**photosynthesis** The process that occurs in plant leaves by which light energy is used to convert carbon dioxide and water to carbohydrates and oxygen. (Section 24.2)

**physical changes** Changes (such as a phase change) that occur with no change in chemical composition. (Section 1.3)

**physical properties** Properties that can be measured without changing the composition of a substance, for example, color and freezing point. (Section 1.3)

**$\pi$  ( $\pi$ ) bond** A covalent bond in which electron density is concentrated above and below the internuclear axis. (Section 9.6)

**$\pi$  ( $\pi$ ) molecular orbital** A molecular orbital that concentrates the electron density on opposite sides of an imaginary line that passes through the nuclei. (Section 9.8)

**Planck's constant ( $h$ )** The constant that relates the energy and frequency of a photon,  $E = h\nu$ . Its value is  $6.626 \times 10^{-34} \text{ J}\cdot\text{s}$ . (Section 6.2)

**plastic** A material that can be formed into particular shapes by application of heat and pressure. (Section 12.6)

**polar covalent bond** A covalent bond in which the electrons are not shared equally. (Section 8.4)

**polarizability** The ease with which the electron cloud of an atom or a molecule is distorted by an outside influence, thereby inducing a dipole moment. (Section 11.2)

**polar molecule** A molecule that possesses a nonzero dipole moment. (Section 8.4)

**polyatomic ion** An electrically charged group of two or more atoms. (Section 2.7)

**polydentate ligand** A ligand in which two or more donor atoms can coordinate to the same metal ion. (Section 24.2)

**polymer** A large molecule of high molecular mass, formed by the joining together, or polymerization, of a large number of molecules of low molecular mass. The individual molecules forming the polymer are called monomers. (Section 12.6)

**polypeptide** A polymer of amino acids that has a molecular weight of less than 10,000. (Section 25.7)

**polyprotic acid** A substance capable of dissociating more than one proton in water;  $\text{H}_2\text{SO}_4$  is an example. (Section 16.6)

**polysaccharide** A substance made up of many monosaccharide units joined together. (Section 25.8)

**porphyrin** A complex derived from the porphyrin molecule. (Section 24.2)

**positron** A particle with the same mass as an electron but with a positive charge, symbol  $\beta^+$ . (Section 21.1)

**potential energy** The energy that an object possesses as a result of its composition or its position with respect to another object. (Section 5.1)

**precipitate** An insoluble substance that forms in, and separates from, a solution. (Section 4.2)

**precipitation reaction** A reaction that occurs between substances in solution in which one of the products is insoluble. (Section 4.2)

**precision** The closeness of agreement among several measurements of the same quantity; the reproducibility of a measurement. (Section 1.5)

**pressure** A measure of the force exerted on a unit area. In chemistry, pressure is often expressed in units of atmospheres (atm) or torr: 760 torr = 1 atm; in SI units pressure is expressed in pascals (Pa). (Section 10.2)

**pressure-volume (PV) work** Work performed by expansion of a gas against a resisting pressure. (Section 5.3)

**primary structure** The sequence of amino acids along a protein chain. (Section 25.7)

**primitive cubic cell** A cubic unit cell in which the lattice points are at the corners only. (Section 11.7)

**probability density ( $\psi^2$ )** A value that represents the probability that an electron will be found at a given point in space. (Section 6.5)

**product** A substance produced in a chemical reaction; it appears to the right of the arrow in a chemical equation. (Section 3.1)

**property** A characteristic that gives a sample of matter its unique identity. (Section 1.1)

**protein** A biopolymer formed from amino acids. (Section 25.7)

**protium** The most common isotope of hydrogen. (Section 22.2)

**proton** A positively charged subatomic particle found in the nucleus of an atom. (Section 2.3)

**pure substance** Matter that has a fixed composition and distinct properties. (Section 1.2)

**pyrometallurgy** A process in which heat converts a mineral in an ore from one chemical form to another and eventually to the free metal. (Section 23.2)

**qualitative analysis** The determination of the presence or absence of a particular substance in a mixture. (Section 17.7)

**quantitative analysis** The determination of the amount of a given substance that is present in a sample. (Section 17.7)

**quantum** The smallest increment of radiant energy that may be absorbed or emitted; the magnitude of radiant energy is  $h\nu$ . (Section 6.2)

**racemic mixture** A mixture of equal amounts of the dextrorotatory and levorotatory forms of a chiral molecule. A racemic mixture will not rotate the plane of polarized light. (Section 24.4)

**rad** A measure of the energy absorbed from radiation by tissue or other biological material; 1 rad = transfer of  $1 \times 10^{-2}$  J of energy per kilogram of material. (Section 21.9)

**radial probability function** The probability that the electron will be found at a certain distance from the nucleus. (Section 6.6)

**radioactive** Possessing radioactivity, the spontaneous disintegration of an unstable atomic nucleus with accompanying emission of radiation. (Section 22; Chapter 21: Introduction)

**radioactive series** A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one. Also called **nuclear disintegration series**. (Section 21.2)

**radioisotope** An isotope that is radioactive; that is, it is undergoing nuclear changes with emission of radiation. (Section 21.1)

**radionuclide** A radioactive nuclide. (Section 21.1)

**radiotracer** A radioisotope that can be used to trace the path of an element in a chemical system. (Section 21.5)

**Raoult's law** A law stating that the partial pressure of a solvent over a solution,  $P_A$ , is given by the vapor pressure of the pure solvent,  $P_A^\circ$ , times the mole fraction of a solvent in the solution,  $X_A$ :  $P_A = X_A P_A^\circ$  (Section 13.5)

**rare earth element** See **lanthanide element**. (Sections 6.8 and 6.9)

**rate constant** A constant of proportionality between the reaction rate and the concentrations of reactants that appear in the rate law. (Section 14.3)

**rate-determining step** The slowest elementary step in a reaction mechanism. (Section 14.6)

**rate law** An equation that relates the reaction rate to the concentrations of reactants (and sometimes of products also). (Section 14.3)

**reactant** A starting substance in a chemical reaction; it appears to the left of the arrow in a chemical equation. (Section 3.1)

**reaction mechanism** A detailed picture, or model, of how the reaction occurs; that is, the order in which bonds are broken and formed and the changes in relative positions of the atoms as the reaction proceeds. (Section 14.6)

**reaction order** The power to which the concentration of a reactant is raised in a rate law. (Section 14.3)

**reaction quotient (Q)** The value that is obtained when concentrations of reactants and products are inserted into the equilibrium expression. If the concentrations are equilibrium

concentrations,  $Q = K$ ; otherwise,  $Q \neq K$ . (Section 15.6)

**reaction rate** A measure of the decrease in concentration of a reactant or the increase in concentration of a product with time. (Section 14.2)

**redox (oxidation-reduction) reaction** A reaction in which certain atoms undergo changes in oxidation states. The substance increasing in oxidation state is oxidized; the substance decreasing in oxidation state is reduced. (Section 4.4 and Chapter 20: Introduction)

**reducing agent, or reductant** The substance that is oxidized and thereby causes the reduction of some other substance in an oxidation-reduction reaction. (Section 20.1)

**reduction** A process in which a substance gains one or more electrons. (Section 4.4)

**refining** The process of converting an impure form of a metal into a more usable substance of well-defined composition. For example, crude pig iron from the blast furnace is refined in a converter to produce steels of desired compositions. (Section 23.2)

**rem** A measure of the biological damage caused by radiation; rems = rads  $\times$  RBE. (Section 21.9)

**renewable energy** Energy such as solar energy, wind energy, and hydroelectric energy derived from essentially inexhaustible sources. (Section 5.8)

**representative (main-group) element** An element from within the *s* and *p* blocks of the periodic table (Figure 6.29). (Section 6.9)

**resonance structures (resonance forms)** Individual Lewis structures in cases where two or more Lewis structures are equally good descriptions of a single molecule. The resonance structures in such an instance are "averaged" to give a more accurate description of the real molecule. (Section 8.6)

**reverse osmosis** The process by which water molecules move under high pressure through a semipermeable membrane from the more concentrated to the less concentrated solution. (Section 18.5)

**reversible process** A process that can go back and forth between states along exactly the same path; a system at equilibrium is reversible if equilibrium can be shifted by an infinitesimal modification of a variable such as temperature. (Section 19.1)

**ribonucleic acid (RNA)** A polynucleotide in which ribose is the sugar component. (Section 25.10)

**roasting** Thermal treatment of an ore to bring about chemical reactions involving the furnace atmosphere. For example, a sulfide ore might be roasted in air to form a metal oxide and  $\text{SO}_2$ . (Section 23.2)

**root-mean-square (rms) speed ( $\mu$ )** The square root of the average of the squared speeds of the gas molecules in a gas sample. (Section 10.7)

**rotational motion** Movement of a molecule as though it is spinning like a top. (Section 19.3)

**salinity** A measure of the salt content of seawater, brine, or brackish water. It is equal to the mass in grams of dissolved salts present in 1 kg of seawater. (Section 18.5)

**salt** An ionic compound formed by replacing one or more hydrogens of an acid by other cations. (Section 4.3)

**saponification** Hydrolysis of an ester in the presence of a base. (Section 25.4)

**saturated solution** A solution in which undissolved solute and dissolved solute are in equilibrium. (Section 13.2)

**scientific law** A concise verbal statement or a mathematical equation that summarizes a wide range of observations and experiences. (Section 1.3)

**scientific method** The general process of advancing scientific knowledge by making experimental observations and by formulating hypotheses, theories, and laws. (Section 1.3)

**scintillation counter** An instrument that is used to detect and measure radiation by the fluorescence it produces in a fluorescing medium. (Section 21.5)

**secondary structure** The manner in which a protein is coiled or stretched. (Section 25.7)

**second law of thermodynamics** A statement of our experience that there is a direction to the way events occur in nature. When a process occurs spontaneously in one direction, it is non-spontaneous in the reverse direction. It is possible to state the second law in many different forms, but they all relate back to the same idea about spontaneity. One of the most common statements found in chemical contexts is that in any spontaneous process the entropy of the universe increases. (Section 19.2)

**second-order reaction** A reaction in which the overall reaction order (the sum of the concentration-term exponents) in the rate law is 2. (Section 14.4)

**semiconductor** A solid with limited electrical conductivity. (Section 12.1)

**sigma ( $\sigma$ ) bond** A covalent bond in which electron density is concentrated along the internuclear axis. (Section 9.6)

**sigma ( $\sigma$ ) molecular orbital** A molecular orbital that centers the electron density about an imaginary line passing through two nuclei. (Section 9.7)

**significant figures** The digits that indicate the precision with which a measurement is made; all digits of a measured quantity are significant, including the last digit, which is uncertain. (Section 1.5)

**silicates** Compounds containing silicon and oxygen, structurally based on  $\text{SiO}_4$  tetrahedra. (Section 22.10)

**single bond** A covalent bond involving one electron pair. (Section 8.3)

**SI units** The preferred metric units for use in science. (Section 1.4)

**slag** A mixture of molten silicate minerals. Slags may be acidic or basic, according to the acidity or basicity of the oxide added to silica. (Section 23.2)

**smectic liquid crystalline phase** A liquid crystal in which the molecules are aligned along their long axes and arranged in sheets, with the ends of the molecules aligned. There are several different kinds of smectic phases. (Section 12.8)

**smelting** A melting process in which the materials formed in the course of the chemical reactions that occur separate into two or more layers. For example, the layers might be slag and molten metal. (Section 23.2)

**solar cell** An electronic device composed of doped semiconductors in which radiant energy can be converted into electrical energy. (Section 12.3)

**sol-gel process** A process in which extremely small particles (0.003 to 0.1  $\mu\text{m}$  in diameter) of uniform size are produced in a series of chemical steps, followed by controlled heating. (Section 12.4)

**solid** Matter that has both a definite shape and a definite volume. (Section 1.2)

**solubility** The amount of a substance that dissolves in a given quantity of solvent at a given temperature to form a saturated solution. (Sections 4.2 and 13.2)

**solubility-product constant (solubility product) ( $K_{sp}$ )** An equilibrium constant related to the equilibrium between a solid salt and its ions in solution. It provides a quantitative measure of the solubility of a slightly soluble salt. (Section 17.4)

**solute** A substance dissolved in a solvent to form a solution; it is normally the component of a solution present in the smaller amount. (Section 4.1)

**solution** A mixture of substances that has a uniform composition; a homogeneous mixture. (Section 1.2)

**solution alloy** A homogeneous alloy, with the components distributed uniformly throughout. (Section 23.6)

**solvation** The clustering of solvent molecules around a solute particle. (Section 13.1)

**solvent** The dissolving medium of a solution; it is normally the component of a solution present in the greater amount. (Section 4.1)

**specific heat ( $C_p$ )** The heat capacity of 1 g of a substance; the heat required to raise the temperature of 1 g of a substance by 1  $^\circ\text{C}$ . (Section 5.5)

**spectator ions** Ions that go through a reaction unchanged and that appear on both sides of the complete ionic equation. (Section 4.2)

**spectrochemical series** A list of ligands arranged in order of their abilities to split the  $d$ -orbital energies (using the terminology of the crystal-field model). (Section 24.6)

**spectrum** The distribution among various wavelengths of the radiant energy emitted or absorbed by an object. (Sections 6.3 and 24.6)

**spin magnetic quantum number ( $m_s$ )** A quantum number associated with the electron spin; it may have values of  $+\frac{1}{2}$  or  $-\frac{1}{2}$ . (Section 6.7)

**spin-pairing energy** The energy required to pair an electron with another electron occupying an orbital. (Section 24.6)

**spontaneous process** A process that is capable of proceeding in a given direction, as written or described, without needing to be driven by an outside source of energy. A process may be spontaneous even though it is very slow. (Section 19.1)

**standard atmospheric pressure** Defined as 760 torr or, in SI units, 101.325 kPa. (Section 10.2)

**standard electrode potential** See **standard reduction potential**. (Section 20.4)

**standard emf, also called the standard cell potential ( $E^\circ$ )** The emf of a cell when all reagents are at standard conditions. (Section 20.4)

**standard enthalpy change ( $\Delta H^\circ$ )** The change in enthalpy in a process when all reactants and products are in their stable forms at 1 atm pressure and a specified temperature, commonly 25  $^\circ\text{C}$ . (Section 5.7)

**standard enthalpy of formation ( $\Delta H_f^\circ$ )** The change in enthalpy that accompanies the formation of one mole of a substance from its elements, with all substances in their standard states. (Section 5.7)

**standard free energy of formation ( $\Delta G_f^\circ$ )** The change in free energy associated with the formation of a substance from its elements under standard conditions. (Section 19.5)

**standard hydrogen electrode (SHE)** An electrode based on the half-reaction  $2\text{H}^+(1\text{ M}) + 2\text{e}^- \longrightarrow \text{H}_2(1\text{ atm})$ . The standard electrode potential of the standard hydrogen electrode is defined as 0 V. (Section 20.4)

**standard molar entropy ( $S^\circ$ )** The entropy value for a mole of a substance in its standard state. (Section 19.4)

**standard reduction potential ( $E_{\text{red}}^\circ$ )** The potential of a reduction half-reaction under standard conditions, measured relative to the standard hydrogen electrode. A standard reduction potential is also called a **standard electrode potential**. (Section 20.4)

**standard solution** A solution of known concentration. (Section 4.6)

**standard temperature and pressure (STP)** Defined as 0  $^\circ\text{C}$  and 1 atm pressure; frequently used as reference conditions for a gas. (Section 10.4)

**starch** The general name given to a group of polysaccharides that acts as energy-storage substances in plants. (Section 25.8)

**state function** A property of a system that is determined by the state or condition of the system and not by how it got to that state; its value is fixed when temperature, pressure, composition, and physical form are specified;  $P$ ,  $V$ ,  $T$ ,  $E$ , and  $H$  are state functions. (Section 5.2)

**states of matter** The three forms that matter can assume: solid, liquid, and gas. (Section 1.2)

**stereoisomers** Compounds possessing the same formula and bonding arrangement but differing in the spatial arrangements of the atoms. (Section 24.4)

**stoichiometry** The relationships among the quantities of reactants and products involved in chemical reactions. (Chapter 3: Introduction)

**stratosphere** The region of the atmosphere directly above the troposphere. (Section 18.1)

**strong acid** An acid that ionizes completely in water. (Section 4.3)

**strong base** A base that ionizes completely in water. (Section 4.3)

**strong electrolyte** A substance (strong acids, strong bases, and most salts) that is completely ionized in solution. (Section 4.1)

**structural formula** A formula that shows not only the number and kinds of atoms in the molecule but also the arrangement (connections) of the atoms. (Section 2.6)

**structural isomers** Compounds possessing the same formula but differing in the bonding arrangements of the atoms. (Sections 24.4 and 25.3)

**subatomic particles** Particles such as protons, neutrons, and electrons that are smaller than an atom. (Section 2.2)

**subshell** One or more orbitals with the same set of quantum numbers  $n$  and  $l$ . For example, we speak of the  $2p$  subshell ( $n = 2, l = 1$ ), which is composed of three orbitals ( $2p_x, 2p_y,$  and  $2p_z$ ). (Section 6.5)

**substitutional alloy** A homogeneous (solution) alloy in which atoms of different elements randomly occupy sites in the lattice. (Section 23.6)

**substitution reactions** Reactions in which one atom (or group of atoms) replaces another atom (or group) within a molecule; substitution reactions are typical for alkanes and aromatic hydrocarbons. (Section 25.4)

**substrate** A substance that undergoes a reaction at the active site in an enzyme. (Section 14.7)

**superconductor** A material capable of carrying an electrical current without apparent resistance when cooled below a transition temperature,  $T_c$ . (Section 12.50)

**superconducting ceramic** A complex metal oxide that undergoes a transition to a superconducting state at a low temperature. (Section 12.1)

**superconducting transition temperature ( $T_c$ )** The temperature below which a substance exhibits superconductivity. (Section 12.1)

**superconductivity** The "frictionless" flow of electrons that occurs when a substance loses all resistance to the flow of electrical current. (Section 12.1)

**supercritical mass** An amount of fissionable material larger than the critical mass. (Section 21.7)

**supersaturated solutions** Solutions containing more solute than an equivalent saturated solution. (Section 13.2)

**surface tension** The intermolecular, cohesive attraction that causes a liquid to minimize its surface area. (Section 11.3)

**surroundings** In thermodynamics, everything that lies outside the system that we study. (Section 5.1)

**system** In thermodynamics, the portion of the universe that we single out for study. We must be careful to state exactly what the system contains and what transfers of energy it may have with its surroundings. (Section 5.1)

**termolecular reaction** An elementary reaction that involves three molecules. Termolecular reactions are rare. (Section 14.6)

**tertiary structure** The overall shape of a large protein, specifically, the manner in which sections of the protein fold back upon themselves or intertwine. (Section 25.9)

**theoretical yield** The quantity of product that is calculated to form when all of the limiting reagent reacts. (Section 3.7)

**theory** A tested model or explanation that satisfactorily accounts for a certain set of phenomena. (Section 1.3)

**thermochemistry** The relationship between chemical reactions and energy changes. (Chapter 5: Introduction)

**thermodynamics** The study of energy and its transformation. (Chapter 5: Introduction)

**thermonuclear reaction** Another name for fusion reactions; reactions in which two light nuclei are joined to form a more massive one. (Section 21.8)

**thermoplastic** A polymeric material that can be readily reshaped by application of heat and pressure. (Section 12.6)

**thermosetting plastic** A plastic that, once formed in a particular mold, is not readily reshaped by application of heat and pressure. (Section 12.2)

**third law of thermodynamics** A law stating that the entropy of a pure, crystalline solid at absolute zero temperature is zero:  $S(0\text{ K}) = 0$ . (Section 19.3)

**titration** The process of reacting a solution of unknown concentration with one of known concentration (a standard solution). (Section 4.6)

**titration curve** A graph of pH as a function of added titrant. (Section 17.3)

**torr** A unit of pressure (1 torr = 1 mm Hg). (Section 10.2)

**transistor** An electrical device that forms the heart of an integrated circuit. (Section 12.4)

**transition elements (transition metals)** Elements in which the  $d$  orbitals are partially occupied. (Section 6.8)

**transition state (activated complex)** The particular arrangement of reactant and product molecules at the point of maximum energy in the rate-determining step of a reaction. (Section 14.5)

**translational motion** Movement in which an entire molecule moves in a definite direction. (Section 19.3)

**transuranium elements** Elements that follow uranium in the periodic table. (Section 21.3)

**triple bond** A covalent bond involving three electron pairs. (Section 8.3)

**triple point** The temperature at which solid, liquid, and gas phases coexist in equilibrium. (Section 11.6)

**tritium** The isotope of hydrogen whose nucleus contains a proton and two neutrons. (Section 22.2)

**troposphere** The region of Earth's atmosphere extending from the surface to about 12 km altitude. (Section 18.1)

**Tyndall effect** The scattering of a beam of visible light by the particles in a colloidal dispersion. (Section 13.6)

**uncertainty principle** A principle stating there is an inherent uncertainty in the precision with which we can simultaneously specify the position and momentum of a particle. This uncertainty is significant only for particles of extremely small mass, such as electrons. (Section 6.4)

**unimolecular reaction** An elementary reaction that involves a single molecule. (Section 14.6)

**unit cell** The smallest portion of a crystal that reproduces the structure of the entire crystal when repeated in different directions in space.

It is the repeating unit or building block of the crystal lattice. (Section 11.7)

**unsaturated solutions** Solutions containing less solute than a saturated solution. (Section 13.2)

**valence band** A band of closely spaced molecular orbitals that is essentially fully occupied by electrons. (Section 12.2)

**valence-bond theory** A model of chemical bonding in which an electron-pair bond is formed between two atoms by the overlap of orbitals on the two atoms. (Section 9.4)

**valence electrons** The outermost electrons of an atom; those that occupy orbitals not occupied in the nearest noble-gas element of lower atomic number. The valence electrons are the ones the atom uses in bonding. (Section 6.8)

**valence orbitals** Orbitals that contain the outer-shell electrons of an atom. (Chapter 7: Introduction)

**valence-shell electron-pair repulsion (VSEPR) model** A model that accounts for the geometric arrangements of shared and unshared electron pairs around a central atom in terms of the repulsions between electron pairs. (Section 9.2)

**van der Waals equation** An equation of state for nonideal gases that is based on adding corrections to the ideal-gas equation. The correction terms account for intermolecular forces of attraction and for the volumes occupied by the gas molecules themselves. (Section 10.9)

**vapor** Gaseous state of any substance that normally exists as a liquid or solid. (Section 10.1)

**vapor pressure** The pressure exerted by a vapor in equilibrium with its liquid or solid phase. (Section 11.5)

**vibrational motion** Movement of the atoms within a molecule in which they move periodically toward and away from one another. (Section 19.3)

**viscosity** A measure of the resistance of fluids to flow. (Section 11.3)

**volatile** Tending to evaporate readily. (Section 11.5)

**voltaic (galvanic) cell** A device in which a spontaneous oxidation-reduction reaction occurs with the passage of electrons through an external circuit. (Section 20.3)

**vulcanization** The process of cross-linking polymer chains in rubber. (Section 12.6)

**watt** A unit of power;  $1\text{ W} = 1\text{ J/s}$ . (Section 20.9)

**wave function** A mathematical description of an allowed energy state (an orbital) for an electron in the quantum mechanical model of the atom; it is usually symbolized by the Greek letter  $\psi$ . (Section 6.5)

**wavelength** The distance between identical points on successive waves. (Section 6.1)

**weak acid** An acid that only partly ionizes in water. (Section 4.3)

**weak base** A base that only partly ionizes in water. (Section 4.3)

**weak electrolyte** A substance that only partly ionizes in solution. (Section 4.1)

**work** The movement of an object against some force. (Section 5.1)
